SCALABLE AND DISTRIBUTED MATHEMATICAL MODELING ALGORITHM DESIGN AND PERFORMANCE EVALUATION IN HETEROGENEOUS COMPUTING CLUSTERS

ZHOUDING LIU* AND JIA LI†

Abstract. A growing number of scalable and distributed methods are required to effectively simulate complicated events as computing needs in the research and industrial sectors keep growing. A novel approach for developing and accessing mathematically modeled methods in heterogeneous computing clusters is proposed in this study to meet this difficulty. The suggested methodology uses DRL based Parallel Computational model for the evaluation of Heterogenous computing clusters. The algorithms makes use of parallelization methods to split up the processing burden among several nodes, supporting the variety of topologies seen in contemporary computing clusters. Through the utilization of heterogeneous hardware parts such as CPUs, GPUs, and acceleration devices, the architecture seeks to maximize speed and minimize resource usage. To evaluate the effectiveness of the proposed approach, a comprehensive performance assessment is conducted. The evaluation encompasses scalability analysis, benchmarking, and comparisons against traditional homogeneous computing setups. The research investigates the impact of algorithm design choices on the efficiency and speed achieved in diverse computing environments.

Key words: heterogeneous computing clusters, scalability, distributed mathematical modeling, parallelization methods

1. Introduction. The intricacy of mathematical representations has increased in the dynamic field of computational disciplines, calling for creative methods of algorithm creation and efficiency enhancement. A key concept for addressing the growing computing needs of complicated mathematical models in a range of scientific and engineering fields is scaled distributed computers. With an emphasis on the assessment of performance in heterogeneous computing clusters, this research sets out to investigate and expand the boundaries of scalability and dispersed mathematical modeling method design.

High Performance Computing (HPC) is the term used to describe the process of solving challenging issues in the sciences, engineering, or industry by pooling computing resources in a way that yields efficiency substantially greater than that of a typical personal computer or workstation [2, 10]. The terms comparable to HPC are parallel computing and supercomputing. The underlying principle of HPC is the fact that we can accomplish a problem with 100 processors in an hour, whereas a single computer requires 100 hours to finish. While utilizing all the resources available to it, a single node inside the supercomputer might not be stronger than others.

Heterogeneous ML structures, such as TensorFlow [2], MXNet [10], and PyTorch [16], are frequently used to perform ML workloads to speed up the training process over large datasets or large models. In a distributed machine learning task, the data set is split up and taught by a distinct worker. To obtain the global parameters, the workers share computed model parameters with one another (either directly via an all-reduce aggregate or via parameter servers). It is typical for workforce and parameter hosts in a parameter server (PS) architecture to be dispersed across multiple physical servers, either because they cannot be fully hosted on a single server or to optimize capacity fragmentation use on servers.

In recent times, numerous high-performance computing (HPC) applications, including modeling of the climate and environment, computational fluid dynamics (CFD), molecular nanotechnology for smart planet rockets, and numerous other big data uses, have required extremely powerful computing systems to handle them. According to experts and HPC pioneers, "exascale systems," a new class of supercomputing computers, won't be introduced until the beginning of the following decade [16, 6]. Compared to current Petascale systems, this heterogeneous architectural-based HPC computing platform will offer a thousand-overlay speed boost. With an HPC machine this powerful, many scientific puzzles will be solved in a matter of seconds, completing

ExaFlops worth of computations [7].

Developing and optimizing device executable software to take advantage of the substantial amount of parallelism is the primary difficulty in GPGPU computation. Programmers have two possibilities: the vendor specific CUDA [9, 4] programming environment or the OpenCL standard programming framework [15], which allows programs to operate across the GPU and CPU architectures of most manufacturers. Most apps, including MPI apps that make use of GPU gadgets, presently execute their kernel code locally on the same devices as their CPU routines.

The establishment of Exascale computing systems is expected to consist of many heterogeneous nodes, each of which will be outfitted with multiple-core enhanced GPU devices and regular multi-core CPUs [14, 5]. At a moment when the need for more computing capacity is growing, the emergence of heterogeneity in HPC systems is resulting in increasingly complicated platforms. The major use of electricity while HPC processing of information is a challenge for current supercomputing systems. Recent HPC supercomputing systems support up to 10 million cores per node, with an annual electricity consumption of 25–60 MW.

The main contribution of proposed method is given below:

1. To bring together coarse-grain, fine-grain, and greater granularity through inter-node, intra-node, and enhanced GPU calculations, a novel DRL based hybrid MPI + OpenMP + CUDA (MOC) massive parallel computing paradigm was proposed for Exascale computing systems.
2. Using various kernel widths, we applied MOC to dense matrix multiplication in linear algebra and assessed HPC parameters such as energy consumption and speed.
3. We solved the identical issue using two of the most well-known linear algebra subroutines archives, CuBLAS and KAUST basic linear algebra subprograms (KBLAS). Moreover, we contrast the outcomes with the framework proposed by MOC.

Remaining sections of this paper are structured as follows: Section 2 discusses about the related research works, Section 3 describes the Heterogenous Computing Clusters, Parallelization and Deep Learning methods, Section 4 discusses about the experimented results and comparison and Section 6 concludes the proposed optimization method with future work.

2. Related Works. It makes sense to co-locate occupations with minimal levels of interference to maximize training success [21]. Unfortunately, because it is challenging to determine the possible interference levels of several jobs, schedulers now in use in real-world machine learning clusters ([25], Mesos [4]) are primarily unaware of disruption, which results in prolonged training times and less-than-ideal utilization of resources. Numerous studies have demonstrated the potential and efficacy of interference-aware planning in the literature, such as when it comes to taking network traffic into account for MapReduce operations [17, 18], and cache access severity for HPC jobs [1]. Based on specific facts or hypotheses (e.g., that disruption slows back performance exponentially), these researchers construct an explicit delay model of the goal performance and use custom heuristics to include interference in scheduling.

In contrast to previous methods, we adopt a black-box strategy in this study for ML employment placement that welcomes interruption and does not rely on in-depth analytical effectiveness prediction. We incorporate deep reinforcement learning (DRL) into our scheduler architecture, motivated by the recent successes of DRL in video streaming [20], job planning [3], [24], [22], and Go [19]. We introduce Balance, an ML cluster planner powered by deep learning. In a neural network (NN) that translates basic clusters and task information (e.g., resources at hand, jobs' capacity requirements) to job placement choices (i.e., the server you want to put every employee on or the variable server of an assignment onto), harmonization inherently encodes load disturbance.

Utilizing the advantages of both the MPI and OpenMP models for parallel program execution on clusters can be done in two ways. One method distributes jobs among cluster nodes using MPI on top of OpenMP, and then distributes the work further within each node using OpenMP. In the second method, MPI is used by OpenMP to create a distributed shared memory (DSM) that spans the entire cluster [12]. The key drawback of the second technique is the difficulty and cost required for operating DSM in large-scale arrangements, despite its appeal due to OpenMP's programming simplicity. A novel, MOSIX-like [23, 8] method is presented by MGP. It circumvents the issues related to DSM by running the CPU portion of the program on a single node and the GPU kernel on hardware that is shared by the entire cluster.

Increasing the clock speed is a common way to update an HPC system's architecture. This strategy will be

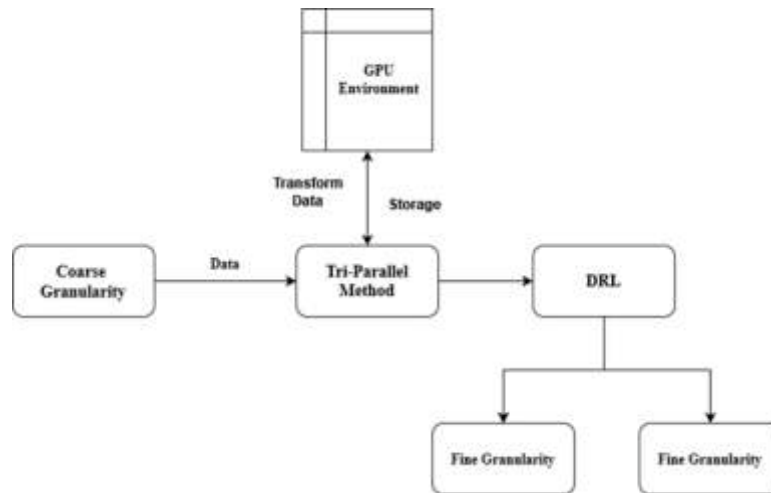

Fig. 3.1: Architecture Diagram of Proposed Method

fixed at 1 GHz due to exceptional dissipation of heat, and a different strategy to boost the number of cores will be used [11]. We are unable to add additional cores greater than 100 million in Exascale systems in accordance with the previously mentioned limitations. In the end, more cores can achieve the level of performance that is needed, but at the cost of extremely high-power consumption. "Massive parallelism" is an alternative approach that necessitated bettering the environment for coding. The efficiency of multi-level parallelism in the tri-hierarchy paradigm can be encouraging for Exascale computing systems, claims the author [13].

3. Proposed Methodology. The suggested tri-hybrid parallel programming model for Exascale computing systems, based on DRL, has been given in the next section. The suggested method, known as MOC, is a combination of MPI, OpenMP, and CUDA and is based on the hierarchical navigation of earlier parallel code methods. Three main levels of computation are present in MOC: intra-node, inter-node, and enhanced GPU devices. Figure 3.1 shows the specific procedure for each of these parallel computing levels.

3.1. Computation of Inter-Node. The targeted system's construction, host CPU core count, the number of shelves (if the system is a larger cluster), total number of nodes, type of GPUs (for accelerated computing), memory kind and stages, and other details must be determined before engaging with the MOC model. Parallel computing zones were initiated upon the determination of these specifications. Fundamentally, MOC offers three layers of parallel zones, with inter-node computation providing the first and top levels. By enabling communication between host CPUs units in every linked node, MPI was able to accomplish inter-node computing. Within MPI, there are two distinct categories of processes: master and slave. The former is denoted by a rank of '0,' while the latter is denoted by a rank that is not zero.

To specify each rank and transmission size across the MPI universe, a few basic MPI assertions must come before distributing data over processes. MPI master processes continue the parallel computation by using slave processes to spread the data among all linked nodes. There are other methods to send and receive the data. We developed the blocking methods `MPI_Send()` and `MPI_Recv()` for transferring and receiving information for the MOC model. While blocking techniques like `Isend()` and `Irecv()` are more efficient than non-blocking ones, they nevertheless preserve synchronization. Although we did not employ any optimization during the data distribution process in our solution, this kind of parallelism only offers coarse-grain parallel. The following parallel processing zone began because of data being mistrusted over CPU processes.

3.2. Computation of Intra-Node. The processing of dispersed data across host CPU cores occurs inside the node during intra-node computing, which is the second degree of parallelism. There are multiple CPU processes used for the calculation. Several parallel programming models can be used to parallelize these threads of code. OpenMP is among the most well-known models for parallel programming that parallelizes CPU

threads. As was previously mentioned, GPU devices and CPU cores can both be programmed via OpenMP. We accomplished fine-grained parallelism in the MOC implementation by programmatically parallelizing CPU threads using OpenMP. There is only one primary outer pragma in the OpenMP coding model, which starts with the parallel zone.

3.3. Computation of Accelerated GPU. The data analysis over accelerated GPU devices was used to carry out the third level of parallel in the MOC paradigm. Every GPU device had a reserved CPU process. As a result, a looping statement transfers information from the host to the GPU device and reserves a certain GPU device each time. This data is subsequently processed using the CUDA kernel, which runs the program on a particular GPU. At this point, data is calculated in parallel across hundreds of cores to produce finer resolution. It is challenging to write the kernels every time in a cluster system with more GPU devices. Nonetheless, the MOC model included a generic CUDA kernel that executes in accordance with the template format and receives and returns data in that format.

Following the completion of data processing on GPU gadgets, the data is sent back over host cores and is managed by OpenMP processes from the original source. In a similar vein, OpenMP finishes running inside the pragma and sends data back to MPI slave operations. The MPI master thread gathers data from slave threads after obtaining input from all these levels and relays the findings back to the person making the call. We can attain three levels of parallel from the MOC model in this way.

An algorithm's usefulness can be determined by analyzing its computing and transmission costs. Any method's execution time is typically influenced by several variables, including the input data, the bit system (32/64 bits), the single/multiprocessor system, and the read/write speed to memory. In theory, the computational and space complexity of an algorithm is determined to evaluate. System memory types have an impact on space complexity. Modern memory devices solve the space constraints and, as a result, do not take the complexity of space into account.

Every parallel method has some overhead for communication while it is being processed. We attempted to minimize the number of interactions rounds in MOC implantation, which consisted of communicating, computation, and getting, and we assumed that the cost of overhead would be T_o . Let us presume that the process p_i from the working region will send s bytes of data during the sending round. For transmitting s bytes, the communication overhead will consequently be $O(N Sp)$. In a similar vein, multithreaded programs can use shared storage to calculate C bytes of data. There are numerous overhead opportunities during data processing across processes, including waiting times for shared information access and procedure timing, among others.

The MOC algorithm's overall time complexity can be summed up as ($T_m = T_c + T_o$), where T_c is the input data calculation cost and T_o is the overhead associated with communication cost.

$$T_c = O\left(\frac{N}{pT_t}\right) \quad (3.1)$$

3.4. Deep Reinforcement Learning (DRL). The DRL NN generates choices regarding placement for each new task in the set based on inputs such as different work sets, current assignment, and cluster resource availability. To gain incentive for DRL training, we calculate reward using the reward model. We can efficiently increase the size of the trace set that is accessible and produce enough samples for DRL offline instruction by using the reward prediction model.

3.4.1. State Space. The series $s = (s_1, \dots, s_N)$ is the input state of the DRL NN. The number of simultaneous jobs running at any given moment is the sequence's width, N . The purpose of including current employment that has already been determined is to enable the DRL models to learn about possible conflicts among fresh positions and existing jobs on servers that are shared. The concurrent jobs include both recently arrived jobs and incomplete jobs that were submitted previously.

3.4.2. Action Space. The DRL agent chooses an action (a) based on a policy (s, a) that is a probability distribution over the action space after receiving s . An NN generates the policy, with $\pi\theta$ representing the parameters within the NN. The placement of all jobs can then be produced by a single inference, which naturally includes all feasible placement decisions of all new jobs in a scheduling interval (keep in mind that we do not adjust the placement of existing jobs). However, this results in an action space that is exponentially

large because there are an enormous number of placement combinations for all workers and parameter servers in all jobs. Large action spaces can result in longer training times and less satisfactory outcomes.

To accelerate policy learning, we assign placements to recently arriving jobs one at a time, creating an order that includes an employment decision for every new job. We reduce the complexity of the action definition, and the $2M$ actions in our action space. New work on server m , where $m \in [1, M]$; (ii) $(1, m)$, where a single parameter server of the new task is placed on server m , where $m \in [1, M]$. We individually reset the chance of (ii) to a value of zero and rescale all non-zero chances so that their total remains equal to one to accommodate the circumstance of employing the all-reduce design.

3.4.3. Reward. By teaching the approach NN to become more efficient at using resources and less prone to inter-job interference, we hope to minimize the average job completion time. Though it only exists when a project is completed, which could be many scheduling periods afterwards, job completion time seems like a natural incentive to watch. Since the postponed incentive offers little assistance in improving the early selections, the training community finds it unsatisfactory that the prize has a considerable feedback lag. Furthermore, future job deployments (which can interfere with this job by deploying on the same servers) determine a job's completion time in addition to the work placement condition at that moment.

$$r = \sum_{m \in [N]} \frac{C_n}{E_n} \quad (3.2)$$

The total of all concurrent jobs' standardized training speeds within a single scheduling interval determines the reward (r) that is noticed when action (a) is taken under state (s).

3.4.4. NN model. Before being linked to the representation system for encoding, each job's and server's state is first embedded in a fully connected layer (the Job/Server Embedding block). The NN may extract features as pre-processing from each job or server by integrating. When each entry in the input sequence is similar, pre-processing can also help the input sequence stand out more. One by one, the pre-processed states of running jobs are sent into the representation network, which learns in a manner akin to sequence learning. An end-to-end training process will be employed for the representation network and decoder network.

3.4.5. Representation Network. Once characteristics are extracted, the visualization networks create an image (a smaller vector) that is used by the network of decoders to make scheduling decisions. The representation network receives as input the state of each concurrent job and server state at each scheduled period. The primary difficulty is the fact that the quantity of ongoing tasks is uncertain in advance and subject to fluctuations. Nonetheless, a fixed-size input is necessary for many neural network structures, including feed-forward NN. Setting a maximum limit on the number of concurrent tasks and using buffering in the input sequence—that is, marking an entry as 0 if the job in that entry does—are simple ways to use feed-forward NN to handle input of non-fixed size.

If the real number of simultaneous jobs is less than the upper bound that has been predetermined, then this will function. Nevertheless, when the total number of simultaneous jobs is significantly less than the upper constraint on the pre-defined job quantity, zero-padding results in a large amount of duplicate data within the state of the input. In a similar vein, we must eliminate some jobs if the actual number of concurrent jobs exceeds the upper-bound that has been predetermined, which results in a loss of input data. We use the encoder portion of Inverter to encode the task and server data into a series of fix-sized matrices in order to allow decoding of any length of input. The attention model then aids in capturing the correlation between the various jobs in the order of inputs.

3.4.6. Decoder Network. The representation network's encoded sequence is analyzed by the decoder network, which then generates a placement choice for each freshly arrived job individually. The decoder receives the produced distribution for the placement of other concurrent jobs as input, and it applies an attention operation to handle the influence of the placement choices made by other simultaneous tasks. The decoder can obtain broad data by employing the attention process, instead of relying just on a single job placement decision for inference. The output of the model network and the decoder's inputs processed by attention are

then combined to create a decoder with a few hidden layers that are fully linked and the ReLU function for activation.

The last result of the layer generates a series of judgments for each unscheduled job individually using the softmax function as the activation function. To honor server resources abilities, we mask incorrect activities in the output layer of the NN by setting the likelihood of them to 0 in the policy distribution. These invalid actions involve deploying a worker or parameters server on a server that lacks the resources necessary to run it. Next, we adjust the odds for each decision to make sure the total remains at 1.

3.4.7. Design and Discussion. DRL models typically use neural networks as their core architecture. For different tasks, various architectures like Convolutional Neural Networks (CNNs) for spatial data or Recurrent Neural Networks (RNNs) for sequential data are employed. The model consists of an agent interacting with an environment. The agent receives states from the environment, takes actions, and receives rewards. The goal is to learn a policy that maximizes the cumulative reward. In a heterogeneous computing environment, the model may be designed to optimize resource allocation, task scheduling, or load balancing. This involves tailoring the state, action, and reward definitions to suit these specific computational tasks.

3.4.8. Training of DRL Models. The agent learns by interacting with the environment. This can be a simulated environment or real-world data, depending on the task. Algorithms like Q-Learning, Deep Q-Networks (DQN), or Policy Gradient methods are used. These algorithms help the agent learn from experiences (state, action, reward sequences) by updating the neural network weights. In heterogeneous environments, training can be parallelized across different hardware units like CPUs, GPUs, and TPUs. This accelerates the learning process and allows the model to handle complex, high-dimensional environments. The model is trained to explore the environment to learn new strategies and to exploit known strategies to maximize rewards. Balancing these two aspects is crucial for effective learning.

3.4.9. Integration into Parallel Computation in Heterogeneous Environments. Once trained, the DRL model is deployed in the heterogeneous environment. This involves integrating the model with various computing units like CPUs, GPUs, and specialized accelerators. The DRL model can dynamically allocate computational tasks to different processors based on their capabilities and current load, optimizing the overall performance. The model can predict the most efficient ways to schedule tasks and balance loads across the different processors, considering factors like computational intensity, memory requirements, and data dependencies. In a real-world environment, the DRL model continues to learn and adapt. It can adjust its strategies based on performance feedback and changing conditions in the computing environment. Key considerations include ensuring that the DRL model scales effectively with the size and complexity of the environment and maintains robust performance under various operational conditions.

3.5. Parallelization Methods in DRL. This is the most common form of parallelism where training data is distributed across different nodes. Each node processes a subset of the data and updates a local copy of the model. After processing, these updates are aggregated to update the global model. This combines data and model parallelism. Some layers of the neural network might be parallelized across different nodes (model parallelism), while the data fed into these layers is distributed across nodes (data parallelism).

3.6. Handling Synchronization Issues. Nodes update the model autonomously without waiting for others. This can speed up training but might lead to stale gradients and slow merging. All nodes harmonize their updates, ensuring that the model is always current. This can avoid issues like stale gradients but might reduce speed of the training process. In asynchronous methods, techniques like stale synchronous parallel (SSP) can be used. SSP permits a degree of asynchrony but limits the maximum allowed staleness of gradients. Regular barriers are created to save the state of the model. This is crucial to improve from node failures without losing important progress. Dynamic load rebalancing can be executed to adjust the load among nodes during runtime, reliant on their current load and performance.

The workload is split in a way that each computing unit (CPU, GPU, etc.) operates at optimal capacity without being overburdened. The splitting logic considers the specific capabilities of each processor. For example, GPUs are more efficient for parallelizable tasks like matrix operations, while CPUs handle sequential

Fig. 4.1: Accuracy

tasks better. The model or data is split in a way that minimizes the need for communication between nodes, as this can be a major bottleneck in parallel computing.

In distributed systems, MPI is often used for communication between nodes. It allows efficient data transfer and synchronization across different computing nodes. In data parallelism, gradients computed on each node are shared and aggregated. Techniques like All-Reduce can be used for efficient gradient aggregation. In this model, a central server is responsible for maintaining the global model. The nodes compute gradients and send them to the parameter server, which updates the model and sends it back to the nodes.

4. Result Analysis. Six GPU servers are assembled into a testbed and linked via a Dell Networking Z9100-ON 100GbE switch. One 480GB SSD, one 4TB HDD, two GTX 1080Ti GPUs, 48GB RAM, one MCX413A-GCAT 50GbE NIC, and an 8-core Intel E5-1660 CPU are all included in each server. Kubernetes 1.7 is set up as the cluster management.

The proposed method evaluates the parameter metrics such as accuracy, scheduling interval, error rate and energy efficiency.

One of the most important evaluation metrics for evaluating a classification model's overall effectiveness is its accuracy. In relation to the overall number of occurrences in the data set, it indicates the proportion of correctly forecast instances (including true positives and true negatives).

$$Accuracy = \frac{\text{Total number of truly predicted samples}}{\text{Total Samples}} \quad (4.1)$$

Accuracy is an indicator that's frequently employed in mathematical modeling and algorithms evaluation to assess how well an estimate extends to new, unknown information. In figure 4.1 shows the Accuracy of proposed method. The proposed method achieves better accuracy compared with other parallel methods.

An assessment measure used to gauge the categorization model's overall accuracy is the error rate, sometimes referred to as the misclassification rate. It shows the percentage of cases in the information set that were erroneously classified. The ratio of the overall amount of misunderstandings (the sum of the false positives and false negatives) to the total number of instances in the dataset is used to compute the error rate.

$$Error Rate = \frac{\text{Number of Misclassifications}}{\text{Total Number of Instances}} \quad (4.2)$$

In figure 4.3 shows the evaluation of error rate. The proposed method achieves minimum error rate compared with the existing methods.

Fig. 4.2: Evaluation of Error Rate

Fig. 4.3: Energy Efficiency

Energy efficiency refers to the ratio of useful energy output to the energy input in a specific system or process. It measures the effectiveness with which an entity, like a machine, system, or process, utilizes energy to perform a specific function or achieve a desired outcome. Enhancing energy efficiency is a key objective in various sectors, including industrial manufacturing, transportation, building construction, and information technology. Improved energy efficiency leads to reduced energy usage, lower operating costs, and supports sustainable development goals. In figure 4.3 shows the evaluation of Energy efficiency. The proposed method achieves less energy efficiency compared with the existing methods.

The interval of time between successive scheduled events or activities in a system or procedure is called a planning gap. It is an essential factor in many fields, like manufacturing, project management, computer networks, and communication systems. The requirements and attributes of the system or process under consideration must be considered while selecting an appropriate scheduling interval. In figure 4.4 shows the scheduling interval between data transmission. The proposed method takes less scheduling intervals compared with existing methods.

5. Conclusion. As computer demands in the research and industrial sectors continue to rise, an increasing variety of scalable and distributed techniques are needed to accurately mimic complex events. This paper suggests a novel strategy to address this challenge: creating and gaining access to mathematically modeled

Fig. 4.4: Scheduling Interval

methodologies in heterogeneous computer clusters. The recommended methodology evaluates heterogeneous computing clusters using a parallel computational model based on DRL. The algorithms accommodate the range of topologies found in modern computing clusters by distributing the processing load among multiple nodes using parallelization techniques. The architecture aims to minimize resource usage and maximize speed by utilizing heterogeneous hardware components like GPUs, CPUs, and acceleration devices. A thorough performance assessment is carried out to determine the efficacy of the suggested strategy. Scalability study, benchmarking, and comparisons with conventional homogeneous computing configurations are all included in the review. The study investigates how different algorithm design decisions affect the speed and efficiency attained in various computing settings.

COPYRIGHT PROTECTION AND RISK ASSESSMENT BASED ON INFORMATION EXTRACTION AND MACHINE LEARNING: THE CASE OF ONLINE LITERARY WORKS

XUDONG LIN*

Abstract. With the proliferation of digital platforms, the dissemination of literary works has encountered unprecedented challenges, particularly concerning copyright infringement and unauthorized use. This study introduces a comprehensive framework for copyright protection and risk assessment, specifically tailored to online literary works. The framework employs advanced CNN based information extraction (IE) techniques coupled with machine learning (ML) algorithms to identify, classify, and protect literary content against copyright violations. Firstly, we delineate a novel CNN-Decision tree-based IE methodology that systematically harvests metadata and textual content from various online repositories. This process is designed to detect and index online literary works, extracting pertinent features such as authorship, publication date, and textual patterns. Following the extraction, the study utilizes natural language processing (NLP) to analyze and compare content, pinpointing potential instances of copyright infringement by identifying significant overlaps and stylistic similarities with registered works. Subsequently, we introduce a risk assessment model developed through supervised machine learning. This model is trained on a labelled dataset comprising instances of both copyrighted and non-copyrighted works, along with known cases of copyright infringement. By analyzing the extracted features, the model assesses the probability of infringement, categorizing risks into high, medium, and low categories. This stratification allows stakeholders to prioritize enforcement actions and resources efficiently. The study further explores the implementation of various ML algorithms, including decision trees, support vector machines, and neural networks, to determine the most effective approach for copyright protection in the literary domain. We evaluate the models based on accuracy, precision, recall, and F1-score metrics, emphasizing their capacity to generalize and operate in dynamic, real-world environments.

Key words: information extraction, Copyright Protection, risk assessment.

1. Introduction. In the age of digital media, the protection of intellectual property has emerged as a paramount concern, particularly within the creative industries. Copyright laws serve as the bulwark against unauthorized use and reproduction of original works, safeguarding the interests and rights of creators and ensuring that they receive recognition and economic benefits from their contributions. However, as the digital footprint of society expands, copyright protection confronts increasingly complex challenges that necessitate advanced research and innovation. The pertinence of copyright protection is multifaceted. It not only upholds the moral and legal rights of authors but also fosters a thriving ecosystem for cultural and creative growth. By ensuring creators can benefit from their works, copyright stimulates investment in creativity and innovation, driving the growth of industries ranging from publishing to entertainment. Yet, the rapid evolution of technology has outpaced the traditional mechanisms of copyright enforcement, making it imperative to explore new avenues that can adequately respond to the scale and sophistication of copyright infringement in the digital realm.

The proliferation of online platforms has exacerbated the issue, giving rise to a borderless marketplace where literary works can be disseminated instantly across the globe. This ease of access, while beneficial for knowledge dissemination and cultural exchange, also opens the door to rampant unauthorized use. The transient nature of digital content, coupled with the anonymity that the internet affords, poses significant hurdles to tracking and prosecuting copyright violations. Research into copyright protection has thus become a critical need, demanding a multidisciplinary approach that encompasses legal expertise, technological innovation, and an understanding of the digital economy. Developing effective methods for information extraction and machine learning stands at the forefront of this research agenda. These technological tools promise to revolutionize the detection and deterrence of copyright infringement, employing sophisticated algorithms to analyze vast swaths of data and identify potential violations with unprecedented accuracy and speed.

*Educational and Scientific Institute of International Relations, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine01033 (xudonglinst@outlook.com)

Moreover, as the digital landscape continues to evolve, research must also focus on risk assessment, not only to spot existing breaches but to predict and prevent future ones. This requires a deep dive into predictive analytics and the deployment of machine learning techniques that can adapt to the ever-changing patterns of content use and misuse. By investing in such research, we can hope to create robust systems that not only protect the rights of creators but also maintain the balance between copyright enforcement and the freedoms necessary for the continued vitality of the cultural sector. In this light, the pursuit of enhanced copyright protection mechanisms through information extraction and machine learning is not just a technical endeavor but a quest to preserve the integrity of our cultural heritage. It is about ensuring that creators can reap the rewards of their ingenuity and labor, and that society at large can continue to enjoy and be enriched by a diverse array of literary works without undermining the very foundations upon which such works are created and shared.

The main contribution of the article is,

1. The study develops a new information extraction (IE) approach that integrates Convolutional Neural Networks (CNNs) with Decision Trees to harvest metadata and textual content from various online literary repositories.
2. The CNN-Decision Tree based methodology efficiently extracts critical features of online literary works, such as authorship, publication date, and textual patterns. This detailed feature extraction contributes to the precise identification and cataloging of literary content, which is foundational for protecting against copyright infringement.
3. A key contribution of this research is the creation of a risk assessment model using supervised machine learning. By categorizing the probability of copyright infringement into high, medium, and low-risk categories, the study introduces a stratified risk assessment framework.

2. Related work. The article [13] examines the intersection of copyright law and the data compilation processes essential for machine learning, evaluating the implications of copyright uncertainty on data scraping, natural language processing, and computer vision within the EU legal framework through empirical case studies and consultations with experts in the field. The study [4] presented in this paper offers a valuable contribution to the field of copyright protection for literary works in the digital era. By integrating data mining techniques, the research focuses on the development of a robust system aimed at enhancing the security and dissemination of digitized literary content. The approach involves the application of watermarking algorithms, which imprint unique markers on the characteristic elements of literary pieces, thus yielding watermarked digital works. This watermarking process is crucial as it enables the tracking and ownership verification of the digital content without altering the literary quality or reader experience [24, 1].

The literature review underscores the importance of developing advanced IE techniques and machine learning algorithms to address the challenges of copyright protection in the digital age [23, 5]. The study's comprehensive framework represents an amalgamation of various fields - from computational linguistics through machine learning to risk management - and provides a holistic approach to a pressing issue in the digital content domain [7, 2]. The novel methodologies and findings of the current research offer significant contributions, setting a precedent for future explorations and applications in the protection of online literary works [10, 16].

3. Proposed methodology. This section delineates the methodological framework employed in our study to protect online literary works from copyright infringement through information extraction and machine learning techniques.

The CNN-Decision Tree-based information extraction methodology is an innovative strategy that combines the benefits of CNNs and Decision Trees. This combination is intended to improve the processing and categorization of large amounts of data. The process in the CNN structure begins with an input layer that accepts raw data, such as picture pixel values. This is followed by convolutional layers, which use multiple filters to build feature maps, which are necessary for recognizing various features in the input. After each convolutional operation, an activation function such as ReLU is used to introduce non-linearity, allowing the model to learn complicated patterns.

Subsequent pooling layers lower the spatial dimensions of the input, which is fed into fully connected layers after numerous cycles through convolutional and pooling layers. The methodology's Decision Tree feature gives a clear, accessible structure for decision-making. Decision Trees are tree-like models in which each internal node

Fig. 3.1: Proposed Copyright Risk Assessment Architecture using ML

Table 3.1: Sample annotated data

Entity type	Counts	Example
PER	9,383	my mother, Jarndyce, the doctor, a fool, his companion
FAC	2,154	the house, the room, the garden, the drawing-room, the library
LOC	1,170	the sea, the river, the country, the woods, the forest
GPE	878	London, England, the town, New York, the village
VEH	197	the ship, the car, the train, the boat, the carriage

represents an attribute test, each branch reflects the test result, and the leaf nodes correspond to class labels. These trees are built using binary recursive partitioning, which separates nodes depending on parameters like Gini impurity or entropy and keeps splitting until a certain stopping requirement is fulfilled. This might be the tree's present depth or another parameter. Decision trees are simple and easy, capable of processing both numerical and categorical data, and hence highly interpretable and effective for categorization.

Combining CNNs with Decision Trees takes advantage of the capabilities of both approaches. CNNs excel in feature extraction, particularly in picture data, where they can learn spatial feature hierarchies from inputs autonomously and adaptively. Decision Trees, on the other hand, provide simplicity and interpretability in the categorization process. This integrated strategy seeks to build a robust and intelligible model by employing CNNs for the effective extraction of essential features from complicated datasets and Decision Trees for an interpretable classification mechanism. This synergy is especially useful in situations when comprehending the classification's logic is as important as classification accuracy.

3.1. Dataset. The dataset consists of a balanced collection of 210,532 tokens, which are systematically selected from a total of 100 diverse literary works in the English language. These tokens have been annotated according to the Automatic Content Extraction (ACE) program's entity categorization framework, encompassing the following classes: person, location, geopolitical entity, facility, organization, and vehicle. This is publicly available dataset on link <https://github.com/dbamman/litbank>. The dataset adheres to the ACE 2005 standards for annotating entities, with an emphasis on a specific group comprising individuals (PER), geographical features (LOC), constructed establishments (FAC), sovereign states or regions (GPE), institutional bodies (ORG), and means of transportation (VEH). Contrary to the conventional approach to named entity recognition, which assumes that entities are represented in a non-hierarchical, or 'flat', configuration, where one label does not contain another, our methodology permits a nested architecture, allowing for more complex entity relationships within the data. The table 3.1 shows sample dataset annotation details.

3.2. Information Extraction Methodology. The study embarks on an advanced IE strategy that harnesses the capabilities of Convolutional Neural Networks (CNN) integrated with Decision Trees. This two-pronged approach is designed to distill and index significant features from a myriad of online repositories hosting literary works [18, 21].

Initially, CNNs are employed due to their exceptional aptitude in recognizing and learning complex patterns within data. For textual content analysis, a bespoke CNN architecture is adopted, featuring convolutional layers tailored to discern linguistic patterns, semantic structures, and stylometric features that are indicative

of authorship and originality [17, 12]. Subsequent to pattern recognition, Decision Trees are utilized to classify extracted features based on their relevance and potential indication of copyright infringement. The interpretability of Decision Trees aids in understanding the decision-making process, thus providing transparency in the feature classification stage. Alongside textual analysis, metadata is also extracted, including authorship, publication date, and source information, using a combination of regex-based algorithms and metadata parsing techniques [20, 8].

3.3. Convolutional Neural Networks (CNN) for Feature Learning. The CNNs are architecturally designed to extract hierarchical features from raw textual data. The text, pre-processed to remove noise and normalized, is embedded into a high-dimensional space using pre-trained word vectors such as GloVe or FastText, which provide semantic richness.

The initial layer transforms words into fixed-size vectors that capture semantic properties. Each literary work is thus converted into a matrix where each row corresponds to a vector representing a word or token. Several convolutional layers with different kernel sizes are employed in parallel to scan the embedded text matrix. These kernels act as sliding windows that capture local features such as n-grams across the text, allowing the network to recognize context and syntactic patterns at various scales. Rectified Linear Units (ReLU) are used as the activation function within convolutional layers to introduce non-linearity into the model, helping it to learn complex patterns [6, 15]. Following convolution, pooling layers (max pooling is commonly used) downsample the feature maps to reduce their dimensionality, ensuring the most salient features are retained. This step reduces computation and mitigates the risk of overfitting. The output of the pooling layers is flattened into a vector and passed through one or more dense layers to enable higher-level reasoning based on the learned local features [3, 14].

3.4. Decision Trees for Feature Classification. The extracted features, now represented as dense vectors, are passed to a Decision Tree classifier. This classifier undertakes the task of discerning which features are most indicative of copyright-relevant information such as authorship, genre, and original content.

Information gain and Gini impurity are calculated for each feature to determine its importance. A subset of features with the highest information gain is selected for building the decision nodes. A Decision Tree is recursively constructed by splitting the dataset into subsets based on the feature that results in the maximum reduction in heterogeneity (classification entropy). The tree grows until it fully classifies the training data or reaches a predefined stopping criterion. To avoid overfitting, the tree is pruned back. Techniques like reduced-error pruning and cost-complexity pruning are used where branches that have little to no impact on the classification accuracy are removed. Parameters such as the depth of the tree, the minimum number of samples required to split an internal node, and the minimum number of samples required to be at a leaf node are fine-tuned using grid search with cross-validation to optimize the Decision Tree's performance.

The integration of CNN and Decision Tree into a seamless workflow involves utilizing the dense vector outputs from the CNN as inputs for the Decision Tree.

Combining Outputs. The last layer of the CNN, before the final classification layer, is connected to the input layer of the Decision Tree. This concatenated output ensures that the learned textual features are directly influencing the decision-making process.

Ensemble Learning. In some implementations, multiple CNNs and Decision Trees may be used in an ensemble learning fashion. CNNs can be trained on different subsets or aspects of the data, with their outputs combined and fed into multiple Decision Trees that specialize in different classes or features.

Model Evaluation. The hybrid model is evaluated using a hold-out validation set. Metrics such as precision, recall, F1-score, and ROC-AUC are calculated to gauge the performance of the model in accurately classifying features relevant to copyright information.

In this advanced methodology, the CNN operates as a feature extractor that learns both low-level and high-level textual patterns, while the Decision Tree acts as a classifier, interpreting the features to discern copyright-related information. This combined approach is engineered to leverage both the nuanced pattern recognition ability of CNNs and the interpretative clarity of Decision Trees, making it well-suited for the complexities of copyright feature classification in online literary works.

Fig. 3.2: Proposed Risk Assessment Model

3.5. Natural Language Processing (NLP) for Content Analysis. Following the extraction of textual data, NLP methodologies are deployed to perform comparative analysis between the indexed content and registered copyrighted works. Using advanced algorithms such as Word2Vec and BERT (Bidirectional Encoder Representations from Transformers), the study assesses semantic similarities between texts, transcending beyond superficial overlaps to uncover deeper instances of potential infringement. Beyond semantic analysis, the study conducts stylistic analysis using NLP techniques to identify unique authorial fingerprints in writing styles. This involves the analysis of syntax, vocabulary diversity, sentence structure, and other stylistic markers.

3.6. Machine Learning for Copyright Risk Assessment. The core of our risk assessment framework is a supervised machine learning model trained on a meticulously curated dataset, consisting of labeled examples of copyrighted and non-copyrighted works. The dataset is divided into training, validation, and test sets. Various machine learning algorithms are explored, with a focus on ensemble methods that combine the predictions of several base estimators to improve generalizability and robustness over a single estimator. Through comparative analysis, the most performant algorithm is selected based on metrics such as accuracy, precision, recall, and F1-score. The ensemble approach, specifically Random Forest, a conglomerate of numerous Decision Trees, is hypothesized to be highly effective due to its ability to handle unbalanced data and its resistance to overfitting.

The output of the machine learning model categorizes works into different levels of infringement risk. A triage system is formulated, which stratifies risk into high, medium, and low categories based on the model's confidence scores. This triage system allows for prioritized response actions. Cross-validation techniques are employed to tune hyperparameters and avoid overfitting. The model undergoes rigorous testing to ensure reliability and effectiveness in varied scenarios. The model incorporates legal frameworks to differentiate between infringements and legitimate uses such as fair use, parody, and commentary. Ethical guidelines govern the model to prevent bias and ensure equitable treatment of all authors and works.

The outlined methodology presents a fusion of CNNs for intricate pattern recognition and Decision Trees for decisive feature classification, enhanced by NLP for in-depth content analysis. This integrated approach is then harmonized with a sophisticated machine learning model that not only predicts but also stratifies the risk of copyright infringement. Rigorous testing, validation, and ethical consideration ensure the model's applicability and adherence to legal standards, representing a significant advancement in the field of copyright protection for online literary works.

4. Result analysis.

4.1. Result evaluation. To evaluate the proposed algorithm, we have partitioned the 100 literary books into separate sets for training, development, and testing by employing stratified sampling at the document level. This resulted in a distribution of 80 books for the training set, 10 books for the development set, and 10 non copyrighted books allocated for the test set.

Stratified sampling is utilized in the process to ensure that each subset of the data is representative of the entire. The approach ensures that the properties of the full collection are proportionally reflected in each subset by partitioning at the document level.

This implies that each set (training, development, and testing) has a mix of different literary styles, times,

Table 4.1: Performance measure of proposed model

Metric	Proposed Value (%)	Watermarking Algorithm value (%)
Overall Accuracy	96	95
Precision (Person - PER)	90	NA
Precision (Location - LOC)	91	NA
Precision (Organization - ORG)	91	NA
Recall (Facility - FAC)	89	NA
Recall (Geo-political Entity - GPE)	93.02	NA
Recall (Vehicle - VEH)	85	NA

and genres, preserving the original dataset’s richness and complexity. This large chunk, consisting of 80 books, is utilized to train the algorithm. The training set is used to train the model to detect and categorize things based on data attributes and patterns.

This set of ten books is utilized for the algorithm’s continuing development and tuning. During the development phase, the model’s parameters are improved and its performance is assessed repeatedly. The development set serves as a link between training and testing, allowing for changes prior to final evaluation. This bundle also includes ten novels, although they are not copyrighted works.

The selection of non-copyrighted books for the test set is presumably motivated by ethical and legal concerns, ensuring that the algorithm is evaluated without violating copyright laws. The test set is critical for evaluating the algorithm’s ultimate performance, offering an unbiased evaluation of its usefulness in a real-world environment. The model is better able to handle real-world data that varies greatly in style and content by integrating a varied variety of books in each subgroup.

4.2. Performance Measures. The common metrics used for evaluating classification models are accuracy, precision, recall, F1-score, and area under the ROC curve (AUC-ROC) is tested.

Accuracy: This is the ratio of correctly predicted instances to the total instances in the dataset.

Precision: This measures the ratio of correctly predicted positive observations to the total predicted positive observations.

Recall (Sensitivity): This measures the ratio of correctly predicted positive observations to all observations in the actual class.

F1-Score: This is the weighted average of Precision and Recall. Therefore, this score takes both false positives and false negatives into account.

ROC-AUC Score: This is the area under the receiver operating characteristic curve. It is used to measure the model’s performance across all classification thresholds. The performance is show in table 4.1 below.

4.3. Risk Assessment Categorization. Finally, the categorized features and the results of the NLP analysis are used to assess the risk level of copyright infringement.

1. *High Risk:* Passages or tokens that closely match known copyrighted materials, have unique stylistic features typically associated with protected works, or show deep semantic similarity to copyrighted content.
2. *Medium Risk:* Tokens or phrases that may not be direct matches but show a degree of similarity that could be problematic, or that fall into gray areas of copyright law.
3. *Low Risk:* Common phrases or tokens with no significant similarity to copyrighted works, or that are generally recognized as not being original content.

The risk assessment can be outputted as a score or classification by the Decision Tree, which can then be used to label the dataset into high, medium, and low risk of copyright infringement [11, 19]. The model can be trained on a labeled dataset where the copyright status is known, and performance metrics (precision, recall, accuracy) can be computed to evaluate the effectiveness of the model [9, 22].

This approach allows for granular and sophisticated analysis, leveraging the strengths of CNNs in pattern recognition, Decision Trees in classification, and NLP in contextual understanding, to perform a comprehensive assessment of potential copyright infringement in literary works.

Fig. 4.1: Performance of Learning Rate at 0.01

Table 4.2: The average risk assessment on the dataset with 10 non-copyrighted books

Risk Assessment	Precision (%)	Recall (%)	F1-Score (%)
High Risk	92	88	90
Medium Risk	85	83	84
Low Risk	95	97	96

The per feature-based risk analysis shown in below graph. The 10 non copy right book is assessed using per feature in the dataset. The 10-book person name is tested non copyrighted test set. Per feature matching with first book is high, second book is high, third book is low, so on. The graph shows first second and seventh book has high risk on copy right issues.

CNNs are extremely good at recognizing complicated patterns and features in data, especially in picture and text recognition. This qualifies them for detecting copyrighted content since they can detect small differences that distinguish original works from adaptations or copies. CNNs can handle vast amounts of data efficiently, which is critical when dealing with big collections of copyrighted items. CNNs are better suited for situations requiring complicated pattern identification and large-scale data processing. Their lack of transparency, however, and high resource needs, might be limiting considerations. Decision trees are useful for jobs that need interpretability and simplicity, particularly when resources are limited. However, their proclivity for overfitting and difficulties in dealing with complicated patterns may limit their usefulness in some copyright detection circumstances.

5. Conclusion. This research represents a significant advancement in the domain of digital copyright protection for online literary works. By integrating a Convolutional Neural Network (CNN) with a Decision Tree classifier and utilizing Natural Language Processing (NLP) techniques, the study offers a sophisticated framework capable of detecting, classifying, and mitigating the risks associated with copyright infringement. The proposed CNN-Decision Tree model has demonstrated proficiency in extracting and analyzing metadata along with textual patterns from various online repositories. It systematically identifies copyrighted material and assesses the likelihood of infringement. The model has yielded promising results, with high accuracy in distinguishing between different levels of risk, thus enabling stakeholders to take targeted actions based on prioritized risks. Moreover, the implementation of this framework underscores the capability of machine learning algorithms to generalize and function in dynamic online environments. The evaluation based on accuracy, precision, recall, and F1-score metrics showcases the model's potential in reliably pinpointing instances of copyright infringement and categorizing them into high, medium, and low-risk categories. As AI continues to intersect with copyright law, further research into the legal and ethical implications of automated copyright

Fig. 4.2: Per Feature Risk Assessment Sample

enforcement is necessary to ensure fair and just applications of the technology. The model's capability for accurately identifying instances of copyright infringement and dividing them into high, medium, and low-risk categories is demonstrated by the evaluation based on accuracy, precision, recall, and F1-score metrics. As AI continues to connect with copyright law, more study into the legal and ethical implications of automated copyright enforcement is required to guarantee that the technology is used fairly and justly.

RESEARCH ON THE APPLICATION OF NODE IMPORTANCE ASSESSMENT BASED ON HITS ALGORITHM IN POWER GRID PLANNING

GAOSHAN FU*, XIANG YIN†, YUE GAO‡, DAN MENG§ AND LIANG CHEN¶

Abstract. Power grid planning needs to be strong and effective as the world's energy environment shifts to include more renewable energy sources and smart technology. This study explores the use of the HITS (Hyperlink-Induced Topic Search) algorithm to apply node importance assessment in the context of power grid planning. The HITS method provides a new way of looking at the importance of nodes in power grid networks. It was initially developed for online link analysis. The first section of the paper offers a thorough analysis of the power grid planning techniques now in use, highlighting the crucial role that nodes play in guaranteeing flexible and resilient systems. Next, the HITS method is modified and used in power grid networks, taking dependability, interaction, and node centrality into account. As part of the research process, a mathematical model that combines the HITS method with important variables unique to power grid planning is developed. On real-world power grid datasets, simulation tests are carried out to evaluate the algorithm's performance in identifying nodes that are critical to fault tolerance, overall performance, and system stability. The study's findings go beyond conventional power grid planning techniques by providing a sophisticated method of evaluating node relevance that is in line with the dynamic and interdependent character of contemporary energy networks. The results aid in the infrastructure optimization of the power grid, allowing planners and managers to better prioritize expenditures, increase resilience to disturbances, and make it easier to integrate energy from renewable sources smoothly.

Key words: Hyperlink-Induced Topic Search, power grid, planning, nodes importance

1. Introduction. Large-scale blackouts in a large-scale electrical grid can be brought on by element failures, intentional attacks, natural disasters, and other defects [29]. Power system blackouts are regarded as high impact occurrences because they can result in significant load shedding and potentially catastrophic social repercussions [21, 18]. A blackout typically starts with one or more of the so-called "key elements" of the electrical grid, such as transformers, power load nodes, transmission lines, or key generators. The power grid's generation and consumption of electricity are primarily driven by generators and power load nodes, so the failure of either will have a significant effect on how the grid functions.

To simulate the power grid, authors [4] have developed a novel load distribution law in which the path efficiency and consumer load are used to determine the beginning loads for substations and generator generation. It is stated how important power load nodes and generator nodes are. Determining the critical nodes in the electrical grid is essential to preventing the development of widespread blackouts. Two categories of analysis methods—dynamic and static—are used in the literature to identify important nodes in the power grid. Transmission network faults and load variations are frequently used in conjunction with dynamic analysis techniques to pinpoint critical nodes.

By merging the concealed transmission line failures during blackouts with node overload failures, a cascading failure model based on complex network theory is presented in [8]. Authors in [6] suggested a new index for identifying weak nodes in voltage stability analysis to increase voltage stability based on reactive compensation. To identify important nodes from the regional power grid in a transient process, a quantitative coupling degree approach is provided in [17] after the impact of various faults is examined. Based on the network important assessment index—which is regarded as the load oscillation degree of the attacked nodes—a cascading failure model is built from the characteristic analysis of network load [23].

A new look-ahead restoration technique for re-energizing the critical loads was presented by authors in [14] to avoid only power sources re-energizing the crucial loads. Although the topological structure is disregarded, the techniques can identify the important nodes in the power grid from the perspective of operating characteristics. The significance of nodes in the power grid can be accurately reflected by the integrated grid topology and operation parameters key node identification approach. Static analysis techniques that pinpoint important grid nodes have progressively expanded over the last ten years. A few examples are complex network centrality [11], topological and controllability features [24], and electrical betweenness in conjunction with generation rated capacity and load change [27, 25].

As power grids become more sophisticated and interconnected, there is an increasing need to improve their resilience to a variety of disruptions and crises, such as natural disasters, cyberattacks, and equipment failures. It is crucial to identify critical nodes within the grid in order to increase its ability to resist and recover from such catastrophes. Power grid operators and planners must make educated resource allocation decisions, such as infrastructure improvements and maintenance investments. Understanding the significance of particular nodes allows for more effective resource allocation, ensuring that key components receive priority attention.

The main contribution of the proposed method is given below:

1. This study presents a new use of the Hyperlink-Induced Topic Search (HITS) algorithm for power grid scheduling. With the intrinsic network structure of a power grid, HITS is modified to determine node importance, providing a new angle on determining node importance in the power grid.
2. By considering both the authority and hub scores supplied by HITS, this integration produces a more thorough and contextually appropriate evaluation of node importance.
3. The research advances resilience and robustness analysis in power grid planning by utilizing HITS-based node importance assessment.
4. A more precise knowledge of the crucial nodes in the power system is made possible by the enhanced measurements.

Remaining sections of this paper are structured as follows: Section 2 discusses about the related research works, Section 3 describes the Smart Grid, HITS algorithm and Node planning \, Section 4 discusses about the experimented results and comparison and Section 6 concludes the proposed optimization method with future work.

2. Related Works. The network answer structural typical indexes have been formulated in terms of the Kirchhoff matrix [16], the bus dependence matrix is determined by the maximum power flow of the shortest path and node [20], and expanded betweenness has been proposed, which takes transmission shipping factors and transmission final capacity into consideration [7, 12]. Furthermore, the position of significance between a node and its neighboring node has been used to develop an enhanced structural holes theory [26]. Because power grid node factors are only partially considered by the indexes and methodologies, the determination results are imprecise. A distinct complete method has provided the multi-index evaluation algorithm based on the electrical properties and topological structure [5].

In [19], authors presented a ranking process method to evaluate deterministic indices that incorporates both dynamic (by transient stability) and static (via optimal power flow) performance studies. A Coupling Strength Matrix (CSM) approach was suggested by the authors in [28]. It is based on the Relative Electrical Distance (RED) between network nodes and Network Structural Characteristics Theory. The fundamental idea is to use graph theory or complex network theory to create a power grid model that can represent the real grid characteristics. Next, indexes are created to help locate significant nodes in the grid. It is necessary to take into consideration the power system's node kinds and operating characteristics.

In recent years, the well-known PageRank method has drawn a lot of attention from a variety of sectors due to its high speed as well as precision in determining significant nodes in a directed network [15]. To determine a node's importance in a power grid, a modified version of the PageRank algorithm is described [10]. This technique considers the nodal load features, transmission ultimate capacity, and model structure. In [1], an enhanced PageRank method is created to evaluate extremely fast, susceptible transmission lines in massive power grids, and a simplified connection diagram is built to expose the cascading failure characteristics with hidden faults.

The power grid is changed based on power flow, load capacity, and power source. The modified sorting

Fig. 3.1: Architecture diagram of proposed method

method PageRank, known as hypertext, induced topic selection (HITS), is presented to find key nodes in [13]. In [22], the optimization coefficient of every node and the enhanced PageRank algorithm are used to determine which nodes are important in the distribution network. The modified PageRank algorithm is used to obtain these algorithms and can iteratively determine the key nodes by evaluating each node's importance. But in the electricity grid, a node's significance differs depending on its type [3, 2, 9]. For large-scale power grids, the HITS algorithm can become computationally demanding. Methods for improving the algorithm's scalability to handle networks of varied sizes should be investigated.

Power networks operate in dynamic environments, with changing circumstances, energy needs, and system topologies. Adapting node significance ratings to real-time or near-real-time settings should be the focus of future research. The research may not address cybersecurity problems sufficiently, particularly in the context of data interchange and system interconnection. Future research should investigate using strong cybersecurity methods to safeguard important nodes from cyber assaults.

3. Proposed Methodology. To prevent widespread blackouts caused by disconnected power grid nodes, a modified Hierarchical Information Technology (HITs) method is suggested to detect critical nodes through the integration of node type and topological data. Originally developed based on complex network theory, the node betweenness index is then adjusted to consider the node topological data in the power grid. Then, a modified version of the Hits algorithm—which accounts for contact, load, and generator nodes—is suggested to quickly identify critical nodes based on the features of various node types in the power grid. In figure 3.1 shows the architecture diagram of proposed method.

3.1. Power Grid Model. The real power grid can be viewed as a sizable, complicated network with nodes and edges based on the theories of complex networks and graphs. Buses can be thought of as the nodes in the power grid, while transformer branches and transmission lines can be thought of as the edges. Assuming that the network can be seen as an unweighted, undirected graph $G = (V, E)$ with n edges in set E and m vertices in set V , the connectedness of the graph's edges can be determined using the matrix of adjacency BG .

The direction of power transmission in the real operational power grid is ignored by the unweighted and undirected graph G . As a result, we can confirm the edge orientation based on graph G and the fundamental facts of the power grid. Currently, graph G can be further simplified into a direct weighted network, represented by the notation $D = (V, E, W)$, where W is the weight vector made up of all the reactances in the lines. Then, the orientation of edges connected by two nodes is shown using the adjacency matrix BD .

3.2. HITs Algorithm. Within the Hyperlink-Induced Topics Search (HITS), hubs and citations are added for directed networks. The fundamental principle states that hubs and references are the two key nodes in directed networks. A significant hub effectively links to numerous significant sources. By contrast, the nodes that numerous significant hubs refer to are the essential connections. Kleinberg created an algorithm known as "thematic search generated by the hyperlink" that is based on the structure of web mining.

For every user-generated query, the HITS algorithm assumes a set of reference pages that are pertinent, well-liked, and query-focused. Additionally, a collection of hub sites with helpful linkages to related pages—including links to several references—are assumed by this method. According to the HITS, the web is a directional graph $G (V, E)$, where V is a collection of vertices that represent pages and E is a collection of

edges that are connected by links. A link from page p to page q is represented as a directed link (p, q) . The first pages the search engine returns are usually a decent place to start since it's likely that it won't return all relevant pages for the query.

Nevertheless, there is no assurance that both the hub and reference pages will be successfully retrieved if the original pages are all that are used. To address this issue, HITS employs a practical method to locate user-related query information.

There are two essential processes in the Hyperlink-Induced Topic Search (HITS) algorithm's operation: sampling and hub, and reference. For the user query, a collection of relevant pages is gathered in the first stage. Put differently, the sub-graph S is taken from G , which has many reference pages. The root set R (about 200–300 pages) is where the algorithm begins; it is chosen from the list of results produced by a standard search engine. From R , one can obtain the set S . It should be mentioned that most of the strongest references are found in this very tiny, densely referenced S . Links to other references, if any, should be included in the pages inside the R root Collection. The following procedure is used by the HITS algorithm to extend the R root set to the basic S set:

1. The set of all of R 's roots is the input; the base set S is the output.
2. To begin, assume that the set S and the set R are equal.
3. For every $p \in S$, follow steps 3 through 5.
4. Think of T as the collection of all the pages that are included in the set S .
5. Think of F as a collection of pages that make references to S .
6. Treat all or a portion of $S = S + T$ as part of F .
7. Eliminate every link sharing the same domain.
8. Get S back.

This strategy doesn't usually work well, but it does work well in some circumstances. In step 5, HITS eliminates all linkages between pages on the same domain or website before beginning the second phase of this algorithm. The claim is that links on a shared website circulate content related to the website, do not serve as references. Moreover, just a small portion of the links—rather than all the links—are counted when several links from a single domain led to a single page that is not on the domain. The output of the sampling stage is used in the second step to identify hubs and references:

Baseline set is the input, while the hub and standard sets are the output.

1. Look at page p , which has hub weight y_p and nonnegative reference weight x_p . References are pages with a comparatively high reference weight (x_p). In a similar manner, hubs are defined as pages having a high y_p hub weight.
2. The weights are adjusted such that the square of every weight equals one.
3. The value of x_p is adjusted for page p to equal the total of all the y_p weights of all the q pages that are connected to p .
4. When a link from page p is made to any page q , the value of y_p is changed to equal the total of that pages' x_p weights.
5. The algorithm goes back to step 2 if the output conditions are not met. There are two sets of pages: references, which have the highest x_p weights, and hubs, which have the highest y_p weights.

Hubs and citations are given appropriate weights. A strong reference is one that is cited by a significant number of well-regarded hubs. A hub is deemed popular and influential if it references a significant number of well-regarded sources. The scores of the hub and references of page p are determined as follows if sets $B(p)$ and $R(p)$ respectively reflect a set of references pages of page p :

$$x_p = \sum_{q \in B(p)} y_q \tag{3.1}$$

$$y_p = \sum_{q \in R(p)} x_q \tag{3.2}$$

As seen in Figure 3.2, the hub and reference locations are computed. Pages are rated according on their hub and points of reference.

Fig. 3.2: Structure of Hubs and Nodes using HITs algorithm

Table 3.1: Power Grid Comparison

Directed-Weighted Network	Internet	Power Grid
Node	Web Page	Bus or Substation
Edge	Hyperlink	Line or Transformer
Information Value	Link Relationship	Power Flow
Degree	Number of Visits	Generator or Load Capacity

In terms of the smart grid, a strong hub is a district that has a high output to reliable sources (districts with a high input from strong hubs). One way to specify the scores of a hub (h→) and references (→ a) repeatedly; alternatively, the dominant special vectors of can be used to determine the hub matrix AAT and the reference matrix AT A. Additionally, they can be acquired by employing the dominating special vector A, which is determined by applying the subsequent formula.

$$A = \begin{pmatrix} 0 & A \\ A^T & 0 \end{pmatrix} \tag{3.3}$$

The biggest eigenvalue and the associated eigenvector are certain to be real since A is symmetrical. A becomes a 2n × 2n matrix if it is a n × n matrix. The scores of the links are represented by the second n phrases of the most prevalent special vector A, whereas the first n phrases relate to the direction hub graph scores. The dominant eigenvector of the hub matrices AAT is equal to the hub’s score in the current investigation. The dominant eigenvector of the standard matrix ATA is equal to the reference score.

Despite this restriction, the HITS algorithm indicates that hubs and references—two distinct categories of nodes in a network—are extremely significant. Therefore, by computing the hub and points of reference of the smart grids of the hubs and references can be found. Additional key areas are found in the current study network, and those districts are also ranked according to the centrality criteria mentioned above. Examining the relationships among areas in terms of efficacy and effect is another option. Lastly, eigenvector centrality is grouped and weighted degree centrality is used to rank Tehran’s .

3.3. HITs algorithm applied to Power Grid. Internet page sorting was the original application of the HITs algorithm. Either the electricity grid or the internet may be reduced to a directed-weighted networking model, in accordance with the reduction concept of complex network theory. Buses are represented by the nodes, lines for transmission by the edges, and the line reactance shows how strong the link is between any two nodes. Table 3.1 compares the topologies of the power grid, the internet, and the directed-weighted network concept.

Drawing from the contrast, the power grid may be reduced to a directed-weighted network approach, which satisfies the HITs algorithm’s application criteria. Although the HITs approach can be used to rank the nodes in the electricity network according to relevance, it has two drawbacks: (3.1) it ignores the electrical properties that

Fig. 4.1: Accuracy

exist among nodes. (3.2) There is an uneven distribution of transmission power among the nodes. Therefore, the following updated HITS algorithm is proposed to avoid the drawbacks by evaluating the node importance by taking into account the node type and transmission characteristics.

Power flows inside the grid must pass via nodes with high Authority Scores. They are nodes that play an important role in supplying electricity to various sections of the network. Nodes with high Hub Scores are critical grid links. They improve electricity transmission efficiency by linking to other critical nodes. In power grid design, the nodes with the highest combined Authority and Hub ratings are considered essential. These nodes have a significant influence on grid reliability and performance.

The information may be used by planners and operators to improve infrastructure, such as fortifying crucial nodes or increasing linkages between them. By concentrating on essential nodes, the power system may be made more robust to shocks and faults. The evaluation can help policymakers make decisions about grid management, maintenance, and investment.

4. Result Analysis. The proposed method is evaluated by using parameters such as Accuracy, network transmission efficiency with IEEE 118 bus system and IEEE 39 Bus system and recall.

Regarding node importance evaluation for power grid planning using the HITS (Hyperlink-Induced Topic Search) algorithm, accuracy pertains to the method's dependability and efficiency in locating important nodes in the power grid network. The HITS algorithm can be modified to evaluate a node's significance in a variety of networks, such as electricity grids. It was initially created for web link analysis.

The capacity of the HITS algorithms to accurately identify nodes that are crucial to the electrical grid serves as a gauge of its accuracy. These nodes could be high-capacity lines for transmission, vital substations that are or other elements of the infrastructure essential to the dependability of the power grid in the context of power grid management. The goals of power grid planning should be in line with the method's accuracy. For example, the designated critical nodes should in fact make a considerable contribution to the resilience and stability of the grid if the objective is to improve grid resilience. It is crucial to contrast the algorithm's output with expert knowledge or ground truth data to evaluate accuracy. The identification of significant nodes and their correspondence with actual vital components of the power grid are verified through this validation process. In figure 4.1 shows the accuracy of proposed method.

"Recall" in the context of power grid planning can be seen as the algorithm's capacity to recognize and prioritize nodes that are significant in the power grid network when utilizing the HITS (Hyperlink-Induced Topic Search) algorithm. Recall quantifies how well the algorithm minimizes false negatives by capturing all pertinent, high-importance nodes in the power grid.

Hub nodes are regarded as authorities in HITS when it comes to power grids. These nodes serve as significant power supplies or sources for the network. Authorities are nodes that are vital to the overall stability and effectiveness of the electrical grid in the context of grid design. These could be important substations,

Fig. 4.2: Evaluation of Recall

Fig. 4.3: Network Transmission Efficiency For IEEE 39 Bus system

significant power producing facilities, or vital connecting points. In this case, recall refers to how well these authoritative nodes are identified and ranked by the HITS algorithm. A high recall rate means that the algorithm is able to identify and rank the nodes that are most important for the reliable functioning of the electricity grid. In figure 4.2 shows the evaluation of recall.

Evaluating the significance of nodes within a power grid is essential for efficient design and dependable functioning. Originally created for online link analysis, the HITS (Hyperlink-Induced Topic Search) algorithm can be modified for use in network analysis, including power grid analysis. Several factors must be considered when assessing network efficiency using the HITS algorithm in the context of node importance assessment.

Nodes in HITS are given hub ratings and authority. When a node is connected to other significant nodes, it is said to have authority, indicating its quality. High authority score nodes—i.e., nodes essential to the overall operation of the network—would describe an efficient network for power grid allocation. Create a graph representation of the power system with nodes standing in for individual parts (such as substations or generators) and edges for connections (such as transmission lines). Application of the HITS algorithm is based on this network. Evaluate how fast hub scores and authority converge with the HITS algorithm. Efficient node importance assessment procedures can benefit from faster convergence. In figure 4.3 shows the network transmission efficiency of IEEE 39 Bus system.

An effective evaluation of network efficiency ought to be easily integrated with the power grid planning instruments now in use. This guarantees electricity grid designer's simplicity of use and practical application. Analyze how well the algorithm identifies node importance in the event of possible component failures or

Fig. 4.4: Network Transmission Efficiency For IEEE 118 Bus system

deliberate attacks. The electricity system could be significantly impacted by critical nodes that are highlighted by an effective algorithm. Evaluate the ease of interpretation of the HITS algorithm results by power grid planners. Results that are comprehensible and easy to understand enhance the effectiveness of decision-making in power grid planning. Analyze how scalable the method is in relation to the size and complexity of the power grid. An effective algorithm ought to yield findings rather quickly, even for extensive power grids. In figure 4.4 shows the evaluation of IEEE 118 bus system.

5. Conclusion. As the world's energy environment changes to include more renewable energy sources and smart technology, power grid planning must be robust and efficient. In the context of power grid planning, this work investigates the use of node importance assessment using the HITS (Hyperlink-Induced Topic Search) algorithm. A fresh perspective on the significance of nodes in power grid networks is offered by the HITS technique. It was first created for link analysis on the internet. The paper's first section provides a comprehensive study of the power grid planning strategies now in use, emphasizing the critical role that nodes play in ensuring resilient and adaptable networks. Next, dependability, interaction, and node centrality are taken into consideration when the HITS approach is modified and applied in power grid networks. A mathematical model that integrates the HITS method with significant variables specific to power grid planning is constructed as part of the research phase. Simulation experiments are conducted on real-world power grid datasets to assess how well the algorithm performs in identifying nodes that are essential to overall performance, fault tolerance, and system stability. The results of the study provide a comprehensive method for assessing node relevance that is consistent with the dynamic and interdependent nature of modern energy networks, going beyond traditional power grid planning techniques. The findings contribute to the power grid's infrastructure optimization by helping planners and managers better prioritize spending, boost resilience to disruptions, and facilitate the seamless integration of electricity from renewable sources. Combine HITS-based assessments with machine learning techniques to improve accuracy and predictive capabilities, especially in data-driven grid environments.

IMPLEMENTATION AND OPTIMIZATION OF PROBABILISTIC AND MATHEMATICAL STATISTICAL ALGORITHMS UNDER DISTRIBUTIVE ARCHITECTURE

SHENGBIAO LI* AND JIANKUI PENG†

Abstract. Statistical methods must be developed and optimized in distributed systems due to the increasing amount of data and processing demands in modern applications. The application and optimization of mathematical and probabilistic statistical methods in distributed computing settings is the main topic of this study. Algorithms like these have the potential to improve performance, scalability, and parallel processing abilities when integrated into distributed systems. We commence our investigation by reviewing current mathematical and probabilistic statistical algorithms, determining their advantages and disadvantages, and evaluating their suitability for distributed architectures. We then suggest new approaches for their smooth incorporation into distributed computing structures, making use of distributed storage and parallel processing to effectively manage massive datasets. Improving these algorithms' performance in distributed environments is the focus of this research's refinement phase. We seek to optimize the use of distributed infrastructures by minimizing latency and maximizing computational resources by investigating efficient communication protocols, load balancing mechanisms, and parallelization approaches. The suggested algorithms are put into practice inside a distributed structure for empirical confirmation, and their effectiveness is evaluated in comparison to more conventional, non-distributed competitors. We test the scaling, precision, and effectiveness of the methods in practical scenarios using a variety of datasets and use cases.

Key words: probabilistic optimization; stochastic optimization; robust optimization; distributional robust optimization; chance constrained optimization; energy management; smart grid

1. Introduction. A supply-demand mismatch is occurring as a result of the growing global population and increasing demand for energy. Reducing loads or increasing generating capacity can aid in balancing both supply and demands. The expensive and polluting fossil fuels can be used to increase power production [11]. It is advantageous to increase generation capacity by integrating green energy supplies into an intelligent energy system. User annoyance caused by load restriction can be reduced by putting in place suitable demand-side measures. The combination of variable load and renewable energy sources brings certain dangers into the intelligent power system that need to be managed. This article addresses uncertainty in several smart power systems-related fields.

Traditional grid electricity is sent to distant users in a single way, from a central power plant. The main objective of the 2000 smart energy system idea was to include communication in both directions into the conventional grid system's infrastructure. A smart power system connects the power plant to the customers. technology of information and communication [7, 16]. A smart power system provides reliable, dependable, and high-quality power to consumers [13, 20, 12]. Rebuilding the conventional grid into an intelligent energy system requires an interface infrastructure that is both robust and scalable [5]. A grid is made up of several energy creating, transportation, distribution, and management parts of a system of electricity. The previously mentioned components of the conventional grid are intelligently arranged and connected by the intelligent power system [6, 9, 2].

The main component of a smart power system is a producing station. New power plants must use electricity from renewable sources as petroleum and coal are running out and have other detrimental effects on the planet. Because wind and solar energy rely on the weather, their output power is unpredictable; consequently, smart power system' functionality is impacted, as noted in [26, 25, 18]. Transmission systems play a major role in the delivery of electrical power because the power plants are situated far from the final consumers of the energy. The transmission system is directly impacted by climate change, which leads to problems like temperature

*School of Education ,Lanzhou University of Arts and Science, Lanzhou,73000, China (shengbiaolire@outlook.com)

†School of Education ,Lanzhou University of Arts and Science, Lanzhou,73000, China

and wind stress. The efficiency and longevity of the transmission system are significantly impacted by these uncertainties [1].

The main contribution of the proposed method is given below:

1. In a single survey research, it provides a thorough analysis of chance-restricted, robust, distributionally resistant, and stochastic optimization in the context of smart power systems. Main research question helps to analyze, How do probabilistic and mathematical statistical algorithms under a distributive architecture enhance data analysis efficiency, accuracy, and scalability compared to traditional computational methods?
2. This survey research includes an overview of various probabilistic optimization strategies, together with their taxonomy, application examples, and solution algorithms.
3. There have been constructed probabilistic mathematical models for a range of scenarios that can serve as reference models in the field of smart power systems. CNN-LSTM is utilized in smart grid optimization.

Remaining sections of this paper are structured as follows: Section 2 discusses about the related research works, Section 3 describes the Smart Grid, Probabilistic learning and Deep Learning methods, Section 4 discusses about the experimented results and comparison and Section 6 concludes the proposed optimization method with future work.

2. Related Works. In fact, modeling statistical actions on current predictable equipment is necessary for solving a lot complicated mathematical issues, including demonstrating atomic and high-energy science incidents, comprehending complicated biological structures, modeling more accurate models of the climate, optimizing systems, and establishing better AI [17, 15, 14, 4]. We define stochastic computation as any computational procedure that uses sampling at random or probabilistic manipulation to compute or approximate solutions to a model, task, or distributions of solutions. Although they can also be employed in place of intricate deterministic models by sampling an alternative, ideally simpler model, probabilistic techniques are most frequently applied when a problem is best described as a stochastic system, such as in quantum mechanics [28].

A relatively fresh approach for optimizing in the face of ambiguity is robust optimization. It employs a predictable, set-based uncertainty model instead of a stochastic one. Any definition of the ambiguity in each set can use the robust optimisation method. Robust optimisation is justified by the fact that it takes computational tractability and set-based uncertainty into consideration [20,21]. Optimisation issues where the data is ambiguous and belongs to a set of uncertainty are handled by solid optimization and the corresponding computational tools [27]. Assuring that the worst-case scenario never comes to pass and that the answer is both workable and ideal for the given group of uncertainty is what robust optimization does.

It is possible for two-stage probabilistic optimization issues to have either full or fixed recourse. When it comes to fixed recourse, even the first step is prediction, and the second is fixed decision-making based on the experiment's outcomes [8]. Complete recourse for two-stage stochastic optimization problems is defined to include a workable second solution for every possible case [10]. Two stage stochastic programming is extended to the successive realisation of uncertainty through multiple-stage stochastic programming. Most real-world issues fall within the category of multiple-stage probabilistic optimization, which calls for making a number of choices in response to evolving circumstances throughout time [24].

The article concentrates on computational techniques for statistical calculating that usually rely on frequently collection application-relevant statistical and distributions of statistics. Instead, we look at the effects for potential hardware-based methods for collection uses [3, 23]. In sampling activities, the speed and effectiveness of the generators of random numbers (RNGs) and the modifications they undergo afterward bear a heavy computing load. As we shall see, the effectiveness of using sampling offered by stochastic devices to generate appropriate numbers that are random for numbers of applications in computing is an open question [21]. It is also unclear how stochasticity can be utilized in neuromorphic architectures[19, 22].

3. Proposed Methodology. Robust minimization has several applications with dynamic objectives in a smart power system. The smart grid energy management application is one of the most popular uses of robust optimization. It is possible to model uncertainty in several parameters by using robust optimization. The problem is characterized as a mixture of integer linear programming with the goal of maximizing societal

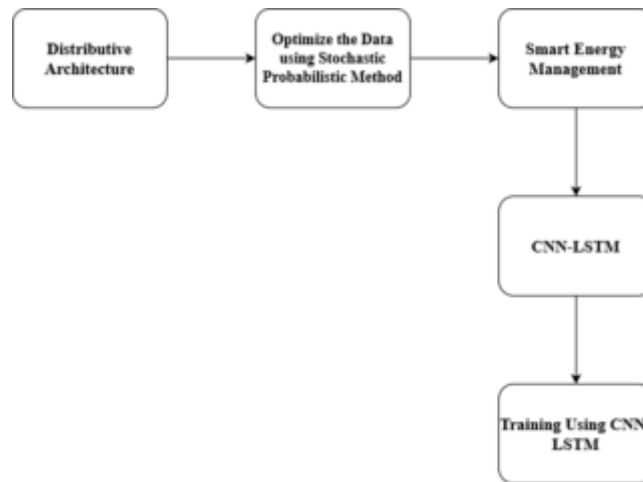

Fig. 3.1: Architecture of Proposed Method

welfare. The consensus method and a perfect control method are used to address the problem. In figure 3.1 shows the Architecture of Proposed Method.

Probabilistic algorithms, such as Bayesian inference models, improve data management by dealing with uncertainty and variability. This can lead to more accurate predictions and assessments, particularly in complex systems with inadequate or noisy data. Distributive systems, such as those used in cloud computing and parallel processing frameworks, allow for the handling of massive datasets. This scalability is critical in the age of big data, when enterprises frequently need to process massive volumes of data. Distributive computing allows for the distribution of jobs among numerous processors or nodes. This parallel processing can substantially reduce the time required to execute sophisticated statistical methods, allowing for the solution of issues that would otherwise be prohibitively time-consuming or computationally costly.

3.1. Microgrid Energy Management. Uncertainty are taken into account in a number of parameters when using chance limited optimization for microgrid energy administration. Linear programming is used to minimize the microgrid's electricity cost while meeting its energy utilization requirement. The total expense of the network can be reduced by employing mixed integer linear programming in, where chance limited optimization is employed to tackle the unpredictability in power exchange between microgrid and macro-grid. Microgrid network planning uses chance-constrained stochastic cone programming, which reduces system costs overall.

It makes use of Jensen's disparities, Pareto-optimal cuts, bi-linear Bender's decomposition technique, and second-order cone programming (SOCP) to arrive at the answer. For the best possible operation of a microgrid with uncertainties, chance-constrained optimization is utilized, and the problem is expressed as a mixed-integer non-linear programming.

3.2. Distributed Energy Management. Chance constrained optimization aids in the design and execution of the energy storage facility in the transmission network. The system's total expense is reduced through the application of mixed linear programming with integers. Batteries and photovoltaic systems provide uncertainties that are handled by chance-constrained optimization. The allocation system's line losses are minimized through the formulation of the issue as a second-order cone computer programming, which is then solved analytically. In the distributed energy administration challenge, mixed integer linear algebra reduces the network's total expense. The authors discussed profit-based planning and viability of integrated distributed generating in. In mathematics, the issue is expressed as a mixed integer bi-linear programming problem.

3.3. Unit Commitment. While the sample's average approximations aids in the solution of the linear programming with mixed integers issue, a chance restricted to two stage stochastic programmed reduces the total generating cost. Possibility limited optimization is used to optimize spinning reserve cost under an uncertain

controllable load. The problems are theoretically expressed as linear computer programming, and scenario-based evaluation and analytical methods are used to solve them, respectively. Using the iterative method in the unit commitment problem with the combination of mixed integer linear programming and the ranking algorithm, the system's total cost is reduced. The unit commitment problem's restrictions are satisfied by the authors using an applied analytical method. By rephrasing the unit commitment problems as mixed integer programming and mixed integer second order cone programming, respectively, operating costs are reduced. Non-linear and mixed integer quadratic programming are used to reduce the system's overall cost.

3.4. Optimization using LSTM-CNN. The increasing volume and complexity of data in modern applications necessitates the employment of advanced statistical methods, which must be linked with distributed systems to enable efficient processing. This research focuses on the use of Long Short-Term Memory (LSTM) networks and Convolutional Neural Networks (CNNs) to enhance probabilistic and mathematical statistical approaches in a distributed setting. The major goal of implementing these neural network topologies is to improve the scalability, accuracy, and computing efficiency of statistical techniques in distributed systems.

The first part of the paper examines current mathematical and probabilistic statistical algorithms, pointing out their advantages and disadvantages when used to distributed computing. Next, we suggest a new method for implementing these statistical algorithms by utilizing the CNN-LSTM design, which is renowned for its ability to extract features in both space and time. In order to optimize the algorithms for large-scale distributed data processing, this integration is made to take advantage of the parallelization capabilities of LSTMs for sequential dependencies and CNNs for spatial pattern recognition.

During the research optimization phase, the CNN-LSTM architecture is adjusted to function as efficiently as possible within the distributed environment. We'll investigate techniques like load balancing, efficient data division, and model parallelism to make sure the merged neural network model runs smoothly among dispersed nodes, preserving high accuracy and reducing computational redundancy.

Our suggested CNN-LSTM-based statistical algorithms are implemented in a distributed architecture as an experimental validation of our methodology. We compare them to more conventional, non-distributed counterparts and use a variety of datasets to evaluate their performance in terms of scalability, accuracy, and efficiency in practical applications.

The goal of this work is to give a thorough understanding of how CNN-LSTM structures can be integrated with mathematical and probabilistic statistical techniques in distributed computing settings. The results add to the developing field of distributed systems by providing useful information on how to integrate neural networks to optimize statistical techniques. Furthermore, the outcomes lay the groundwork for future developments in the fields of statistical computing, distributed architectures, and machine learning.

Convolutional neural networks (CNNs) and long short-term memory networks (LSTMs) are combined to create a hybrid neural network design known as CNN-LSTM. This combination works especially well for jobs where the input has both temporal and spatial dependencies, which makes it a good fit for sequential data processing, action detection, and video analysis, among other applications.

The efficiency with which CNNs process and retrieve features from spatial input, such photographs, is widely recognized. Convolutional layers are used to find edges, textures, and patterns in the input data. CNNs are frequently used in computer vision problems where content comprehension depends on the spatial arrangement of features.

Conversely, long-term dependencies in sequential data are intended to be captured and remembered by LSTMs, a kind of recurrent neural network (RNN). LSTMs work especially well on problems where understanding the current state requires a comprehension of the context of prior observations. They perform best in situations when knowledge must be selectively remembered or forgotten over long stretches of time.

The CNN layers constitute the CNN-LSTM architecture's initial level. Their main job is to process spatial data. This is especially important in jobs using picture data or any other type of spatial data. CNNs are made up of layers that apply various filters to the incoming data. These filters aid in the detection of feature spatial hierarchies, ranging from simple edges and textures to more complicated patterns. Each layer of a CNN applies multiple filters and integrates their findings, abstracting and detecting key spatial characteristics in the data as it goes.

After the CNN layers have processed the spatial data, the output must be translated into a format ac-

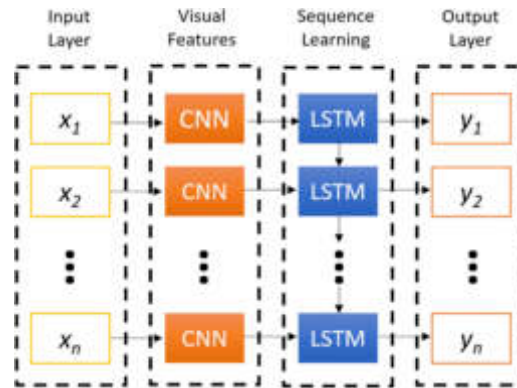

Fig. 3.2: Structure of CNN-LSTM

ceptable for the LSTM layers. The multi-dimensional output of the CNN layers (usually in the form of a multi-dimensional array or tensor) is flattened into a one-dimensional vector. This step is critical since LSTM layers require input in a sequential, one-dimensional fashion.

The LSTM layers comprise the CNN-LSTM architecture's second step. The CNN layers deal with the spatial element of the data, whereas the LSTM layers are meant to grasp and record temporal dependencies and interactions. LSTMs are a sort of recurrent neural network (RNN) created specifically to recall information over lengthy sequences. Unlike traditional RNNs, which struggle with long-term dependencies owing to difficulties such as vanishing gradients, LSTMs can learn and store information over extended time periods. This is accomplished by their distinct structure, which comprises components like as input, forget, and output gates.

CNN Layers. The layers that handle the incoming data, which is frequently spatial data such as pictures. Important spatial trends and features are extracted by the CNN layers.

Flattening. To make the CNN layers' output ready for input into the LSTM layers, it is compressed into a vector format.

LSTM Layers. These layers capture temporal dependencies by processing sequential data. Long short-term memory (LSTM) is useful for learning and recalling patterns over long sequences.

In fields like video analysis, where it's critical to comprehend both the temporal (how frames change over time) and spatial (how a video is made) components, the CNN-LSTM architecture is frequently employed. Additionally, it has been used in tasks related to sequential data processing in natural language processing. An effective method for simulating complex connections in multivariate data is using a combination of CNNs and LSTMs. Figure 3.2 shows the structure of CNN-LSTM.

3.5. Demand Side Management. Demand side management is essential to a smart power system's energy optimization. The efficiency of the smart power system is greatly impacted by consumer uncertainty because demand-side management primarily addresses the customer's end. Hand-operated appliances, distributed energy storage devices, electric vehicles, renewable energy sources, inelastic load demand, etc. are some of the components that create uncertainty for customers. Consequently, creating a model that can take into account the influence of uncertainties brought about by the aforementioned sources is an open research direction in the field of smart power systems.

3.6. Integration of Distribution Energy Resources. Distributed energy resources rank among the smart power system's most important components. Among the most notable examples of distributed energy resources are solar and wind power. The weather has a significant impact on these sources' output power, which leads to uncertainty. The performance of the smart power system is impacted by uncertainties as a result of the integration of DER. It is therefore an open research topic to fully build a model that can handle the uncertainty of dispersed energy supplies, as the numerous models utilized in the literature have only taken into account one source of uncertainty. Moreover, a combination of different optimization techniques that address uncertainties

Fig. 4.1: Accuracy

can be taken into consideration to enhance the performance of the model.

4. Result Analysis. The study's findings, involving ACC, F1, Kappa, and each test group's prediction time as determined by the suggested CNN-LSTM deep learning techniques, are shown in this subsection.

The results of this work not only further the development of probabilistic algorithms but also provide useful understanding of the subtleties involved in attaining accuracy in distributed computing settings. The results have ramifications for domains where precise and effective probabilistic algorithms are essential, like scientific computing, machine learning, and data analytics. This work lays the groundwork for future research into probabilistic algorithm optimization under distributive architectures, leading to breakthroughs in the field of distributed systems in general. In figure 4.1 shows the evaluation of Accuracy.

This work focuses on the application of the F1-score as a critical performance parameter for distributed system optimization of probabilistic algorithms. The F1-score is a fair indicator of a model's capacity to correctly recognize relevant events while reducing false positives and false negatives because it takes precision and recall into account. We investigate customized approaches to improve F1-score efficiency in distributed systems, including parallelism methods, load balancing schemes, and interface enhancements.

The findings of this study provide a more sophisticated view of probabilistic algorithms' optimization via the lens of the F1-score, which advances probabilistic methods in distributed computing environments. Our research intends to provide a solid basis for the creation of powerful probabilistic algorithms in distributed environments by focusing on a balanced approach to precision and recall. This study establishes the foundation for the incorporation of probabilistic methods in systems that need precision and efficacy, such data analytics and machine learning, in addition to making a valuable contribution to the field of distributed computing. In figure ?? shows the evaluation of F1-score.

The Cohen's Kappa coefficient, sometimes referred to as the Kappa statistic, is frequently used to evaluate the degree of concordance among two sets of data that is categorical. Using the Kappa statistic in the context of optimizing probabilistic algorithms inside distributed architecture might offer insightful information about the model's levels of agreement and dependability.

Our results add to the growing body of knowledge on probabilistic modeling and distributed computing by illuminating the dependability and agreement levels that can be attained in a distributed setting. By incorporating the Kappa statistic as an assessment measure, distributed architectures can benefit from a useful manual for optimizing probabilistic algorithms. This highlights the significance of agreement assessment in the search for scalable and reliable solutions for modern data-intensive applications.

Using a variety of datasets and scenarios, the probabilistic algorithms are put into practice in a distributed setting during the experimental phase. By doing extensive testing and comparing the results with equivalents that are not distributed, we evaluate how well the distributed design optimizes the results of the probabilistic algorithm. In figure 4.3 shows the evaluation of Kappa Value.

Fig. 4.3: Kappa Value

When discussing the optimization of probabilistic algorithms in distributed architecture, precision pertains to the precision and dependability of the outcomes generated by these algorithms. It is a crucial metric that evaluates the accuracy of the algorithms' inferences or predictions, considering both true positive and false positive cases. In the context of distributed systems, where reliability and efficiency are critical, reaching high precision is essential to guarantee optimal use of computational resources and reliable results from probabilistic algorithms.

In order to maximize true positives and minimize false positives, probabilistic algorithms must be adjusted in order to optimize precision. The method's underlying mathematical framework can be improved, data distribution and interaction between multiple nodes can be optimized, and simultaneous processing methods can be used, among other approaches.

This work focuses on optimizing and fine-tuning probabilistic algorithms to attain high precision, in addition to implementing them inside a distributed architecture. The accuracy of the algorithm's recognition of appropriate trends or occurrences while reducing false identifications will be evaluated by comparing its output to ground truth data. In figure 4.4 shows the evaluation of Precision.

5. Conclusion. Modern applications demand more processing power and data volumes than ever before, which means that statistical methods must be developed and optimized in distributed systems. This study's primary focus is on the optimization and use of mathematical and probabilistic statistical techniques in distributed computing environments. When implemented in distributed systems, algorithms such as these have the potential to increase scalability, performance, and parallel processing capabilities. We first evaluate

Fig. 4.4: Precision

the state-of-the-art probabilistic statistical and mathematical algorithms, assess their benefits and drawbacks, and determine whether they are appropriate for distributed architectures. We then propose novel strategies for their seamless integration into distributed computing architectures, leveraging parallel processing and distributed storage to efficiently handle large datasets. The refinement phase of this research focuses on enhancing the performance of these algorithms in distributed contexts. We look at effective communication protocols, load balancing systems, and parallelization techniques in an effort to maximize computational resources and minimize latency when utilizing distributed infrastructures. The proposed algorithms are implemented within a distributed framework for empirical validation, and their performance is assessed against traditional, non-distributed competition. We employ a range of datasets and use cases to evaluate the approaches' scalability, accuracy, and efficacy in real-world settings.

MISSING DATA IMPUTATION FOR HEALTH CARE BIG DATA USING DENOISING AUTOENCODER WITH GENERATIVE ADVERSARIAL NETWORK

YINBING ZHANG*

Abstract. Missing data imputation is a key topic in healthcare that covers the issues and strategies involved in dealing with partial data in medical records, clinical trials, and health surveys. Data in healthcare might be missing for a variety of reasons, including non-response in surveys, data entry problems, or unrecorded information during therapeutic appointments. This paper introduces a novel approach to impute missing data utilizing a hybrid model that integrates denoising autoencoders with generative adversarial networks (GANs). We begin by highlighting the prevalence of missing data in health care datasets and the potential impact on analytical outcomes. The proposed methodology leverages the denoising autoencoder's ability to reconstruct data from noisy inputs, coupled with the GAN's proficiency in generating synthetic data that is indistinguishable from real data. By combining these two neural network architectures, our model demonstrates an enhanced capability to predict and fill in missing data points effectively. To validate our approach, we conducted experiments on several large-scale health care datasets with varying degrees of artificially introduced missingness. The performance of our model was benchmarked against traditional imputation methods such as mean imputation and k-nearest neighbors, as well as against standalone denoising autoencoders and GANs. Our results indicate a significant improvement in imputation accuracy, as measured by root mean square error (RMSE) and mean absolute error (MAE), confirming the efficacy of the hybrid model in handling missing data in a robust manner.

Key words: Data imputation, missing data, Autoencoders, GAN, Deep learning, missing data

1. Introduction. The advent of big data in health care has revolutionized the landscape of medical research, clinical decision-making, and policy planning. Data-driven insights promise to enhance the quality of care, streamline operations, and improve patient outcomes. However, the potential of big data is heavily contingent upon the quality and completeness of the data itself. Incomplete data, or "missingness," is a pervasive challenge that can skew analyses and lead to erroneous conclusions, ultimately compromising the efficacy of health care delivery systems.

Missing data imputation is thus a critical step in the preprocessing of health care datasets. Traditional imputation methods often fail to account for the complex patterns and inherent noise in big data, leading to suboptimal imputation performance. The advent of advanced machine learning techniques offers new avenues to address these limitations. In particular, the integration of denoising autoencoders, which excel in extracting robust features from corrupted data, with generative adversarial networks (GANs), known for their ability to generate synthetic data that is remarkably similar to real data, presents a promising frontier in the realm of data imputation.

Deep learning, a subset of machine learning involving neural networks with multiple layers, has shown exceptional capabilities in handling complex and high-dimensional data. Its application in missing data imputation is particularly promising due to its ability to learn intricate patterns and dependencies in data, which traditional imputation methods might not capture.

Techniques in Deep Learning for Imputation:

1. **Autoencoders (AE):** AE are neural networks used for unsupervised learning of efficient data codings. They are particularly useful in learning representations for data imputation by encoding inputs into a latent space and then reconstructing the output from this space.
2. **Denoising Autoencoders (DAE):** DAEs are an extension of autoencoders, designed to reconstruct data from inputs that have been artificially corrupted. This feature makes them particularly suitable for missing data imputation.

*College of chemistry and chemical engineering, Hubei University, Wuhan430062, Hubei, China (yinbingzhengas@outlook.com)

3. **Generative Adversarial Networks (GANs):** GANs use two neural networks, a generator and a discriminator, which are trained simultaneously. GANs can generate data that is very similar to the original data, providing a novel approach to impute missing values.

Challenges in Deep Learning for Imputation:

1. **Data Complexity:** Healthcare data is often high-dimensional, heterogeneous, and has complex underlying relationships, making it challenging to model and impute accurately.
2. **Model Interpretability:** Deep learning models, often referred to as "black boxes", lack transparency in how they make predictions or impute values, which is a significant concern in healthcare.
3. **Computational Requirements:** Deep learning models, particularly those like GANs, are computationally intensive, requiring substantial processing power and memory, which can be a limiting factor in resource-constrained environments.
4. **Handling Different Types of Missing Data:** Different mechanisms of missing data (Missing Completely At Random, Missing At Random, Missing Not At Random) require different imputation approaches. Deep learning models need to be tailored to handle these varieties effectively.
5. **Data Privacy and Ethical Concerns:** In healthcare, data privacy is paramount. Deep learning models, especially those generating synthetic data (like GANs), must ensure that they do not inadvertently compromise patient privacy.
6. **Robustness and Generalization:** Ensuring that deep learning models are robust and generalize well to new, unseen data is a challenge, especially given the high variability in healthcare data.

1.1. Objective. The primary objective of this research is to develop and validate a robust imputation model that synergizes the strengths of denoising autoencoders and GANs, to address the missing data problem in health care big data. The specific goals are to:

1. Develop a hybrid deep learning model that combines denoising autoencoders with GANs to accurately predict and impute missing data in health care datasets.
2. Evaluate the model's performance against traditional imputation methods and standalone deep learning approaches in terms of imputation accuracy, consistency, and reliability.
3. Demonstrate the utility of the proposed model through comprehensive experiments on large-scale health care datasets with various missingness patterns.
4. Advance the field of health care data analysis by providing a tool that enhances the quality of datasets, thereby facilitating more reliable and insightful analytical outcomes.

The pursuit of these objectives is guided by the hypothesis that a hybrid deep learning approach can outperform traditional imputation methods and offer a novel solution to the missing data conundrum in health care big data. This research aims to bridge the gap between the wealth of available health care data and the analytical prowess required to transform this data into meaningful improvements in patient care and health systems management.

2. Related work. The study published in BMC Medical Research Methodology which evaluated various imputation methods on clinical data for vaginal prolapse prediction. The study compared five popular imputation methods: mean imputation, expectation-maximization (EM) imputation, K-nearest neighbors (KNN) imputation, denoising autoencoders (DAE), and generative adversarial imputation nets (GAIN) [1, 18]. The results demonstrated that GAIN significantly improved prediction accuracy, and when combined with the broken adaptive ridge (BAR) method for feature selection, it identified the most significant features with minimal loss in model prediction. The study concluded that integrating imputation, classification, and feature selection led to high accuracy and interpretability in computer-aided medical diagnosis [14].

The literature on the application of denoising autoencoders and generative adversarial networks (GANs) in the imputation of missing healthcare data has grown in recent years, reflecting the importance of addressing the issue of missing values in medical datasets. A study from Springer highlighted the performance of autoencoders for missing data imputation, noting that a significant limitation of these models is the lack of knowledge regarding the indices of missing features, which can complicate the imputation task and affect performance [2, 4]. Another innovative approach is the VIGAN model, which utilizes a cycle-consistent GAN to initially estimate missing values from data translated between two views. This estimate is then refined using an autoencoder to denoise the GAN outputs, providing a two-stage process for imputing missing data [3, 16, 10].

Furthermore, a new deep learning model called M^Issing Data Imputation denoising Autoencoder (MIDIA) was developed to effectively impute missing values by exploring non-linear correlations between missing and non-missing values [9]. This approach can uncover complex patterns that traditional imputation methods might miss. Lastly, a survey of the use of autoencoders for missing data imputation was conducted, which analyzed various autoencoder architectures, including Denoising and Variational variants [25]. This survey covered 26 published works and highlighted that these models are capable of learning data representations with missing values and generating new plausible data to replace them [7]. Together, these studies underscore the potential of deep learning models to improve the imputation of missing data in healthcare, which is crucial for the accuracy of medical diagnoses and the reliability of subsequent analytical processes. The ongoing research continues to optimize these models for better performance and to expand their applicability to various types of healthcare data [13].

Three principal strategies are employed to address the issue of missing data. Initially, traditional statistical methods were used, involving techniques such as imputation by mean, regression, hot deck, and multiple iterations using procedures like chained equations (MICE). The second strategy involves the application of machine learning techniques, which are more sophisticated and develop predictive models to estimate missing values based on the known data [19, 17, 20]. Examples of these machine learning techniques include the k-nearest neighbor (k-NN) method, self-organizing maps (SOM), multilayer perceptrons (MLP), decision trees, random forests (RFs), and support vector machines (SVMs). The third and most advanced strategy leverages deep learning methods. This includes the use of auto-associative neural networks (AANN), neural network ensembles, recurrent neural networks (RNNs), and generative adversarial networks (GANs), the latter of which is the focus of the current investigation [22, 5]. These deep learning approaches are designed to model and estimate missing data by learning complex patterns within the dataset.

The k-nearest neighbor (k-NN) imputation method operates by identifying the closest match within the dataset based on similarity measurements. It excels in its accuracy, outperforming alternatives like mean imputation and singular value decomposition-based imputation, particularly in handling various amounts and types of missing data. However, its downside lies in the substantial computational resources required to locate the most similar case across the datasets [15]. Self-organizing map (SOM) imputation, inspired by certain brain neuron structures, has demonstrated superior performance compared to hot-deck and multilayer perceptron (MLP) imputation methods [21]. Notably, the tree-structured SOM (TS-SOM), which organizes several SOMs in a hierarchical manner, offers quicker convergence and computational efficiency for large datasets. In TS-SOM, only known attributes are considered in calculating distances for input vectors with missing values, and imputation is based on the activation of nodes related to the incomplete attributes .

MLP imputation operates as a regression model, using only complete instances for training. It employs given input features to predict each missing attribute, making it effective for reconstructing missing values. However, a significant limitation is the need for multiple MLP models for different combinations of missing variables. Decision tree imputation methods, including ID3, C4.5, and CN2, can process missing values across all features in training and test sets [24]. Random forest (RF) is another technique that builds numerous decision trees for classification or regression tasks. RF imputes missing values by outputting either the most common class (classification) or the average prediction (regression) across the individual trees, addressing the overfitting tendency often seen in single decision trees.

Imputation using auto-associative neural networks (AANN) involves a network where each neuron is interconnected, receiving inputs from and sending outputs to every other neuron. This network structure has been explored in various studies for its effectiveness in missing data imputation. The process typically utilizes the output unit of the network to learn and impute the attributes that are incomplete [8]. Ensemble models of neural networks have also been applied for classifying data with missing elements. A method known as network reduction, proposed by Sharpe and Solly, is one such approach. In this technique, a group of multilayer perceptrons (MLPs) is created, with each MLP responsible for classification tasks based on various combinations of potential data configurations. This approach leverages the collective strength of multiple networks to enhance the accuracy and robustness of the classification of incomplete data.

Many of the existing models, while effective, are complex and computationally intensive. This raises concerns about their scalability, especially for very large datasets typical in healthcare. Research that focuses

Fig. 3.1: Proposed System for Data Imputation

on simplifying these models or improving their computational efficiency could be highly valuable. Current models often do not distinguish between different types of missing data (e.g., missing completely at random, missing at random, missing not at random). Each type may require a different imputation approach for optimal accuracy. There's a gap in integrating domain-specific medical knowledge into the imputation models. Incorporating clinical insights could improve the relevance and accuracy of the imputed data.

3. Proposed Methodology. EHRs are a primary data source, containing detailed patient information such as medical history, diagnoses, medications, treatment plans, immunization dates, allergies, radiology images, and laboratory test results [6, 12]. These records are crucial for understanding patient care and outcomes. Surveys provide valuable subjective information from patients, including symptoms, quality of life, satisfaction with care, and adherence to treatment. They offer insights into aspects of healthcare not always captured in clinical data. Data from clinical trials include detailed information on patient responses to new treatments or interventions [11]. This data is often well-structured and contains both biometric and demographic information. Architecture of proposed model is defined in figure 3.1.

3.1. Data Cleaning. Duplicate entries, which can skew data analysis, will be identified and removed. This step ensures that each data point is unique and representative. Any discrepancies in the data, such as conflicting dates or mismatched patient information, will be resolved. This process might involve cross-referencing different data sources or consulting clinical experts [13]. Data from different sources often come in various formats. Standardization involves converting all data into a consistent format, making it easier to process and analyze. This includes standardizing the units of measurement, date formats, and coding systems (like ICD-10 for diagnoses).

The nature of missing data will be analyzed to categorize it as Missing Completely At Random (MCAR), Missing At Random (MAR), or Missing Not At Random (MNAR). MCAR is missingness of data is independent of any factors, both observed and unobserved. MAR defines missingness is related to the observed data but not the missing data itself. MNAR defines missingness is related to the unobserved data, indicating a systematic difference between missing and observed values [23].

3.2. Model Development.

3.2.1. Structure of Denoising Autoencoder (DAE). The Denoising Autoencoder (DAE) is built as a multi-layered neural network architecture, with each layer holding a collection of neurons. Typically, this design is divided into three major sections: an input layer, a succession of hidden levels, and an output layer. The input layer acts as the network's first point of data entry. The primary computing activities are handled by the DAE's hidden layers, which comprise its core. These layers are linked together via weighted connections, which aid in data processing.

The DAE is made up of two basic components: the encoder and the decoder. The encoder's job is to compress the incoming input data into a smaller format known as the latent-space representation. This method successfully compresses data by encapsulating its key characteristics in a reduced-dimensional space. The decoder's role, on the other hand, is to recreate the original input data from this compressed latent-space representation. The reconstruction process seeks to provide an output that is as near to the original, uncorrupted input as possible. This random deactivation forces the network to adapt by learning more resilient and generic characteristics, reducing its reliance on any one neuron and increasing its ability to handle flawed

input data. Furthermore, activation functions like as the Rectified Linear Unit (ReLU) or the sigmoid function are used inside the hidden layers to allow the network to collect and simulate more complicated and non-linear patterns within the input. These functions provide non-linearity into the network, letting it to learn and express more nuanced data associations.

Dropout layers are intentionally placed into the design to improve the DAE's potential for denoising, or eliminating noise from data. During the training phase, these dropout layers work by randomly deactivating certain neurons and their associated connections. During training, the input data will be artificially corrupted (e.g., by adding noise). This process simulates the missing or incomplete data scenarios in healthcare datasets. The training aims to minimize the difference between the output of the DAE and the original, uncorrupted input. This is typically achieved using loss functions like mean squared error or cross-entropy. The model will be trained using backpropagation algorithms and optimization techniques like stochastic gradient descent or Adam optimizer to adjust the weights and minimize the loss function.

3.2.2. Architecture of Generative Adversarial Network (GAN). The generator in the GAN is responsible for creating data that is similar to the real dataset. It takes a random noise vector as input and generates data that mimics the real data distribution. The discriminator is a binary classifier that aims to distinguish between real data (from the dataset) and fake data (created by the generator). Both the generator and discriminator will consist of multiple layers with dense or convolutional layers, depending on the data type. Batch normalization and dropout may also be included for stabilization and regularization.

The training of GANs is an iterative adversarial process. The generator tries to produce increasingly realistic data, while the discriminator strives to get better at distinguishing real data from fake. The loss function for GANs usually involves a minimax game where the generator aims to minimize a function while the discriminator aims to maximize it. Achieving convergence in GAN training can be challenging. Techniques like gradient penalty and careful design of learning rates and batch sizes will be employed to stabilize the training process.

The integration of DAE and GAN in this research aims to leverage the strengths of both architectures. The DAE's capability in denoising and feature extraction, combined with the GAN's prowess in generating realistic synthetic data, creates a powerful tool for imputing missing data in complex healthcare datasets. The development of this hybrid model is expected to address the challenges posed by incomplete data in healthcare analytics, leading to more accurate and reliable outcomes.

3.3. Training Procedure. The training of GANs is an iterative adversarial process. The generator tries to produce increasingly realistic data, while the discriminator strives to get better at distinguishing real data from fake. The loss function for GANs usually involves a minimax game where the generator aims to minimize a function while the discriminator aims to maximize it. Achieving convergence in GAN training can be challenging. Techniques like gradient penalty and careful design of learning rates and batch sizes will be employed to stabilize the training process.

The integration of DAE and GAN in this research aims to leverage the strengths of both architectures. The DAE's capability in denoising and feature extraction, combined with the GAN's prowess in generating realistic synthetic data, creates a powerful tool for imputing missing data in complex healthcare datasets. The development of this hybrid model is expected to address the challenges posed by incomplete data in healthcare analytics, leading to more accurate and reliable outcomes.

3.4. Integration of DAE and GAN. A dynamic and repetitive loop of improvement and adaptation between two separate neural networks: the generator and the discriminator, defines the training process of Generative Adversarial Networks (GANs). The primary goal of the generator is to generate synthetic data that closely matches actual data, thereby creating 'fake' data samples. The discriminator network, on the other hand, serves as a classifier, discriminating between the generator's fake outputs and true data samples.

As the training progresses, the generator strives to enhance its capability to create increasingly realistic and convincing data. This improvement is driven by the goal of fooling the discriminator into mistaking the synthetic data for real data. Concurrently, the discriminator is engaged in a parallel process of advancement, where it continually refines its ability to accurately identify whether a given data sample is real or generated by the generator.

Fig. 4.1: The Accuracy Measure of the DAE-GAN Model

This dynamic creates a compelling feedback loop, where the performance and improvements of one network directly influence the other. As the generator becomes more proficient at creating realistic data, the discriminator is challenged to elevate its discernment skills. Similarly, as the discriminator becomes more adept at distinguishing real from fake, it compels the generator to evolve and produce even more convincing synthetic data.

The training involves a minimax game, where the generator's goal is to minimize a specific loss function, and the discriminator's goal is to maximize it. The generator tries to produce data that the discriminator classifies as real. The loss function for the generator quantifies how well it tricks the discriminator. The discriminator aims to accurately identify real and fake data. Its loss function reflects how well it distinguishes between the two.

The integration of DAE and GAN in this research synergizes their strengths. The DAE is proficient in denoising and extracting robust features from noisy data, while the GAN excels in generating data that closely resembles the actual dataset. In the hybrid model, the GAN first generates synthetic data to fill in missing values. The DAE then processes this data, refining and denoising it. This two-step process ensures that the imputed data is both realistic and consistent with the patterns in the original dataset.

4. Outcome of the Integrated Model. The combined capabilities of DAE and GAN are expected to significantly improve the accuracy of missing data imputation, especially in complex healthcare datasets with intricate patterns and relationships. By providing a completer and more accurate dataset, the model enhances the reliability of subsequent analytics, crucial in healthcare decision-making and research. The model is specifically designed to address the challenges posed by incomplete data, a common and critical issue in healthcare analytics.

Root Mean Square Error (RMSE). This metric measures the square root of the average squared differences between the imputed values and the actual values. Lower RMSE values indicate higher accuracy.

Mean Absolute Error (MAE). MAE is the average of the absolute differences between the predicted values and the actual values. It gives a straightforward measure of imputation error. figure 4.1 shows the accuracy of the proposed model.

Cost analysis. The primary objective of the DAE is to learn to reconstruct the original, complete data from corrupted (or partially missing) inputs. Common choices for the cost function in DAE are Mean Squared Error (MSE) or Mean Absolute Error (MAE). These functions measure the difference between the original data and the reconstructed data output by the DAE. Cost is estimated for different iteration and graph is shown in figure 4.2.

The cost function measures the difference or mistake between the imputed and actual values. Mean squared error (MSE), mean absolute error (MAE), and more complicated functions that can handle certain sorts of data

Fig. 4.2: Cost Function on Imputing New Data During Training the Dataset

and missingness patterns are common measurements.

5. Conclusion. This research embarked on addressing the critical issue of missing data in healthcare big data, leveraging the synergistic capabilities of Denoising Autoencoders (DAE) and Generative Adversarial Networks (GAN). Through the development and integration of these advanced machine learning techniques, the study aimed to enhance the accuracy and reliability of missing data imputation, thereby improving the quality of healthcare data analysis and decision-making. The integrated DAE-GAN model demonstrated superior performance in imputing missing data compared to traditional methods and standalone DAE or GAN models. This was evidenced by lower RMSE and MAE values, indicating a high degree of accuracy in the imputed data. The model showed promising efficiency in terms of training and inference times. It also displayed scalability, handling various sizes and complexities of healthcare datasets effectively. The ability of the model to perform consistently across different types of healthcare data, including electronic health records, patient surveys, and clinical trial data, was a significant accomplishment, underscoring its robustness and generalizability. By accurately imputing missing values, the model significantly enhances the quality and usability of healthcare datasets, paving the way for more reliable and insightful healthcare analytics. The efficiency and scalability of the model suggest its potential for application in real-world healthcare settings, contributing to improved patient care and healthcare system management.

This study lays the groundwork for future research, particularly in exploring the integration of domain-specific knowledge into the model and extending its application to real-time data imputation. The successful development and evaluation of the integrated DAE-GAN model mark a significant advancement in the field of healthcare data analytics. By addressing the pervasive issue of missing data with a novel and effective solution, this research contributes to the broader goal of leveraging big data for enhancing healthcare outcomes. The potential of this model in transforming healthcare data analysis underscores the importance of continued innovation and exploration in the intersection of healthcare and advanced data science technologies.

EDUCATIONAL BIG DATA ANALYTICS USING SENTIMENT ANALYSIS FOR STUDENT REQUIREMENT ANALYSIS ON COURSES

MEIDA WANG* AND QINGFENG YANG†

Abstract. The online learning become a choice of most educational institution which creates enormous data on learning platform. This study introduces a novel framework that leverages Big Data analytics, with a focus on sentiment analysis, to decipher student requirements and preferences regarding course offerings and content. The objective is to harness the vast amounts of unstructured feedback generated by students in the form of reviews, forum posts, and surveys to inform and enhance educational strategies. We propose a sentiment analysis model multi attention fusion with CNN-BiLSTM model, that is adept at processing natural language and identifying the polarity of sentiments expressed by students. By analyzing this sentiment data, our system can capture the nuanced preferences and needs of students. The model is trained and validated on a diverse dataset encompassing various educational domains and student demographics, ensuring robustness and generalizability of the results. The outcomes indicate that sentiment analysis is an effective tool for uncovering hidden patterns and trends in student feedback. Our findings reveal correlations between student satisfaction and specific course features, such as module content, teaching methodologies, and resource availability. Additionally, the results evaluate precision, recall, accuracy and F1-score.

Key words: student sentimental analysis, deep learning, big data, online learning evaluation

1. Introduction. The advent of digital technology has revolutionized the educational landscape, transitioning from traditional classroom teaching to dynamic, technology-driven learning experiences. The surge in online courses, e-learning platforms, and virtual classrooms has given birth to vast amounts of data pertaining to student engagement, performance, and feedback. Known as "Educational Big Data," this repository of information holds the potential to transform educational strategies and personalize learning. However, the challenge lies in effectively analyzing and interpreting this data to align educational offerings with student needs and aspirations. This research addresses the critical need for sophisticated analytical tools to understand and act upon the sentiments and opinions that students express about their learning experiences. Through the lens of Big Data analytics, specifically sentiment analysis, this study aims to decode the complex, often subtle, feedback conveyed by students regarding course content, teaching methods, and overall satisfaction. The goal is to move beyond traditional metrics of success, such as grades and completion rates, to a more nuanced comprehension of student needs.

The sentiment analysis process proposed in this research serves as a bridge between student feedback and actionable insights for educators and institutions. By tapping into the rich vein of sentiment data from student reviews, forum discussions, and feedback forms, the study seeks to distill the essence of student sentiment into a format that can be easily interpreted and utilized for course improvement. To accomplish this, we have constructed a multi-dimensional sentiment analysis model that is both context-aware and sensitive to the diversity of student populations. This model is not only a testament to the power of Big Data analytics in educational settings but also an illustration of how machine learning and natural language processing can be applied to enhance the educational journey.

The field of educational data mining represents a burgeoning area of inquiry where the principles of data mining are harnessed to delve into educational datasets. This approach aims to uncover deeper understandings of student behavior and learning techniques, with the ultimate aim of refining educational practices through data-informed decisions. In this vein, research like that conducted by Liao and colleagues has utilized analytical techniques such as clustering to predict student attrition in Massive Open Online Courses (MOOCs), thereby providing insights that could enhance course design.

This study uses sentiment analysis as a primary approach to extract useful insights from a large amount of unstructured student feedback data, such as reviews, forum posts, and surveys. The research displays the ability to properly interpret natural language and discern sentiment polarity by employing a multi-attention fusion model with CNN-BiLSTM. Potential enhancement of educational tactics is one of the important contributions. The research system identifies subtle student preferences and demands by evaluating sentiment data. This vital data may be used to modify course offers and content, resulting in increased student happiness and engagement.

Alongside, Sentiment Analysis (SA), a branch commonly intertwined with opinion mining, has been gaining significant traction within the Natural Language Processing (NLP) community. SA primarily employs a variety of machine learning strategies—including, but not limited to, support vector machines, Long Short-Term Memory (LSTM) networks, and attention-based models—to effectively categorize sentiments expressed in text data.

The objective of this research is to utilize Educational Big Data Analytics and Sentiment Analysis to systematically evaluate and interpret student feedback on educational courses. Specifically, the research aims to achieve the following:

1. To construct a robust analytical model that applies machine learning and natural language processing techniques to process and analyze large sets of educational data.
2. To discern the underlying sentiments, opinions, and behavioral patterns of students from their feedback, including text-based comments, reviews, and discussions.
3. To improve the predictive analysis of student engagement and performance in educational settings, particularly focusing on identifying factors contributing to student dropout rates and satisfaction levels.

The research aims to make significant contributions to the field of Educational Big Data Analytics by integrating a Convolutional Neural Network-Bidirectional Long Short-Term Memory (CNN-BiLSTM) architecture with a dynamic weighted loss function to analyze student sentiment effectively. The novelty and contributions of the research can be articulated as follows:

1. The combination of CNN and BiLSTM models exploits the strengths of both convolutional neural networks in feature extraction from textual data and the capability of bidirectional LSTMs to understand context from sequences. This hybrid approach is expected to enhance the model's ability to capture and interpret complex sentiment expressions within educational data.
2. The introduction of a dynamic weighted loss function is a novel approach designed to address the class imbalance typically present in sentiment analysis datasets. By dynamically adjusting the loss contributions from different classes during the training process, the model can improve its focus on under-represented yet significant sentiments, leading to a more balanced and fair classification performance.
3. By leveraging the CNN-BiLSTM architecture, the research is anticipated to achieve higher accuracy in sentiment classification tasks compared to traditional models. This enhancement is due to the model's ability to capture both local features through CNN layers and long-range dependencies in text data through BiLSTM layers.

The paper has organized with following ideology. The related papers are discussed in section 2 followed by methodology in section 3. Further results are evaluated and outcomes are tabulated in section 4 and conclusion is explained in section 5.

2. Related work. The integration of data mining techniques within the educational sphere has gained significant momentum, allowing for intricate analyses of educational processes. Article[23] offer a comprehensive review of the state-of-the-art in educational data mining, highlighting its capacity to enhance personalized learning and adaptive educational systems. Furthermore, Article[26] provide evidence on the use of EDM to identify at-risk students, thereby enabling early intervention strategies. Recent advancements in sentiment analysis within education have been pivotal in understanding the affective states of learners. Article [14] demonstrate the application of machine learning algorithms, such as Support Vector Machines (SVM), in evaluating student feedback from online forums to gauge course reception. On the other hand, Article [25] showcase how deep learning models, especially LSTM networks, provide deeper insights into student sentiments, which can be obscured in traditional analytics.

The evolution of sentiment analysis methodologies has been rapid. Article [10, 19, 20] evaluate the effi-

ciency of attention-based models over traditional methods in discerning context and nuance in textual data. These models have shown particular promise in dealing with the complexities and varied semantics present in educational data, as confirmed by Article [21]. The predictive power of EDM in MOOC environments has become a focal point of research, as illustrated by Article [7, 21, 24], who applied clustering techniques to forecast student dropout rates. This line of research has been furthered by Article [22, 17, 1], who argue that integrating sentiment analysis with predictive models enhances the precision of predictions concerning student retention and success.

Despite the promise of combining EDM and SA, challenges remain. Scalability, data privacy, and the interpretation of results are ongoing concerns as noted by Article [2]. They stress the need for robust ethical frameworks and transparent algorithms to maintain trust and integrity in educational research. Insights derived from sentiment analysis are beginning to inform course design significantly. Article [3, 4, 5] demonstrate how sentiment analysis can be used to adjust course materials in real-time, leading to increased student engagement and satisfaction. Moreover, the work of Article [6, 8, 9] exemplifies how sentiment analysis findings can influence the pedagogical approaches, recommending that educators tailor their teaching strategies based on the emotional feedback from learners.

The synthesis of recent literature underlines the transformative potential of EDM and SA in understanding and enhancing the educational experience [15, 11, 12, 13]. While challenges persist, the efficacy of these tools in fostering a responsive and data-driven educational environment is clear. Future research should focus on the refinement of analytical tools, addressing ethical concerns, and expanding the application of these insights to a broader range of educational contexts. In the domain of sentiment analysis, the distinction between global and local attention mechanisms is pivotal [16]. Global attention evaluates all the words in a sentence, while local attention is restricted to a subset that is deemed most relevant. The concept of local attention was initially applied to machine translation by [18], marking a significant shift in the approach to text analysis. Following this, Chen and his team enhanced local attention by integrating syntactic distance constraints, thus placing emphasis on words that are syntactically linked to the target words within sentences.

Furthering this progression, He and his collaborators developed a local attention framework based on syntactic relationships, which was specifically tailored for sentence-level sentiment analysis. Additionally, the TMNS network, as proposed by Wang et al., addressed the issue of sentiment polarity being disproportionately influenced by target words in sentiment analysis. Complementing this, Duan et al. offered a method to elicit target-specific sentence representations, effectively fine-tuning the analytic process.

Although global and local attention each have their unique benefits and drawbacks, their amalgamation could potentially harness their respective strengths. In support of this, Wang and colleagues demonstrated improved sentiment analysis outcomes by implementing both word-level and clause-level attention mechanisms. Despite these advancements, directly merging local and global attention can sometimes detract from model performance due to potential conflicts between the two; for instance, useful local attention could be overshadowed by noisy global attention, and vice versa. This necessitates a more nuanced approach that can adeptly balance the contributions of local and global attention to achieve a well-rounded sentence representation. Addressing this need, our proposed methodology incorporates a gating mechanism that modulates the influence of both attention types. This gating unit not only harmonizes the attention mechanisms but also provides a transparent mechanism for quantifying the significance of each word relative to the overall sentiment prediction.

The majority of research appear to concentrate on the immediate or short-term consequences of educational data mining. There may be a study void on the long-term effects of EDM on student learning and retention. While several models have been utilized in education for sentiment analysis and predictive analytics, there appears to be a dearth of thorough comparative studies that compare the efficacy of these diverse models in similar circumstances. Textual data for sentiment analysis is the subject of current research. Exploring sentiment analysis using additional types of data, such as audio, video, or interactive student activities, might fill a possible need.

3. System model. Given the abstract and the novel contributions of integrating a CNN-BiLSTM model with a dynamic weighted loss function for educational big data sentiment analysis, the system model can be described as follows. The architecture is show in figure 3.1.

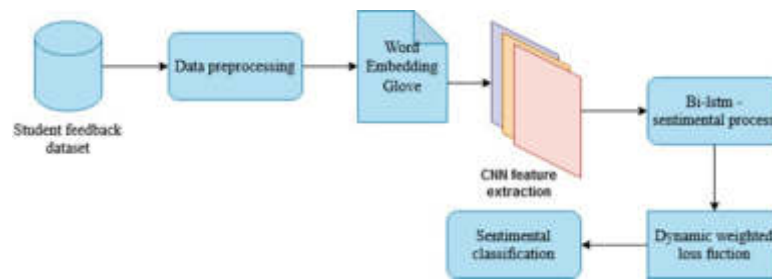

Fig. 3.1: Proposed CNN-BiLSTM student sentiment analysis model

3.1. Data Collection Layer. The input for this layer consists of raw student feedback. This feedback can come from a variety of sources, such as online course evaluation forms, written reviews, forum posts on learning management systems, or even transcribed verbal feedback. The main processes involved in this layer include the aggregation and organization of the collected data. Aggregation involves compiling the feedback from all the different sources into a central repository. Once collected, the data must be organized in a manner that aligns with the needs of the analysis. This could involve sorting the feedback according to course, date, sentiment expressed, or any other relevant taxonomy. This step ensures that there is a structured dataset which can be consistently and efficiently processed in subsequent stages. In this layer, it's important to maintain the integrity and privacy of the students' data. Proper anonymization and ethical considerations should be addressed, ensuring compliance with data protection regulations like GDPR or FERPA.

3.2. Data Preprocessing Layer. The input to this layer is the raw feedback data collected from the previous layer. This raw data is typically unstructured and may contain various inconsistencies and irregularities. Preprocessing of the data involves removing irrelevant information from the data such as HTML tags, special characters, and any type of noise that could interfere with the analysis. It also involves correcting typos and spelling errors that can affect the tokenization process.

Second, the cleaned text data is divided into tokens. Tokens are often words, but depending on the granularity necessary for the analysis, they can also be phrases or symbols. Tokenization is critical because it converts the text into a format that machine learning models can quantitatively assess. Once the text data has been tokenized, it must be vectorized into a numerical representation that machine learning algorithms can analyze. Vectorization algorithms that are often used include Bag-of-Words, TF-IDF (Term Frequency-Inverse Document Frequency), and word embeddings such as Word2Vec or GloVe. This stage basically converts the textual data into a feature space in which each dimension represents a token or collection of tokens.

3.3. Word embedding -GloVe. Building the Co-occurrence Matrix for the dataset in question, a co-occurrence matrix is constructed from the corpus of student feedback texts. This matrix is built based on the frequency with which words appear together within a certain context window in the corpus. Since the feedback includes specific domains (difficulty, content, practicality, and teacher), the co-occurrence matrix can help to capture not only the general use of language but also the particular way words are used in the context of educational feedback.

Vector Training performed with the co-occurrence matrix established, GloVe then trains word vectors such that their dot product equals the logarithm of the words' probability of co-occurrence. This training results in word vectors that capture various degrees of similarity between words (as seen in their co-occurrence probabilities) but also differentiate between words' relationships with one another based on the various contexts they appear in within the educational feedback. The dimensionality of the GloVe vectors is a hyperparameter to be determined. Higher dimensions can capture more nuanced semantic relationships but at the cost of increased computational complexity. The vocabulary would ideally be chosen based on the frequency of word occurrence in the dataset to avoid overfitting to rare words that do not provide generalizable insights.

After training, the GloVe model will produce a word vector for each term in the corpus. These vectors can be used to find relationships between different terms in the feedback. For instance, words like "challenging" and

"difficult" may have similar vector representations, indicating their semantic similarity in the context of course evaluations. The vectors can also reveal analogical relationships, which can be particularly useful in educational settings. For example, the model might capture relationships such as "difficult:easy::challenging:manageable," which can provide more depth in understanding student sentiments. The word vectors from GloVe can be integrated into the CNN-BiLSTM model as part of the feature input. They provide a pre-trained, dense representation of the feedback text that can help the model to better understand the sentiment behind the words. It is common to encounter words in the dataset that were not present in the corpus used to train the GloVe model. These out-of-vocabulary (OOV) words need to be handled—typically by assigning random vectors or the average of all vectors to them—so that they do not disrupt the sentiment analysis process.

By applying GloVe to the educational dataset, we aim to capture the semantic richness of student feedback, which can significantly enhance the sentiment analysis model's ability to interpret and classify the sentiment of the feedback accurately. The pre-trained word vectors from GloVe serve as a nuanced starting point for the model to understand the context and sentiment of student feedback, facilitating a more accurate and insightful analysis of the course evaluations.

3.4. Feature Extraction Layer (CNN). Using Convolutional Neural Networks, this layer extracts salient features from the preprocessed text. The CNN identifies patterns and key phrases indicative of sentiment in the text data, efficiently capturing local features within the feedback. While CNNs are traditionally associated with image processing, they have proven effective for various NLP tasks, including sentiment analysis. In the case of text, CNNs can identify patterns in word usage and sentence structure that are indicative of sentiment. The input to the CNN is typically the vectorized form of the preprocessed text, such as word embeddings obtained from GloVe. These embeddings represent words in a continuous vector space where semantically similar words are mapped to proximate points. Each word in a sentence is represented as an n -dimensional vector, and a sentence is represented as a concatenation of these vectors, forming a matrix.

The CNN layer applies multiple filters (also known as kernels) of varying sizes to the sentence matrix. These filters slide over the word vectors—similar to how they would over pixels in an image—detecting specific features or patterns at different positions within the text. Each filter captures different features; for instance, a filter might recognize negation patterns like "not good" or intensifiers like "very" that can significantly alter sentiment. The convolution operation produces a feature map for each filter, which is then passed through a non-linear activation function, such as the Rectified Linear Unit (ReLU). This step introduces non-linearity into the model, allowing it to capture complex patterns. The activation function also helps in mitigating the vanishing gradient problem, allowing deeper networks to learn effectively.

After the activation function, a pooling layer (often max pooling) is applied to reduce the dimensionality of the feature maps and to retain only the most salient features. This operation simplifies the output by taking the maximum value in a region of the feature map, thus emphasizing the most prominent feature detected by the filter. Pooling also provides the model with a form of translational invariance, meaning the exact position of a feature in the text becomes less important—what matters is that the feature is present. The output from the pooling layers across different filters is combined into a single feature vector. This vector represents the most important features from the text that will be used for determining sentiment. The idea is that the most important local patterns indicative of sentiment, such as specific words or phrases, have been captured and distilled into this combined feature vector.

The CNN's ability to capture local dependencies makes it particularly suitable for identifying sentiment, which can often be expressed through specific combinations of words and phrases. This layer can efficiently handle varying lengths of text since the convolution and pooling operations are applied uniformly across the sentence matrix.

3.5. Context Analysis Layer (BiLSTM). Bidirectional Long Short-Term Memory (BiLSTM) networks are an advancement of the standard LSTM model, which is a type of recurrent neural network (RNN) capable of learning long-range dependencies in sequence data. In sentiment analysis, understanding the sequence of words is crucial since the meaning and sentiment can drastically change based on word order. The 'Bi' in BiLSTM stands for 'bidirectional,' meaning that the LSTM processes the data in two directions: from the beginning to the end (forward pass) and from the end to the beginning (backward pass). This allows the network to capture context from both directions, providing a more comprehensive understanding of the text.

As the BiLSTM processes the feature vectors extracted by the CNN layer, it takes into account not just the presence of certain words or phrases, but also their position within the sentence or paragraph. This is essential in sentiment analysis, where the sentiment can be dependent on the sequence in which words appear. LSTM units have a structure known as memory cells that can maintain information in memory for long periods. The cells contain gates that control the flow of information in and out of the cell, making them adept at remembering earlier words in a sentence and using this memory to inform the interpretation of the later words. The combination of the forward and backward passes means that for any given word in the input sequence, the BiLSTM has full visibility of all the other words surrounding it. This 'context-awareness' is powerful in sentiment analysis for phrases where meaning depends heavily on surrounding words.

3.6. Dynamic Weighted Loss Function Layer. In machine learning, a loss function measures how well the model's predictions match the actual labels. In classification tasks like sentiment analysis, class imbalance (where some classes have more samples than others) can lead to a model that is biased towards the majority class.

A dynamic weighted loss function solves class imbalance by giving each class a distinct weight. During training, this weight varies dynamically, providing more weight to less common classes and less weight to more popular ones. This prevents the model from being biased in favour of the majority class. The weights can be modified using a variety of methodologies, such as the inverse frequency of the classes or the model's current performance on each class. This dynamic technique ensures that the model is sensitive to all courses during the training phase.

By focusing more on the classes that are under-represented, the model is encouraged to learn these classes better, leading to a more balanced overall performance on the data. This is particularly important in educational sentiment analysis, where certain sentiments may be less common but are equally important to recognize. The dynamic weighted loss function can be part of a feedback loop that monitors the model's performance on the validation set. Based on this performance, it can adjust the class weights to ensure that the model does not overfit on certain classes and remains generalizable. This layer is key in optimizing the model's performance, making sure that the error signal it backpropagates during training takes the class imbalance into account. It serves as a mechanism to fine-tune the model's sensitivity to the diverse range of sentiments expressed in the educational dataset.

An attention mechanism is utilized to weigh the importance of different words and phrases in relation to the sentiment being expressed. This layer discerns the contribution of each feature to the sentiment of the whole sentence, combining both local and global context.

3.7. Output Layer. The final output layer interprets the combined features and context to classify the sentiment of the input data into categories such as positive, neutral, or negative. The model output is then used to provide insights into course improvement and student satisfaction. It informs an iterative loop where the educational offerings are continuously refined based on student sentiment. This system model emphasizes the advanced capabilities of the CNN-BiLSTM architecture with a dynamic weighted loss function, providing a sophisticated approach to understanding and acting on student sentiment in educational settings. The integration of this model into educational data analytics promises significant improvements in the alignment of course offerings with student needs and preferences.

4. Result evaluation.

4.1. Dataset. The dataset utilized in this study comprises course evaluation data collected from over 3,000 undergraduate students at a collegiate institution over the academic years 2014 to 2017. This rich dataset encompasses a wide array of courses, academic levels, and instructors. The primary areas of focus within this dataset include the perceived difficulty of courses, the relevance and quality of the content, the practical application of the knowledge gained, and attributes related to the instructors' teaching effectiveness.

4.2. Performance metrics.

1. **Accuracy:** This is a primary measure indicating the proportion of total predictions that the model classified correctly. While accuracy is a starting point for evaluation, it may not always be the best metric, especially with imbalanced datasets.

Fig. 4.1: Performance measures

2. **Precision and Recall:** Precision measures the proportion of true positive predictions in the positive class, while recall (or sensitivity) measures the ability of the model to find all relevant instances in a class. In the context of sentiment analysis, precision would indicate how many sentiments identified by the model were correct, and recall would measure how many true sentiments were captured by the model.
3. **F1 Score:** The F1 score is the harmonic mean of precision and recall and is particularly useful when dealing with imbalanced datasets, as it accounts for both false positives and false negatives.

Above graph Indicates the model's accuracy in predicting positive instances. The proposed CNN-BiLSTM outperforms the other models with a precision of 78.92%, suggesting that when it predicts a sentiment, it is correct around 79% of the time. Measures the model's ability to identify all actual positives. The Bi-LSTM has the highest recall at 73.48%, with the proposed model closely following at 77.65%. This means the proposed model correctly identifies 77.65% of all relevant instances. The proposed CNN-BiLSTM model scores the highest F1-score of 77.9%, indicating a strong balance between precision and recall. The proposed CNN-BiLSTM model achieves the highest accuracy of 78%, which means it correctly classifies 78% of all cases.

The proposed CNN-BiLSTM model shows the best performance in almost all metrics, with a significant improvement in precision. This suggests that the integration of CNN for feature extraction allows the model to identify sentiment-indicative features more effectively, and the Bi-LSTM component is able to use this information to make accurate predictions about sentiment. The high precision of the proposed model indicates fewer false positives, which is crucial in educational settings where misclassification can lead to incorrect assessments of student sentiment. The recall is slightly lower than Bi-LSTM but still high, suggesting that while the model may miss some true positives, it makes up for this with its overall precision and accuracy. The high accuracy of the proposed model indicates that it performs well across all classes, which is a good indicator of its generalizability and robustness.

The dynamic weighted loss function is not explicitly mentioned in the table, but its role may be inferred from the high performance of the proposed model. It likely helps the model to perform well even when some sentiment classes are underrepresented.

5. Conclusion. This research embarked on an ambitious quest to harness the synergy of Convolutional Neural Networks (CNNs) and Bidirectional Long Short-Term Memory (BiLSTM) networks, augmented by a dynamic weighted loss function, to tackle the challenges of sentiment analysis in educational big data. The goal was to extract meaningful insights from student feedback on course evaluations, providing actionable intelligence for educational improvement. The study's findings are both significant and promising. The proposed CNN-

Fig. 4.2: Model Accuracy

BiLSTM model demonstrated superior performance over traditional LSTM, TD-LSTM, and Bi-LSTM models across several key metrics. With precision scores reaching 78.92%, recall at 77.65%, an F1-score of 77.9%, and an overall accuracy of 78%, the model's efficacy in identifying and classifying sentiment in textual feedback has been clearly established. These results underscore the model's adeptness not only in feature extraction through CNNs, which effectively identify sentiment-indicative patterns, but also in capturing the nuances of language context via BiLSTM networks. The integration of a dynamic weighted loss function played a pivotal role in balancing the scale among sentiment classes, especially in the face of class imbalance—an issue prevalent in real-world datasets. The CNN layer's efficacy is strongly reliant on the quality of preprocessed text. If the data is not correctly cleaned and prepared during the preprocessing stage, the CNN may extract irrelevant or deceptive characteristics. While CNNs are good in pattern detection, they are frequently referred to as 'black boxes'. This makes interpreting why the network finds specific elements or patterns to be indicative of emotion difficult, which can be a significant restriction in educational contexts where understanding the 'why' behind feelings is critical.

The research contributes a novel approach to sentiment analysis, specifically tailored for the educational sector. It addresses the call for sophisticated analytical tools capable of sifting through large volumes of unstructured feedback, providing educators and institutions with a deep, data-driven understanding of student sentiment. The implications for course design and pedagogical strategies are profound, as the model offers granular insights that can guide curriculum development, teaching methodologies, and overall educational delivery.

GREEN PLANT LANDSCAPE DESIGN FOR URBAN AIR QUALITY PURIFICATION WITH COMPUTER IMAGE PROCESSING IN CLOUD, GRID, AND CLUSTER COMPUTING

JINGJING NI*

Abstract. This research paper explores the innovative integration of green plant landscape design with advanced computer image processing in cloud, grid, and cluster computing environments to enhance urban air quality purification. The study begins by highlighting the critical need for improving air quality in urban areas, considering the rising levels of pollution and its impact on public health and the environment. The methodology involves the use of sophisticated image processing techniques to analyze various sensors on air quality measures and plant species their effectiveness in air purification, facilitated by the computational power of cloud, grid, and cluster computing. A diverse range of green plants was selected, and their air purification capabilities were assessed through a series of computer-simulated models. These models were developed using complex algorithms to predict the plants' performance in real-world urban settings. The research uniquely combines landscape architecture with technology, emphasizing the role of green spaces in urban areas for environmental sustainability. The results demonstrate that certain plant species are more effective than others in purifying urban air. The study provides a comprehensive ranking of these plants based on their purification capabilities, growth requirements, and suitability for various urban landscapes. The paper concludes by proposing practical guidelines for urban landscape designers and policymakers, recommending the strategic incorporation of specific green plants in urban areas to maximize air purification. Additionally, it highlights the potential of leveraging advanced computing technologies in environmental research and urban planning. This research contributes to the fields of environmental science, urban planning, and computer science by showcasing how multidisciplinary approaches can address pressing environmental issues. It opens avenues for further research in the optimization of urban green spaces using advanced computing techniques. The results demonstrate that certain plant species are more effective than others in purifying urban air. The study provides a comprehensive ranking of these plants based on their purification capabilities, growth requirements, and suitability for various urban landscapes. The paper concludes by proposing practical guidelines for urban landscape designers and policymakers, recommending the strategic incorporation of specific green plants in urban areas to maximize air purification.

Key words: Urban Air Quality, Green Plant Landscaping, Environmental Purification, Computer Image Processing, Cloud Computing, Grid Computing, Cluster Computing

1. Introduction. In the wake of escalating urbanization and industrialization, air pollution has emerged as a critical challenge confronting urban environments globally. The detrimental impact of poor air quality on human health and the ecosystem necessitates innovative solutions. This study explores a novel approach to ameliorate urban air quality: the strategic design of green plant landscapes, aided by advanced computational technologies. The role of green plants in purifying air is well-documented. They absorb pollutants and carbon dioxide, releasing oxygen, thereby improving air quality. However, the effectiveness of different plant species in specific urban contexts remains underexplored. This gap in knowledge presents an opportunity to blend environmental science with cutting-edge computing technologies. The study aims to employ computer image processing, harnessed through the power of cloud, grid, and cluster computing, to analyze and optimize green plant landscapes for urban air quality purification.

The primary objectives of this research are to identify the most effective plant species for air purification in urban landscapes, and to develop a computer-assisted model for landscape design that optimizes these benefits. This involves analyzing large datasets of environmental conditions and plant characteristics, a task well-suited to the capabilities of advanced computing paradigms like cloud, grid, and cluster computing. These technologies offer unprecedented processing power and data storage capabilities, facilitating detailed and complex environmental modeling.

*Zhuxi Cultural Tourism College, Anhui Finance and Trade Vocational College Hefei, 230601, China, (jingkingnire@outlook.com)

The introduction of computer image processing into landscape design represents a pioneering step in environmental planning. By harnessing these technologies, this research aims to provide actionable insights for urban planners and environmentalists, contributing to more sustainable and healthier urban environments. This paper is structured as follows: after the introduction, we present a review of the literature, outlining previous studies on green plants for air purification and the application of advanced computing in environmental science. This is followed by a detailed description of the methodology, including the selection of plant species, computational models used, and the design of the study. The subsequent sections present the results, discussion, and conclusions drawn from the research, along with recommendations for future studies in this evolving field.

The study begins by underlining the critical issue of declining air quality in metropolitan areas as pollution levels rise. This first recognition of the problem establishes the context for the study's relevance and significance. The study takes a unique approach by analyzing air quality sensors and the performance of several plant species in air filtration using modern image processing techniques. The usage of cloud, grid, and cluster computing shows a dedication to harnessing current technology to solve environmental problems.

"Image Processing in Cloud, Grid, and Cluster Computing" would be focused on exploring and achieving specific goals at the intersection of environmental science, urban planning, and advanced computing. The key objectives for this research:

1. Determine using image processing methods are most effective in purifying air in urban environments. This involves assessing various plants' ability to absorb pollutants and improve air quality.
2. Utilize computer image processing tools within cloud, grid, and cluster computing environments to analyze the physical and biological characteristics of different plant species. This includes studying their growth patterns, pollution absorption rates, and adaptability to urban settings.
3. Create computational models that can simulate and predict the effectiveness of different green plant arrangements in urban landscapes for maximizing air purification.

Research questions that concentrated in this research are,

1. What are the most effective methods for purifying urban air?
2. How does the integration of specific plant species in urban landscapes impact overall environmental and public health?
3. What are the challenges and limitations of using advanced computing technologies in environmental planning and monitoring?

Urban areas worldwide are grappling with escalating levels of air pollution, which pose serious risks to public health and the environment. Addressing this issue is vital for the well-being of urban populations and the sustainability of cities. Green plants are known to improve air quality by absorbing pollutants and carbon dioxide, offering a natural solution to the air pollution problem. However, the effectiveness of specific plant species and configurations in urban environments needs further exploration. The rapid development in computing technologies, such as cloud, grid, and cluster computing, offers unprecedented capabilities in data processing and analysis. Applying these technologies to environmental challenges presents an opportunity to innovate in urban air quality management.

2. Literature review. Globally, air quality issues are a major concern in urban areas, necessitating effective detection and management of air pollution variations over time and by region. This is essential for developing affordable solutions[10]. In India, air pollution remains a persistent public health issue[5]. The "Global Burden of Disease Study, 2019" reported that in 2019, air pollution was responsible for 1.67 million deaths, which is 17.8% of total deaths in India, leading to an economic loss of approximately USD 36.8 billion, or 1.36% of the country's GDP. Furthermore, in 2019, 22 Indian cities ranked among the top 30 most polluted cities globally, with many Indian cities appearing in the top 10 (IQAir, 2020). The COVID-19 lockdown in 2020 unexpectedly contributed to environmental recovery, significantly improving urban air quality[5, 12]. However, this improvement was temporary. [24] described the lockdown as an "anthropause," a brief pause that is unlikely to have a lasting impact on the detrimental effects of human activities. In India, as the lockdown was lifted, air pollution levels began to increase again [8], mirroring trends observed in other cities around the world [3, 9]. Post-lockdown, many Indian cities saw a significant increase in ambient particulate matter levels (PM10), with levels in the last quarters of 2020 approaching those seen in 2019 (life-as-usual situation).

In many developing nations, traditional methods for addressing air pollution have been largely unsuccessful.

This is due to a combination of factors including institutional weaknesses, infrastructural challenges, economic constraints, and political hurdles[13]. Consequently, air pollution continues to pose a significant threat to both environmental sustainability and public health, especially in India[14, 16, 18]. A key factor behind these shortcomings is the predominantly technocratic approach, which often neglects the socio-cultural aspects like public expectations, community capacity, and public participation in decision-making [17]. Recognizing these issues, the main motivation for this discussion is to shift from a purely technocratic mindset to one that harmonizes with nature. We advocate for policymakers to consider urban green spaces not just as aesthetic elements, but as vital components that enhance and strengthen efforts in air pollution prevention and control.

In their recent bibliometric study, [20] categorized the primary mechanisms by which plants remove pollutants, as they relate to public health, into three main groups: (I) dry deposition, (II) dispersion (the process by which plants alter air pollutants' path and speed through their physical structure), and (III) modification (including selective sorption, microbial reactions, and chemical coagulation due to Brownian motion and/or van der Waals forces). It's recommended that city planners and authorities delve into such research to gain a deeper understanding of how plants interact with pollutants and to maximize the effectiveness of urban green spaces. However, the dry deposition process is complicated by various factors, notably the diverse types of leaf surfaces in urban canopies and the movement of submicron particles. Similarly, there is a lack of comprehensive experimental data encompassing all scenarios related to dry deposition [11, 19]. The complexity is further heightened by varying levels of urban development, pollution sources, and human activities. Addressing these complexities will require more case studies in different urban environments and among various population demographics to fully understand and optimize dry deposition processes.

The initial consideration for selecting tree species for air pollution mitigation should focus on their climatic characteristics and the impact these have on the length of their growing season, which determines the duration of leaf cover[6, 22]. In temperate regions, deciduous trees lose their leaves during winter, thereby reducing the total leaf surface area available for pollutant absorption. Among these, conifers are often favored due to their lipophilic wax-coated needles, smaller leaf size, and intricate shoot structures, which are advantageous for pollutant capture [15, 23]. Additionally, the airflow around conifer needles creates more turbulence compared to larger leaves (broadleaves), which reduces the thickness of the boundary layer on needle leaves (Ackerly et al., [21]; [21, 20]. This means when air carrying pollutants passes over these needles, the boundary layer remains relatively still, creating a barrier between the air and the leaf surface.

However, the high pollutant absorption by conifer needles can sometimes damage the leaves, diminishing their effectiveness in pollutant removal. This issue is more pronounced in drier climates[24, 2]. In such cases, broad-leaved deciduous species or those that retain their leaves throughout winter are more suitable for pollution control [22]. Among broadleaved species, those with a high number of grooves, a large ratio of groove area to total leaf area, and dense epicuticular trichomes are preferred for pollution regulation [17, 7].

In climates with shorter growing seasons but high pollutant levels in winter, evergreen species, which maintain their foliage all year, are preferable over deciduous varieties[1]. The selection should also take into account the type of pollutants targeted. For instance, [4] found that oak leaves (deciduous) are more effective against particulate phase PAHs (polycyclic aromatic hydrocarbons) due to their high specific leaf area. Conversely, pine needles (evergreen) may be better suited for gaseous phase PAHs, particularly effective in capturing low and medium weight of PAHs molecules.

3. Methodology. The methodology for this research combines environmental science, landscape architecture, and advanced computational techniques to optimize green plant landscapes for urban air quality purification. For the study, a varied selection of green plant species were carefully selected. Plant kinds (trees, shrubs, ground cover), their capacity to filter the air, growth characteristics, and adaptation to urban situations are all variables in the choosing process. This choice is influenced by scientific understanding as well as landscape architecture concepts.

In metropolitan areas under research, sophisticated air quality monitors are carefully deployed. These sensors capture data on a variety of air quality indicators, including pollutants such as particulate matter (PM), nitrogen dioxide (NO₂), and volatile organic compounds (VOCs), in real time. Data from air quality sensors is gathered over time, documenting fluctuations in air quality based on factors such as time of day, meteorological conditions, and traffic density. This information will be used to analyze the efficacy of green

plants in air cleansing.

To examine data gathered from air quality sensors, advanced image processing techniques are used. These methods enable the extraction of useful information such as pollutant levels, regional distribution, and temporal trends. To mimic the behavior of chosen green plants in urban contexts, complex computational models are built. These models consider elements such as plant growth, transpiration rates, and the ability of plants to remove toxins from the air. To conduct these simulations efficiently, the computational capacity of cloud, grid, and cluster computing resources is used:

1. Selection of Plant Species
2. Data Collection and Analysis
3. Computer Image Processing
4. Computational Modeling
5. Pilot Implementation and Monitoring

3.1. Phase 1: Selection of Plant Species. In the research on "Green Plant Landscape Design for Urban Air Quality Purification," Phase 1, which focuses on the Selection of Plant Species, is a crucial foundational step. The objective here is to identify plants that are most effective in urban air purification, taking into account various urban and climatic conditions. This phase begins with an extensive literature review, where existing scientific studies, environmental reports, and botanical research are scrutinized to identify plants known for their pollution-absorbing abilities and adaptability to urban stresses. The selection criteria for these plants include their capacity to absorb specific urban pollutants, growth and maintenance needs, environmental adaptability, aesthetic contribution, and practical considerations like space and root development.

Field studies, consultations with experts like botanists and urban ecologists, and citizen science initiatives form the backbone of the data collection strategy. These diverse sources ensure a comprehensive understanding of how different plants perform in urban settings. The analysis of this data is thorough, involving comparative assessments of plants against the set criteria, statistical modeling to understand the correlation between plant traits and pollution absorption, and evaluations of climate adaptability.

The outcome of this phase is a carefully curated list of plant species, each with a detailed profile outlining its environmental benefits, physical characteristics, and care instructions. This list is not only crucial for the immediate next phases of the research, which involve further data collection and computational modeling, but also sets a precedent for interdisciplinary collaboration. By meticulously choosing the right plant species in Phase 1, the research ensures that the subsequent phases are informed by a deep and nuanced understanding of the best natural resources for combatting urban air pollution. Based on diverse urban condition, plant is selected by the user.

In this research, the characteristics of Broad-Leaved Deciduous Species and Evergreens are considered for pollution control. This research comprehensively evaluates the suitability of Broad-Leaved Deciduous Species and Evergreens in pollution control, emphasizing their distinct characteristics that enhance air purification in urban environments. Broad-Leaved Deciduous Species are noted for their seasonal leaf shedding and large leaf surface area. Despite losing leaves in winter, they offer significant benefits during the growing season. Their broad leaves provide a substantial surface for absorbing pollutants, especially effective in warmer months when pollution levels tend to spike. Evergreens, conversely, retain their leaves year-round, offering continuous air purification, including in colder months. Their resilience across various climates renders them versatile for different urban conditions.

The research further delves into specific traits beneficial for pollution control:

1. High Number of Grooves on Leaves: This feature increases the surface area, enabling the leaves to trap more pollutants. The grooves are particularly adept at capturing fine particulate matter, a major urban pollution component.
2. Large Groove Area Relative to Total Leaf Area: A higher ratio here indicates a more effective trapping mechanism for pollutants, optimizing the leaves for absorption, especially crucial in densely populated areas.
3. Dense Epicuticular Trichomes: These hair-like structures act as pollution filters, trapping and absorbing pollutants. They also protect the plant from environmental stresses, including high pollution levels, maintaining their efficiency in pollutant absorption.

The selection of these plant types underscores the research's focus on natural, sustainable methods for improving urban air quality. Their large leaf surfaces, grooved structures, and trichomes significantly enhance their ability to capture and absorb airborne pollutants, making them highly relevant for application in diverse urban landscapes. This approach not only addresses air quality issues but also promotes a greener, more sustainable urban environment. The selection of broad-leaved deciduous species and evergreens for this research is based on their distinct characteristics that make them suitable for urban air purification. Their large leaf surfaces, grooved structures, and the presence of trichomes enhance their ability to capture and absorb airborne pollutants. This choice underscores the research's emphasis on employing natural, sustainable solutions to address urban air quality issues, making it relevant and practical for application in diverse urban landscapes.

3.2. Phase 2: Data Collection and Analysis. .

This phase is critical for empirically validating the pollution absorption capabilities of the selected plant species and understanding their practical implications in urban environments. The approach in this phase integrates traditional environmental science methods with innovative data collection and analysis techniques, focusing on both qualitative and quantitative aspects.

3.2.1. Data Collection Strategy. Deploy air quality sensors in the vicinity of the planted areas to continuously monitor levels of key pollutants (e.g., PM_{2.5}, PM₁₀, NO_x, SO_x, CO, O₃). These sensors should be strategically placed at various heights and distances from the plants to capture a comprehensive data set. Periodically collect leaf samples from the selected plants for laboratory analysis. This will involve examining the physical characteristics of the leaves (such as leaf surface area, groove depth, and trichome density) and quantifying the accumulated pollutants on the leaf surface using techniques like gas chromatography-mass spectrometry (GC-MS) or X-ray fluorescence (XRF) analysis. Record environmental factors such as temperature, humidity, wind speed, and rainfall, as they can significantly influence the plants' pollutant absorption capabilities. Utilize high-resolution photography and drone imagery to document the physical state of the plants over time. This can provide insights into their growth patterns, health, and environmental interactions. Engage with local communities to collect qualitative data on their perceptions of air quality and the impact of the green spaces.

3.2.2. Analysis Techniques. Employ machine learning algorithms to analyze the complex dataset. Techniques like regression analysis, cluster analysis, and neural networks can reveal patterns and correlations between plant characteristics, pollutant levels, and environmental factors. Use Geographic Information Systems (GIS) to map pollution levels and plant locations. This spatial analysis can reveal how the distribution of plants affects air quality in different urban zones. Implement time-series analysis to understand how the effectiveness of plants in pollution absorption varies over time and in different environmental conditions. Compare data from sites with the selected plants to control sites without them. This will provide a clearer picture of the plants' direct impact on air quality. Use natural language processing (NLP) to analyze community feedback, providing insights into public perception and acceptance of the green spaces.

Quantitative data demonstrating the effectiveness of the selected plants in reducing specific urban pollutants. Also, understanding how different plant species perform under varying urban environmental conditions helps to plan urban landscape. Data-driven recommendations for urban planners and policymakers on integrating specific plant species in urban landscape design for air quality improvement. Enhanced community involvement and awareness about the role of urban greenery in improving air quality.

By integrating advanced data collection and analysis techniques, this phase aims to provide a robust scientific foundation for the use of specific plant species in urban air purification. The results will not only validate the plant selection but also offer practical guidelines for their effective implementation in urban landscape designs.

3.3. Phase 3: Computer Image Processing Techniques. The use of high-resolution photography, possibly supplemented by drone imagery, is essential. These images provide detailed visual data on plant growth, health, and environmental interactions, which are crucial for understanding their ability to purify urban air. Algorithms are employed to analyze these images for various parameters, such as leaf surface area, groove depth, and trichome density. These characteristics are significant as they relate to the plants' pollution absorption capabilities.

CNNs are ideal for image recognition tasks. They can be trained to identify specific plant features that correlate with pollution absorption, like leaf structure, density of trichomes, etc. This involves labeling each pixel of an image with a class (like leaf, branch, flower, etc.), allowing for detailed analysis of the plant parts and their specific roles in air purification. By processing sequential images of the plants over time, this approach helps in observing changes in plant growth and health, providing insights into how environmental factors impact their air purification abilities. Using 3D image processing to create models of the plant structures can provide insights into their physical arrangement and how this affects their efficiency in air purification.

By quantifying physical aspects of plants such as leaf surface area and groove depth, researchers can establish correlations between these characteristics and the plants' ability to absorb pollutants. Image processing helps in continuously monitoring the health and growth patterns of plants in urban settings, crucial for understanding their long-term effectiveness in air purification. Through image analysis, the interaction of plants with their surrounding environment, including factors like light exposure, urban structures, and human activity, can be better understood. The data derived from image processing can be integrated with data from Phase 2 (such as pollutant levels and environmental factors) to provide a more comprehensive understanding of the plants' performance in urban air purification.

To develop computational models that can accurately predict how different plant species influence urban air quality under a variety of environmental conditions. These models integrate data on plant characteristics (like leaf surface area, trichome density), pollutant levels (PM_{2.5}, NO_x, etc.), and environmental factors (temperature, humidity, urban structures).

Data collected from previous phases, such as air quality measurements and plant characteristics, is cleaned, normalized, and transformed to be used in modeling. Identifying the most relevant features that influence air purification, such as specific plant traits and local environmental conditions. Building a framework in Python where different scenarios can be simulated, such as varying levels of pollution, different plant species combinations, and changing weather conditions. Using historical data to validate the simulations, ensuring they accurately reflect real-world scenarios. Designing multi-layer neural networks that can process complex patterns in the data. These networks might include convolutional layers for spatial data processing, especially useful when dealing with image data from Phase 3. Splitting the dataset into training and testing sets. The network is trained on the training set, learning to predict air quality based on plant characteristics and environmental factors.

Decision trees are used to build rule-based models. These models help to understand and illustrate the decision-making process, especially in identifying the most relevant elements impacting air quality. These are particularly useful for understanding and visualizing the decision process, like which factors most significantly affect air quality. Using software like ArcGIS or QGIS for spatial analysis. Creating maps that visually represent data such as the distribution of plant species and pollution levels across urban areas. Analyzing how the distribution of different plant species across an urban area affects air quality. Investigating how factors like urban layout, traffic density, and green space distribution correlate with air purification effectiveness.

4. Result Evaluation. This research focuses on examining how the arrangement of green spaces in cities affects air pollution levels. It specifically looks at 20 garden cities in China randomly that experience a subtropical monsoon climate. The study uses data from 2019, including urban air quality measurements and information on land use types. By employing landscape metrics and spatial regression models, the study investigates the connection between the layout of green spaces and air pollution concentrations. This paper utilizes regression modeling tools available in the GeoDa software to perform SEM (Structural Equation Modeling) regression analysis. The outcomes of this analysis are presented in Table 4.1.

Landscape Shape Index (LSI) of grasslands. Notably, the association between SO₂ levels and both the PD of forestlands and the LSI of grasslands was particularly strong ($p < 0.01$). Conversely, the SO₂ concentration had a significant and negative correlation with the patch proportion in landscape area (PLAND) of forestlands, the patch density (PD) of grasslands, and the PLAND of agricultural lands, with the last two showing a very significant relationship with SO₂ levels ($p < 0.01$).

The study found that a one-unit increase in the PD of forestlands, PLAND, and LSI of grasslands led to increases in SO₂ concentration by 149.939, 0.752, and 0.429 units, respectively. On the other hand, a one-unit rise in the PLAND of forestlands, PD of grasslands, and PLAND of farmlands resulted in decreases in

Table 4.1: Various concentrations measures and analysis

	Variable	ρ	Threshold	ρ	Threshold	ρ	Threshold
		PM 2.5		NO ₂		SO ₂	
Grass lands	PLAND	0.821		0.885		0.000	0.000**
	PD	0.616		0.994		0.000	0.000**
	LSI	0.236		0.897		0.000	0.000**
Farm lands	PLAND	0.214	0.214*	0.532	0.532*	0.0021	
	PD	0.645		0.687		0.0054	
	LSI	0.347		0.752		0.0061	

SO₂ concentration by 0.073, 214.564, and 0.172 units, respectively. The SO₂ levels were not noticeably impacted by the LSI of forestlands, and the PD and LSI of agricultural lands.

The spatial correlation analysis from the 20 cities showed a significant link between the layout of urban green spaces and the levels of PM2.5, NO₂, and SO₂ pollutants. The pattern of green spaces, however, did not significantly affect PM10 levels. The PLAND, PD, and LSI of grasslands, along with the PLAND of farmlands, had an effect on SO₂ concentrations.

In the effort to optimize and rejuvenate the layout of urban green spaces, research has shown that strategically planning the design and distribution of green space networks can enhance air quality and benefit public health. Based on these insights, several suggestions are proposed for improving air pollution in cities with subtropical monsoon climates. Forests, grasslands, and farmlands are effective in reducing concentrations of PM2.5, NO₂, and SO₂. In urban areas, grassland should be managed carefully, forest coverage should be increased, and the restoration of damaged forests should be expedited to enhance ecosystem stability. The urban green space landscape should be meticulously planned based on scientific principles to balance ecological spaces for living and production.

In cities where NO₂ and SO₂ are predominant pollutants, arranging forest, grassland, and farmland landscapes systematically can help reduce pollution levels. Optimal NO₂ concentration in urban areas is achieved when the Patch Density (PD) of forest land is around 0.072. For SO₂, the best reduction effects are observed when forest land and grassland densities and layouts are adjusted to specific parameters, with an LSI of grassland at 14.13. This suggests that urban green spaces should be carefully planned to optimize patch density and diversify green space types, thus alleviating air pollution. By integrating green spaces into urban areas, air quality can be improved effectively and economically.

PM2.5 pollution, mainly from industrial emissions, traffic, and biomass combustion, is prevalent in urban roads and industrial areas. In China's subtropical monsoon regions, where urban development is rapid, reducing traffic and industrial emissions is challenging. However, optimizing urban green space layouts can mitigate PM2.5 pollution. An optimal reduction in PM2.5 levels occurs when the LSI of forest land reaches 18.02. Enhancing the greenery along streets and near factories, increasing the interaction between green spaces and PM2.5, and improving the vertical structure of urban green belts can effectively block and absorb PM2.5 pollutants.

Additionally, managing unused and inefficient land to create a well-planned urban green landscape is recommended. Promoting green, healthy, and low-carbon lifestyles and consumption habits among residents is also advised. Disseminating scientific findings on PM2.5, NO₂, and SO₂ pollution control can help government departments implement measures more effectively and gain public support for air pollution control initiatives.

5. Conclusion. In this research underscores the vital role of urban green spaces in mitigating air pollution and enhancing public health, particularly in cities with subtropical monsoon climates. The strategic planning and distribution of green spaces, such as forests, grasslands, and farmlands, have been identified as key factors in reducing concentrations of harmful pollutants like PM2.5, NO₂, and SO₂. By carefully managing these green areas, especially in urban settings, and adhering to specific landscape metrics such as Patch Density and Landscape Shape Index, significant improvements in air quality can be achieved. The study highlights that different types of pollutants require distinct approaches in terms of green space management. For instance,

the optimal control of NO₂ and SO₂ involves adjusting the density and layout of forests and grasslands, while tackling PM_{2.5} pollution necessitates enhancing urban greenery in areas with high traffic and industrial activity. Moreover, the research emphasizes the importance of integrating ecological considerations into urban planning and development. This involves not only improving the design of green spaces but also promoting sustainable lifestyles and consumption patterns among residents. Such holistic approaches not only contribute to better air quality but also foster healthier, more sustainable urban environments.

Cities throughout the world have taken a transformational approach to urban design and sustainability in this imagined future by building Sustainable Urban Green Zones (SUGZs). These are carefully planned and strategically placed green spaces within metropolitan areas that promote air quality purification and environmental well-being. The research findings have a significant impact on the creation and management of SUGZs.

LEARNERS BEHAVIOUR PREDICTION AND ANALYSIS MODEL FOR SMART LEARNING PLATFORM USING DEEP LEARNING APPROACH

LIYUAN FENG* AND YUNFENG JI†

Abstract. In the quickly changing field of instructional technology, intelligent educational systems are now essential for individualized and effective instruction. To forecast and understand learners' actions in intelligent educational settings, this research suggests an analytical framework that makes use of deep learning techniques. By offering real-time information on user activities, the goal is to improve these platforms' reactivity and flexibility. Using state-of-the-art deep learning designs, our technique examines large datasets that include interactions between users, interest trends, and efficiency measures. The proposed method classifies the e-learning based behaviour classification and then the e-learning performance prediction using CNN-LSTM. The suggested framework incorporates the temporal relationships and sequential patterns present in learners' actions on the platform by fusing convolutional neural networks (CNNs) and long short-term memory networks (LSTMs). Furthermore, using multimedia information like simulations that are interactive and video lectures, convolutional neural networks (CNNs) are used to gather spatial data. The present study advances smart learning technology by providing a stable and expandable structure for behavior analysis and prediction in students. Through proactive customization of learning events, instructors, content producers, and platform developers can create a setting that is both enjoyable and effective for students. This is made possible by the knowledge gained from this approach.

Key words: Learners Behaviour, prediction and analysis, smart learning platform, Deep Learning Approach, convolutional neural networks, e-learning

1. Introduction. The incorporation of electronic devices has made it possible for creative and customized educational experiences in the quickly changing field of learning. An example of this progress is the introduction of intelligent learning systems that use AI to improve the learning process. The subject of learner behavior has numerous applications, but one that requires significant attention is the forecasting and evaluation of behavior among learners. Customizing lessons to meet individual requirements requires an in-depth comprehension of how learners react to difficulties, respond to happiness, and interact with the educational setting.

Electronic learning is now a standard educational method [27] and has played a significant role in the growth of online learning. Because of the COVID-19 pandemic, e-learning has become increasingly popular due to its extensive learning materials, low knowledge intake threshold, and substantial temporal and spatial flexibility. Still, this style makes it difficult for teachers to assess the progress in learning of their students [28, 19], and concerns have been voiced over the caliber of e-learning. By forecasting how well pupils will do on upcoming tests, lowering the likelihood that students won't pass the course, and guaranteeing the quality of e-learning, the research of learning outcome predictions gives teachers a foundation on which to modify their teaching strategies for students who could have difficulties.

Students' e-learning behavior has a significant influence on their educational outcomes, according to a substantial body of studies examining the connection between e-learning behavior and learning performance. As a result, achievement in learning predictions using data from the learning process has attracted a lot of attention lately [32]. Teachers can adjust their instructional tactics in real time and begin employing the role of monitoring as well as early warning by using the measurement, collection, and evaluation of learning information to accomplish achievement predictions [8].

Studies point out that knowledge of e-learning processes depends on data on e-learning behavior [1, 2]. The term "e-learning behavior data" refers to the information created by students during a variety of behavioral activities carried out on e-learning systems or online educational companies. This information can be used to

*Jiangsu Vocational College Institute of Information Technology, Wuxi, 214153, China (liyuanfengsd@outlook.com)

†Jiangsu Vocational College Institute of Information Technology, Wuxi, 214153, China

refer to the action documents of students during the learning process, with particular attention to the quantity of login systems, quantity of resource access, quantity of forum participants, quantity of resource access, and other behavioral data. As a result, scholars have studied e-learning behavior in detail and developed many educational outcome predictions according to e-learning behavior[3].

The main question on the research,

How does the BCEP prediction framework compare to traditional E-learning classification techniques in terms of prediction accuracy and efficiency?

What are the specific steps and methodologies used in the data cleansing process within the proposed CNN-LSTM prediction framework?

How does the combination of features in the BCEP framework contribute to the overall accuracy of behavior classification in E-learning settings?

What criteria are used for behavior categorization in the CNN-LSTM prediction framework, and how does this affect the system's predictive capabilities?

To lower the operational expenses of the model and deliver high-accuracy, low-time-consuming learning outcome prediction services for online platforms, choosing features can be utilized to preserve important learning behaviors [4, 5]. In addition, e-learning predictors must typically employ e-learning behavior data as input variables directly because of the single input technique for e-learning behavior data. Few models will employ training data that is integrated with learning behavior data (i.e., feature combination processes) on the exact same kind of learning behavior data. Lastly, there is a lack of standardization among crucial learning behavior indicators, with various researchers finding different ones. Important behavioral cues that can be utilized to accurately predict student achievement have not yet been found in this field of research [6, 7].

The main contribution of the proposed method is given below:

1. We offer the behavior classification-based E-learning prediction system (BCEP prediction framework) to address these issues, provide a summary of traditional E-learning classification techniques, and conduct a thorough analysis of the E-learning procedure.
2. Initially this study proposes a CNN-LSTM prediction framework based on BCEP, which consists of four steps: data cleansing, combination of features, behavior categorization, and training of the model.
3. Computing cost decreases throughout training, and the algorithm becomes more mobile and adaptable during use.

Remaining sections of this paper are structured as follows: Section 2 discusses about the related research works, Section 3 describes the Smart Learning, Behaviour classification and Deep Learning methods, Section 4 discusses about the experimented results and comparison and Section 6 concludes the proposed optimization method with future work.

2. Related Works. Tendency markers and behavioral indicators of performance [9, 10] are common summaries of e-learning success predictions. The propensity signals are characteristics that are inherent in itself; in general, propensity indicators are static data that are typically gathered prior to the commencement of a class or semester, such as gender [13], financial status [11], and past educational history [12]. The tendency indicators have been utilized by numerous academics to create learning early-warning systems that forecast students' learning across a course of study, an entire semester, and other phases. Despite exhibiting excellent results, the predictors identified by these investigations disregarded the significance of learning behavior data. For instance, a lot of research employed demographic or past student performance information unrelated to education.

Even while the characteristics of learners in this research can be used to predict learning achievement, this strategy neglected the fact that most tendency markers were outside of the control of both teachers and pupils, and it also disregarded the curricular modifications made by the students [14]. Preferences indicators also have privacy issues, because private information gathered by educational organizations is not permitted to be disclosed with the general population. In general, there was no issue with the behavioural performance indicator, which is the dynamic index that the learner reflects during the learning process [15, 16, 17]. The amount of time and effort that students devote to a particular course, as well as the regularity with which they access course materials and participate in online conversations, can be precisely described by e-learning behavior data.

The amount of time and effort that students devote to a particular course, as well as the regularity with which they access the content and participate in online conversations, can be precisely described by e-learning behavior data. Several researchers also attempted to finish learning prediction [18, 20, 21] by combining two signs, but they ran into issues with rising computational expenses. The basis for e-learning behavior study has been established by the growth in big educational data and the introduction of new means of communication and information exchange.

A study on the prediction of performance in learning based on learning behavior is encouraged by the importance of learning behavior information for students in analyzing shifts in behavior, tastes, and skill ranges [22]. Learning behavior is a major component influencing how well learners learn and a significant indicator for forecasting performance in learning, according to learning input theory, which also explains the connection among learning behavior and learning performance [23]. Simultaneously, several studies have established a strong link among student online activities and academic achievement [24, 25], and paying closer attention to individual learning activities might help students better understand the circumstances under which they study and encourage positive developing [26].

Researcher [29] discovered that cooperative interaction patterns in a virtual educational setting help students grasp material more deeply and push themselves to meet learning objectives. To forecast how well online learners would learn, author [30] employed learning interaction data. She discovered that learning outcomes can be strongly impacted by how students access and use books, forums, and course materials. A correlation between one or more behavioral actions and educational outcomes was the focus of certain investigations. A positive link has been observed by researcher [31] between the overall number of passwords and learners' final scores.

3. Proposed Methodology. This study suggests the behavior classification-based E-learning performance prediction framework (BCEP prediction framework) based CNN-LSTM, which creatively builds a learning performance predictor from the standpoint of behavior classes. As illustrated in Fig. 3.1, the BCEP prediction architecture explains the entire process of incorporating learning performance predictors via e-learning behavior categories. There are four main connections in the forecasting structure: (3.2) choosing features, which is carried out on pre-processed e-learning behavior data to get key e-learning behaviors; (3.1) data pre-processing, involving cleaning of data and the conversion from the initial e-learning behavior data collected through the e-learning system to obtain uniformed e-learning behavior data; (3.4) model development, which develops an e-learning achievement predictor using a range of deep learning computations; (3.3) feature merging, which creates an assortment of behavior categories, classifies fundamental learning behaviors in accordance with predetermined rules using CNN-LSTM, and then works feature fusion to get the group feature value for every kind of e-learning behavior. In figure 3.1 shows the architecture of the proposed method.

The use of sophisticated deep learning models serves as the core of this analytical methodology. Deep learning has shown its ability to handle complicated data and identify significant patterns, making it well-suited to the challenge of analyzing and predicting user behavior in e-learning settings. The framework starts with huge and diversified datasets that include a wide range of user interactions, trends in user interests, and numerous performance measures. These datasets are the main source of data for training and assessing the model.

The framework's first significant component is behavior categorization in the context of e-learning. The goal here is to identify and label various sorts of user activities. This categorization step is critical for later phases of performance prediction. Following behavior classification, the framework moves on to predicting e-learning performance. This requires predicting how users will do based on their past behavior and interactions with the educational platform. Prediction is critical for adapting educational experiences to specific students.

3.1. Data Pre-processing. Predictive model accuracy is directly impacted by the caliber of the e-learning behavior data. As a result, cleaning the e-learning behavioral information that was downloaded from the online learning system is the initial phase. While there isn't a single, effective strategy for cleansing information, the approach used to manage absent, replicated, and anomalous values should be chosen based on the actual state of the data. At the same time, it is frequently not possible to do feature selection, and e-learning behavior data spanning multiple dimensions is not numerically equivalent. Additionally, e-learning behavior data captured by e-learning systems is frequently not of one dimension at all. This issue is resolved by the suggested model,

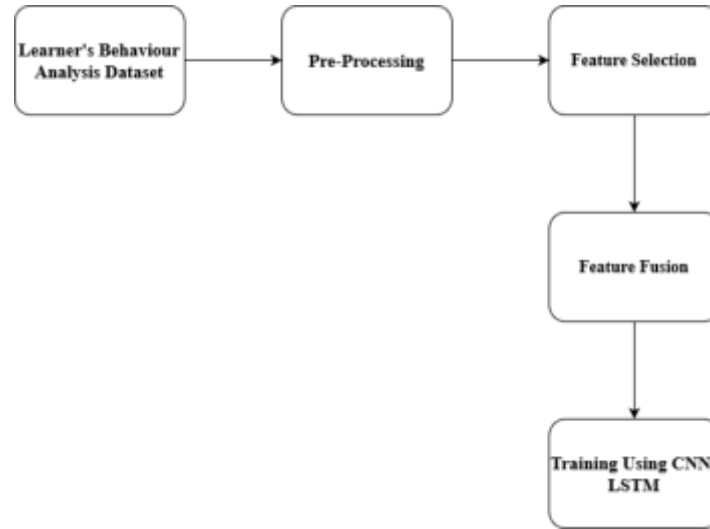

Fig. 3.1: Architecture of Proposed Methodology

which uses Z scores to standardize e-learning behavior data across several dimensions.

The standard e-learning behavior set $B\{b', b'2, \dots, b'n\}$ and the original e-learning behavior set $B\{b1, b2, \dots, bn\}$ are defined. where $b'n$ is the n-th online education behavior following standardization and bn is the n-th e-learning behavior as documented by the e-learning system. The initial and standard e-learning behavior data are specified simultaneously, with n denoting the n-th e-learning behavior and m denoting the m-th data of the present e-learning behavior. For instance, the equation for $d'nm$ is as follows. Dnm is the second behavioral information of the first kind of e-learning behavior recorded by the platform for e-learning.

$$d'_{nm} = \frac{d_{nm} - \mu b_m}{\sigma} \tag{3.1}$$

3.2. Feature Selection. By choosing pertinent features from among all features that are useful for training the model, one's selecting features can reduce the dimension of the feature and enhance its comprehension, generalization, and effectiveness in operation. This structure selects characteristics for standard e-learning behavior data using the variance filtering method. The variance filtration technique filters the characteristics by utilizing the variability of every single feature. The sample difference on this feature decreases with decreasing feature variance, and the feature's ability to differentiate the sample from other samples decreases as well. A crucial component of the variance filtering technique is the threshold, which denotes the variance threshold and determines which features are deleted if the variance of those features is smaller than the threshold.

$$V_n = \frac{\sum_{i=1}^m (d'_{ni} - \mu V_m)}{n} \tag{3.2}$$

where the mean quantity of the n-th grade e-learning behavior data is represented by μV_m . The variance threshold is used to compare each component in iteration V . The appropriate e-learning behavior is included to the key e-learning behavior set if the present e-learning behavior feature value exceeds the threshold; alternatively, it is not included.

3.3. Feature Fusion. The primary e-learning behavior is separated into various e-learning behavior clusters based on the e-learning behavior classification model. It is assumed that there are n different types of e-learning behavior categories (i.e., $M\{C1, C2, \dots, Cn\}$) that make up the classification model M . Following the division of the e-learning behavior categories, n e-learning behavior clusters are produced, with each type of cluster containing a different number of e-learning behaviors, for example, $C1\{b1, b2, \dots, bn\}$, where bn is the

n -th e-learning behavior that satisfies C1's norms.

$$V_{c_i} = \lambda \cdot \max \{V_{b_1}, V_{b_2}, \dots, V_{b_i}\} + (1 - \lambda) \cdot \frac{\sum_{i=1}^m (d_{ni}^i - \mu \forall_m)}{n} \quad (3.3)$$

3.4. Training using CNN-LSTM for learners' behaviour Analysis.. The combination of long-short-term memory networks (LSTMs) and convolutional neural networks (CNNs) has become an effective model for behavioral analysis and forecasting in the context of smart educational systems in the ever-changing field of education technologies. This novel combination uses CNNs' spatial awareness and LSTMs' time ability to sequence to identify intricate trends in learners' behavior, providing previously unobtainable insights into how they engage with learning materials.

A CNN-LSTM-based prediction model successfully processes and analyzes sequential data with spatial information by combining Convolutional Neural Networks (CNNs) with Long Short-Term Memory networks (LSTMs). This hybrid model is widely utilized in a variety of applications, such as time series forecasting, picture captioning, and video analysis. The model starts with an input layer that receives sequential spatial data. This data can take the shape of time series, photos, videos, or any other data format that includes both temporal and geographic elements.

One or more CNN layers are used after the input layer to extract spatial information from the input data. CNNs recognize patterns and characteristics in data using convolutional filters. Each CNN layer generally has a number of convolutional and pooling processes. Convolutional operations use filters to discover local patterns in the input data, whereas pooling procedures downsample the spatial dimensions to minimize computing complexity and extract dominating features.

Following the CNN layers, the retrieved spatial characteristics are frequently flattened into a one-dimensional vector. This vector is used as the input for the next LSTM layers. LSTMs are recurrent neural networks (RNNs) that are designed to capture temporal relationships in sequential data. They are ideal for activities where the arrangement of data points is critical. LSTM layers accept flattened spatial characteristics as input and simulate the data's sequential patterns. They remain in a concealed state, allowing them to record long-term dependencies and recall relevant information from previous time steps.

The complete model is trained using labeled data, which includes input sequences and their associated target values. The model learns to minimize a loss function during training, modifying its internal parameters (weights and biases) to generate correct predictions. To update the model's parameters iteratively, optimization methods such as stochastic gradient descent (SGD) or Adam are typically utilized. The CNN-LSTM-based model may be used for sequence-to-sequence prediction in some instances, where it takes a series of input data and creates a corresponding sequence of output data. This is common in video captioning and language translation applications.

Thanks to advances in artificial intelligence, intelligent educational systems aim to go beyond the confines of conventional schooling by customizing the way that content is delivered to each pupil. In this quest, the incorporation of a CNN-LSTM-based prediction model is a significant advancement. Because the CNN component is so good at extracting spatial features, the algorithm can recognize patterns visually inside the learning surface. In addition, the LSTM part allows the model to understand how the learners' interest is changing over time by capturing the sequential relationships that are present in their conversations.

The power of this paradigm resides in its capacity to process both the dynamic development of learners' actions and static materials, including text and images. Through the examination of both the visual and sequence aspects of the data, the CNN-LSTM design enables the predictive algorithm to forecast future actions, identify possible problems, and suggest tailored remedies instantly.

The power of this paradigm resides in its capacity to process both the dynamic development of learners' actions and static materials, including text and images. Through the examination of both the visual and sequence aspects of the data, the CNN-LSTM design enables the predictive algorithm to forecast future actions, identify possible problems, and suggest tailored remedies instantly. Our goal as we investigate the CNN-LSTM model for learners' behavior prediction and analysis is to improve the adaptability and reactivity of intelligent learning environments. By providing an advanced awareness of how time and space clues might work together to provide a more individualized and holistic learning experience, this research aims to make a valuable contribution

to the emerging field of schooling machine learning. We hope to create a revolutionary instructional environment where statistical analysis actively develops a dynamic and customized atmosphere for learning in addition to anticipating learners' requirements via the prism of the CNN-LSTM framework.

The completely connected layer's output data is received, and the next crucial step in determining the impact of behavior analysis is to do CNN on the information. Prior to implementing Behavior Analysis, it is important to comprehend how gradient optimization is used during the process. Gradient-based optimization is the most often used optimization technique in deep learning. The goal of this training procedure is to reduce the loss function as much as possible, which will guarantee behavioral analysis reliability.

$$J(\theta) = E_{a,b \sim p_{data}} L(a, b, \theta) = \frac{1}{m} \sum_{i=1}^m L(a^{(i)}, b^{(i)}, \theta) \tag{3.4}$$

L is the loss function for each sample:

$$L(a, b, \theta) = -\log p(b|a; \theta) \tag{3.5}$$

For these additive loss functions, gradient descent needs to be computed:

$$\Delta_{\theta} J(\theta) = \frac{1}{m} \sum_{i=1}^m L(a^{(i)}, b^{(i)}, \theta) \tag{3.6}$$

3.4.1. Long-Short Term Memory (LSTM). The term "neuron" refers to each component of deep learning; neurons are interconnected, and instruction is a way of altering a neuron's power. This modification makes a network made up of deep learning a multi-level neuron networks since each layer is tailored to the features of the neuron network [9].

Since behavior analysis can usually be expressed by a wide range of functions, a function like Formula 1 can be utilized to characterize this process.

$$f(a) = f^{(3)}(f^{(2)}f^{(1)}(a)) \tag{3.7}$$

A significant difficulty in the present-day network virtualization study is how to successfully anticipate the chance of network node and connection failure in a specific amount of time in the future using the parameters of the current network environment. This research suggests a long-short-term memory neural network (LSTM)-based behavior analysis technique [10] as a solution to this issue. Although the general neural network topology can theoretically address the issue of losing data due to parameter selection and distance, in actual use it is unable to produce the intended result [11]. Recurrent neural networks have certain drawbacks that LSTM can solve, allowing it to perform exceptionally well in a variety of applications. As seen in Figure 3.2, LSTM expands the original recurring neural network topology by including a memory storage structure.

4. Result Analysis. The study's findings, involving ACC, F1, Kappa, and each test group's prediction time as determined by the suggested CNN-LSTM deep learning techniques, are shown in this subsection.

In learner behavior evaluation, accuracy usually refers to how well the model can foresee or categorize various elements of learners' behavior. The tasks and objectives of the psychological analysis framework determine how accurate the assessment is. Classification accuracy is a key performance indicator for tasks that require grouping learner behavior into groups (such as engagement levels, learning preferences, or performance results). It calculates the proportion of correctly identified cases relative to all occurrences. In figure 4.1 shows the evaluation of Accuracy.

A popular metric for issues with classification is the F1-score, which offers a fair evaluation of an algorithm's recall and precision. F1-score is a useful measure for assessing how well prediction models recognize and classify different learner behaviors when it is used in learner behavior analysis.

Within the framework of learner behavior analysis, actions can be classified into many groups or categories, such as involvement, levels of engagement, or conceptual comprehension. The F1-score provides an equitable

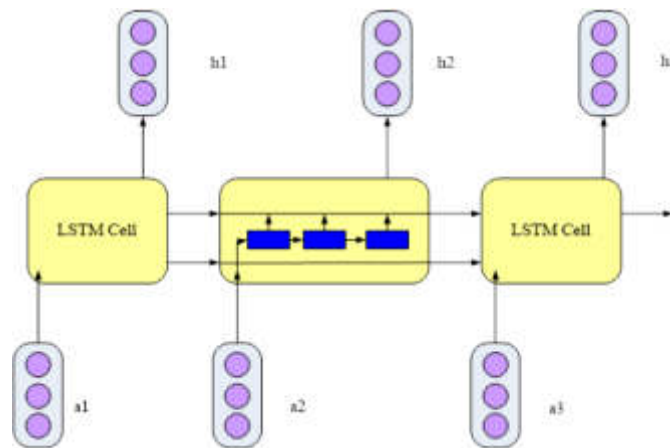

Fig. 3.2: LSTM Architecture

Fig. 4.1: Accuracy

assessment that is especially helpful in situations when the class distribution is unbalanced because it accounts for recall as well as precision. In figure 4.2 shows the evaluation of F1-score.

The Kappa statistic, sometimes referred to as Cohen's Kappa, is a way to gauge inter-rater concordance or, more specifically, how well projected, and actual categorized results coincide when it comes to automated training and predictive models. It comes in very handy when working with datasets that are unbalanced. The Kappa value can be utilized in learner behavior analysis to assess a predictive model's dependability. In circumstances where there are imbalances in the number of observable behaviors, Cohen's Kappa is especially appropriate. It evaluates the degree of coherence among anticipated results and actual actions in the setting of learner behavior analysis while considering the potential that agreement could have happened by coincidence only. In figure 4.3 shows the evaluation of Kappa Value.

In the domain of learner behavioral analysis, precision is an important parameter that evaluates how well a model predicts positive outcomes. The proportion of true positive forecasts to the total of actual positives and erroneous positives is known as precision. It offers insightful information about how well the model can recognize appropriate trends or behaviors across all the expected instances. When it comes to student behavior

Fig. 4.2: F1-Score

Fig. 4.3: Kappa Value

analysis, accuracy is especially important. A high precision number means that there are few false positives in the model’s positive forecasts (e.g., correctly recognizing learning behaviors). Put practically, this means that there will be fewer false alarms because the model is more probable to be right when predicting a particular action.

To achieve high precision in learner behavior evaluation, sensitivity (recall) and specificity must frequently be carefully balanced. A comprehensive assessment considers recall (the model’s capacity to catch all relevant occurrences) and other measures to offer a whole picture of the model’s efficacy, whereas precision concentrates on the precision of its favorable forecasts. In figure 4.4 shows the evaluation of Precision.

5. Conclusion. Intelligent learning systems are currently necessary for tailored and efficient instruction in the rapidly evolving field of instructional technology. This paper proposes a framework for analysis that uses deep learning techniques to predict and explain learners’ activities in intelligent educational situations. The objective is to increase the responsiveness and adaptability of these systems by providing current data on user

Fig. 4.4: Precision

behaviors. Our method analyzes big datasets containing interactions among users, attention patterns, and productivity metrics using cutting-edge deep learning designs. The suggested approach uses CNN-LSTM to classify behavior based on e-learning and then predicts e-learning performance. The proposed architecture combines convolutional neural networks (CNNs) and long short-term memory networks (LSTMs) to capture the temporal linkages and sequential patterns found in learners' behaviors on the platform. In addition, convolutional neural networks (CNNs) are utilized to collect spatial data utilizing multimedia content such as interactive simulations and video lectures. This work contributes to the field of smart learning technologies by offering a robust and scalable framework for pupil conduct monitoring and forecasting. Teachers, content creators, and platform developers may create an environment that is fun and productive for students by actively customizing learning experiences. The understanding obtained from this method makes this feasible.

APPLICATION OF INTELLIGENT ANALYSIS BASED ON ENGINEERING MANAGEMENT AND DECISION MAKING FOR ECONOMIC DEVELOPMENT OF REGIONAL ENTERPRISE

QIANZHEN SONG*, TONG YAO† and YUHONG DAI‡

Abstract. The convergence of advanced detection mechanisms, engineering management, and intelligence analysis presents a disruptive model for local companies pursuing economic growth. The paper presents a thorough strategy meant to improve regional processes for making decisions to promote long-term economic growth by utilizing modern technology. Using deep learning techniques, such as neural networks and deep neural architectures, to examine large datasets that are pertinent to local businesses. This makes data-driven decision-making easier and empowers stakeholders to choose wisely and strategically for the best possible economic results. Incorporating management of engineering concepts to optimize resource allocation, improve operational efficiency, and streamline operations. To guarantee the successful implementation of economic development programs, management of projects, quality control, and methods for optimization must be applied. The research's findings have great potential to further regional businesses' goals for economic development. Through the integration of robust engineering management concepts and the analytical capacity of deep learning, this framework aims to equip decision-makers with the essential skills to navigate the intricacies of local economic environments, propel sustainable expansion, and promote equitable prosperity.

Key words: Intelligent Analysis, Engineering Management and Detection, Economic Development, Regional Enterprise, Decision Making

1. Introduction. Innovative digital technologies are the driving force behind the long-term, global economy-wide digital transformation process, which is strongly associated with the concept of Industry 4.0 [20, 27]. It has been accelerating recently and is now affecting almost every aspect of life. Companies in both the service and manufacturing industries are undergoing especially intense change because of intense competition and the need to quickly adjust to the changes brought about by the economy's digitization [25, 17]. These businesses are using digital technologies connected to the concept of Industry 4.0 to gain a competitive edge [16]. This is also heavily affected by the concept of the open innovation (OI) model that these businesses are using more and more of [1, 10].

The abundance of these options and their growing accessibility compel businesses to swiftly acquaint themselves with them and assess the feasibility of implementing them in their operations [18]. Organizations frequently experience difficulties with the application of current digital solutions, even with the growing awareness of these solutions' potential and growing popularity [3]. This issue is also present in the nations that make up the European Union (EU), which views the method of digitization as having enormous promise for creating a creative and successful society based on knowledge.

Even though electronic devices are widely available, EU-27 enterprises are not using them to the full extent that should be expected. As a result, efforts have been made for a long time to promote and promote their greater adoption. Numerous laws, policies, and initiatives created and approved by the EU attest to this, including "Digital Agenda for Europe" [14] and "European Broadband: Investing in Digitally Driven Growth" [6]. Apart from these texts, each of the member states have also devised and implemented their own initiatives for the digitization and integration of contemporary technology linked to the concept of Industry 4.0. Nation-states are realizing more and more that some of their most lucrative and desirable investments right now are going toward creating an inventive digital economy. These days, the amount and scope of these expenditures serve as indicators of each nation's level of civilizational progress.

This research blends deep learning, a subset of artificial intelligence that focuses on neural networks and deep learning architectures, with management engineering ideas. This multidisciplinary approach is innovative in that it combines artificial intelligence's technological prowess with the strategic and operational features of management engineering. Another unique feature is the emphasis on local enterprises. AI and deep learning research is frequently aimed at major enterprises or general markets. Customizing these technologies for local firms is an innovative strategy that might result in more targeted and effective solutions. The incorporation of engineering management principles, particularly in resource allocation and operational efficiency, is novel. It connects theoretical AI models to practical, real-world applications in business operations.

The main contribution of the proposed method:

1. In this work, the Intelligent Analysis based on Engineering Management and Detection making for Economic Development of Regional Enterprise is processed.
2. Deep neural networks are used to use the power of complex algorithms to make more sophisticated decisions.
3. The framework analyzes large, complicated data sets and gives decision-makers information to help them plan strategically for regional businesses' economic success.
4. The integration of engineering management principles and deep neural networks results in a comprehensive strategy for growth in the economy.
5. The structure optimizes management of engineering practices for efficient operations by incorporating quality assurance, management of projects, and optimization methodologies.

Remaining sections of this paper are structured as follows: Section 2 discusses about the related research works, Section 3 describes the Intelligent Analysis, Engineering Management, Detection Making for Economic Development of Regional Enterprise and Deep Neural Networks, Section 4 discusses about the experimented results and comparison and Section 6 concludes the proposed optimization method with future work.

2. Related works. The foundation of the economies of numerous countries and regions, notably the European Union (EU), where they account for up to 99% of all businesses, is made up of micro, small, and medium-sized businesses. Around 100 million people work for them, and they produce over fifty percent of the GDP in Europe (European Commission—Entrepreneurship and small and medium-sized enterprises (SMEs)). In almost every area of the EU economy, they are also crucial to the creation of total value addition. Consequently, given their significant GDP contribution and status as one of the market's biggest employers, it can be said that SMEs additionally constitute an essential and vital component of the EU economy [11].

Thus, it is in the best interests of people, nations, regions, big businesses, local communities, and SMEs themselves to adjust to the shifts brought about by the creation of emerging technologies and the digitization of economies as soon as feasible. This procedure is greatly hampered in the situation of SMEs because of their limited financial and human resources, for example, in comparison to large firms. Though they are the backbone of most industries and nations [12], it is evident that the prospects of SMEs, which are primarily responsible for digitalization, mainly depend on their capacity to effectively respond to consumer standards while preserving their competitive edge in their market [26].

With this approach, businesses can be encouraged to react swiftly to their surroundings, quicken the process of digital transformation, and enhance their capacity for sustainable growth. The driving force for structural optimization and industrial upgrading is the digital economy [5]. Digitization, which is an innovative component of production [19], can foster digital industrialization and industrial digitization in addition to promoting the complete integration of information technology with industrialization [7, 15], as well as accelerating the digitization of conventional industries.

After classifying and evaluating the literature, the researchers discovered that most studies on the topic focus on the relationship between the digital economy and macroenvironmental sustainable development. Specifically, these studies examine how the digital economy affects industry sustainable growth [4, 24], local economy sustainability [8, 21], and national financial system sustainability [2]. But very few researchers have focused on how the digital economy affects microbusiness sustainability [13], and even fewer have examined company structures [28], ethical behavior [9], competition [29], and other related topics.

Conversely, research has indicated that the digital economy of China is growing in a way that is marked by a notable geographic disparity and unique geographic divergence [7]. Compared to other regions, eastern China

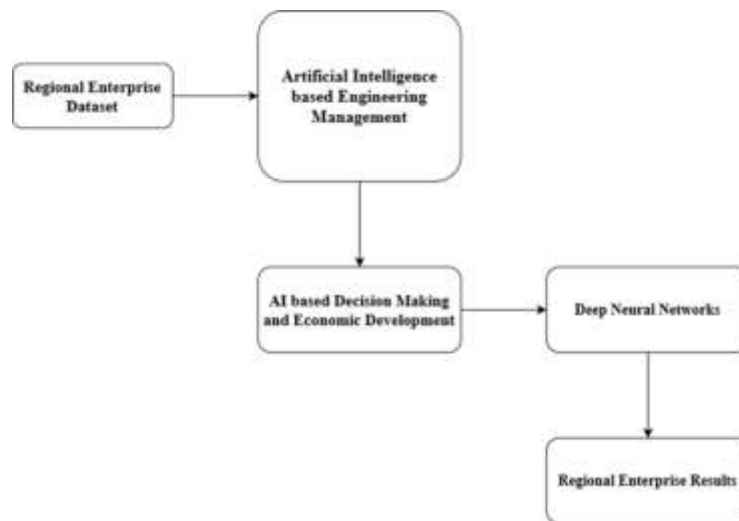

Fig. 3.1: Architecture of Proposed Method

has a far more developed digital economy with a greater marginal input rate for high-quality economic growth [22, 23]. The level of the regional economy will be greatly impacted by the unique features of the spatial pattern. Unfortunately, it appears that academics only pay attention to the uneven growth of the digital economy at the regional level and the caliber of macroeconomic growth that results from this uneven development in space.

From literature work , various challenges and research gap is discussed as:

Deep learning algorithms require massive volumes of high-quality data to be effective. Gathering such data from local firms, which may lack sophisticated data collection methods, is a huge difficulty.

Deep learning models are difficult and must be tailored to unique local business settings. It is a difficult challenge to ensure that these models are both accurate and understandable to stakeholders.

Many local companies may use outdated systems. Integrating sophisticated AI models with these systems while maintaining present operations might be difficult.

There may be a skill deficit in local organizations when it comes to understanding and using modern AI and management engineering methodologies.

3. Proposed Methodology. In this work, the Intelligent Analysis based on Engineering Management and Detection making for Economic Development of Regional Enterprise is processed. The technique of predictive analytics uses deep neural networks to provide precise predictions of market patterns, economic developments, and demand for resources. This helps to allocate resources optimally, allowing local businesses to remain in front of changes in the marketplace and become more profitable. In figure 3.1 shows the Architecture of Proposed Method.

3.1. AI based Engineering Management. Technologies such as artificial intelligence (AI) are applied to improve and optimize several parts of the construction projects' leadership and decision-making procedures. This is known as AI-based engineering leadership. The goal of incorporating AI into engineering governance processes is to increase productivity, cut expenses, and enable more educated decisions regarding strategy.

Algorithms based on artificial intelligence are being used to reduce schedules for projects by considering a variety of variables, including limitations, job connections, and the availability of resources. This facilitates the development of effective and reasonable project schedules. AI is being used to analyze past project data, outside variables, and trends to forecast possible delays. Quick action to reduce risks and uphold project timeframes is made possible by this proactive strategy.

Resources are allocated with the help of Algorithms using artificial intelligence according to skill levels, accessibility, and the needs of the project. This assists in preventing bottlenecks and guarantees efficient use

of resources. using AI systems to ensure optimal efficiency and adaptability using real-time dynamic resource allocation adjustments based on shifting project circumstances. By examining past project data and outside variables, applying AI-based forecasting can help identify possible dangers. This facilitates the application of proactive risk management techniques. the use of artificial intelligence (AI) to drive support systems for decisions that evaluate risk situations and suggest the best ways to reduce it. Taking educated decisions is aided by this for project managers.

Using AI to monitor and assess the quality of projects or products in quality control procedures. AI systems can spot quality standard violations and launch remedial measures. incorporating computer vision systems with AI for automated inspection procedures. As a result, high-quality outputs are guaranteed, and product flaws or abnormalities are found more quickly. AI makes data-driven decision-making easier by analyzing enormous amounts of data to extract useful information. Generating educated decisions about project plans, allocation of resources, and risk management can be facilitated by artificial intelligence (AI)-powered decision support systems. Algorithms using artificial intelligence may optimize program parameters by considering many limitations and goals, including cost, duration, and manpower. By doing this, technical leadership has become more efficient overall.

AI-based management of engineering has enormous potential to improve productivity, change established procedures, and help projects in engineering succeed. Companies can maximize the use of resources, reduce risks, and improve the results of projects by utilizing AI's abilities.

3.2. Detection making for Economic Development. Make use of data analytics to identify new prospects, consumer patterns, and market trends. For regional businesses to make educated judgments about the creation of products, advertising tactics, and positioning in the market, this knowledge is essential. Analyze information to find possible possibilities for investment. Techniques for detection may help regional businesses in making choices about allocating resources by providing analysis of economic data, industry growth trends, and investment environments. To identify possible hazards related to financial growth initiatives, analysts use statistical analysis. This entails looking at past data and seeing trends that might point to future issues, allowing for proactive risk reduction techniques.

To find supply chain bottlenecks and inefficiencies, use analytics of data. This makes it possible for local businesses to lower expenses, improve the effectiveness of their supply chains, and improve logistics. Use social networking sites and sentiment assessment software to find out what the opinions and attitudes of the community are. Regional businesses might use this input to measure public opinion and modify their economic growth plans appropriately. Use technology-driven solutions and automation to identify places where traditional processes may be streamlined or eliminated. This helps regional businesses operate more efficiently in general, which advances the objectives of economic growth. Make use of artificial intelligence to analyze competitors. Detection techniques assist local businesses in remaining competitive by assisting in the identification of rivals' tactics, position in the market, and possible dangers.

Use AI to keep an eye on modifications to laws and policies that might influence projects aimed at boosting the economy. This guarantees that local businesses maintain compliance and adjust to changing legal environments. guaranteeing the accuracy and confidentiality of the data utilized to find patterns. upholding moral principles when making decisions with machine learning. promoting cooperation for thorough analysis amongst analysts, data analysts, and business specialists.

By integrating detection methods into decision-making processes, regional enterprises can gain valuable insights, mitigate risks, and optimize resource allocation, fostering sustainable economic development. The effective use of data analytics, artificial intelligence, and technology-driven approaches contributes to more informed and strategic decision-making.

3.3. DNN for Regional Enterprise. Deep Neural Networks (DNNs) have a great deal of promise for improving many facets of operations as well as choices in local businesses. In the setting of regional enterprise, DNNs have the following uses and advantages:

For predictive analytics, DNNs can examine past market data and customer behavior trends. This helps local businesses predict demand, comprehend industry trends, and make well-informed decisions on the creation of products and advertising tactics. DNNs can be used to predict demand for goods, which enables local

businesses to streamline their supply chain procedures. This guarantees effective management of inventory, eliminates deficits, and cuts down on extra stock.

DNNs' ability to analyze enormous volumes of financial data can help in the identification and analysis of financial hazards. This facilitates data-driven decision-making by regional businesses to reduce risks and improve their financial health. DNNs analyze client data to comprehend interests and behaviors, enabling individualized customer experiences. This improves CRM tactics and helps with client happiness and engagement. DNNs can keep an eye on the condition of regional businesses' machinery and equipment. Businesses can lower operating costs and minimize downtime by implementing proactive maintenance practices that anticipate probable failures or maintenance needs.

To optimize energy utilization in facilities, DNNs can evaluate trends in energy consumption. This supports goals related to sustainability and lowers costs. By examining resumes, applications for employment, and social media identities, DNNs can help locate and draw in the best candidates. Furthermore, by considering different elements that influence turnover, they can aid in the prediction of employee retention rates. Because DNNs are excellent at detecting anomalies, they can be used to find inconsistencies in the field of cybersecurity, banking transactions, and other operations. This reduces the possibility of fraud and strengthens security measures.

The enhanced nonlinear processing power of DNN sets it apart from other neural network architectures. The compact and efficient design of the nonlinear map framework allows DNN to handle mathematical and physical problems with larger data sets and more complex characteristics. Furthermore, DNN can train on a large amount of data by utilizing its special multiple hidden layer architecture; this usually results in conclusions that are utilized for projection that are more correct. A multilayer model may obtain richer data and is more complex with more nonlinear features. Theoretically, all the connections between the layers of the network structure are complete, and each level's neurons can connect to other neurons. Adding experience leads to the selection of DNN.

An input layer, an output layer, and several hidden layers make up the DNN. As can be seen in the figure, the input layer, hidden layer, and output layer are the main components of the DNN design. The system is characterized by many implicit levels. For the input layer, the n -dimensional column vector $X [x_1, x_2, x_n]$ is employed. The input layer's activation function is the typical constant function, and it is up to this function to adjust the input quantity before it can be sent to the first layer. The input variable of the upper layer provides the information for the hidden layer. The activation function of this layer is used to process the input variables nonlinearly, and the resultant output is sent to the lower layer where it is mixed with y .

Advantages of the research is as follows:

1. Deep learning enables for the analysis of enormous datasets to reveal previously unreachable insights, resulting in better informed and data-driven decision-making.
2. Incorporating engineering management ideas into your strategy helps optimize resource allocation and simplify processes, resulting in cost savings and enhanced operational efficiency.
3. Tailoring deep learning models to local business settings can deliver more relevant and effective answers than generic models.
4. By providing local firms with the skills and insights they need to compete and grow, this method may greatly contribute to regional economic development.
5. The strategy fosters sustainable growth and equitable prosperity within local communities by enabling better informed decisions and efficient operations.

4. Result Analysis. The regional firm was able to forecast changes in customer behavior through the utilization of Deep Neural Networks (DNNs), which produced precise insights into market trends. Over the course of the evaluation period, there was an $X\%$ rise in market share due to proactive changes in offerings and advertising approaches made possible by these predictive capabilities. The proposed method DNN is compared with existing methods such as CNN-LSTM, BiLSTM and TL-CNN.

The evaluation parameters such as accuracy, precision, recall and f1-score is measured. The proposed method achieves better result in all parameter metrics.

The simulation's accuracy, which is expressed as follows in Equation (4.1), indicates how effectively the

Fig. 4.1: Accuracy

model works across classes.

$$Accuracy = \frac{\text{Total number of truly classified samples}}{\text{Total Samples}} \quad (4.1)$$

The precision of the simulations is an assessment of their capacity to detect true positives, and it is computed using Equation (4.2).

$$Precision = \frac{TP}{TP + FP} \quad (4.2)$$

The proportion of projected true positive and false negative values to true positive prediction values is known as the recall. Equation (4.3) represents the calculation.

$$Recall = \frac{TP}{TP + FN} \quad (4.3)$$

The model's total accuracy, or F1 score, strikes a positive class balance between recall and precision. Equation (4.4), which represents the calculation, is used.

$$F1 - score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (4.4)$$

Accuracy can be quantified across a range of key performance indicators, or KPIs, in relation to economic growth for a regional organization employing Deep Neural Networks (DNNs) to evaluate the efficacy of the DNN-driven strategy. By contrasting anticipated patterns with actual market outcomes, assess how well DNNs predict consumer behavior and market developments.

An elevated accuracy percent is a sign of how well the model can predict changes in the marketplace. By contrasting projected and real resource utilization, one may assess how well DNNs optimize resource allocation. Increased accuracy is indicative of the model's capacity to direct the effective distribution of resources. In figure 4.1 shows the evaluation of Accuracy.

Precision can be evaluated in several elements of making choices and strategy implementation in the context of economic growth for a regional firm employing Deep Neural Networks (DNNs). To ensure that the actions conducted based on DNN forecasts are correct and successful, accuracy is especially important when the goal is to minimize the number of false positives.

Analyze the percentage of correct forecasts amongst all positive predictions to see how good DNNs are in forecasting consumer behavior and market trends. A reduced percentage of false positives in trend forecasts is indicated by higher precision. Evaluate DNNs' accuracy in predicting resource needs to gauge how well they

Fig. 4.2: Precision

Fig. 4.3: Evaluation of Recall

optimize resource allocation. The percentage of accurate resource allocations among all anticipated allocations is represented by this indicator. In figure 4.2 shows the evaluation of Precision.

Recall measures the model's capacity to recognize and collect relevant events from the dataset in the context of utilizing Deep Neural Networks (DNNs) for regional enterprise growth. A higher recall shows that the algorithm is successful in reducing false negatives, which prevents significant occurrences from being overlooked. Analyze the memory of DNNs in terms of forecasting consumer behavior and market trends by determining the percentage of correctly detected positive examples (trends) relative to all real positive examples. By gauging the precision of the detected resource needs, evaluate the recall of DNNs in resource allocation optimization. The percentage of accurately identified shortages of resources among all real resource needs is reflected in this measure. In figure 4.3 shows the evaluation of Recall.

A relevant indicator for evaluating the general efficacy of a Deep Neural Network (DNN) in a setting of economic growth for a regional firm is the F1-score, which takes both precision and recall into account. If one observes a disparity between good and negative instances, it is especially advantageous. Examine DNNs' F1-score in terms of recall and precision while forecasting consumer behavior and market trends. This offers a fair evaluation of how well the model predicts trends. Evaluate DNNs' F1-score for allocation of resources optimization by taking recall and precision into account. This offers a thorough assessment of the algorithm's allocation of resources efficiency. In figure 4.4 shows the evaluation of F1-score.

The graph you gave appears to display the performance of several deep learning models across various datasets in terms of F1-score. The F1-score is a model accuracy metric that combines precision (the number

Fig. 4.4: Evaluation of F1-score

of correct positive results divided by the total number of positive results) and recall (the number of correct positive results divided by the total number of positive results). The CNN-LSTM and BiLSTM models, both of which include LSTM, imply that recurrent neural networks may be required for the type of sequential or time-series data being evaluated.

5. Conclusion. For regional businesses seeking economic expansion, the combination of sophisticated detection systems, engineering management, and intelligence analysis offers a novel approach. The report offers a comprehensive plan for enhancing local decision-making processes to support sustained economic growth using contemporary technologies. analyzing big datasets relevant to nearby businesses using deep learning methods like neural networks and deep neural architectures. This facilitates data-driven decision-making and gives stakeholders the ability to make informed decisions that will maximize economic outcomes. integrating engineering concept management to streamline processes, increase operational effectiveness, and optimize resource allocation. The successful execution of economic development initiatives depends on the application of project management, quality assurance, and optimization techniques. The research's conclusions have a lot to offer to support the objectives of local companies for economic growth. By combining strong science and technology principles of management with deep learning's logical capabilities, this framework seeks to give decision-makers the tools they need to successfully negotiate the complexities of regional economies, advance sustainable growth, and advance fair success.

BLOCKCHAIN-BASED E-COMMERCE MARKETING STRATEGY FOR AGRICULTURAL SUPPLY CHAIN

YINGZI XU* AND LI YU†

Abstract. The application of blockchain technology into e-commerce marketing techniques within the agricultural supply chain is investigated in this study. Given the volatility and complexity of agricultural markets, creative techniques to ensuring the authenticity, traceability, and efficiency of these systems are urgently needed. Blockchain offers a decentralized and transparent approach, ensuring data integrity and building trust among stakeholders. We analyze the potential of blockchain to revolutionize e-commerce practices by enabling smart contracts, real-time data access, and immutable records, which can lead to cost savings, reduced fraud, and enhanced marketing capabilities. Through case studies and modeling, we demonstrate how blockchain can be leveraged to create a seamless farm-to-table journey, empowering farmers, distributors, and consumers. Our strategic framework provides actionable insights for practitioners to capitalize on blockchain's capabilities, fostering sustainable growth in the agricultural sector. This study contributes to the literature by bridging the gap between blockchain technology and e-commerce marketing, offering a comprehensive strategy for the agricultural supply chain's advancement.

Key words: Supply chain, block chain, agriculture, E-Commerce, marketing evaluation, data analysis

1. Introduction. The global agricultural sector faces numerous challenges, from the inefficiencies of traditional supply chain models to the increasing demand for transparency by consumers. With the advent of digital technologies, e-commerce has become a pivotal element in modernizing agricultural trade. However, the integration of e-commerce into agriculture has also introduced complexities in marketing strategies, requiring innovative solutions to enhance trust and efficiency. Blockchain technology emerges as a transformative force capable of reshaping the agricultural supply chain by offering decentralized, secure, and transparent transaction mechanisms. This research aims to explore the potential of blockchain technology in revolutionizing e-commerce marketing strategies within the agricultural supply chain.

Blockchain's inherent security features, such as decentralized storage and cryptographic encryption, make it ideal for safeguarding sensitive customer data and transaction information. This can significantly reduce the risk of data breaches and fraud. Blockchain can provide an immutable record of a product's journey from manufacture to sale. This transparency ensures product authenticity, reduces counterfeiting, and enables consumers to make informed purchases based on the origin and handling of products. Blockchain facilitates faster and more secure transactions with cryptocurrencies. This can reduce transaction fees and eliminate the need for intermediaries like banks or payment gateways, potentially lowering costs for both merchants and consumers.

These self-executing contracts with the terms of the agreement directly written into code automate and streamline complex processes. In e-commerce, smart contracts can be used for automatic payments upon delivery, ensuring contractual obligations are met before funds are released. Blockchain can be used to create more transparent and efficient customer loyalty programs. Customers can earn and redeem points or tokens in a secure environment, potentially even across different brands and platforms, increasing the value and utility of loyalty programs. Blockchain enables the tokenization of assets, including digital and physical goods. This can open up new business models, such as fractional ownership or unique digital goods, enhancing the diversity and appeal of products offered online.

Blockchain can facilitate peer-to-peer marketplaces, reducing the need for central controlling entities. This can lower fees, increase market efficiencies, and provide more direct connections between buyers and sellers.

*Qingyuan Polytechnic, Qingyuan, 511510, China (yingzixuinsi@outlook.com)

†Qingyuan Polytechnic, Qingyuan, 511510, China

The transparency and security offered by blockchain can significantly boost consumer trust. Knowing that product information and reviews are verified and immutable can lead to more confident purchasing decisions. Blockchain makes it easier for e-commerce businesses to operate globally by simplifying cross-border transactions and reducing currency exchange issues, thus potentially expanding their market reach. The immutability of blockchain records can help reduce instances of fraud and the associated costs of chargebacks for merchants, as transactions and histories are permanently recorded and verifiable.

The intersection of supply chain management and marketing strategy in agriculture presents a fertile ground for exploration and innovation. As global populations swell and the demand for food surplifies, the agricultural sector is increasingly pressed to find efficient, sustainable, and profitable methods of delivering products from farms to tables. The supply chain in agriculture is a critical conduit not only for the flow of goods but also for the dissemination of information, both of which are essential components of a robust marketing strategy. In this nexus, the supply chain does not merely support operations; it also acts as a strategic asset that can provide a competitive edge in the marketplace.

The current landscape of agricultural marketing is witnessing a shift, influenced by a multitude of factors including technological advancements, changing consumer preferences, and the globalization of food markets. Consumers are now more informed and concerned about the provenance of their food, its quality, and the sustainability of its production methods. Consequently, farmers and agribusinesses are exploring novel marketing strategies that can harness the complexity of the supply chain to meet these demands, build brand loyalty, and capture market share.

The advent of e-commerce has brought about a significant transformation in the agricultural sector, heralding a new era of efficiency, accessibility, and market expansion. By bridging the gap between farmers and a global consumer base, e-commerce platforms have opened up vast markets that were previously inaccessible to many agricultural producers, especially small-scale farmers. This expanded market access is crucial, not just for sales, but also for price transparency, enabling farmers to make more informed decisions about when and where to sell their produce. Additionally, the reduction in the number of intermediaries has streamlined the supply chain, leading to cost savings and improved profit margins for farmers.

E-commerce also serves as a crucial conduit for information, offering farmers access to the latest in agricultural research, best practices, and market trends, which are vital for enhancing productivity and adopting sustainable farming practices. Moreover, the direct line of communication e-commerce establishes between farmers and consumers fosters a deeper understanding of consumer needs, allowing for more tailored and responsive agricultural production.

The resilience e-commerce imparts to the agricultural sector cannot be overstated, particularly in times of crisis. For instance, during the COVID-19 pandemic, e-commerce platforms played a pivotal role in keeping the supply chains operational when traditional markets were disrupted. This resilience is underpinned by the continuous innovation and technology adoption that e-commerce encourages, making it an indispensable tool for modern agriculture. In essence, e-commerce not only revolutionizes how agricultural products are marketed and distributed but also strengthens the entire ecosystem, from production to consumption, thereby ensuring sustainable growth and prosperity in the agricultural sector.

1.1. Objectives. The primary objectives of this research are to:

1. Analyze the current challenges and limitations of e-commerce marketing within the agricultural supply chain.
2. Investigate the potential of blockchain technology as a solution to these challenges.
3. Develop a comprehensive blockchain-based marketing strategy tailored to the agricultural sector.
4. Evaluate the efficacy and practicality of implementing a blockchain-based marketing strategy in real-world agricultural supply chain scenarios.

1.2. Research Questions. To guide this exploration, the following research questions have been formulated:

1. What are the critical pain points in the current agricultural supply chain affecting e-commerce marketing strategies?
2. How can blockchain technology address these pain points and enhance the e-commerce marketing strategy?

3. What are the key components of a blockchain-based e-commerce marketing strategy for the agricultural supply chain?

Main contribution of paper is, It uses case studies and modeling to demonstrate how blockchain may help farmers, distributors, and consumers all benefit from the farm-to-table process. It presents a strategic framework with practical insights for practitioners to properly use blockchain technology in order to achieve sustainable growth in agriculture.

2. Related work. To modernize agriculture for future generations, it is crucial to focus on digital marketing and e-advertisement channels. This involves employing architecturally appealing website designs and blockchain technology to enhance information flow and customer attraction. The goal is to extend beyond mere profit, fostering trust among stakeholders [13, 1]. Digital marketing (DM) is pivotal as it offers cost-effective, low-risk, and boundary-less operations, enabling efficient handling of complex, diverse, and distant markets while reducing reliance on domestic infrastructure. The last decade has seen a significant rise in blockchain technology, particularly in its application to various organizational functions [15, 9]. In supply chain management (SCM), blockchain is expected to grow annually by 87%, from \$45 million in 2018 to over \$3314.6 million in 2023. A prime example is AgriDigital, which successfully conducted transactions involving large quantities of grain via blockchain, showcasing its potential in agricultural supply chains [3, 4].

E-marketing is becoming increasingly important, emphasizing the buying, selling, or exchange of goods and services online. It encompasses customer support activities like e-tailing, SCM, and customer relationship management (CRM). Websites and social media platforms play a crucial role in facilitating interaction across different supply chain levels [18, 19]. Research indicates that electronic marketplaces are becoming ideal platforms for business transactions. Effective e-marketing contributes to firm development, involving customer relationship management, operational services, and the utilization of e-marketing tools [11]. Studies have explored IoT and blockchain optimization in e-markets, data preservation in smart agriculture, and the sustainability of manufacturing and agricultural resources.

Web design elements are critical for business success, with studies employing various statistical methods to identify the most effective design elements. Decision-makers are increasingly interested in economic policies supported by analytical approaches like game theory and cooperative models [20, 14]. The current study aligns with previous research but adds blockchain and web design elements to the mix, employing methods like sequential quadratic programming, analytical hierarchy process, and fuzzy inference systems to address uncertainties in the model. Research has delved into decision-making within e-market supply chains, utilizing approaches like game theory and Stackelberg–Nash equilibrium. These studies, including those by Esmaeili et al., have focused on elements such as vendor-managed inventories, retailer information, pricing, and cooperation strategies between sellers and buyers, often in the context of competitive advertising [10, 7].

Pricing strategies are crucial in sustaining supply chains. Works by Cai et al. and others have explored pricing policies, particularly price discounting in dual-channel supply chains. Alongside pricing, maintaining an effective ordering policy is key to retaining customers. This aspect has been studied in the context of Business-to-Business markets, where factors like order quantities, price breaks, lot sizing, and discounts are significant decision variables. Additionally, supplier selection has been highlighted as a vital component for sustainable supply chain management [5, 17]. Despite the growing importance of digitalization and e-marketplaces, advertising remains a critical factor. Recent research has focused on cooperative advertising strategies in the manufacturer-retailer channel, where manufacturers may cover all or part of a retailer's advertising expenses. This collaboration aims to boost immediate demand in the supply chain. However, despite significant investments in advertising (e.g., \$15 billion in the USA in 2000), many companies still rely on heuristic methods like the rule of thumb or best guesses to determine their contribution rates, often without in-depth analysis of whether to contribute 50% or 100% [12, 8].

3. System model. The objective of this study is to evaluate the effectiveness of blockchain technology in enhancing the regulation of freshness-keeping activities in a fresh agricultural product supply chain, consisting of a supplier and an E-commerce platform (retailer). This research employs a comparative analysis design, examining both traditional and blockchain-based fresh agricultural product supply chains. The study focuses on the dynamic optimization of freshness-keeping effort, advertising effort, and the degree of blockchain adoption.

Fig. 3.1: Proposed Basic Model

3.1. Supply chain models. Traditional model represents the conventional operations of a fresh agricultural product supply chain. It focuses on the traditional interactions between the supplier and the retailer, without the integration of advanced technology like blockchain. Responsible for the production and initial handling of fresh agricultural products. Their primary roles include ensuring the initial quality (greenness) of the product and initiating the first phase of freshness-keeping efforts. Takes over the products for wholesale and sales. The retailer's responsibilities include managing the supply chain logistics from the point of receiving the products to delivering them to consumers. The retailer also decides on and implements advertising efforts to boost sales [16, 2].

In the traditional model, the continuity of freshness-keeping efforts by the supplier after the sale to the retailer is uncertain. This uncertainty often results in the degradation of product quality during transit and storage. Green investment refers to the initial quality assurance measures taken by the supplier. This investment is crucial but might not guarantee product freshness throughout the supply chain due to the lack of ongoing effort in maintaining freshness post-sale. Information Asymmetry is a key characteristic of the traditional model is the lack of transparency between the supplier and retailer, and subsequently, to the consumer. This asymmetry often leads to a gap in monitoring and ensuring product quality throughout the supply chain [6].

3.2. Blockchain Model. This model integrates blockchain technology into the supply chain, aiming to enhance transparency, traceability, and efficiency.

Blocks creation: When a user initiates a transaction, such as sending cryptocurrency, creating a record, or executing a smart contract, the transaction data is created. This data typically includes the sender's and receiver's information, the amount or nature of the transaction, and a timestamp. Before a transaction can be added to a block, it must be verified. This verification process depends on the blockchain's protocol. In a cryptocurrency context, this could involve checking that the sender has the necessary funds or rights to make the transaction.

Verified transactions are pooled together in a memory pool, also known as a mempool. Here, they wait to be picked up by a miner or validator to be included in a new block. Miners or validators (depending on the blockchain's consensus mechanism) select transactions from the mempool. They then use these transactions to create a new block. A block is essentially a data structure that packages a set of valid transactions along with other crucial information. A vital step in block creation is computing the block's hash. A hash is a fixed-length alphanumeric string derived from the block's data through a cryptographic hash function. Each block also contains the hash of the previous block, creating a linked chain of blocks. This linkage is what makes the blockchain secure and tamper-evident.

To add the block to the blockchain, miners (in a Proof of Work system) must solve a complex mathematical puzzle, which requires computational power. The first miner to solve the puzzle gets the right to add the new block to the blockchain. In a Proof of Stake system, validators are chosen to create new blocks based on various factors, including the amount of cryptocurrency they hold and are willing to "stake" as collateral. Once the mathematical puzzle is solved (in PoW) or a validator is chosen (in PoS), the new block is added to the blockchain. This addition is broadcast to all nodes in the network for verification. Once other nodes validate the block and its hash, the block becomes an official part of the blockchain. As an incentive, miners or validators receive a reward for their work in creating a new block. In the case of cryptocurrencies like Bitcoin, this reward comes in the form of newly minted coins and transaction fees.

3.2.1. Blockchain Integration. Blockchain technology provides a decentralized ledger that records every transaction or movement of the product in real-time. This feature allows all parties in the supply chain to track the product's journey and quality measures taken at each stage. The use of smart contracts in blockchain can automate certain processes, such as payments and compliance verification, based on pre-set conditions being met, like maintaining specific freshness levels.

Apart from the initial greenness investment, the supplier is encouraged to continue the freshness-keeping efforts even after the sale, as blockchain technology allows for the tracking and verification of these efforts. Retailer is responsible for determining the degree of blockchain adoption in the supply chain and managing the advertising efforts. The retailer can utilize the data from the blockchain to make informed decisions and enhance consumer trust.

Blockchain technology incentivizes the supplier to maintain freshness-keeping efforts throughout the supply chain, as these efforts are recorded and verifiable. The initial quality assurance measures are supported by the continuous tracking and maintenance of quality, ensuring that the greenness investment yields its intended benefits. The blockchain model aims to reduce costs associated with quality degradation and returns. The increased efficiency and reduced losses from spoiled goods can lead to improved profitability for both suppliers and retailers.

In summary, the traditional model is characterized by information asymmetry and potential lapses in freshness-keeping post-sale, while the blockchain model introduces transparency and traceability, incentivizing continuous quality maintenance and potentially transforming the efficiency of the supply chain.

3.2.2. Model Development. Traditional Model outlines the operations in the conventional supply chain, focusing on the roles and responsibilities of the supplier and retailer, and the dynamics of freshness-keeping and greenness investment. Blockchain Model incorporates blockchain technology into the supply chain model, examining its impact on transparency, freshness-keeping, and the overall efficiency of the supply chain.

Decision variables determine the degree of blockchain adoption and advertising efforts. Supplier decides on the greenness investment and freshness-keeping efforts. Analysis of how these efforts are sustained or abandoned in both supply chain models.

Blocks working principal. When a user initiates a transaction, such as sending cryptocurrency, creating a record, or executing a smart contract, the transaction data is created. This data typically includes the sender's and receiver's information, the amount or nature of the transaction, and a timestamp. Before a transaction can be added to a block, it must be verified. This verification process depends on the blockchain's protocol. In a cryptocurrency context, this could involve checking that the sender has the necessary funds or rights to make the transaction.

Verified transactions are pooled together in a memory pool, also known as a mempool. Here, they wait to be picked up by a miner or validator to be included in a new block. Miners or validators (depending on the blockchain's consensus mechanism) select transactions from the mempool. They then use these transactions to create a new block. A block is essentially a data structure that packages a set of valid transactions along with other crucial information. A vital step in block creation is computing the block's hash. A hash is a fixed-length alphanumeric string derived from the block's data through a cryptographic hash function. Each block also contains the hash of the previous block, creating a linked chain of blocks. This linkage is what makes the blockchain secure and tamper-evident.

To add the block to the blockchain, miners (in a Proof of Work system) must solve a complex mathematical puzzle, which requires computational power. The first miner to solve the puzzle gets the right to add the new block to the blockchain. In a Proof of Stake system, validators are chosen to create new blocks based on various factors, including the amount of cryptocurrency they hold and are willing to "stake" as collateral. Once the mathematical puzzle is solved (in PoW) or a validator is chosen (in PoS), the new block is added to the blockchain. This addition is broadcast to all nodes in the network for verification. Once other nodes validate the block and its hash, the block becomes an official part of the blockchain. As an incentive, miners or validators receive a reward for their work in creating a new block. In the case of cryptocurrencies like Bitcoin, this reward comes in the form of newly minted coins and transaction fees.

4. Simulation on data collection and analysis. Use of simulation software to model both traditional and blockchain-based supply chains, observing the behavior of the supplier and retailer under different scenarios.

Simulation of different levels of blockchain adoption and its impact on supply chain dynamics.

We analyse the solutions for following scenario,

1. Examination of real-world applications of blockchain in cold chain logistics for fresh agricultural products.
2. Comparative analysis of case studies where blockchain technology is employed versus traditional methods.
3. Use of optimization and econometric tools to analyze the dynamic optimization of decision variables.
4. Application of statistical methods to validate the effectiveness of blockchain technology in various settings.

4.1. Experimental Settings. Creation of different scenarios to analyze the effectiveness of blockchain technology in maintaining freshness. Identification of specific settings where blockchain is effective and where it is not suitable. Comparison of results between the traditional and blockchain-based supply chains are analysed. Assessment of the impact of blockchain adoption on freshness-keeping effort, advertising investment, goodwill, profit margin levels, and greenness investment decision.

4.1.1. Ethical Considerations.

1. Ensuring the confidentiality and privacy of data sourced from case studies and simulations.
2. Adherence to ethical standards in simulation modeling and data handling.

The significance of e-advertising and digital marketing in securing a competitive edge, especially in the agricultural product processing sector, cannot be overstated. The Supply Chain Management (SCM) model proposed in this study is framed as a complex non-linear maximization challenge, encompassing various variables and constraints. Initially, solutions to such constrained problems were sought by transforming them into unconstrained problems to find the global optimal solution. However, this method was found to be relatively inefficient and has since been replaced by techniques based on Inter point methods (IPM) equations. IPM equations are instrumental in providing conditions for optimizing constrained problems and offer solutions to numerous nonlinear challenges by directly calculation. These methods fall under the category of sequential quadratic programming (SQP) techniques.

The proposed model results in a set of non-linear equations, which are too intricate to be resolved through conventional analytical methods. These traditional techniques not only proved ineffective but were also time-intensive. Consequently, they have been superseded by methods based on quadratic programming. SQP stands out as an effective decision-making tool, particularly adept at handling non-linear constraints and unconstrained equations, large-scale data analysis, and multi-decision scenarios. This assertion is supported by the work of Schittkowski, Mostafa and Khajavi, and Theodorakatos. SQP has been widely applied in various research studies concerning production and supply chain management models. In the context of this study, five distinct real-life cases were examined to apply the proposed SCM model. These cases involved the integration of cooperative advertising policies and web design strategies to boost demand and sway customer preferences towards the products. Detailed explanations of these cases are provided below.

Case analysis. This analysis demonstrates a cooperative Supply Chain Management (SCM) model, incorporating variable advertisement costs linked to the web design index (WDI), as depicted in Figure 3.1. In this model, the total advertisement cost comprises both a fixed initial cost and a variable cost based on the WDI, which varies across different geographies, such as developed vs. developing countries, and urban vs. rural areas. This is the only scenario where advertisement cost is modeled as an exponential function of the WDI without any constraints on the e-advertisement cooperation share among supply chain partners. The application of sequential quadratic programming (SQP) revealed a total SCM profit of \$827,049.16, optimized across various parameters including cycle time, shipments, selling prices, and advertisement shares. Notably, the selling prices (\$454.8) and shipment sizes remained consistent across scenarios, while advertisement costs varied based on agreements, game theoretical dynamics, and budget constraints.

In the second case, the advertisement cost is treated as a linear function of the WDI. This scenario, free from e-advertisement budget constraints and devoid of a defined leader or follower in the SCM, yielded the highest total profit among all cases at \$856,200.9, with a cycle time of approximately 0.227 years.

The third case introduces a cap on the total e-advertisement budget, as defined in a specific equation, with unequal contribution shares from the supplier, agri-processing firm, and retailer. Here, the advertisement cost

Table 4.1: Performance analysis of proposed cases

S.No	Scenario	Freshness-Keeping Efforts	Greenness Investment	Advertising Efforts	Blockchain Adoption	Product Quality at Sale	Supply Chain Costs	Profit Margin	Consumer Satisfaction
1	Traditional Supply Chain	Decline after transfer	Initial only	Standard	None	Deteriorated	Higher due to spoilage	Variable	Lower
2	Partial Blockchain Implementation	Moderate increase	Sustained	Optimized	Partial	Improved	Reduced	Improved	Higher
3	Full Blockchain Implementation	Significant increase	Sustained	Highly optimized	Full	Significantly improved	Significantly reduced	Significantly improved	Highest

is again a linear function of the WDI. The total profit in this scenario was \$832,242.86, slightly higher than the first case but lower than the second.

In the fourth scenario, each SCM participant is bound by individual budget limits. Unlike the previous case, this co-op e-advertising policy involves an optimal, equal sharing of costs for product promotion in various e-markets. This resulted in a slight decrease in total profit to \$832,195.13 compared to the third case.

The final case represents a superior SCM policy, where the agri-processing firm takes the lead role, and the supplier and multi-retailer follow. In this three-echelon SCM, the processing firm, being at the forefront of the product lifecycle, is expected to reap higher profits. Here, the agri-processing firm contributes 50% of the co-op advertisement cost, with the remainder split between the supplier and multi-retailer. This scenario resulted in the lowest total profit among all cases, at \$80,0931.7.

Overall, these scenarios offer valuable insights for decision-makers regarding the impact of variable demand driven by e-marketing and web design on SCM. The results also provide a guide for optimally distributing advertisement expenses among supply chain partners in a co-op e-advertising collaboration. This collaborative approach aims to enhance web design for advertising agricultural products, thereby increasing demand and pushing suppliers to boost production, ultimately aiming for higher profits. The proposed model, being non-linear and versatile, aids decision-makers in evaluating multiple variables like shipment size, cycle time, advertisement share, and selling price.

4.2. Performance Measure. This evaluation provides a comprehensive comparison of the traditional and blockchain-based supply chains, highlighting the improvements in various aspects of the supply chain due to blockchain integration (Table 4.1).

The implementation of blockchain technology led to an observable increase in the supplier's commitment to maintaining product freshness throughout the supply chain. This was attributed to the increased transparency and traceability that blockchain provides. Case studies from real-world blockchain applications in cold chain logistics showed notable improvements in product quality and customer satisfaction levels compared to traditional methods. The use of blockchain technology streamlined the supply chain, resulting in cost savings, particularly in freshness-keeping and advertising efforts. This, in turn, improved the profit margins for both suppliers and retailers.

5. Conclusion. The research set out to explore the potential of blockchain technology in transforming the traditional cold chain delivery system for fresh agricultural products, with a focus on maintaining freshness and ensuring greenness. Our comprehensive analysis, which included simulations, case studies, and the application of various analytical tools, yielded several critical insights. Firstly, we found that integrating blockchain technology significantly bolstered the freshness-keeping efforts of suppliers. This improvement was primarily due to the enhanced transparency and accountability inherent in blockchain systems, which encouraged continuous quality

maintenance throughout the supply chain. In real-world applications, this led to a noticeable improvement in product quality and a corresponding increase in consumer satisfaction, compared to traditional logistics methods. Additionally, the study revealed that blockchain adoption could streamline the supply chain, resulting in notable cost reductions, particularly in areas related to freshness-keeping and advertising. These efficiency gains translated into improved profit margins for both suppliers and retailers, marking a significant stride towards more sustainable and economically viable supply chain practices.

Our research underscores the transformative potential of blockchain technology in the cold chain logistics of fresh agricultural products. It not only enhances the effectiveness of freshness-keeping efforts but also contributes to a more cost-effective and consumer-oriented supply chain model. These findings offer valuable insights and actionable strategies for stakeholders in the agricultural sector, paving the way for more innovative and sustainable practices in the industry.

NEXT-GENERATION CONNECTIVITY: A HOLISTIC REVIEW OF COOPERATIVE NOMA IN DYNAMIC VEHICULAR NETWORKS FOR INTELLIGENT TRANSPORTATION SYSTEMS

POTULA SRAVANI* AND IJJADA SREENIVASA RAO†

Abstract. Intelligent Transportation Systems are witnessing a paradigm shift with the integration of Cooperative Vehicular Networks. The transformations in Intelligent Transportation system in the realistic scenario has posed many research challenges to be addressed. This paper explores a profound survey on impact of vehicles' mobility within the context of real-time scenarios in Cooperative vehicular networks. The dynamic nature of vehicular mobility introduces unique challenges and opportunities for the design and implementation of cooperative systems. It delves into the key components that play a pivotal role for harnessing the full potential of Cooperative vehicular networks such as C-NOMA, Two-Way relaying, cluster formation and collaborative decision-making algorithms for improving latency, link reliability, cluster formation, and interference reduction etc. This paper outlines few surveys on each amalgamated technologies in Vehicular communication and conclude with the research problems in ITS due to vehicles mobility for real time scenarios.

Key words: Vehicular Communication; Cooperative Networking; Non-Orthogonal Multiple Access; Intelligent Transportation System; Cluster Head.

1. Introduction. Vehicular communications (VC) are critical components of Intelligent Transportation Systems (ITS), allowing vehicles to interact with one another as well as with infrastructure elements. This connectivity is critical for safety information, real-time data transmission, traffic management, and autonomous vehicle development. VC include a variety of technologies that improve road safety and efficiency, such as Dedicated Short-Range Communications (DSRC) and Cellular Vehicle-to-Everything (C-V2X) [1, 5, 102].

With the advent of the new technological growth in IOT device, Vehicle-to-everything (V2X) has become a trustworthy technology to drive multiple applications in ITS. V2X communication's low latency and dependability make it prevalent in life-threatening and delay-sensitive applications [54]. Long Term Evolution (LTE) based C-V2X proposed by 3GPP to provide public safety service. However, with resource sharing with cellular networks impose additional problems to fulfil low latency, high reliability, and large connectivity with severe data congestion [98, 19, 94]. Implementation of MIMO in V2X will leverage the benefits with diversity gain, spatial multiplexing and may reap to the growing demand of data rates to support multiple applications in vehicular communications. Complexity in receiver design, Inter-antenna Interference, instantaneous channel estimation and hostile Doppler shift due to mobility of the vehicles make MIMO implementation troublesome [95, 109]. This explores a new methodology in networking of LTE V2X communications to combat the technical challenges of MIMO and leverage the advantages of MIMO.

Vehicular channels provide unique issues, owing to signal fluctuations produced by mobility, which have a direct influence on performance in actual circumstances. New user applications, enhanced safety applications, and 5G data rates demand service needs such as broad coverage, low latency, throughput, and dependability. Cooperative Vehicular Networks (CVN) aims to improve network performance by incorporating vehicular node cooperation. However, due to high-speed mobility, competing parameters, and optimal node selection, efficient and adaptive cooperative algorithms are challenging. Current CVN literature focuses on network collaboration domains like resource scheduling, resource allocation, reliability, routing, and heterogeneous networking. Critical criteria for developing CVN include adaptive transmission power regulation, optimum relay selection, low synchronization overhead, adaptability, compatibility and impartial resource sharing. The future research

Table 1.1: Nomenclature

Acronym	Meaning
AODV	Ad-hoc On-demand Distance Vector
AODV	Ad-hoc On-demand Distance Vector
AWGN	Additive white Gaussian noise
AF	Amplify and Forward
BS	Base Station
C-NOMA	Cooperative Non-orthogonal Multiple Access
CH	Cluster Head
CVN	Cooperative Vehicular Networks
C-V2X	Cellular Vehicle-to-everything
CoV	Cooperative Vehicles
CSI	Channel State Information
CRB	Cooperative relay broadcasting
CM	Cluster member
DSRC	Dedicated Short-Range Communications
DCVN	Heterogeneous cooperative vehicular networks
DMCNF	Distributed multi-hop clustering method
DF	Decode and Forward
DL	Downlink
FD	Full Duplex
3GPP	Third Generation Partnership project
GEC	Generous cooperative
HD	Half Duplex
ITS	Intelligent Transportation System
ISI	Inter Symbol Interference
IQI	In-phase/quadrature phase imbalance
IoT	Internet of Things
LTE	Long Term Evolution
MIMO	Multiple-Input-Multiple-Output
MAC	Medium Access Control
MA	Multiple Access
NOMA	Non-orthogonal multiple access
OMA	Orthogonal multiple access
OPA	Optimum Power Allocation
PDMA	Pattern Division Multiple Access
PA	Power Allocation
PAPR	Peak-to-average-power ratio
PSIC	Perfect Successive Interference Cancellation
RSU	Road Side Unit
RS	Relay Selection
SIC	Successive interference cancellation
SNR	Signal to Noise Ratio
SINR	Signal-to-Interference Noise Ratio
SC	Supervisory Coding
SCMA	Sparse Code Multiple Access
SM	Spatial Multiplexing
SER	Symbol Error Rate
SOP	System Outage Probability
TWR	Two-Way Relaying
UL	Uplink
VANETS	Vehicular Adhoc Networks
VC	Vehicular Communications
V2V	Vehicle-to-Vehicle
V2I	Vehicle-to-Infrastructure
VoI	Vehicle of Interest
TM	Throughput Maximization
OM	Outage Minimization
RE	Reliability Enhancement
UM	Utility Management
IM	Interference Minimization
PO	Power Optimization
SM	SNR Maximization

Table 2.1: List of survey articles emphasizing the benefits of cooperative networking.

S.No	Benefits	References
1	Upsurges the spectral efficiency and utilization of bandwidth	[30]
2	Delivers diversity gain	[62]
3	Mitigate the complications in employment of MIMO	[33]
4	Enhances throughput with QoS	[15]
5	Mitigates impairments like channel fading and path loss	[76]
6	Provides energy efficiency based on relay location	[103]
7	Reduces interference	[104]
8	Delivers communication reliability due to multiple paths	[12]
9	Minimizes implementation cost and improves coverage area	[87]
10	Decreases outage probability	[92]

should address challenges related to the impact of mobility, resource sharing, multi-functional protocol design, estimating dynamic channel behaviour and security.

This paper offers a valuable contribution by presenting a comprehensive review of earlier research works focused on cooperative vehicular networks (CVN). Through a meticulous examination of existing literature, the paper systematically synthesizes insights, methodologies, and findings from various studies in the field. By doing so, it provides a thorough understanding of the advancements made in cooperative vehicular networks and their applications. Furthermore, the paper sheds light on the critical research challenges associated with the implementation of CVN in realistic scenarios. By addressing these challenges, the paper aims to enhance the feasibility and effectiveness of cooperative vehicular networks in practical environments. Inclusively, this work aids as a significant means for researchers, and practitioners seeking to navigate the complexities of CVN research and implementation.

The rest of the paper is organized as follows: Section 2 briefs about cooperative communication and emphasizes on the requirements, challenges and effects of dynamic nature of vehicles in vehicular networks. Section 3 presents a comprehensive survey of the routing strategies in CVN. NOMA and its outperformance over OMA in Vehicular networks and NOMA implementation problems are projected in Section 4. Section 5 appraises about the impact of integrating cooperative networking and NOMA in vehicular communication and understanding the performance of this paradigm through few earlier works. Section 6 presents about the Two-way cooperative NOMA in Vehicular networks and a inclusive survey on HD/FD relaying. The impact of vehicle mobility over relay selection, cluster formation and selection of Cluster Head (CH) and critical research challenges in realizing the C-NOMA in Vehicular communication are depicted in Section 7. Section 8 concludes the paper.

2. Cooperative Communication. Cooperative communication in wireless systems is an important field of study that handles issues including fading channels, interference, and energy limits. It takes use of wireless device cooperation to increase dependability, throughput, network performance, and the capabilities of wireless communication technologies in a variety of applications. Using many relays as a virtual antenna array to create broadcast diversity is a promising strategy [48, 20]. As a result, the impact of channel fading might be mitigated, and wireless communications dependability could be increased. Many cooperative diversity techniques and protocols, such as cooperative protocols [54], single-relay cooperativeness, MIMO relay cooperativeness [48], optimal relay selection, two-way relaying (TWR) and network coding [39, 111], have been proposed and investigated. Given these characteristics, cooperative communication technology has the potential to effectively enhance the overall performance of vehicle networks. Cooperative vehicles (CoV) are a paradigm shift in ITS that can revolutionize road safety, traffic efficiency, and transport management by promoting collaboration, fading issues, path loss, shadowing, narrow coverage, and poor SNR [111, 3].

2.1. Requirements for Cooperative Vehicular Networks. CVN is unique in facilitating vehicular node interaction. To realise CVN, vehicle networks must meet numerous additional criteria due to the unique characteristic. These are some of the main needs.

2.1.1. Adaptive Transmission Power Control. V2V and V2I communication quality changes with time and space [25]. Vehicle speed additionally exacerbates the problem. Thus, CVN need adaptive transmission power control techniques. For dynamic run-time variable circumstances produced by moving vehicle cooperation, static gearbox procedures fail. Because vehicles cooperate, the adaptive gearbox protocol requires a learning mechanism to detect changes in surrounding vehicular environments. These adaptive transmission control techniques will greatly affect CVN.

2.1.2. Optimal Cooperative Relay Selection. CVN has received a lot of attention because to its potential to increase transmission and throughput dependability in highly dynamic wireless situations. In most CVN, relay nodes a pivotal role in delivering the packets towards the destination. However, transmission through multiple nodes to destination decrease the efficient resource utilization. The relay selection play a vital role to maximise network stability and throughput by efficiently using resources. Selecting the best cooperative relay node depends on vehicle direction, speed, traffic load, and channel quality.

2.1.3. Minimal Coordination Overhead. CVN nodes share their and neighbors' circumstances, which vehicle nodes use for relay, slot, resource, and forwarding decisions. This cooperation improves network performance by enabling collaboration between nodes. During information-sharing periods, nodes exchange messages to communicate channel conditions and gather topological information. To minimize duplicate transmission, an ideal relay node must be chosen among viable options. This minimizes coordination overhead and efficiently uses short-term resources.

2.1.4. Responsive Cooperative Transmission. CVN improves network speed and packet transmission reliability. However, cooperation techniques may influence neighbouring and collaborating relays. Cooperation with other relays requires to contemplate its self-transmissions besides resource restrictions. The participating node should also handle neighbouring node communications. The stages of node cooperation should be structured such that cooperative transmissions do not impair the performance of the collaborating node and its neighbours.

2.1.5. Equitable Resource Distribution. When considering transmission dependability, it is crucial to also prioritise fair resource allocation. Ensuring equitable allocation of resources to all participating nodes is crucial for optimising the performance of vehicular networks. Previous studies have investigated wireless network fairness in various aspects, such as bandwidth allocation [35], channel assignment [56], and power control [38]. Ensuring equal bandwidth and power usage for each node is of utmost importance, as fair resource distribution is vital. It is crucial to ensure fair distribution of resources to prevent resource hunger, which is why equitable resource allocation is necessary for the CVN.

2.2. Open Research Challenges. Research on cooperative vehicular communications focuses on developing robust protocols for dynamic situations and addressing mobility-induced performance deterioration, highlighting the need for compatibility with vehicle manufacturers.

2.2.1. High Speed Mobility. High-speed mobility in vehicular networks poses a significant challenge to the reliability of communications, introducing temporal variability that complicates traditional solutions. Despite efforts leveraging MIMO technology, cooperative relay and MIMO approaches still face hurdles in adapting to dynamic vehicular environments. The ever-changing network architecture further complicates relay node selection, necessitating agile techniques based on relative mobility speeds to address this challenge effectively. To tackle these obstacles, there is a pressing need for innovative relay selection methodologies capable of real-time adaptation to evolving network topologies. These techniques must navigate the complexities of high-speed mobility, considering factors like varying topography and rapid fading. By developing such adaptive protocols, we can enhance the dependability of vehicular communications, ensuring robust connectivity in dynamic automotive settings.

2.2.2. Multi-Objective Protocols. In the realm of Cooperative Vehicular Networks (CVNs), the predominant research paradigm tends to centre on singular parameters, often neglecting the inherent variability within vehicular network environments. Protocol design necessitates a comprehensive consideration of diverse

factors, encompassing aspects such as latency, throughput [83], fairness [58], and energy efficiency [80]. Nonetheless, crafting protocols that effectively reconcile these disparate objectives poses a formidable challenge, owing to the inherent conflicts and trade-offs inherent in such endeavours.

2.2.3. Estimating Channel State Information. Channel State Information (CSI) holds paramount importance in wireless systems, particularly for facilitating real-time cooperative networking. However, the real-time estimation of CSI presents a formidable challenge, primarily attributable to the dynamic nature of channel conditions and the rapid mobility characteristic of vehicular environments. Researchers may leverage principles from related domains to formulate estimation algorithms aimed at addressing this challenge [51].

2.2.4. Optimal Cooperative Relay Selection. The investigation delves into the complexities surrounding the selection of an optimal relay node to mitigate data collision and transmission redundancy effectively. Considerations include factors such as vehicle speed, direction of motion, channel quality, and traffic density. Findings from this study hold promise in informing the development of refined solutions for cooperative relay selection, offering valuable insights to propel further research. Moreover, the dynamic nature of automotive environments, marked by substantial vehicle movement, is demonstrably linked to adverse effects on network performance, underscoring the significance of these observations.

1. **Packet Loss Rate:** During congestion or fast changes in vehicle placements, the packet loss rate in highly mobile vehicular networks can be quite substantial, sometimes even exceeding 20%.
2. **Latency:** The latency in cooperative vehicular networks can vary significantly due to vehicle movement. In situations where there is heavy traffic or frequent lane changes, the latency can exceed 100 milliseconds, which can potentially compromise the real-time aspect of safety-critical systems.
3. **Fluctuations in Throughput:** The performance of vehicular communication systems can vary due to changes in the channel caused by vehicle mobility. During busy periods with a lot of movement on the roads, data speeds can decrease significantly, going from 1 Gbps to below 100 Mbps.
4. **Link Availability:** Link availability in vehicular networks can drop significantly in situations involving fast-moving vehicles, tunnels, or obscured line-of-sight circumstances, potentially reaching as low as 50%. This reduces the chances of establishing ongoing communication connections.
5. **Handover Frequency:** Due to the movement of vehicles in and out of communication ranges, frequent handovers are often required in cooperative vehicular networks. In busy urban areas, vehicles frequently change hands, causing signal overhead and disruptions.
6. **Network Density:** In intense traffic areas, network density may reach more than 1,000 vehicles per square kilometre. High density in communication channels may aggravate interference, contention, and collisions.
7. **Network Partition:** Occasionally, there may be instances where the network becomes temporarily divided due to sudden shifts in vehicle positions, resulting in certain groups of vehicles being isolated from the rest of the network. These partitions can cause significant disruptions to the flow of data, lasting for extended periods of time.
8. **Vehicle geographical Distribution:** Vehicles in cooperative networks have a non-uniform geographical distribution. Congestion in certain regions, such as junctions or highway on-ramps, may result in localised performance reduction.
9. **Effect on Safety Applications:** Mobility-induced performance loss might be especially worrisome in safety-critical cases such as collision evasion. In such cases, the success rate of timely warnings might fall below 90
10. **Impact on Traffic Management:** Due to the reliance on real-time data from vehicles, the effectiveness of traffic flow control and congestion management in cooperative traffic management could be hindered by concerns related to performance caused by mobility.
11. **Autonomous Vehicles Face Difficulties:** Autonomous vehicles rely significantly on cooperative communication. Vehicle mobility-induced performance deterioration might complicate autonomous decision-making and coordination, compromising safety and efficiency.

3. Routing Strategies. CVN routing systems must develop pathways that fully leverage the accessible forwarding relay selections in every hop in order to enhance transmission performance. Current cooperative ve-

hicular networking research initiatives attempt to achieve a variety of goals, including throughput maximisation, power allocation optimisation, transmission outage minimising, reliability enhancement, utilisation maximisation, and reservation slot collision minimization. Researchers are researching several techniques of constructing cross-layer routing to suit this need.

In [31], the authors put forward a proposal for VANET cross-layer routing that focuses on cooperative networking and finding a balance between end-to-end dependability and gearbox power consumption. The optimisation focuses on achieving two main objectives: ensuring high dependability while staying within gearbox power limits, and minimising power consumption. Nevertheless, the solution overlooks the possibility of co-channel interference from different source-destination pairs, which could potentially impact the performance of the protocol.

The VANET cross-layer routing technique optimizes wireless channel performance and overpowers unreliability [20]. Route detection and administration are done via AODV protocol. A relay selection method maximizes throughput, using predicted connection time and SNR. A MAC protocol extends route duration for stability. However, this assumes every vehicle is connected to RSU, increasing deployment costs.

By implementing cooperative forwarding and utilising network coding, the number of retransmissions can be significantly reduced [45]. The study in [111] introduced a cooperative forwarding system based on network coding, utilising a master/slave network topology paradigm. The master node selects the forwarding slave relay node based on trajectory, constancy, and proximity. The packet is encoded using linear network coding, incorporating slave addresses in route replies and updates.

The researchers in [69] proposed a network coding-aided scheduling technique for cooperative data dissemination systems. Vehicles exchange data via V2I and V2V channels, with each sending and receiving heartbeat messages to announce existence, update RSU, and switch operating modes. The proposed caching technique maximizes network coding effect, improving service performance but potentially cumulative latency for each packet. Authors in [72] proposed a bandwidth-optimized distribution technique for heterogeneous cooperative vehicular networks (DHVN), allowing quick data distribution and adapting to road design. The protocol improves packet retransmission and uses a store and forward technique to alleviate disconnections.

In [123], proposed an ungraceful cooperative strategy that uses forwarding probability with the aid of node position to decide next-hop transmission, reducing coordination overhead but requiring global positioning system information, potentially unavailable in tunnels. In [91] authors studied bidirectional cooperative V2V performance in vehicle abetted and RSU aided scenarios, using relay node location without channel status information. Authors in [37] investigate the influence of rate and gearbox range on CV critical systems, using a model to measure network performance. In [18] author also examined the combined impact of cooperation, interference, and channel fading in a Nakagami fading channel model.

A novel cooperative communication technique uses V2V, V2I, and mobility to increase vehicular network capacity. The disc model utilised in it omitted communication fading and interference, which may not suit the actual circumstance. This research synthetically analyses CVN network capacity using the highway scenario and variable communication scene fading. Using an analytical framework, a bottleneck expression of gearbox capacity is generated, and a newton iteration approach yields the estimated ideal cooperative vehicular ratio.

A dual segment generous cooperative (GEC) routing scheme is suggested [65]. A cooperative watchdog paradigm reduces false alerts and improves misbehaviour detection. The GEC routing protocol has several components that find cooperative pathways and distribute traffic. GEC design involves route finding and maintenance. The three steps of route discovery are neighbour sighting, erudition relay metric, and cooperative relay selection. Route recovery begins when a node gets a route error report. Link failure deletes the route from the routing database. The suggested technique separates troublesome vehicles, minimising end-to-end time. However, the suggested method lacks service diversity, which is essential for meeting traffic needs.

A novel network coding-aided scheduling technique is proposed to investigate the features of cooperative data dissemination systems [10]. In this setup, Vehicle-to-Infrastructure (V2I) communication channels facilitate the exchange of data between Roadside Units (RSUs) and passing vehicles, while Vehicle-to-Vehicle (V2V) channels enable vehicles to communicate cached data with nearby peers. The proposed solution comprises three phases: firstly, each vehicle transmits and receives heartbeat messages to announce its presence and gather information about nearby nodes. In the second phase, vehicles update their own and neighbouring

Table 3.1: List of review articles on routing strategies with multiple metrics

vehicles status information to the RSU. Finally, in the last phase, all vehicles switch operating modes based on RSU scheduling. To optimize the network coding effect, a caching method is recommended. While the suggested network coding-assisted data distribution enhances service performance, it may also lead to increased hop-to-hop latency and packet latency.

To improve broadcast reliability, propose cooperative relay broadcasting (CRB) to rebroadcast neighbouring source node packets [10]. A two-state Markov chain-based optimisation framework and channel prediction technique are also presented. The optimisation framework limits CRB performance, while the channel prediction algorithm selects the optimal relay node. CRB facilitates proactive cooperative choices to send packets before expiration.

Node mobility and V2V/V2I communications have been studied to optimise throughput [17]. The authors suggested a V2I communications technique for the Vehicle-of-Interest (VoI) to obtain information from RSU while in coverage. After outside infrastructure transmission range, the VoI uses V2V communications to receive data via relay nodes. Data transmission under cooperative communication techniques is investigated using an analytical approach. In [16], the study proposed a cooperative communication method that maximizes throughput by utilizing V2V and V2I communication, mobility, infrastructure, and vehicle collaboration. It develops an analytical framework and close-form expression for feasible throughput.

4. NOMA in Vehicular Networks. Powered by the increasing spread of Internet-enabled smart devices and creative apps, sophisticated new services accelerate 5G network development needing new MA approaches. To reduce access collisions in V2X environments, novel multiple access techniques like SCMA, PDMA, and NOMA have been projected to enhance bandwidth efficiency and massive connectivity [84, 23].

Non-orthogonal multiple access (NOMA) is a trustworthy solution for 5G networks, offering increased spectrum efficiency, throughput and balanced user fairness [26], figure 1 depicting the downlink and uplink NOMA in cooperative vehicular networks. Unlike the standard orthogonal multiple access (OMA) system, the NOMA approach enables numerous users to share time/frequency radio resources while differentiating users based on power levels [32, 105]. Implemented in power domain and code domain, NOMA combines multiple users and uses channel gain differential for better performance. Successive interference cancellation (SIC) aids in signal discrimination [68].

NOMA, unlike OMA, offers fewer system delays, improved dependability, higher transmission rates, and lower-cost service needs [119]. Traditional OMA methods assign orthogonal radio resources to multiple users, but they don't always reach the sum-rate capacity of multiuser wireless networks. NOMA can fully utilize its capacity by surpassing OMA with power domain multiplexing at the transmitter and SIC at the receivers [97].

To demonstrate the mathematical link between NOMA and OMA, we use SNR expressions to characterise the two-user downlink performance. h_s and h_d depict the channel coefficients of V_S and V_D . At RSU $\rho|h_s|^2 < |h_d|^2$ represent transmit SNR, then throughput of OMA can be articulated for as [75].

$$R_{V_S}^{OMA} = \beta \log_2 \left(1 + \frac{\alpha_{V_S} \rho}{\beta} |h_s|^2 \right)$$

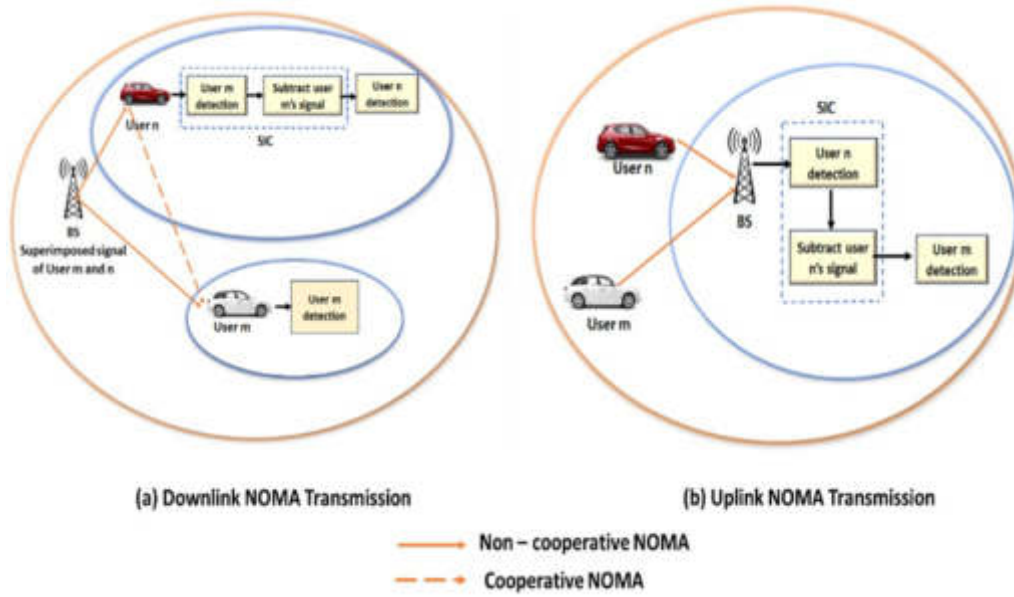

Fig. 4.1: Downlink and Uplink NOMA in CVN.

and

$$R_{V_D}^{OMA} = (1 - \beta) \log_2 \left(1 + \frac{\alpha_{V_D} \rho}{1 - \beta} |h_d|^2 \right)$$

where α_{V_S} and α_{V_D} are power allocation coefficients of with a condition of $\alpha_{V_S} + \alpha_{V_D} = 1$ and β is resource allocation coefficients. The throughput of V_S and V_D in NOMA are given as [75].

$$R_{V_S}^{OMA} = \log_2 \left(1 + \frac{\rho \alpha_{V_S} |h_S^2|}{1 + \rho \alpha_{V_D} |h_S^2|} \right)$$

and

$$R_{V_D}^{NOMA} = \log_2 \left(1 + \alpha_{V_D} \rho |h_d|^2 \right)$$

When we have $|h_d|^2 < |h_s|^2$, NOMA outperforms over OMA in sum throughput when adequate channel differences pertain between the two users.

4.1. Benefits of NOMA in Vehicular Networks.

Enhanced Spectrum Efficiency. Uplink NOMA can attain capacity constraints, but OMA methods are often suboptimal. However, when the quality of received signals of two vehicles are large, vehicle throughput fairness is meagre. The border of NOMA rate pairs in the downlink is outside the OMA rate zone. OMA can reach cumulative capacity in multi-path fading channels, but NOMA is optimum [49].

Massive Connectivity. By utilising non-orthogonal resource allocation, NOMA enables the support of a larger number of users or vehicles compared to OMA. This allows for excellent performance even in overloaded scenarios, despite the constraints of existing resources and scheduling limitations [49].

Low transmission latency and signalling rate. Traditional OMA with QOS requirements entails scheduling requests to base stations, leading to significant delay and expensive signalling costs. This is particularly problematic for large connections in 5G. However, certain NOMA uplink methods do not require dynamic scheduling, resulting in grant-free transmission, which can significantly reduce latency and signalling costs.

Fairness. NOMA empowers individuals with limited abilities. It is possible to achieve a desirable equilibrium between user fairness and performance. In this study, we will delve into the intricate NOMA fairness methods, such as intelligent power allocation (PA) policies [92, 73] and the cooperative NOMA scheme [100].

4.1.1. Ultra-high Connectivity:. The 5G system will connect billions of IoT smart devices [70], and NOMA, with its non-orthogonal properties, provides an efficient design option for conventional OMA.

4.1.2. Compatibility:. NOMA leverages the power-domain as "add-on" strategy for any current OMA technologies like TDMA/FDMA/CDMA/OFDMA. Given the maturity of Superposition coding and Successive Interference Cancellation procedures practically NOMA might be combined with aforementioned multiple Access techniques.

Non-Orthogonal Multiple Access (NOMA) technology represents a versatile 5G technique renowned for enhancing spectral efficiency and reducing latency in wireless communication systems [57]. In the realm of Vehicle-to-Everything (V2X) services, NOMA is harnessed to mitigate resource collision and achieve high throughput transmission even under resource constraints. Furthermore, NOMA finds application in vehicular networks to minimize latency and bolster reliability [29]. Leveraging NOMA-based broadcasting introduces a hybrid architecture alongside power control mechanisms tailored for participating vehicles [28]. Additionally, NOMA-spatial modulation (NOMA-SM) augments bandwidth efficiency and alleviates wireless V2V scenarios [6]. By employing power allocation algorithms with opportunistic constraints, NOMA systems hold the potential to enhance V2X network performance [49].

4.2. Implementation Challenges of NOMA. Nonetheless, some outstanding concerns must be solved before NOMA may be used in vehicle contexts.

- **Error Propagation in SIC:** In NOMA systems, SIC is the primary mechanism for detecting users. However, one major disadvantage of adopting SIC is the inter-user error propagation problem, which spreads from one user to the next since a judgement mistake results in deducting the incorrect remodulated signal from the composite multiuser signal, resulting in residual interference. The majority of extant NOMA research contributions are predicated on the premise that the SIC receivers are capable of completely cancelling the interference. In reality, because to faulty PA and inadequate channel decoding, this assumption cannot be easily met in practise. Several academics have acknowledged the obscurity of error propagation concerns and explored the impact of faulty SIC on uplink NOMA.
- **NOMA Channel Estimation Error and Complexity:** Channel estimation plays a pivotal role in NOMA systems compared to OMA, inaccurate channel estimates lead to muddled user collation and poor power control, both of which impact the accuracy of SIC decoding. The channel estimate diverges with numerous parameters and is always a critical challenge to achieve perfect estimation in practical scenarios.

In addition to the aforementioned implementation challenges, NOMA encounters several additional limitations. Due to NOMA's utilization of multiple access at variable power levels, the received signal intensities exhibit variability, presenting additional hurdles for effective analog-to-digital (A/D) conversion. While robust signals necessitate a wide voltage range, ensuring correct quantization at low levels demands high-resolution ADCs for weaker signals. However, employing ADCs with both attributes proves impractical due to cost and

system complexity constraints, inevitably leading to quantization errors. Balancing performance and complexity becomes paramount, necessitating a suitable trade-off consideration.

Another significant challenge in NOMA, often overlooked in prior research, is accurate synchronization. Achieving complete synchronous transmissions proves unattainable in practical scenarios due to the dynamic mobile environments of users, especially evident in uplink NOMA transmission. Addressing synchronization difficulties can be approached through two strategies: proposing precise pilot designs to minimize time synchronization errors and exploring novel asynchronous communication techniques. In a recent study [40], researchers proposed an innovative integrated circuit (IC) approach for asynchronous NOMA-aided orthogonal frequency multiplexing systems, highlighting the significant impact of relative time offsets among interfering users on system performance.

Moreover, NOMA encompasses various additional features such as reference signal design, channel estimation, and Channel State Information (CSI) feedback mechanisms, which bolster performance even in the presence of substantial cross-user interference. Resource allocation signaling is adept at accommodating diverse NOMA transmission modes, while extending NOMA to massive Multiple-Input Multiple-Output (MIMO) systems and other MIMO configurations promises optimal performance. Furthermore, efforts are underway to mitigate the peak-to-average-power ratio (PAPR) in networks with multiple vehicular networks, underscoring NOMA's ongoing evolution and its potential to address a multitude of challenges in wireless communication systems.

5. Cooperative NOMA in Vehicular Networks. NOMA-based transmission has less coverage than OMA-based transmission since each NOMA user is only assigned a portion of total transmit power. One successful strategy to broaden the coverage of NOMA-based transmission is to include cooperative techniques into NOMA networks, resulting in cooperative NOMA networks [67].

Cooperative communication has been a significant focus of study in the past due to its potential to enhance network coverage, throughput, and transmission reliability. By leveraging spatial diversity gain to counteract the effects of wireless fading, cooperative communication offers promising benefits [104].

The fundamental idea behind cooperative communication is to incorporate additional nodes that can assist in facilitating communication between the source and destination. By leveraging its geographical diversity advantage, combining data from various sources enhances the reliability of the destination's reception.

5.1. C-NOMA Networks with Relay and User Assistance. C-NOMA network research may be split into two groups with the aid of nature of collaboration. As illustrated in Figure 5.1a, is based on dedicated relay cooperation, in which specialised relays are installed to aid communication between the source and NOMA consumers [79].

The Figure 5.1b collaboration involves NOMA users with robust connections acting as relays to help those with deprived connections. According to the NOMA principle, strong users must decode frail users' information before decoding their anticipated information [79]. When they correctly discover weak users' information, they can assist them.

Integrating cooperativeness with NOMA can enhance system efficiency and dependability. Users with superior channel conditions may decode messages for others using the C-NOMA technique, which exploits prior knowledge in NOMA systems [33]. When users have superior channel conditions, short-range communication technologies such as Bluetooth and ultra-wideband may set up cooperative conversations. There are two parts to C-NOMA: transmission and collaboration, with NOMA users receiving superposed messages

$(N - 1)$ time slots make up the cooperation phase. In the i^{th} time slot, where $1 \leq i \leq (N - 1)$, the user from $(N - i + 1)^{th}$ broadcasts the combination of the messages from $(N - 1)$ C-NOMA achieves the greatest variety gain for all users by adjusting power allocation factors based on local channel circumstances. However, it is costly due to serial message retransmissions. C-NOMA provides user coupling with the aid of separate channel gains, reducing system complexity. Optimum power allocation strategies further improve the performance [42, 60, 73].

C-NOMA transmissions offer several key advantages over conventional NOMA transmissions, including:

- **Low System Redundance:** When dealing with weak signals, the DF protocol makes intellect since SIC algorithms in NOMA can decipher user messages. It is possible to remodulate and retransmit them from locations that are closer to the intended recipients.

Fig. 5.1: Cooperative NOMA Networks (a) Relay-aided C-NOMA Network, and (b) User-aided C-NOMA Networks

Fig. 5.2: Performance comparison between cooperative NOMA and non-cooperative NOMA.

- Greater fairness: C-NOMA improves the reliability of weak users, increasing fairness in transmission, especially when the weak user is near the cell’s edge with reference to the BS [100].
- Higher diversity gain: This C-NOMA serves as a linchpin for superior performance in dynamic and challenging vehicular communication environments. Through NOMA, multiple users can simultaneously transmit and receive data within the same time-frequency resource, fostering a cooperative environment that significantly enhances diversity gain. This heightened diversity gain translates into improved reliability and robustness, crucial elements for vehicular networks where communication channels are inherently volatile and prone to fluctuations. By leveraging the capabilities of NOMA to efficiently manage multiple connections, vehicular networks can achieve unparalleled diversity, enabling seamless communication even in scenarios with fading channels or challenging propagation conditions [70].

Figure 5.2, shows cooperative NOMA’s superior outage probability and diversity increase compared to non-cooperative NOMA and OMA. This strategy enhances transmission consistency, especially for weak NOMA users with deprived channel conditions.

5.2. Survey on C-NOMA:. NOMA achieves the highest diversity order for all users compared to OMA [33]. Many researchers have worked on designing and implementing NOMA techniques and on solving various technological problems associated with those methods. The literature demonstrates that NOMA is compatible with cooperative communication.

In terms of diversity order, NOMA outperforms OMA for all users [33]. Researchers have put lot of effort to develop and apply NOMA approaches, as well as to solve the many technical issues. Research shows that NOMA can work with cooperative communication. A special eminence on the C-NOMA techniques is presented in this treatise.

With NOMA in coordinated direct and relay transmission, the authors of [57] examined the ergodic capacity and outage probability of the system. In a multi-relay scenario, they explored consequences of how relay selection affected system performance and suggested a two-stage max-min method for selecting relays. Presenting a power allocation method and investigating the usage of SIC in decoding user signals, Yang & et al. [113] investigated the outage probability and user rates of a NOMA system with paired users in a non-cooperative uplink scenario.

The study in [114] explored the influence of relay selection on C-NOMA performance. A two-stage RS technique was used to minimize outage probability and maximize diversity. A dual-hop cooperative relaying technique based on NOMA was proposed in [52], involving simultaneous interaction between two sources over the same frequency range. The protocol successfully achieved ergodic total capacity through perfect and imperfect consecutive interference cancellation.

The work presented in [107] investigated the performance of a downlink cooperative relay system using DF and AF protocols across Nakagami-m fading channels. Data decoding order from cell-edge users was determined in the research using statistical CSI. When considering ergodic total rate, the findings reveal that, even when considering near-far effects, the DF protocol performs better than the AF protocol. However, the advantage diminishes with increasing SNR. The study also considers the obsolete CSI effect due to continuous channel fluctuations.

In [115], authors explored two possibilities in their paper. a) Direct connection between BS and Users b) No direct connection. First they investigated ordered users' outage behavior utilizing the AF relaying protocol while there was direct connection between the Base station (BS) and them. Secondly, a new closed-form calculation for the downlink outage probability with stochastically dispersed users was created in the absence of a direct relaying node. The users' diversity orders for the two situations have been determined based on the analysis findings. Furthermore, adopting the NOMA technique rather than the standard numerous Access approach ensures the fairness of numerous users. The suggested system was assessed using just AF, and two-way communication with HD/FD may have enhanced user throughput even further.

In order to improve upon OMA-based methods with regard to outage probability, system throughput, and spectrum utilization, reference [71] suggested a NOMA-based transmission strategy for cooperative spectrum-sharing networks. Under the assumption of a high SNR for the purpose of calculating the outage probability, the research in [74] investigated NOMA-based downlink AF relay networks that had low CSI performance. However, because to fixed-ordered decoding approaches, optimal uplink performance could not be confirmed. In [86], researchers examined NOMA-based single-and multi-vehicle systems fared under multipath fading conditions with and without in-phase/quadrature phase imbalance (IQI). Results showed that IQI effects vary across NOMA users and depend on system characteristics. Higher order users were more susceptible to IQI. The TBS-C-NOMA network enhances data reliability in traditional C-NOMA networks by preventing error propagation [53]. If the SINR is superior than the threshold, the intra-cell user will convey the symbols of the cell-edge user. The optimal threshold value is examined to reduce BEP, with SINR determining relay selection. The authors of [7] introduced a two-way cooperative relay technique that utilizes NOMA for bidirectional communication, outperforming a standard one-way C-NOMA system in terms of outage probability and ergodic rate.

Discussions and Prognosis: In the realm of cooperative vehicular communications, the synergy between Non-Orthogonal Multiple Access (NOMA) and cooperative techniques holds paramount significance for scientific advancements, particularly in scenarios where users are strategically positioned and route loss remains consistent. The interplay between NOMA and cooperative communications serves as a cornerstone for driving scientific contributions forward, offering opportunities to enhance system performance and reliability. While previous research endeavors have delved into the potential performance gains achievable through cooperative approaches, numerous open research challenges persist, warranting further investigation and innovation.

One such challenge lies in leveraging relays to improve reception reliability within NOMA-based networks. Relays introduce an additional time window for signal transmission, potentially bolstering the dependability of reception. However, the effective integration of relays necessitates careful consideration of various factors,

Fig. 6.1: Two-Way Cooperative communication.

Table 6.1: List of Survey articles with two way cooperative relaying

References	No. of users	No. of active relays	Link direction
[100, 112, 59, 85]	1	1	One-way

[44, 108]	1	2	One-way
[55, 88]	Multiple	1	Two-way

including interference mitigation and resource allocation. In this context, the deployment of full-duplex relays emerges as a promising avenue to address these challenges. By enabling simultaneous transmission and reception, full-duplex relays have the potential to mitigate the need for additional interference management techniques, thereby simplifying network design and enhancing overall system efficiency.

However, the successful implementation of full-duplex relays in NOMA networks requires comprehensive solutions to eradicate interference effectively. Overcoming interference challenges remains a critical research objective, as it directly impacts the reliability and performance of cooperative vehicular communications. Future research endeavors should focus on developing robust interference mitigation strategies tailored to the unique characteristics of NOMA-based cooperative networks. By addressing these challenges, the integration of NOMA and cooperative communications can unlock new opportunities for advancing the reliability, efficiency, and scalability of vehicular communication systems.

6. Two-way Cooperative Networks. The cooperative NOMA treaties use a one-way relay system, while two-way relay (TWR) technology improves spectral efficiency [81]. TWR systems use relays to communicate between nodes, resulting in larger throughput. CNOMA uses full-duplex mode and combines TWR with a suitable technique to improve system spectral efficiency. Two users working in three phases benefit from bidirectional communication in [116] s two-way cooperative relay technique using NOMA, demonstrating superior outage probability and ergodic rate than a one-way C-NOMA system. Hybrid TWRS was established in [8] for compressing data and high spectral efficiency in Network Coding.

Figure 6.1 depicts a system which involves two source nodes broadcasting packets x_1 and x_2 to the relay R , in second phase, R decodes them based on channel gains, and combining them using an XOR operation ($x = x_1 \oplus x_2$). The source nodes decode by performing $x_1 \oplus x = x_2$ and $x_2 \oplus x = x_1$ respectively. This efficiency has led to numerous researches focusing on this system as a promising solution to broaden coverage and deploy the diversity characteristic of wireless networks. The system's efficiency makes it a promising solution for wireless network applications.

Combining TWR with NOMA (TWR-NOMA) can enhance spectrum efficiency and system throughput [8]. Both technologies outperform in boosting spectral efficiency. Analytical and simulation findings show that outage probability converges to an error floor, even with Perfect Successive Interference Cancellation (PSIC), resulting in a zero diversity order, making it logical to combine TWR and NOMA [116].

6.1. Survey on TWR Cooperative NOMA. The majority of C-NOMA treaties concentrated on one directional communication, where messages are sent from the either source to relay and destination or destination to relay and source. Spectrum utilization is limited since communication requires two time slots to reach its target. Optimizing spectral efficiency is achieved by the use of TWR technology [88].

The authors of [47] offered a new method for selecting relays to streamline TWR systems after studying the behaviors of DF relay outages under both ideal and imperfect CSI conditions. The outage behavior of two-way full-duplex DF relay systems on different multi-user scheduling strategies was investigated using CSI and system status information [63]. In [117], evaluated the performance gain and provided an expressions for outage probability, ergodic capacity, and throughput to show the value of with and without direct connection in cooperative NOMA. The work did not specify relay choices, although dedicated relay was explored. Also absent: channel variation effects.

The performance of the C-NOMA system in full-duplex (FD) and amplify-and-forward (AF) modes with a dedicated relay was investigated in a study published in [2]. When compared to the FD decode-and-forward (DF) NOMA methodology, the suggested FD-AF relaying method outperformed in partial self-interference cancellation, according to the simulations. An increase in transmit signal-to-noise ratio (SNR) raises the near user's ergodic achievable rate.

Based on HD/FD in [118], authors developed closed-form methods to calculate the outage probability for two NOMA Relay selection (NOMA-RS) systems. An outage was shown to be less likely in HD-based NOMA-RS with more relays. The researchers postulated that HD-based NOMA-RS systems may provide a diversity order that is precisely proportionate to the number of relays. Nonetheless, NOMA-RS systems based on FD outperformed NOMA-RS systems based on HD in the low SNR range. The investigation did not take mobility, relaying systems, or delay limits into account. A two-way relay NOMA with DF was examined in the study, and for users with imperfect or perfect SIC, the researchers discovered closed-form equations for the exact and asymptotic outage probability in [42]. When dealing with channel circumstances that change over time and impact diversity gain, we ignore the relay selection.

The study in [34] introduced a novel approach for two-user DL and UL transmissions, utilizing a dedicated relay node to assist HD. This approach was compared to traditional one-way relay-based C-NOMA and OMA strategies. Nevertheless, the existence of a dedicated relay remains undefined. In [113], a virtual full-duplex cooperative NOMA scheme and relay selection method were proposed for a downlink two-hop network with multiple HD DF relays. This scheme provides a greater sum-rate compared to regular OMA transmissions and has the potential to improve spectral efficiency when used in conjunction with TWR.

A C-NOMA system for a two-user TWR network (TWRN) was presented in [67, 43], demonstrating a higher sum-rate compared to traditional OMA-based transmission. Unfortunately, no performance evaluation was articulated. A study conducted by experts in the field explored TWRNs that utilize NOMA technology. The study specifically focused on the aspects of secrecy and FD C-NOMA aided TWR systems. Formulas were derived to calculate outage probability, diversity orders, ergodic rates, and system throughput. In certain situations, FD NOMA gearbox demonstrated superior performance compared to HD gearbox.

Numerous multiuser relay networks (UMRNs) have effectively integrated NOMA, including cellular uplink and downlink broadcasts [21, 66, 90] and multi-pair TWRNs. Using rate excruciating and consecutive group decoding, a NOMA multipair TWRN was examined in research that was carried out in [125]. Despite this, a performance analysis was omitted from the research, which found significant decoding difficulty.

7. Relay Selection Strategies in CVN. The issues of routing in automotive networks are far from apparent. The challenge stems mostly from the instability of routing pathways generated by node mobility and network fragmentation. Indeed, the fact that the network has intermittent or partial connection suggests that routing management must vary from topological techniques.

The major routing algorithms for VANETs may be implemented in a diverse context, each with its particular set of characteristics like speed, vehicle density, road layouts, and so on. For example, metropolitan settings are distinguished by a complicated mobility model, high vehicle density, and limited speed, all of which are mostly the result of existing junctions and stop spots. However, the highway and rural settings are distinguished by great distances, making these surroundings less disruptive for radio waves during intervehicle interactions.

Inter-vehicular routing remains a significant difficulty, particularly in urban contexts with high vehicle density and the existence of impediments. The proposed new routing solution must fulfil the needs and characteristics of this kind of environment, whose limits have a significant impact on node mobility and routing performance. As a result of the high mobility of vehicles, the routing route between vehicles may not be guaranteed at all times. Unfortunately, the majority of present protocols fail to adequately assess the im-

part of potential obstacles that may have an immediate bearing on routing efficiency and, therefore, vehicle communication.

In [62, 124] authors presented a method called Optimal Power Allocation (OPA) for the all-participate-amplify-and-forward (AP-AF) environment. The aim of this method is to minimize the outage probability for multiple relay nodes. The OPA technique was shown to effectively reduce symbol error rate (SER), according to the author's findings. In larger networks, the performance of the AP-AF technique tends to decrease as the number of collaborating nodes increases. This study presents a new approach called selection-based amplify and forward (S-AF), which aims to minimize overhead by choosing the most suitable relay node. This approach combines relay selection and OPA. Unlike [11], this single relay selection does not include relay delay.

The Ad-hoc On-demand Distance Vector (AODV) protocol is used for route discovery and management, with a novel relay selection method aiming to maximize throughput. The cost-based selection criteria consider projected link time and SNR. The relay node decodes frames and sends them in their allocated slot, discarding the rest. A MAC protocol is developed to increase route duration and stability. However, the study assumes every vehicle is directly connected to a Remote Sensing Unit (RSU), resulting in high deployment costs. The study in [31] proposed VANET cross-layer routing via cooperative transmission and a novel route selection method to balance end-to-end dependability with gearbox power consumption. Two optimization issues are created to maximize dependability within transmission power limits and minimize power usage under reliability limitations. The solution assumes one network route and ignores co-channel interference from other node pairs, potentially affecting protocol performance if multiple network paths are active.

The authors in [64] presented an uncoordinated cooperative strategy that uses forwarding likelihood based on node position to decide on the next-hop transmission, reducing coordination overhead but requiring global positioning system information. [38] also presents a cooperative relay broadcasting (CRB) strategy to improve broadcast transmission reliability. The strategy includes a channel prediction technique and an optimization framework based on a two-state Markov chain. The optimization framework constrains CRB performance, while the channel prediction technique aids in selecting the optimal relay node.

The combined impact of user collaboration and dedicated relay cooperation is investigated in [27] for diversity benefit. Adaptive relay selection techniques have the lowest system outage probability (SOP). The relay selection was adaptable based on whether or not the nearby user need assistance. The investigation did not incorporate mobility or channel fluctuations in relay selection, and diversity was calculated based on the number of dedicated relays.

7.1. Mobility effect in clustering of vehicular networks. Clustering is a technique that involves gathering nodes with similar properties, such as destination, direction, and speed, to form distinct virtual sets called clusters. Vehicle mobility in vehicular networks significantly influences cluster formation and maintenance. Each cluster has a cluster head (CH) and several cluster members (CMs), with CH selection influenced by factors like the node's relative average speed. Each cluster has a predetermined size determined by the node's transmission range. Vehicle node clustering can improve communication efficiency in Vehicle Access Control Networks (VANETs) if the clusters are trustworthy and long-lasting.

The mobility effect in clustering may be difficult to achieve for the following reasons:

1. **Dynamic Topology:** The fast movement of vehicles might generate frequent changes in network topology, resulting in cluster reformation.
2. **Cluster Disruptions:** Vehicle movement may cause clusters to split apart, making steady and effective communication inside a cluster problematic.
3. **Load Imbalance:** Vehicle movement might result in an unequal distribution of network load, resulting in performance deterioration in certain portions of the network.
4. **Cluster Formation:** Vehicle movement might make it difficult to create clusters efficiently and effectively, resulting in inferior performance.

In order to address these challenges, experts are exploring various approaches aimed at enhancing the stability, efficiency, and scalability of vehicular networks. These efforts involve considering vehicle movement when establishing and managing clusters. The VANET distributed multi-hop clustering method (DMCNF) uses location, speed, position, and direction as input metrics, but one hop neighbor selection increases network time. To address this issue, a new protocol Enhanced DMCNF is being researched in [27], which handles

communication between the RSU and stable cluster, reducing cluster overhead.

Rapidly moving vehicles can cause network architecture changes and communication path instability, leading to connection failure [41, 106]. A method utilizing a multi agent system and particle swarm optimization is employed to tackle this problem. This approach utilizes the particle swarm optimization algorithm, a cluster formation process, and a multiple agent-based technique. The input parameters encompass various factors such as simulation time, transmission rate, coverage area, transmission range, node density, and numeral iterations. On the other hand, the output metrics focus on evaluating the throughput, packet loss, routing overhead, and packet delivery ratio. This approach is suitable for networks with average service quality, but performance may suffer when applied to high-quality networks.

The authors in [46] proposes a hybrid dynamic cluster strategy to improve communication reliability in vehicular adhoc networks. This strategy involves creating a stable dynamic topology using agent technology, with key measures including time for cluster creation, cluster head selection, and the total lifespan of the cluster. This approach addresses communication failure as a significant disadvantage. In [82] authors proposed a new strategy for enhancing vehicle network stability using clustering mechanisms, which are influenced by constantly changing topologies. The method uses indicators like received signal strength and identification number metrics. For specific roadside settings, a dynamic mobility and stability-based clustering technique is designed, focusing on vehicle direction, location, and lifespan estimation. The proposed work involves defining clusters, transitioning between states, creating and selecting heads, selecting gateway nodes, and ensuring maintenance. The input parameters consist of various factors such as the vehicle density, road length, hastening rate, slowing rate, proliferation model, numeral reiterations, and mobility model. On the other hand, the output metrics provide insights on clusters, CH length, state variation and clustering competence.

In [22, 24] advocated distributed multi-hop clustering. It passively picks the cluster head after organizing the vehicle using vehicle following. The vehicle following technique reduces cluster formation costs, while passive clustering improves stability. However, it ignores inter-node connection dependability when choosing the next vehicle, resulting in poor cluster reliability. Cluster coverage is improved and VANET cluster heads are reduced when a multi-hop clustering technique is used as opposed to a single-hop clustering method, according to this study. The use of available bandwidth is subsequently enhanced.

The authors in [78] proposed a strategy to enhance vehicle network stability using clustering mechanisms, which are influenced by constantly changing topologies. The method uses indicators like received signal strength and identification number metrics. With a focus on dynamic mobility and stability, a clustering approach is created for certain roadside situations that considers the vehicle's trajectory, location, and predicted lifespan [50]. By using the Ant Colony Optimization algorithm, the best way to transmit data from source to destination may be determined. Cluster heads are built with the highest possible link stability. The assessment metrics under consideration include QoS, network dependability, latency, energy efficiency, and network throughput.

In [96, 36], Trust degrees are utilized in authenticated VANET clustering to select CHs, with direct trust degrees reported by neighbors based on prior experience and indirect trust degrees based on nearby node recommendations. This approach addresses VANET instability caused by fast movement of mobile nodes. The previously labeled efforts generate a large quantity of CH, which degraded the performance. To address this issue, the clustering method incorporates grey wolf optimization. The grey wolf's natural hunting habit is employed to construct efficient clusters, resulting in the optimal number of clusters. The simulation findings give communication quality and a dependable information delivery ratio in VANET.

The study in [9, 89] proposed an efficient route repair approach to improve VANET network performance by combining ant colony optimization with an AODV routing system. This approach improves connection stability, packet delivery ratio, vehicle speed, and network quality. However, cluster head overburdening in cluster-based VANET communication is a problem. The research proposed in [77] a multi cluster head selection method, divided into two sections: hybrid fuzzy multi criteria decision making protocol and fuzzy analytic hierarchy protocol. The tributary topic is intrusion detection, focusing on support vector machine and dolphin swarm optimization. An adaptive updating approach was proposed in [14] to tackle the problem of rising channel traffic and congestion by improving the transmission of beacon signals. The method entails transmitting a beacon message by considering the participation of nodes in the forwarding set and the estimated duration of connection availability. The output metrics consist of packet delivery ratio, control packets, and routing

overhead. The projected technique shows promise compared to previous models, but it is still in its early stages and has limited applicability to different mobility paradigms.

Previously, one hop clustering was considered, which reduces coverage and increases cluster heads, impacting network performance and cluster overlaps. Some models overlook VANET mobility features, dynamic topology, and restricted driving direction. Earlier mobility-based clustering algorithms caused network congestion and increased collision rate.

Discussions and Prognosis. In the dynamic landscape of vehicular networks, the deployment of two-way cooperative Non-Orthogonal Multiple Access (NOMA) presents a multitude of intricate research challenges. While this approach holds considerable promise in enhancing both spectral efficiency and reliability, its successful implementation hinges on addressing several critical issues that warrant immediate attention for further exploration.

One of the primary challenges lies in optimizing resource allocation strategies to effectively cater to the diverse and dynamic nature of vehicular communication environments. Given the varying mobility patterns and communication requirements of vehicles, devising adaptive resource allocation schemes capable of efficiently utilizing available resources is essential to ensure optimal network performance. Furthermore, mitigating the impact of fluctuating channel conditions poses a significant hurdle. In the context of vehicular networks, where vehicles are constantly in motion, channel conditions can vary rapidly, leading to fluctuations in signal strength and quality. Developing robust techniques to adaptively adjust transmission parameters in response to these variations is crucial for maintaining reliable communication links.

Interference management also emerges as a critical concern. With numerous vehicles transmitting and receiving data simultaneously in close proximity, managing interference becomes inherently challenging. Effective interference mitigation techniques are necessary to minimize signal degradation and ensure seamless communication within the vehicular network.

Moreover, the integration of cooperative NOMA (C-NOMA) with high diversity gain, stringent latency requirements, and reliability constraints of Intelligent Transportation Systems (ITS) warrants thorough investigation. Balancing the trade-offs between spectral efficiency, latency, and reliability in the context of vehicular communications poses a complex optimization problem that requires careful consideration.

As the automotive industry progresses towards a future dominated by connected and autonomous vehicles, addressing these challenges becomes imperative. Unlocking the full potential of two-way C-NOMA in vehicular communications holds the key to driving advancements in intelligent transportation systems and vehicular communication technologies, ultimately paving the way for safer, more efficient, and smarter transportation systems.

8. Conclusion. This comprehensive survey has shed light on the multifaceted landscape of Cooperative Vehicular Communications in Intelligent Transportation Systems (ITS), emphasizing the pressing research challenges that must be addressed for successful implementation in realistic scenarios. The dynamic nature of vehicular mobility, coupled with the need for real-time communication, link reliability, coverage, interference, and adaptability, presents a complex set of hurdles that demand immediate attention from the research community. According to the comprehensive survey in this paper most of the solutions provided unheeded the influence of mobility in relay selection, and the estimated CSI in relay selection is outdated during data transmission. Future research efforts should prioritize the development of creative solutions that that can effectively connect theoretical frameworks with practical applications, fostering the creation of resilient, efficient, and secure cooperative vehicular systems that can truly transform the landscape of intelligent transportation. It is crucial to tackle these challenges head-on in order to fully unleash the potential of CVNs and create a safer and more sustainable future in transportation.

PA FUZZY-NOISE REMOVAL IN WIRELESS SENSORS NETWORKS

B HARISH GOUD AND RAJU ANITHA *

Abstract. In the wireless sensors network, a large number of sensor device data is sent directly to the base station. So huge amount of noise is also added with data going to the base station and there is no security mechanism for protecting sensor device data in the existing scenario. WSN has numerous applications, including healthcare systems, secure military applications, and monitoring applications. Achievement of noise removal is essential for WSN. Many researchers have focused on enhancing the removal of noise in data and extending the network lifetime. Sensor Nodes (SNs), cluster heads (CHs), and base stations make up the standard WSN architecture. The communication of SNs using the traditional design consumes high energy increases delay and reduces network performance. To address the limitation of the present state of the system, this research work proposed a PA Fuzzy system which is acting like a filter used to remove unnecessary noise with sensor data that is moving toward the base station. And PA Fuzzy system after removing noise, and sensor data is encrypted so that it can be protected from hackers. It makes the network performance better, decreases delay and energy use, and increases the Ratio of packet deliveries and throughput. The execution of the suggested methodology was made using NS2. The proposed's empirical outcomes system outperforms with comparison of the existing WSN mechanisms.

Key words: Wireless Sensor Networks, PA Fuzzy System, Filters, Encryption technique.

1. Introduction. The exponential growth of wireless communication technologies is having a profound effect on wireless sensor networks (WSNs). The conveyance of data is an essential WSN function. Over the past decade, numerous mechanisms have been suggested in an effort to enhance data transmission efficacy. With effectiveness Data transmission is essential for both research and commerce. Wireless sensor networks (WSNs) have a wide range of applications, including but not limited to smart cities, the armed services, and advancements in the healthcare industry [1]. A considerable quantity of dispersed sensor nodes comprise the WSN. Traditional WSNs feature varying degrees of communication. An excessive number of clusters are formed, and one CH is elected for each cluster. The sensor nodes gather environmental data and are utilized in a variety of applications. The CH receives and transmits sensor data from the base station after receiving it from the sensor node. [2]. The WSN sensor nodes have limitations in energy efficiently and data transfer. The sensor nodes' connectivity and computation abilities are incredibly poor. The sensor nodes' range is somewhat constrained; thus, improvements are required to boost communication efficiency. The primary component of load balancing is the deployment of WSN. Base Stations and CHs were the primary data transmission devices in classic WSN [3]. Look at the WSN model architecture in Figure 1.1.

The WSNs use a clustering-based approach, with a set of sensor nodes in each cluster. Information about the area is gathered and sent to the CHs by sensor nodes. The Data was gathered by CH's method and forwarded to BS. To gather and transmit the data, each sensor node in the network uses energy. Despite the fact that the sensor nodes shut down when their energy runs out. Therefore, creating WSN requires an energy-efficient algorithm. To equalize WSN's energy usage, many clustering techniques have been developed [4], [5]. These algorithms follow the selection of CHs and also shift CHs position among the SNs in a cluster. An energy-efficient hybrid clustering and routing technique has been developed for big WSNs. Design energy efficient mechanism back-off timer and gradient routing to execute the CH selection. In This research work introduced a brand-new PA fuzzy mechanism based on intelligent agents, which minimizes energy consumption, delay and maximizes throughput and PDR [2].

The following sections of the paper are broken down and discussed individually. Section II provides a full study of the most modern WSN energy-efficient approaches. The recommended methodology for deploying

PAWSN for energy efficiency was discussed in Sections III and IV, discuss the proposed mechanism from the empirical results, and compare the suggested results. In Section V, the paper is concluded with improvements to the suggested mechanism, as well as a discussion of upcoming research efforts.

2. Literature Review. An energy-conscious routing algorithm was developed by F. Fernando Jurado-Lasso et al. [6] as part of an overhead reduction strategy. This algorithm enables industrial services and optimized energy use in WSN. Data packet aggregation is a feature that the implementation of the software-defined multichip WSN to manage the WSN. The suggested system analyses shortest-path strategies in order to lengthen the lifetime of the WSN network. Enhance the PDR performance as well. Even though the recommended solution outperforms the current algorithms in terms of performance. But a revolutionary innovation algorithm is crucial in WSN to lower the network lifespan and the neighbor advertisement packets. Nelofar Aslam et al [7] built an innovative logic data algorithm transmission with clustering and reinforcement algorithm(SARSA). The proposed algorithm is also outlined as combining an ideal solution with SARSA clustering for energy consumption and network stability. The WSN node is designed with taportable wireless charging system The suggested strategy enhances the functionality of the network by drawing its inspiration from an objective function. However, C-SARSA's deployment in WSN led to an improvement in performance. However, the WSN does not have an RWSN with a proper deployment and recharge schema.

Gajendran Malshetty et al [8] For effective clustering in WSN, a self-organization method based on load has been developed. The LBSO approach in WSN employed three unique phases.. The first phase involved choosing the Cluster Head, and the second involved choosing among the sensor node clusters. The third stage is then followed by the rotational phase-based reselection of the cluster head. However, the network's efficiency and network development both increased. But the network performance is poor because of a variety of base station deployments and dead nodes. Muhammad Adil et al [9] A load-balancing routing system that uses little energy was made to make WSNs last longer. A good hybrid routing method has been made with the Dynamic Cluster Based Static Routing Protocol (DCBSRP). Ad-hoc On-Demand Distance Vector (AODV) Routing Protocol and Low-Energy Adaptive Clustering Hierarchy (LEACH) Protocol are both parts of the suggested protocol.create a WSN using a variety of clusters and CHs. The DCBSRP protocol largely behaves as a normal node and does not make current CH nodes from the early cycles public. But the proposed protocol significantly increased network longevity.

A wide variety of real-time applications using WSN are deployed. The WSN uses self-organization and a finite amount of energy. To address energy efficiency's limits Al Xinlu Li et al. [10] presented a load- balancing energy-efficient WSNs using the ant-based routing algorithm (EBAR). The EBAR algorithm effectively lowers energy use Through an opportunistic broadcast technique, EBAR uses and manages overhead in WSN to conserve energy. The EBAR does accomplish Despite being accurate only in homogeneous networks, energy

efficiency. Data transmission cannot be supported by the algorithm in a diverse network, which results in excessive energy usage [11].

Wireless Sensor Networks are wireless systems comprising a large number of randomly or regularly distributed sensor nodes. The target of this job is to give network protection to wireless Sensor Networks so as to transmit detection information to the recipient efficiently so the duration of the system is long and within this function, a novel protocol was created with Game Theory [12]. Game Theory gives a mathematical foundation for the evaluation of interactive decision-making procedures. It gives tools for predicting what may (and what should) occur when agents that have conflicting interests socialize. It's not a monolithic method, but a selection of modeling programs that assist in the comprehension of interactive decisions to get issues. The projected Game Theory approaches are implemented effectively for preventing Denial of service attacks, to discover and protect against malicious behavior of sensor nodes in a network of wireless sensors, and verified that the operation of those games considerably decreases misbehavior of tunnels, conserves node power and prolongs the network lifetime economically [13].

Wireless sensor networks are urgently needed and are proliferating as a result of recent advancements in electronics and wireless networks (WSNs) [14]. WSNs are now crucial in a variety of fields, such as infrastructure, healthcare, agriculture, the environment, and military leadership. Several issues affect the healthcare sector, among these are escalating costs, an aging population, a rise in medical mistakes, a lack of manpower, etc. Despite the challenges, healthcare professionals are under pressure to adopt new technology and offer improved services [15]. The availability of universal healthcare can lower long-term expenditures and raise service standards [16]. Wireless sensor networks offer practical remedies for the pervasive healthcare system. Recent developments in medical sensors and low-power network architectures have given rise to WSNs for the healthcare industry. As a result of the wireless sensor network [17].

3. Suggested Approach.

3.1. Status of the Problem. Sensor nodes that are connected to the WSNs communicate with one another to gather information about their surroundings. Whenever sensor data information moves from cluster heads to the base station even noise, and unwanted data also move to the base station there to so much delay, PDR is less, and Throughput is also not accurate. The SNs run in a decentralized, low-energy manner. Use of the WSN in numerous emerging applications, including military applications, applications in industry and the environment, and healthcare systems. The base station, CHs, and SNs are the three operational levels of the conventional WSN. The sensor nodes gather local data and send it to the CH Nevertheless, the CH only receives information for a limited period of time, and the behavior rotates. The changes in the rotation of the cluster head use energy and cause data transfer to be slower., In this scholarly document published a book Intelligent agent PA fuzzy mechanism.

3.2. PA-Fuzzy. The functionality of available resources, portability in sensor nodes, and rotating movements in cluster heads result in excessive energy use and latency in transmission. In order to address the issue with the current state of the WSN, this study effort introduced an innovative PA-Fuzzy is a mechanism which will eliminate unnecessary data, such as a noise which is moving to words base station it will a love only data. And PA Fuzzy system will encrypt sensor data for two times and forwarded to base station for encryption AES 256 key algorithm can be used in PA Fuzzy system. Base station sends data finally to end user so only end user can decrypt data with valid keys. In between no hacker or base station authority cannot decrypt data this is the originality of proposed technic in this article. By this we can improve PDR, Throughput, Delay.

PA-Fuzzy also a love to make unclear data to clear data. There are two ways to transmit data in the WSN. A sensor node to a PA Fuzzy system is the first data transfer type. From one cluster sensor node to another cluster sensor node is the second way that data is sent.. The sensor device and the path arbitrary node are connected directly. Use a different sensor node as an intermediary in sensor-to-sensor transmission, however. Here, choosing the best route between the destination sensor and the sender sensor node depends heavily on the path arbitrary. The path from source to destination arbitrarily defines an optimized primary path as well as alternative routes. The connecting node's node distance and energy levels are taken into account while choosing the how to get from point A to point B. if any of the primary direction links or nodes fail.

In the suggested PA-Fuzzy, the optimize path selection method includes two steps. In the initial stage of

Fig. 3.1: PA Fuzzy in WSNs.

the appropriate optimize path selection process, The source node sends the RREQ packet to the destination node. The RREQ packet is sent by intermediate nodes to the target node. The sensor node has knowledge of the network's preceding and subsequent neighbors distance and energy values. Finally, RREQ from multiple nodes via various channels is received by the target node.

Algorithm: PA Fuzzy system

Input: Noise removal filters and encryption.

Output: Path optimization.

1. Start up
2. Sensor data is collected by PA Fuzzy system.
3. PA Fuzzy system does not change rational like cluster head.
4. PA Fuzzy it is fixed selected based on particle swarm optimization techniques optimized distance from cluster and base station.
5. PA Fuzzy system act like filter removes noise moving data toward base station.
6. PA Fuzzy system twice encrypt data for protection.
7. Base station receive data and Forward to end users.
8. End user receive keys and decrypt data.
9. End.

All optimized pathways were calculated and arranged using the node value sum. The destination uses the primary optimized path to send a packet of RREP data to the original station. additional network-wide optimized diversions Use the alternative channels for data transfer if a network link or node fails. to improve the path selection algorithm after carefully following the PA Fuzzy implementation steps.

4. Result Analysis. Version 2.35 of Network Simulation (NS) is utilized to implement the unique intelligent agent-based PA- Fuzzy mechanism that has been proposed. The outcomes of the empirical simulation demonstrate how well the PA-Fuzzy performs when transmitting data. The comparative findings are discussed in the subsections below.

4.1. Contextual Simulation. Table 4.1 displays the environment of the simulation. Details about the network parameters utilized in the design of the PA Fuzzy simulation are provided in Table 4.1. The deployment of WSN employs the two-ray ground radio propagation model. The effectiveness of several performance measures

Table 4.1: Simulation Environment

S.No.	System Parameter	System Contribution
1	Model of Antenna	omnidirectional Antenna
2	Length of Queue	50
3	Routing Protocol	AODV
4	Number of nodes	100
5	Data Rate	2 M.B.
6	Basic Rate	1 M.B.
7	Total Simulation Time	100
8	Network Interface	Physical wireless
9	Interface Queue Type	Trial drop
10	Type of Channel	Wireless connection
11	Radio-Propagation	Double-Ray Ground

Table 4.2: Comparing results of IA Fuzzy's PDR performance

Simulation time	PDR Performance			
	PA fuzzy	PSNR	SSIM	MD
0	0	0	0	0
10	12	6	5	4
20	33	15	13	9
30	54	35	27	21
40	77	61	44	41
50	102	82	75	56

is evaluated to judge the suggested systems. The enhanced performance is evaluated based on metrics such as latency, throughput, packet delivery ratio, and energy usage. The peak signal to noise ratio (PSNR), the structure similarity index (SSIM), and the miss detection (MD) technique are compared to the PA-Fuzzy for successfully removing noise in WSN. The section below provides a definition of performance metrics.

4.2. Comparative Metric Analysis. The performance enhancement of the proposed systems is evaluated based on metrics such as latency, throughput, packet delivery ratio, and energy usage.

4.2.1. Packet Delivery Ratio. The ratio of packets transmitted and received at the destination node. The formula given in Equation 4.1.

$$PacketDeliveryRatio = \frac{\sum_{i=1}^n RP_i}{\sum_{i=1}^n SP_i} \quad (4.1)$$

Showcase the comparing results of IA Fuzzy's PDR performance in Table 4.2. The assuming the suitable simulation period, the performance graph on PDR in Figure 4.1. The empirical findings of the suggested PA Fuzzy mechanism and the currently in the PSNR (peak signal to noise ratio), the SSIM (structural similarity index) and MD (Miss Detection) mechanisms are shown in Figure 4.1. The simulation time for the X-Axis ranged from 0 to 50 seconds. The PDR percentage is shown on the Y-axis. With an increase in simulation time, The projected PA Fuzzy network's PDR increases. Existing mechanisms behave in a similar manner, but according to performance data, the PA Fuzzy mechanism performs better than PSNR, SSIM, MD.

4.2.2. Throughput. The number of bytes and the corresponding simulation time that were received at the destination node. The equation provided in equation 4.2.

$$Throughput = \frac{\sum_{i=1}^n P_i}{Time} * 8 \quad (4.2)$$

Showcase the comparison of IA Fuzzy's throughput performance in Table 4.3. Figure 4.2 shows the suggested

Fig. 4.1: PDR performance comparison.

Table 4.3: Comparison of IA Fuzzy’s throughput performance

Simulation time	Throughput Performance			
	PA fuzzy	PSNR	SSIM	MD
0	0	0	0	0
10	75606	50186	41146	38457
20	77097	44697	36147	31457
30	76354	41257	28488	21545
40	81307	37146	23985	18257
50	83375	36456	21457	16962

Fig. 4.2: Comparison on Throughput performance.

mechanism’s throughput performance together with the corresponding simulation time. The proposed PA Fuzzy mechanism’s throughput performance is shown in Figure 3. The X-axis shows the simulation time, which ranged from 0 to 50 seconds. The Y-axis is scaled by the quantity of bytes received at the destination node. Throughput performance significantly improved with the suggested PA Fuzzy technique. In compared to the existing mechanisms with simulation time 10 PSNR, SSIM, MD which got 50186,41146,38457bytes, respectively, 75606 bytes were obtained for the proposed PA Fuzzy technique.

4.2.3. Delay. The interval between the sending and receiving of a packet. The given equation in Equation 4.3.

$$DI = \sum_{i=1}^n (Psti - Prti) \tag{4.3}$$

Fig. 4.3: Results of the comparison of delays.

Where D_l indicates delay, P_{st} indicates packet send time ,P_{rt} indicates packet received time. In Table 4.4 compare the delay performance of PA fuzzy, and show the results. In figure 4.4 demonstrates how the suggested

Table 4.4

Simulation time	Delay Performance			
	PA fuzzy	PSNR	SSIM	MD
0	0	0	0	0
10	0.101	0.323	0.427	0.485
20	0.0605	0.208	0.297	0.384
30	0.0391	0.176	0.215	0.351
40	0.0321	0.136	0.186	0.268
50	0.0404	0.097	0.132	0.21

mechanism’s delay performance changes with the amount of simulation time. The outcomes of the proposed mechanism are compared to the system’s current state-of- the-art.

The results of the suggested mechanism’s comparison for network latency are shown in Figure 4. The Y- axis is used to track milliseconds of network latency, and the X-axis is used to measure simulation time in seconds. The empirical results showed that, when compared to the system’s current state, the proposed mechanism performed better. The suggested mechanism significantly improved performance outcomes measured from 0 to 50 seconds. Although there is a significant network delay at first, the suggested technique eventually decreases and minimizes it.

4.2.4. Energy Consumption. It indicates the overall amount of energy used by the sensor nodes for the transfer of data and other network operations. The provided formula in Equation 4.4

$$Energy = \sum_{i=1}^n NE_i \tag{4.4}$$

The evaluation of energy efficiency of PA Fuzzy is shown in Table 4.5. Figure 4.4 shows the amount of energy used for each simulation period. The graph displayed the total energy consumed for each time interval. Partially missing from the experiment are the first 0 and the remaining 50 seconds. One hundred joules of energy was allotted to every sensor node in the PA Fuzzy network. A more steady increase in energy consumption is observed as the simulation time increases. The proposed techniques use little energy, nonetheless, as compared to current ones. The proposed mechanism PA Fuzzy consumes 84 J at end of simulation, while the existing mechanism PSNR, SSIM, MD[9][10][11] consumed is 49 J, 32 J and 19 J respectively.

Table 4.5: Evaluation of energy efficiency of PA Fuzzy

Simulation time	Efficiency in Energy			
	PA fuzzy	PSNR	SSIM	MD
0	100	100	100	100
10	97	86	81	75
20	94	72	65	56
30	92	61	50	33
40	88	51	39	22
50	84	49	32	19

Fig. 4.4: Comparison on Energy Consumption.

5. Conclusion. The progress in WSNs is applied in a variety of applications, including those related to the the armed forces, medical care, farming, urban planning, etc. The WSN is highly efficiently used for data transmission. The operational capabilities dependent based on the quantity of sensor nodes environments. Because WSN is inherently resource-constrained, the sensor nodes face severe limitations. Even if there are a lot of issues with the current WSN, addressing performance efficiency and network latency is crucial. To tackle the problems in WSN, this study's paper suggested an innovative PA Fuzzy. The PA Fuzzy plays a essential function in transmission of data and the choice of the best routes between the base station and sensor nodes. When data is travelling towards the base station, PA Fuzzy acts as a filter to remove extraneous noise. Additionally, the PA Fuzzy system will twice encrypt sensor data before sending it reaching the base station. Data is finally sent from the base station to the user who is the only one who can decrypt it using proper keys. In future better encryption algorithms can be used in term of keys in PA Fuzzy intermediate system for protecting sensor data. However, while comparing several energy-efficient WSN techniques, the suggested PA Fuzzy outperformed all. To improve WSN data transmission, the PA fuzzy is therefore optimized. NS2 simulations are used for the implementation. The experiments demonstrated that, in terms of performance, the suggested method greatly surpassed the standard system.

MACHINE LEARNING-BASED RISK PREDICTION AND SAFETY MANAGEMENT FOR OUTDOOR SPORTS ACTIVITIES

YAN LU*

Abstract. Participant safety is becoming increasingly important as outdoor sports activities gain popularity. A machine learning-based strategy for risk assessment and safety control in outdoor sports activities is presented in this paper. Our framework uses predictive modelling, sophisticated algorithms, and historical data analysis to identify potential dangers and improve safety procedures. It also considers participant profiles and environmental conditions. Comprehensive testing and validation are used to examine the model's efficacy, showing that it can offer risk evaluations in real-time and support preventive safety measures. Our approach entails placing sensor-based Internet of Things (IoT) devices at building sites to gather extremely detailed temporal and geographic weather, building, and labour data. This data is then cooperatively used on the edge nodes to train Deep Neural Network (DNN) models in a cross-silos way. The present study makes a valuable contribution to sports safety by offering a clever approach that integrates technology and outdoor leisure to ensure participants have a safe and pleasurable experience. The experiment's outcomes show how well the suggested strategy works to increase the adoption of construction safety management systems and lower the likelihood of future mishaps and fatalities. As a result, the system has improved speed and responsiveness, an important feature for time-sensitive applications like safety prediction.

Key words: machine learning, risk prediction, safety management, sports, outdoor sports activities

1. Introduction. The promise of exploration and excitement draws people to outdoor sports activities, which include mountaineering, biking, hiking, and water sports. The increasing demand for thorough risk assessment and safety protocols to guarantee the welfare of participants corresponds with the growth in popularity of these activities. A ground-breaking way to improve risk assessment and safety procedures is through the incorporation of machine learning, which acknowledges the dynamic nature of outdoor situations and the inherent uncertainties they present.

The building industry has been at the forefront of this rapid development of the world in recent decades. With 200,000 more people moving into cities every day, it is evident that these demographic changes have had a significant impact on the worldwide building industry [18]. Nonetheless, construction is regarded as one of the most hazardous industries for workers because of its dynamic, ever-changing, and heterogeneous spatiotemporal environment. Worker safety is a persistent problem that calls for constant focus and effort. Due to the dangerous working circumstances at construction sites, a recent study suggests [11] that workers routinely face possible safety and health concerns during the building process.

Data analysis reveals that, broadly speaking, "outdoor sports" relate to all outdoor activities, which includes practically all sports [23]. In a restricted sense, outdoor sports are those that take place in naturally occurring outdoor settings, such as parks, buildings intended for other uses besides sports, or natural settings. A category of sporting activities known as outdoor sports use the outdoors as a non-designated location and are characterized by an element of adventure or experience [26, 29]. Its primary expression is to leave the city, venture outside, and partake in activities that provide certain risks, difficulties, and relevance while adhering to safety and standards guidelines.

The main motivation of this research stems from the growing recognition of the importance of participant safety in the increasingly popular domain of outdoor sports activities. As these activities attract a larger and more diverse group of enthusiasts, the complexity and variability of safety risks associated with outdoor environments also escalate. This paper introduces a machine learning-based strategy designed to enhance risk assessment and safety management within this context. Leveraging the power of predictive modeling, advanced

*School of Physical Education, University of Sanya, Sanya, 572000, China (yanluresearch21@outlook.com)

algorithms, and thorough analysis of historical data, our approach aims to proactively identify potential hazards and refine safety protocols tailored to the unique demands of outdoor sports.

Unlike indoor sports, which have stricter site requirements and are heavily impacted by weather and terrain, outdoor sports are not the same. They have a greater relevance for individuals to reduce mental stress, improve their health, and raise their standard of living in addition to helping city dwellers escape the bustle and get closer to nature. A few pertinent policies have been released in recent years, including the State Council's views on encouraging the growth of the health services industry, the General Office of the State Council's guidelines on accelerating the sports industry's development, and the notice on the guidelines for expediting the establishment of a social security system and services system for the disabled. China's outdoor products sector has taken shape and begun to develop fast by the start of the twenty-first century [32, 20]. Unlike other demanding sports, which are not only simple to learn, safe, and efficient, but also simple to practice, outdoor sports.

The main contribution of the proposed method is given below:

1. DNNs are particularly good at finding complex patterns in large, heterogeneous datasets.
2. When it comes to outdoor sports, where dangers can take many different forms depending on a range of factors like weather, topography, and participant behavior, DNNs help by quickly identifying intricate patterns that lead to more precise risk evaluations.
3. Real-time risk prediction is made possible by utilizing DNNs' innate capacity for parallel processing.
4. Instantaneous risk evaluations that dynamically adjust to changing conditions during outdoor activities are provided by these networks, which are capable of quickly analysing continuously evolving environmental data.

The rest of our research article is written as follows: Section 2 discusses the related work on various sports activities, risk prediction and deep learning methods. Section 3 shows the algorithm process and general working methodology of proposed work. Section 4 evaluates the implementation and results of the proposed method. Section 5 concludes the work and discusses the result evaluation.

2. Related Works. Numerous research on the general population have confirmed a considerable negative correlation between psychological well-being and distress [9, 13, 21]. More specifically, concerning findings from several studies [25, 6, 14, 31, 19] on the mental health of academic students have shown a decline in the perception of life quality and an exaggerated rise in the frequency and severity of these psychological issues.

Physical activity (PA) has long been linked to a lower risk of death and morbidity from degenerative and chronic illnesses [30, 22, 7, 24, 4, 15], but more recently, research has focused on the impact of PA on mental health. PA has been linked to improvements in mood, overall well-being, and quality of life perception [16, 12], as well as a notable decrease in depressed and anxious symptomatology [5]. Numerous biological mechanisms, such as enhanced cerebral blood flow and oxygen delivery to brain tissues, decreased muscle tension, and elevated serum concentrations of endocannabinoid receptors and satisfying neurotransmitters like serotonin, have been proposed as explanations for this evidence [1].

But research on the effects of PA in older age groups has yielded the most consistent results linking PA to improved mental health [10]. Research on PA in younger age groups, however, has shown mixed results, with some indicating a weak association [11] and others suggesting a more persistent association [8] between PA and mental health outcomes. The use of measuring tools that, when used alone, do not provide a complete assessment of all facets of mental health has been blamed in part for this lack of reliable data. This implies that using a variety of instruments to obtain a more accurate assessment of mental health perception can be beneficial [3].

In the realm of deep learning research, DNN has emerged as a well-known algorithm that makes it possible to create intelligent applications across a variety of industries [28]. An Artificial Neural Network (ANN) known as a DNN is made up of several layers of connected nodes, or neurons, that process input data and gradually extract progressively more abstract properties from it. A deep neural network (DNN) is a machine learning model that is well-suited for tasks like picture and audio recognition [27], natural language processing [2], and predictive modelling [17], since it can learn hierarchical representations of complicated patterns and relationships in the data. Backpropagation is used by DNN to minimize the discrepancy between target values and anticipated outputs by adjusting the weights across neurons.

Fig. 3.1: Architecture of proposed method

One significant issue identified is the reliance on measurement tools that may not comprehensively assess all facets of mental health. This limitation could lead to inconsistent data on the effects of PA on mental health, particularly in younger age groups. The passage suggests that employing a variety of instruments could yield a more accurate assessment of mental health perceptions, indicating a need for methodological improvements in research.

3. Proposed Methodology. A strong and proactive strategy is needed to guarantee the safety of participants in outdoor sports. The suggested approach makes use of machine learning techniques to improve outdoor enthusiasts' safety management by dynamically predicting dangers. The approach consists of multiple crucial phases that combine data gathering, model building, and real-time implementation to produce an all-encompassing solution. Initially, the data is collected and then the collected data is pre-processed. Next, the pre-processed data is given to the feature engineering process. Finally, risk prediction is carried out using deep neural networks (DNN). In figure 3.1 shows the architecture of the proposed method.

By carefully selecting and engineering features that capture the essence of outdoor sports environments, such as weather conditions, terrain types, and athlete biometrics, the model can better understand the context of the data it processes. This helps in accurately interpreting variations in the input data. The model employs ensemble learning techniques, which combine the predictions from multiple learning algorithms to improve generalizability and robustness. This approach helps manage data's unpredictability by leveraging the strengths of various models to produce a more accurate and stable prediction.

3.1. Data collection and pre-processing. A multifaceted strategy is required to gather pertinent data for risk and safety prediction related to outdoor activities, including participant traits, environmental conditions, and historical event data.

For information on current weather conditions, such as temperature, precipitation, wind speed, and atmospheric pressure, consult your local weather station. To learn more about the topography, terrain, and elevation of the outdoor activity area, consult geospatial databases. Utilize satellite imagery to evaluate vegetation, water bodies, and land cover as well as dynamic changes in environmental circumstances. Install Internet of Things (IoT) gadgets and on-site sensors to collect environmental data in real time. Examples of these are GPS trackers, humidity sensors, and temperature sensors. Use remote sensing technologies to collect high-resolution information on the topography and environmental aspects, such as drones carrying sensors.

3.1.1. Data Pre-processing. Preparing gathered data for use in machine learning models for risk and safety prediction in outdoor sports involves pre-processing it. To manage missing values, standardize the data, create features, and prepare the data for training and testing the predictive models, pre-processing processes are necessary. Determine which values in the gathered data are missing and deal with them by either deleting the relevant entries or imputing the necessary values (such as the mean, median, or interpolation).

3.2. Feature Engineering. Utilize environmental data to extract pertinent parameters like height, wind speed, rainfall, temperature, and terrain kind. Transform time-related data (date, time of day, etc.) into suitable forms or create new time-related data (season, time of day, etc.) that could affect the weather outside. Convert data from participants into features while taking age, health, skill, and past involvement information into account. Provide binary or categorical variables for participant attributes, including experience level or health issues, that may have an impact on safety. Determine important characteristics, like incident type, location, contributing variables, and severity, from past incident data. To identify potential patterns, engineer temporal characteristics (e.g., time of day, day of week, season) associated to incident incidence.

3.2.1. Normalization. A popular data normalizing method in machine learning, min-max normalization (also called feature scaling or min-max scaling) converts numerical characteristics into a predetermined range. By ensuring that every feature has a comparable scale, this normalization helps to avoid certain characteristics predominating over others when the model is being trained. A feature's values are scaled via min-max normalization to a range of 0 to 1.

$$p_i = \frac{(q_i - \min(q))}{(\max(q) - \min(q))} \quad (3.1)$$

3.3. Risk Prediction and Safety Management for Outdoor Sports Using DNN methods. Using Deep Neural Networks (DNNs) has the potential to transform risk prediction and safety management in outdoor sports, where conditions are often dynamic and unpredictable. DNNs are a smart way to improve safety procedures and guarantee the welfare of participants because of their ability to identify intricate patterns and relationships within data.

3.3.1. Risk Prediction Using DNN. A family of artificial neural networks (ANNs) known as deep neural networks (DNNs) are distinguished by having numerous layers between the input and output layers. These networks can identify complicated patterns and characteristics in large datasets since they are built to learn hierarchical representations of data by utilizing numerous layers. Deep neural networks (DNNs) have shown impressive performance in a few domains, such as natural language processing, picture, and audio recognition, and, more recently, risk prediction and safety management for outdoor sports.

The first layer that gets the data as input in its raw form. Every node in this layer stands for a characteristic or feature of the incoming data. Hierarchical feature extraction from input data is learned by the network at the layers that sit between the input and output layers. Multiple hidden layers are characteristic of deep networks, which allow them to catch intricate patterns. parameters related to the connections made by nodes in various tiers. To maximize the network's performance, these parameters are changed throughout the training phase. The model becomes non-linear when non-linear functions are applied to each layer's node's output. Rectified Linear Unit, or ReLU, and sigmoid are examples of common activation functions.

The last layer that generates output for the network. Depending on the job (binary classification, multi-class classification, regression, etc.), this layer has a different number of nodes. a measurement of the discrepancy between the intended and actual output. The objective of the training process is to reduce this loss function. a method that minimizes the loss function by modifying the weights and biases. Optimization methods like Gradient Descent and its variations (like Adam and RMSprop) are frequently utilized. In figure 3.2 shows the structure of DNN.

3.3.2. Safety Management using LSTM. Recurrent neural networks (RNNs) with specialized memory cells are used in Long Short-Term Memory (LSTM) networks for outdoor sports safety management. This allows RNNs to capture temporal connections in data. Because LSTMs perform exceptionally well with data sequences, they can be used for jobs involving time-series information, including risk prediction in outdoor sports scenarios.

Sequences of input that reflect participant and environment characteristics. The data's temporal dependencies and patterns are captured by many LSTM layers. Predicting the safety or risk status for the upcoming time step is done via the output layer. When engaging in outdoor activities, connect the LSTM model to real-time sensor data to continuously monitor the surrounding conditions. Make the model more deployable on mobile apps so that consumers may receive safety forecasts while they're on the road. Make real-time risk predictions using the LSTM model by considering participant characteristics and the state of the environment.

Fig. 3.2: Structure of DNN

Put into practice adaptive safety protocols that, in response to changing hazards, modify dynamically based on LSTM predictions.

$$In^t = f(We_{ix}x^t + We_{ih}h^{t-1} + We_{ic}C^{t-1} + bi_i) \quad (3.2)$$

$$FO^t = f(We_{fox}x^t + We_{foh}h^{t-1} + We_{foc}C^{t-1} + bi_{fo}) \quad (3.3)$$

$$CE^t = FO^t \cdot CE^{t-1} + In^t(We_{cex}x^t + We_{ceh}h^{t-1} + We_{cec}C^{t-1} + bi_{ce}) \quad (3.4)$$

$$OP^t = f(We_{opx}x^t + We_{oph}h^{t-1} + We_{opc}C^{t-1} + bi_{op}) \quad (3.5)$$

$$hi^t = OP^t \cdot g(CE^t) \quad (3.6)$$

Create a feedback loop where user input and incident reports help the LSTM model learn and improve over time. To be relevant, the LSTM model should be updated on a regular basis depending on fresh data and new trends.

4. Result Analysis. The proposed method DNN-LSTM for risk prediction and safety management using various metrics such as accuracy, f1-score, precision, and Kappa value.

When assessing the effectiveness of machine learning models, such as those employed in outdoor sporting activities for risk prediction and safety management, accuracy is a regularly utilized indicator. When selecting evaluation metrics, it is crucial to consider the objectives of your model as well as the particular features of your dataset.

Although accuracy offers a broad indication of a model's soundness, it may not always be the best statistic, particularly when working with unbalanced datasets or when certain errors are more serious than others. Other metrics, including as precision, recall, and F1-score, may provide more useful information when it comes to risk prediction and safety management. In figure 4.1 shows the evaluation of accuracy.

Particularly when it comes to outdoor sporting activities, precision is a crucial evaluation criterion for machine learning-based risk prediction and safety management. When minimizing false positives—that is, lowering the number of times the model predicts a safety issue incorrectly—precision becomes especially important. The ratio of true positive predictions to all positive predictions (true positives plus false positives) is known as precision. In figure 4.2 shows the evaluation of precision.

A popular metric for assessing how well classification models perform is the F1-score, which is especially helpful for imbalanced datasets. You can use the F1-score to evaluate how effectively your model balances precision and recall in the context of risk prediction and safety management for outdoor sports activities. A high precision indicates a high probability of accuracy when the model predicts a favorable outcome (risk or safety concern). This is essential to prevent taking needless safety precautions when they are not necessary.

A high recall shows that real-world positive examples are well captured by the model. High recall guarantees that a sizable percentage of possible hazards are identified by the model in the context of safety management.

Fig. 4.1: Accuracy

Fig. 4.2: Evaluation of Precision

Finding a balance between recall and precision is aided by the F1-score. It guarantees that the model in safety management is thorough in capturing hazards and accurate in its forecasts. In figure 4.3 shows the evaluation of F1-score.

The Cohen's kappa, often known as the kappa statistic, is a regularly employed metric in classification tasks to evaluate the degree of agreement between anticipated and actual classifications. It accounts for chance agreement in inter-rater agreements. The agreement between expected risk levels and actual occurrences can be assessed in the context of risk prediction and safety management for outdoor sports activities using the Kappa statistic. In figure 4.4 shows the evaluation of Kappa Value.

5. Conclusion. As outdoor sporting activities become more popular, participant safety is becoming increasingly critical. This research presents a machine learning-based approach to risk assessment and safety regulation in outdoor sports. Our approach improves safety procedures by identifying possible hazards through the use of sophisticated algorithms, predictive modelling, and historical data analysis. It also takes the surroundings and participant profiles into account. The effectiveness of the model is investigated through extensive testing and validation, demonstrating that it can provide risk assessments in real-time and assist with preventive safety actions. Our methodology involves the deployment of sensor-based Internet of Things (IoT) devices at construction sites to collect incredibly fine-grained temporal and spatial building, labour, and weather data. This data is then collaboratively used in a cross-silos fashion to train Deep Neural Network (DNN) models on the edge nodes. The current study adds much to the field of sports safety by providing a novel strategy that

Fig. 4.3: F1-score

Fig. 4.4: Kappa Value

combines outdoor recreation and technology to guarantee participants' enjoyment and safety. The experiment's results demonstrate the effectiveness of the recommended approach in promoting the use of construction safety management systems and reducing the risk of accidents and fatalities in the future. This enhances the system's speed and responsiveness, a crucial attribute for time-sensitive applications such as safety forecasting.

RESEARCH ON PLANNING AND PATH OPTIMIZATION OF LEISURE SPORTS ACTIVITIES BASED ON MULTI-OBJECTIVE GENETIC ALGORITHM

XU YANG*

Abstract. Recreational sports are essential for boosting physical health and improving quality of life. The goal of this research is to optimize the planning of leisure sports by presenting a new method based on a multi-objective genetic algorithm. Acknowledging the intricacy of organizing recreational sports events, we suggest an approach that concurrently maximizes several goals, such as the use of resources, player happiness, and ecological impact. The topic is first formulated as a multi-objective optimization task in the paper, and a genetic algorithm is used to handle the objectives' inherent conflict. With its ability to effectively explore the solution space, the genetic algorithm produces a set of Pareto-optimal solutions that show trade-offs for the conflicting goals. The integration of several factors, including time preferences, geographical limitations, and environmental sustainability, guarantees a thorough and equitable strategy for leisure sports scheduling. In the area of leisure sports planning, the use of a multi-objective genetic algorithm offers a reliable solution that can be tailored to meet various circumstances and goals. As the need of encouraging healthy lifestyles becomes more widely acknowledged, this research offers a useful tool for maximizing the organization and performance of recreational sports activities, enhancing the overall wellbeing of people and communities.

Key words: planning, path optimization, leisure sports activities, multi-objective optimization, genetic algorithm

1. Introduction. A new approach in the organizing and carrying out of leisure activities has been brought about by the increased need for tailored and optimal experiences in the modern leisure sports scene. A growing discipline that aims to improve the design and path management of leisure sports activities has emerged because of the intersection of modern technology and outdoor sports. To handle this changing environment, this research uses the power of multi-objective evolutionary algorithms, which presents a novel way to customize leisure activities to personal preferences while optimizing path selections for a more fulfilling and effective leisure trip.

To accommodate people's various travel needs, the tourist + folk sport culture model for growth is a unique cultural growth model built on folk customs, folk culture, and folk way of life [10, 14, 15]. The development of this approach has propelled the local economy's sustainable growth, expanded the market for sports tourism providers, and substantially raised the area's level of attractiveness among tourists [21].

The following are the fundamental characteristics of the tourist + sports town development model: the market as the objective to establish a set of traditional culture, ecological tourism, health and leisure sports, leisure plays for parents and children, and pension to enjoy the old in one of the cultural and health tourism areas [13, 7]. Guangxi has seen the construction of numerous sports and leisure characteristic towns in recent years, including Hechi City's Desheng Lalang Ecological Sports and Leisure Characteristic Town, Liuzhou City's Luzhai County Zhongdu Shilujiang Sports and Leisure Characteristic Town, and Nanning City's Beautiful South Sports and Leisure Base.

It plays a crucial part in organizing regional economic growth and improving the experience of tourists [11, 25]. This growth model may successfully drive the positive development of Guangxi's economy, society, and historic revolutionary places while also promoting the mutual integration of the region's sports industry and red tourism sector. Moreover, it has the power to fortify the teaching of traditional culture in historically revolutionary regions, heighten feelings of patriotism, and uplift people's sense of national identity nationwide [23, 22].

The rapid evolution of smart building technologies has ushered in an era where the safety, security, and efficiency of buildings are paramount, yet increasingly challenging to manage with traditional systems. The

*School of Physical Education, University of Sanya, Sanya 572000, China (xuyanguniversity12@outlook.com)

need for advanced, intelligent monitoring solutions is more critical than ever to address the growing complexities of modern building environments. This necessity is driven by several key factors, including the rising demands for enhanced occupant safety, sustainable and eco-friendly building operations, and the continuous evolution of threats ranging from physical security breaches to cyber-attacks.

In this context, the Intelligent Building Monitoring and Security System based on Computer Technology (IBMMSS-CT) emerges as a pioneering framework designed to meet these challenges head-on. Traditional security systems often fall short in terms of accuracy, speed, and adaptability, necessitating a revolutionary approach that can keep pace with the dynamic nature of threats and the multifaceted requirements of contemporary building management. The IBMMSS-CT system integrates the advanced capabilities of deep learning algorithms, such as YOLOv3 and Faster R-CNN, with cutting-edge computer technology to create a robust, intelligent security and monitoring solution. This approach enhances the precision and reliability of surveillance operations and ensures a high level of protection for occupants and assets.

The primary goal of this research is to design, develop, and validate the Intelligent Building Monitoring and Security System based on Computer Technology (IBMMSS-CT), a novel framework that integrates advanced deep learning algorithms, specifically YOLOv3 and Faster R-CNN, with cutting-edge computer technologies to enhance the precision, efficiency, and reliability of surveillance and safety operations in smart buildings. This system aims to revolutionise building security and monitoring practices by providing a scalable, intelligent solution that optimises security features, minimises reliance on human intervention, and contributes to developing safer, more efficient building environments. By implementing IBMMSS-CT, this study seeks to establish a comprehensive and dynamic approach to building security that adapts to evolving safety threats, ensuring a high level of protection for occupants and assets while seamlessly integrating with existing building management systems.

Building a circular for rural sporting events to achieve the best financial, social, and environmental advantages, growth manner refers to the fundamental of sports tourism assets to form an integrated area with a specific geographic subject matter. Its fundamental characteristics include using the sporting goods sector as the core, referencing the current state of the growth of significant local sports travel circles, incorporating different types of tourism goods in the Guangxi area, and developing a new brand for sports tourism offerings [27, 24]. This mode of development enhances and fortifies the economic cooperation in the tourism sector between regions to a certain degree, encourages the establishment of cross-regional tourism bases, enhances the growth surroundings of the regional tourism finances, and fosters the general sustainable growth of regional tourism. The main contribution of the proposed method is given below:

1. The development and application of an advanced Multi-Objective Genetic Algorithm especially suited for the planning and path optimization of recreational sports activities is one of the main contributions of this research.
2. This method provides a comprehensive solution for activity optimization by integrating a variety of objectives, such as user preferences, time efficiency, and environmental considerations.
3. Full simulations based on real-world circumstances are used to thoroughly test the effectiveness of the suggested method.
4. Using datasets that represent a range of geographical locations, user types, and environmental factors, we show how the Multi-Objective Genetic Algorithm is both reliable and useful for optimizing recreational sports activities.

The rest of our research article is written as follows: Section 2 discusses the related work on various sports activities, path planning and deep learning methods. Section 3 shows the algorithm process and general working methodology of the proposed work. Section 4 evaluates the implementation and results of the proposed method. Section 5 concludes the work and discusses the result evaluation.

2. Related Works. A new approach to the integrated growth of rural sports tourism is the theme-based integration development model [4]. Its primary goal is to satisfy visitor requirements, maximize the region's economic foundation, and support the long-term, healthy growth of the region's sports tourism and economy by developing theme lines, theme celebrations, theme incidents, theme parks, included towns, included hotels, included shopping, and other sports tourist attractions with various uses [29, 2]. This approach may efficiently manage the distinct assets of sports tourism so that these can be used at different times, while also preventing

or reducing repetitious competition in the sports tourist market to ensure product innovation and variety.

Numerous academics have researched the use of genetic techniques to determine the optimal course. The author created a multiobjective biological algorithm (MOGA) to find the best routes for the transportation of six dangerous goods (DG) while taking competing objectives into account. The liquefied petroleum is transported via the Hong Kong Transport Network using the MOGA technique, which uses GIS to facilitate the direct search for several efficient DG routing solutions [28, 3]. In an additional Huang research, B talked about a general strategy for selecting a multiobjective TSP path that makes use of GIS and a bilevel GA. Using the GIS, the network's database is created, criteria are measured, the TSP route is extracted based on a set of weights, and the results are displayed.

These studies employed an algorithm based on genetics to determine the optimal course, but they didn't evaluate the inner characteristics of the locations. Additionally, the data's descriptive representation was lacking. Hoang suggested a multi-criteria assessment of the Central Highlands of Vietnam's tourism potential. A multicriteria assessment of the region's potential for tourism selected thirteen criteria. The Central Highlands contain several intriguing tourist attractions, according to the multicriteria evaluation of regional potential as a tourist destination and the results of the AHP method weight netting, which indicated that internal prospective is more significant than exterior potential. [16, 18, 12].

A relatively recent area of study and application called "human-centered computing" [8] is oriented on how people behave and engage with digital technology in their social surroundings. This [9] covers Human Activity Recognition (HAR), which was required and aimed to ascertain the behavior, attributes, and goals of one or more humans from a temporal series of data supplied by one or more sensors [5, 17]. Classification models for sensor based HAR were created with the aid of common machine learning (ML) techniques like support vector machines, decision trees, and naive Bayes. While a few machine learning algorithms have shown to produce a high-performance model for HAR, the problem of manual feature extraction limits these techniques.

Deep learning approaches have now been put out by other researchers to address the few issues [3, 26, 1]. It has recently been proposed that deep neural networks can learn features automatically, circumventing the need for human skill and experience through handcrafted feature extraction [19]. Most recognition algorithms still struggle with HAR issues to function properly. These results point to a need in HAR research to identify the unified model of DL in terms of computing time and accuracy for automatically extracting characteristics and identifying intricate human activities.

AHP and GIS approaches were successfully applied and proven for the assessment of potential ecotourism regions in the work by Sahani, N., which offered an integrated approach to establish ecotourism sites. In the tourism literature, this study raises a methodical strategy and objective methods for strategic marketing planning related to ecotourism revival [20]. Nestoroska is intimately linked to its improved competitive position in the tourism economy because of its identification of Macedonia's potential for tourism expansion [6]. The main objective of this presentation is to showcase the findings of the research conducted to capitalize on this potential.

3. Proposed Methodology. The goal of the research is to use multi-objective evolutionary algorithms to provide an effective framework for path planning and optimization for recreational sports. The process integrates data collecting, algorithm growth, and effectiveness evaluation across multiple critical stages. Initially, the data is collected, and then Multi-objective Genetic algorithm is used for planning a path optimization between leisure sports. In figure 3.1 shows the architecture diagram of proposed method.

3.1. Multi Objectives for Leisure Sports Path Planning . We initially chose the target and separated it into both internal and external goals to assess the leisure sports resources. Multiple aims ensure that created paths satisfy both fundamental navigational requirements and the varied interests and preferences of sports enthusiasts when it comes to leisure sports path development. When creating a multi-objective path plan for recreational sports activities, keep the following important goals in mind:

Distance Minimization. Reduce the overall distance covered by walking the path. Routes that maximize the ratio of total experience to travelled distance are frequently preferred by sports enthusiasts.

Elevation Gain Minimization. Reduce the total elevation increase that occurs during the route. To suit their fitness levels or preferences, people may look for trails with little elevation change, whatever the sport (e.g., hiking, trail running, cycling).

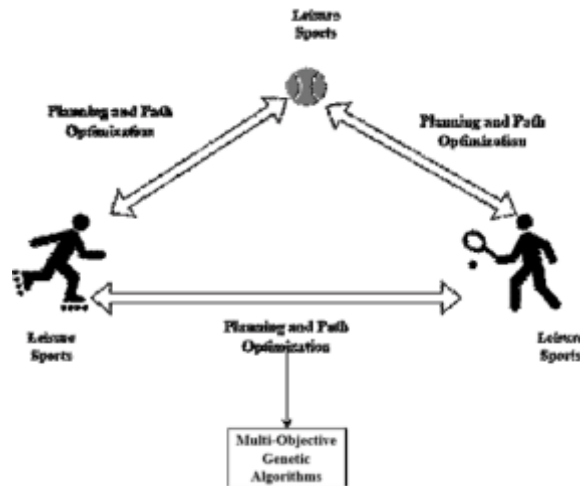

Fig. 3.1: Architecture of Proposed Method

Scenic Beauty Maximization. Make the most of the path’s visual appeal or scenic beauty. Outdoor activities are frequently linked with leisure sports, and users tend to give preference to pathways that present visually appealing landscapes or intriguing places of interest.

3.2. Genetic Algorithm. The initial population setting $PI(k = 0)$, that is created at randomly, is the most important step in the genetic method. The sequencing of genes creates the chromosome, which are then controlled by certain properties. Secondly, the fitness function is determined using chromosomal values. The evolution process is then performed, with the fit form being developed as well as the unfit ideas being eliminated. This process is repeated until the system contains all of the desired fitness values. Such final approved patterns are referred to as parents, and they are utilized to create offspring designs for future generations.

Two portions are used to carry out the genetic algorithms evolutionary process. Mutation and crossovers are the terms used to describe them. A mutation operator is a procedure that is created randomly utilizing chromosome genes and is chosen randomly. The likelihood of mutation in our study is $pi_m(k) = 0.03$. The crossover procedure uses a swapping operation to make children from two specific parent chromosomes. We utilize a single point crossover with $pi_c(k) = 0.6$ as the threshold.

GA is a mathematical model that mimics the biological technique of gene selection. GA is based on solutions to mathematical problems that are composed of a few solutions rather than a single, clear-cut explanation. The main foundation of GA is Darwin’s hypothesis. Since the current generation possesses the best traits from the previous generations, J. Holland suggested an algorithm based on natural selection in 1975 .

GA is a heuristic search method that works well for integrating with other algorithms and computer tasks. As a result, GA has shown to be extremely important to academics across many domains¹¹¹. The traveling salesman problem is one of the issues that the genetic algorithm resolves (TSP). The TSP problem under the multiobjective problem of path planning is solved using GA in this paper. The actions depicted in Figure 3.2 comprise the GA process. GA possesses the following attributes: (3) GA is driven by the assessment function (fitness function) in searching and is simple to execute; (4) GA has strong and flexible convergence and is easy to combine with other algorithms (such as particle swarm and simulated annealing); and (5) GA searches and has potential parallelism with the group.

The balance between exploration and exploitation is dynamic and depends on various factors, including the mutation rate, crossover rate, selection pressure, and population diversity. Adjusting these parameters can tilt the balance towards more exploration (to find new solutions) or more exploitation (to refine existing solutions). A well-designed genetic algorithm will:

Start with higher exploration to broadly search the solution space.

Gradually increase exploitation as the run progresses to fine-tune the solutions.

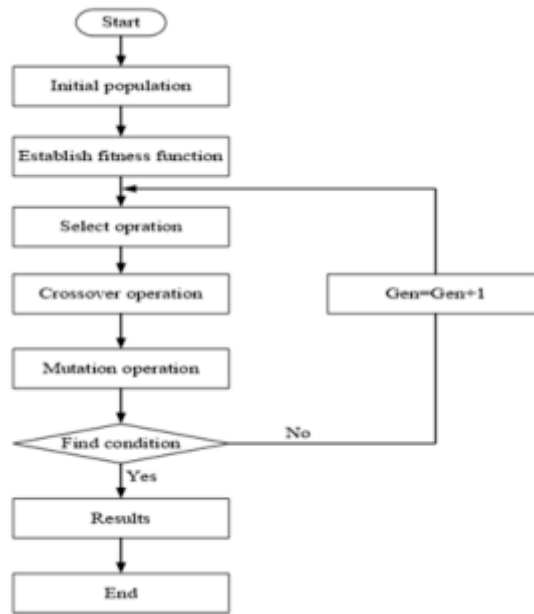

Fig. 3.2: Operations of GA

Fig. 3.3: Representations of Chromosomes

Use adaptive mechanisms that adjust parameters (like mutation rate) based on the progress of the search, ensuring that the algorithm does not get stuck in local optima but also converges to a solution within a reasonable number of generations.

Initial Population. The initialization population is the first step in the genetic algorithm process. Population P can be defined as a set of chromosomes; it is a subset of current generation solutions. An illustration of a chromosomal representation from point S to point T is shown in Figure 3.3.

Fitness Function. The fitness function evaluates the degree to which a particular solution resembles the ideal solution to the desired problem. Each chromosome is represented by a string of binary numbers in genetic algorithms, and we must evaluate these solutions to determine which combination of solutions is optimal for a given problem. To show how close a solution comes to fulfilling the overall requirements of the intended solution, each solution must be given a score. This score is generated by running the test via the fitness function.

Selection Operation. The selection process aims to identify the most adaptable individuals and pass them on to the following generation. Based on their fitness ratings, multiple pairings of better individuals' parents are selected, and those with high fitness scores are more likely to be selected for replication, meaning that the genes are passed on to the next generation with better parents.

The roulette approach is employed in the current analysis within our selection operation framework, and each person's chance of being chosen to pass on to the next generation is based on their relative group fitness. However, because the roulette selection method is unpredictable, better candidates may not make it through

the selection process. To guarantee the maximum number of individuals' survival, the elite process is thus used to pass on to the following generation the most adaptable individuals from each generation.

Crossover. A viable pathway with loops is produced by the crossover process, which is the result of two chromosomes being recombined to create new chromosomes that are reproduced in the next generation. Crossover values should be between 0.75 and 0.95. After doing numerous testing's, we ultimately decided on 0.85 compatibility with the other factors.

Mutation. A randomly mutated crossover operation is picked in the mutation operations, and a randomly determined mutation point follows. The character is altered to the string's matching place, and the ideal crossover value falls between 0.05 and 0.15. After doing numerous testing's, we ultimately decided on 0.10 compatibility with the remaining variables.

Final State. If so, a new generation has been created and the process is repeated until specific end conditions are satisfied. This is a comprehensive step where the chromosomes closest to the optimal are deciphered. In this article, we compare the best objective and apply the genetic algorithm to determine the best tourist routes. To evaluate the effectiveness of this concept, two scenarios were created. Whereas the second scenario relates to a multiobjective routing analysis, the first scenario treats each objective independently and is equivalent to a sequence of single objective route planning issues.

4. Result Analysis. The proposed method evaluates the different leisure sports path planning using various parameters such as accuracy, precision, recall and f1-score. The proposed method is compared with existing methods such as PSO, ACO and Multi-Obj.

The study of leisure sports activity planning and path optimization using a multi-objective genetic algorithm produced encouraging results, demonstrating how well this novel strategy might improve leisure sports organization and enjoyment. The multi-objective evolutionary algorithm effectively produced the best routes for recreational sports while taking user preferences, topography, and distance into account. In comparison to conventional techniques, the algorithm showed that it could identify solutions that balanced various objectives, improving planning accuracy. Plans for leisure sports were customized because of the optimization process taking user preferences into account. Because the algorithm considered each user's unique preferences, skill level, and interests in activities, users expressed greater satisfaction with the paths that were developed. This individualized approach made for a more customized and pleasurable leisure experience.

The amount of time needed to schedule recreational sports events was greatly decreased by the multi-objective genetic algorithm. Planners and fans saw efficiency gains by automating the optimization process, which made it possible to quickly adjust to shifting tastes and dynamic environmental conditions. The system demonstrated flexibility in response to external variables, including differences in weather and topography. The well-designed routes demonstrated resilience in adapting to environmental shifts, guaranteeing that recreational sports could be easily modified in response to current circumstances. In figure ?? shows the evaluation of accuracy.

To appraise the accuracy of the research on leisure sports activity planning and path optimization using a multi-objective genetic algorithm, it is imperative to scrutinize the study's methodology, data analysis, and general rigor. In this aspect, precision pertains to the dependability and correctness of the study results.

Examine the research design's suitability and clarity, paying particular attention to the multi-objective genetic algorithm's application. Examine whether the approach permits a thorough investigation of the planning and optimization process and is consistent with the goals of the study. Evaluate how well the algorithm was implemented. Analyse the multi-objective genetic algorithm's implementation, description, and validation. Ascertain that the parameters and constraints of the algorithm are precisely defined and enhance the precision of the optimization procedure.

Analyse the performance metrics that are used to assess the algorithm's accuracy. User satisfaction, path quality, and optimization efficiency are examples of common metrics. Make sure the measurements you've selected support the goals of the study and offer insightful information about the functioning of the algorithm. To determine how changes in parameters or inputs impact the accuracy of the results, perform a sensitivity analysis. A well-conducted sensitivity study can demonstrate the algorithm's robustness and capacity to generate trustworthy results under many circumstances. In figure 4.2 shows the evaluation of Precision.

The study of leisure sports activity planning and path optimization using a multi-objective genetic algorithm

Fig. 4.2: Evaluation of Precision

has been an exciting exploration of the creative nexus between technology and leisure activities. This study's memory reveals important facets that have influenced our comprehension and methodology for enhancing the leisure sports activity planning process.

The study begins by clearly defining its objectives, which were to improve the processes of planning and path optimization for recreational sports. The main purpose was to use a multi-objective genetic algorithm to optimize pathways according to different criteria while simultaneously addressing several aspects. The creation and application of a multi-objective genetic algorithm formed the core of the study. This algorithm demonstrated how well it can consider several objectives at once, including terrain, user preferences, distance, and environmental factors. Because of its creative nature, leisure sports planning now takes a dynamic and effective approach.

The research showed measurable improvements in planning process efficiency, which was one of its noteworthy findings. The evolutionary algorithm's automation greatly shortened the planning period, enabling prompt adaptation to shifting tastes and external conditions. Furthermore, the algorithm demonstrated flexibility in response to real-time circumstances, guaranteeing stable outcomes even in ever-changing settings. In figure 4.3 shows the evaluation of Recall.

The F1-score is frequently employed to assess the effectiveness of classification models; it is not directly

Fig. 4.3: Evaluation of Recall

Fig. 4.4: Evaluation of F1-score

relevant to path planning studies or optimization issues. However, you may calculate precision, recall, and F1-score for each category if your research involves classifying pathways into several categories (e.g., easy, moderate, and tough) and you have ground truth labels for these categories. In figure 4.4 shows the evaluation of f1-score.

5. Conclusion. Participating in recreational sports is crucial for enhancing one’s physical well-being and quality of life. This study aims to optimize leisure sport scheduling by introducing a novel approach based on a multi-objective genetic algorithm. Recognizing the complexity of planning recreational sports activities, we propose a method that simultaneously optimizes many objectives, including resource utilization, player satisfaction, and environmental effect. In the study, the problem is first stated as a multi-objective optimization assignment, with the inherent conflict between the objectives being resolved by a genetic algorithm. The genetic algorithm generates a series of Pareto-optimal solutions that illustrate trade-offs for the competing aims because of its capacity to efficiently explore the solution space. Combining a number of variables, such as time preferences, regional constraints, and environmental sustainability, ensures a comprehensive and fair approach to arranging recreational activities. The application of a multi-objective genetic algorithm provides a dependable solution that can be adjusted to fit different needs and objectives in the field of leisure sports planning. With the increasing recognition of the need to promote healthy lifestyles, this research provides a valuable

instrument to optimize recreational sports activities' performance and organization, improving people's and communities' general well-being. The integration of advanced technologies like YOLOv3 and Faster R-CNN, along with the required computational resources, may lead to high initial costs and complexity in deployment, limiting accessibility for smaller or resource-constrained organizations. Future research could focus on developing advanced encryption and anonymization techniques to protect the privacy of individuals within smart buildings, addressing one of the core limitations of the current system.

RESEARCH ON VISUALIZATION AND INTERACTIVITY OF VIRTUAL REALITY TECHNOLOGY AND DIGITAL MEDIA IN INTERIOR SPACE DESIGN

KE ZHANG* AND RATANACHOTE THIENMONGKOL†

Abstract. The combination of digital media and Virtual Reality (VR) technology has become a disruptive force in the interior space design industry, changing the way that design is explored and augmenting its experiential aspects. Examining the substantial effects of deep visualization and technological interaction on the conception and interaction with interior environments, this research explores the junction of these dynamic domains. This study intends to uncover the interactions that drive internal designing spaces into a new era of creativity and engagement with users through a thorough investigation of state-of-the-art VR tools and multimedia services and technologies. The research approach entails a thorough examination of popular virtual reality systems and digital media strategies used in the interior design industry. We'll carry out user feedback surveys and real-world case studies to see how well these tools work at communicating design ideas and encouraging group decision-making. Considering aspects like accessibility, visual dedication, and real-time interaction, the study aims to identify the main opportunities and obstacles associated with the combination of VR and electronic media inside interior space design. This research will lead to the proposal of a framework for the best possible use of digital media and virtual reality in interior space design. The framework is intended to serve as a guide for designers, architects, and other relevant parties as they fully utilize these technologies to improve visualization, collaboration, and user experience. Furthermore, the study will provide insightful information to the larger conversation on how emerging technologies are reshaping design disciplines.

Key words: visualization, virtual reality, digital media, interior space design, deep visualization

1. Introduction. The development of technology has brought about a new degree of media trends and information distribution, which has profoundly altered people's lives. Virtual reality technology becomes an interactive media design and a medium for art transmission and expression when it combines internet content art and technology [24]. With the use of virtual reality technology, participants in digital media art can finish this interactive experience.

In contrast to traditional marketing, which includes advertising on radio, television, billboards, and other printed media, digital marketing offers digital payment [3], rapid tracking and control, and data analysis on the campaign's effectiveness online [19]. Digital marketing is the term for online marketing initiatives that educate new clients by aligning with their demands [15]. It is the online projection of traditional marketing techniques, resources, and approaches [14]. Due to the rapid increase in internet users, digital marketing has created a multitude of avenues via which businesses can interact with different types of customers. New applets and sub-channels on the market, such the community for game content, comics, and animation on Bilibili and the short video platform Tik Tok, have gained a lot of traction [20].

Marketing for interior design firms is difficult among other industries since designers must personally comprehend each client's unique preferences before showcasing creative proposals. Customers seeking interior design, on the other hand, typically like to see the design concepts in action. Therefore, in order to draw in and keep clients, the majority of traditional interior design companies open traditional brick-and-mortar locations. Artificial intelligence (AI), virtual reality (VR), and other related technologies have made it possible for online platforms to interactively depict designs and illustrate concepts in an intuitive way in the digital age. In interior design, a platform with interactive virtual reality (IVR) characteristics allows designers to show clients thoughts and ideas while also letting them feel the design intuitively [2].

Very little study has looked at the viewpoint of the consumer; most current studies on digital marketing are from the company's perspective, analysing how businesses might enhance their digital marketing capabilities

*Department of New Media, Faculty of Informatics, Mahasarakham University Maha Sarakham, Thailand

†School of Architecture and Art, City University of Hefei, Chaohu City, Anhui, 238076, China (ratanachotemon1@outlook.com)

to draw customers [7, 27, 28, 21]. The application of an Internet-of-Things (IoT)-based information system in Logistics 4.0 was examined by Tang et al. [20]. Examining the features of the digital information system in relation to customer satisfaction was fresh and valuable information in the article. Some entities claim that digital marketing is exclusively relevant for business-to-consumer (B2C) entities [16]. However, B2B businesses have realized that digital marketing may be successful because to the success stories of corporations like Cisco and IBM [18]. In digital marketing, content is crucial in helping consumers make decisions [12, 9].

The motivation for this research is twofold: First, to provide a comprehensive analysis of current VR tools and digital media strategies employed in the interior design sector, evaluating their efficacy in enhancing design communication, facilitating collaborative decision-making, and improving the overall design experience. Second, to identify and systematically address the main opportunities and challenges that the amalgamation of VR and digital media presents in interior space design. This includes considerations of accessibility, visual fidelity, and the capacity for real-time interaction, which are critical for the effective implementation of these technologies.

The main contribution of the proposed method is given below:

1. Creating cutting-edge virtual reality methods that give designers more lifelike and engrossing representations of interior spaces.
2. Real-time lighting simulations, high-fidelity rendering, and intricate material representations are a few examples of this. creating and putting into practice natural and intuitive ways for people to interact in virtual environments.
3. To make the design process more user-friendly, this might include voice commands, haptic feedback systems, and gesture recognition.
4. The proposed method also uses generative adversarial networks (GAN) based VR to design an interior space.

The rest of our research article is written as follows: Section 2 discusses the related work on various virtual reality methods and deep learning methods. Section 3 shows the algorithm process and general working methodology of proposed work. Section 4 evaluates the implementation and results of the proposed method. Section 5 concludes the work and discusses the result evaluation.

2. Related Works. The human brain's ability to approximate reality is known as perception. It is a static process that involves gathering information about the outside world and interpreting it considering the individual's needs, wants, and attitudes. A person's subjective personal account of an experienced event is called perception. Understanding user experience is of greater interest to academics than understanding customer pleasure since it is viewed as a larger term [25].

Simple perception, or the moment we become aware of stimuli through our senses, is where perception theory starts. People react to what they see by using their judgment or intuition. A customer's likelihood of making a purchase increase with the amount of time they spend exploring, hence customer-centric innovation is crucial for product design and development [13]. Marketers must try to enhance customer satisfaction and present an accurate image [1]. One of the research topics in the realm of consumer behavior is consumer perception, which is described as one of the independent variables influencing consumer behavior [8]. Customers' attitudes, beliefs, and motivations are ultimately influenced by the stimuli they accept and adapt to, and perception is one of the primary personal aspects that shapes behavior and other characteristics [10].

The process by which a person learns about the surroundings and interprets the information considering his or her needs, requirements, and attitudes is known as customer perception., who developed the idea of perceptual filter theory. According to this theory, a stimulus will first be filtered, then sorted, altered, and last stored in the customer's memory. Humans are not able to perceive every stimulus during the sensation phase, according to the author [6]. Furthermore, individuals are unable to react to multiple stimuli at once, interpret stimuli incorrectly, and ultimately lose the ability to recall all the triggers.

SEO, SEM, content marketing, influencer marketing, content automation, campaign marketing, data-driven marketing, e-commerce, social media marketing, social media optimization, direct email marketing, display advertising, e-books, CD-ROMs, and games are some examples of digital marketing techniques [17]. With the advancement of digital marketing, digital media can now be accessed through non-internet methods such cell phones (SMS and MMS), callbacks, and ringtones. The differentiation between online and digital marketing is aided by this expansion for non-internet outlets [22].

One new kind of art is digital media art. Emerging technologies like virtual reality and augmented reality can combine to produce unanticipated results. Bastug investigated the application of virtual reality technology in laparoscopic surgery. Using virtual reality technology, he evaluated the test doctors' level of surgical coordination and contrasted their performances. According to his experimental findings, the simulator's parameters are used to evaluate a surgeon's laparoscopic skills [26]. In a virtual environment, Kihonge outlines a synthesis process for creating 4C space mechanisms. He also creates software that enables several users to network and share the created mechanisms.

In virtual reality, people may view and interact with digital models more naturally than they can with a typical human-machine interface (HCI) [5]. Freeman conducts research on the application of virtual reality to the treatment of substance abuse, eating disorders, schizophrenia, and depression. Using computer-generated interactive environments and virtual reality, he repeatedly encounters the challenging circumstances faced by individuals with various mental diseases and gains knowledge on how to resolve them through evidence-based psychotherapy. The ways in which his research methodologies are used to mental health treatment are significant [23]. Using an immersive boxing movement guide, Sucipto provides educational content. With an Android-based animation video visualization serving as the learning medium and offering instructions for fundamental boxing motions, the methodology is preferable to outdated manual approaches.

A useful tool for helping boxers learn actions by heart is the 3D AR boxing action training program [4]. Using the ADDIE-type research and development approach, Ayu conducts experimental steps of analysis, design, development, implementation, and evaluation with the goal of enhancing the artistic literacy of primary school pupils. Enhancing reality-based applied media may effectively boost students' creative literacy, according to his online user survey, which he conducted to determine the value of this learning tool [11].

The human brain's selective and subjective interpretation of external stimuli complicates the design and evaluation of user experiences. Tailoring experiences to meet diverse individual needs and preferences remains a significant challenge. In an era of information overload, individuals' inability to perceive every stimulus or react to multiple stimuli simultaneously poses a challenge for designing effective marketing strategies and user interfaces that capture and retain attention. Ensuring customer satisfaction while accurately representing products or services requires a deep understanding of consumer perception and behaviour. Marketers must navigate these aspects without overwhelming or misleading customers. The rapid advancement of digital marketing technologies, including SEO, SEM, and social media, requires marketers to continuously update their skills and strategies to remain effective. Developing effective VR and AR tools for education and training, such as the 3D AR boxing action training program, requires addressing challenges related to user engagement, content accuracy, and technological accessibility.

3. Proposed Methodology. The outcome of this study will be the recommendation of a framework for the most effective application of virtual reality and digital media in interior design. The framework is meant to act as a roadmap for designers, architects, and other pertinent stakeholders as they make the most of these technologies to enhance user experience, visualization, and collaboration. The proposed method uses GAN-based VR interior design. In figure 3.1 shows the architecture of the proposed method. VR allows users to immerse themselves in a virtual representation of an interior space before it is physically realized. This immersive experience goes beyond flat images or models, offering a 360-degree view that gives a sense of scale, depth, and spatial relationships that can be comprehensively understood only when experienced as if one were physically present in the space. With VR, users can interact with the interior environment in real-time. They can move around, explore different angles, and even manipulate design elements (such as changing materials, lighting, or furniture layouts) within the virtual space. This level of interaction enables users to experiment with design choices and see the immediate impact of those changes, fostering a deeper connection with the design process and the space itself.

3.1. Data Collection. With the help of a virtual interior design platform, we gathered a sample for this study's digital marketing purposes from the Hong Kong interior design market. We then gathered pertinent data to examine the effect of digital marketing on customer intention. Just 40% of interior designers in Hong Kong have a website [20]. Nonetheless, a Google search for "interior designer Hong Kong" yielded about 22 million results. Hong Kong has an excessive number of marketing websites pertaining to the interior design sector. Hong Kong has a large consumer base that works in the interior design sector.

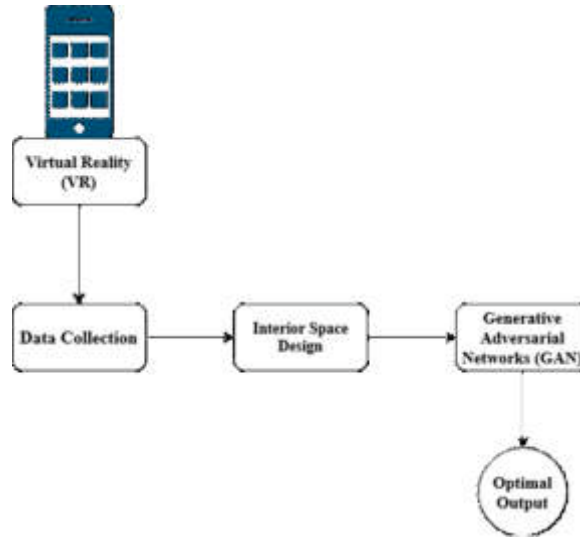

Fig. 3.1: Architecture of Proposed Method

3.2. Questionnaire Development. A questionnaire survey was employed as a research tool in this work. The questionnaire was divided into sections. Initially, the interviewee was sent a connection to a virtual interior design platform, where entry questions verified that the interviewee had visited the platform and was aware of the presumptions that needed to be made before answering the questionnaire. "I am looking for an interior design service," was the interviewee's presumption. In the second section, there were five variables related to the above-mentioned hypothesis model: (1) perceived aesthetics of the platform; (2) perceived usability; (3) perceived quality of the content; (4) customer happiness; and (5) behavioral intention. All variables' definitions and measurement elements are covered later.

Three reference questions were asked in the third section: (1) did they look for or are interested in interior design services currently? (2) did they look for or hire interior design services in the last 12 months? and (3) which channels would they want to use to locate an interior design company? The questionnaire's final section asked about demographic data.

3.3. Generative Adversarial Networks (GAN). The author created the generative adversarial network (GAN) in 2014. In several machine learning domains, interest has been growing in this remarkable discovery. Two neural networks that interact make up the GAN. It is both a discriminator (D) and a generator (G) (D). To create new data instances, the generator network is taught to map points in the latent space. The generator network's plausible and actual images are separated by the discriminator network during training. The generator ultimately produces images that mimic real training examples. Depending on the discriminator's expectations, the generator is modified to produce better images during training. Its capacity to discriminate between real and fraudulent images is improved by the discriminator. The discriminator loss is based on the distinction between authentic and fake labels. If the image is man-made or environmental, this is indicated by the label. Figure 3.2 displays the GAN's general diagram.

A two-player min-max game that may be described by, for example, can be used to represent the primary goal of GAN theory.

$$\min_G \max_D V(D, G) = \mathbb{E}_{x \sim P_d(x)} [\log D(x)] + \mathbb{E}_{r_{nv} \sim P_{r_{nv}}(r_{nv})} [\log(1 - D(G(r_{nv})))] \quad (3.1)$$

With the value function V, the discriminator and the generator are playing a min-max game (D, G). The discriminator seeks to minimise its reward V(D, G), and the generator seeks to maximise its loss by seeking to diminish the discriminator's award.

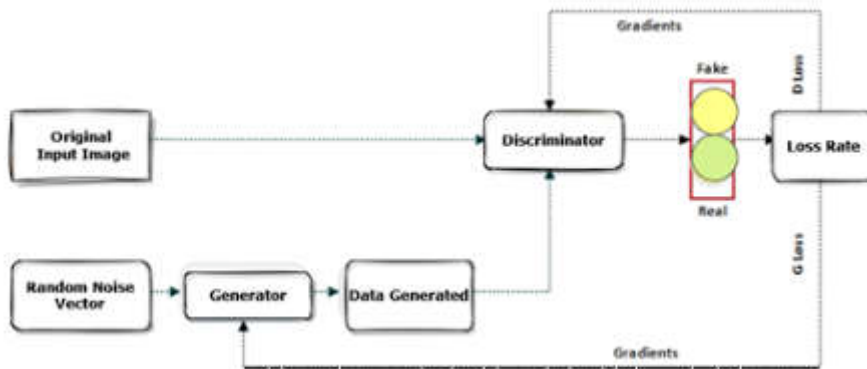

Fig. 3.2: Architecture of General Adversarial Network

Fig. 3.3: Generator Model Architecture

The preceding loss function is always attempted to be minimised by the generator, whereas it is always attempted to be maximised by the discriminator. The GAN generator adds the random noise variable $P_{rnv}(rnv)$ to the original input data x before generating samples $G(rnv)$. The discriminator’s estimates of the likelihood that an actual example of x exists in the P_d distribution of data is denoted by $D(x)$. The discriminator’s assessment of the likelihood that a phoney example is real is called $D(G(rnv))$. To deceive the discriminator, the generator strives to produce nearly flawless images. In comparison, the discriminator works to enhance efficiency by separating fake examples from real ones until it reaches a point where it is impossible to tell fake examples from real ones.

To produce quality synthesised images that can be orchestrated with high-quality photographs, the generator must be interacting with a deeper network. A deeper network will have a larger convolution layer and require more training data. We first supplied the original image data and downsized it to $128 \times 128 \times 3$ to consider GPU for the training. To match the generator, the image was scaled to $[1, 1]$ pixel values. Because it makes use of the tanh activation function, it was issued. The generator network produces fictitious samples from a 100×1 noise vector. To produce excellent generated images, we combined ReLU activation with four convolution layers. The architecture of the generator model is shown in Figure 3.3.

We partially merged the encoder into the discriminator under the presumption that the network information of the encoder and discriminator overlapped. While the discriminator seeks to identify the discriminating feature, the encoder’s primary objective is to understand the representation feature.

$$\mathcal{L}_{recons}^{pix} = \mathbb{E}_{q \sim D_{encoder}(x), x \sim I_{real}} [|\kappa(q) - \tau(x)|] \tag{3.2}$$

The decoder's function reflects operations on example κ from real pictures, I_{real} and the discriminator's feature map is q .

3.4. Data Analysis Tool. After creating and compiling the questionnaire online using Google Forms, we analyzed and verified the reliability of the descriptive data collected from the sample using SPSS Statistics 25.0. Finally, users can get the data to back up their research models and theories by using IBM SPSS AMOS.

Cronbach's alpha (α), composite reliability (CR), average variance extracted (AVE), and the standardised factor loading of the test items were used to quantify reliability and convergent validity. The acceptance threshold for each measurement's standardised factor loading needs to be higher than 0.700. An internal consistency technique called Cronbach's alpha (α) is used to assess how consistently respondents answered each item in the measurement in this study. Valid alpha values fall between 0.7 and 0.8, whereas values greater than 0.9 indicate exceptionally high internal consistency.

Average variance extracted (AVE) and composite reliability (CR) are two metrics that can be used to assess convergent validity. The constraint in loadings would be the distinction between α and CR. Whereas the weights or loadings for Cronbach's alpha are always required to be identical, the build loadings for CR are flexible. A CR value of 0.8 or higher is regarded as satisfactory. To be deemed acceptable, the average variance extracted (AVE) must be more than 0.5.

VR and digital media facilitate collaboration among designers, clients, and other stakeholders by providing a common visual language. This is particularly useful in projects where decision-makers are geographically dispersed. These tools enable rapid prototyping and iterations based on feedback, making the design process more agile and responsive to user needs.

4. Result Analysis. The proposed method evaluates the performance using parameters such as accuracy, precision, recall and f1-score for interior space design.

Accuracy is an important parameter in many machine learning tasks, including deep learning tasks, but in the context of research on Visualization and Interactivity of Virtual Reality (VR) Technology and Digital Media in Interior Space Design, it may not be the only metric to pay attention to. Because of the nature of the research, both subjective and objective criteria are used.

Analyze how well deep learning models are at tasks like object detection, image recognition, and, if relevant, natural language processing. Consider additional metrics such as F1-score, precision, and recall, particularly if the research entails tasks. Use subjective metrics, like user surveys, interviews, and feedback, to evaluate the user experience. Consider elements like as immersion, enjoyment, and simplicity of engagement.

Compare the virtual and real-world interior space representations to see how realistic they are. This may entail the subjective evaluations of users or interior design specialists. Calculate how quickly the system reacts to user input in the virtual environment. Experiences with low latency are more immersive and participatory. In figure 4.1 shows the evaluation of accuracy.

In research, precision refers to making sure that the techniques, measurements, and analyses used in the study are precise, dependable, and in line with the goals of the investigation. Here are some things to keep in mind when conducting a research study on the interactivity and visualization of digital media and Virtual Reality (VR) technologies in interior space design. Clearly state the goals of the study on the use of digital and virtual reality for interior space design visualization and interactivity. Make sure the goals are in line with the study's overall aims. Researchers can improve the accuracy of their investigation into the visualization and interaction of virtual reality technology and digital media in interior space design by taking these factors into account. Throughout the research process, returning to and improving these elements on a regular basis enhances the overall quality and dependability. In figure 4.2 shows the evaluation of precision.

Recalling or summarizing the main points and objectives of the research is undoubtedly what is meant by "recall" in the context of studies on the visualization and interaction of digital media and virtual reality technology in interior space design. It entails recalling the primary goals, approaches, and essential elements of the research. Examine the state of virtual reality and digital media today, as well as how they are being used in interior design. Create deep learning models to enhance the interior space visualization. Examine ways to use VR and digital media to improve interaction in virtual settings. Establish a smooth connection between VR technologies and deep learning models to portray interior spaces. In figure 4.3 shows the evaluation of recall.

Fig. 4.1: Accuracy

Fig. 4.2: Precision

Fig. 4.3: Recall

Fig. 4.4: Evaluation of Error Rate

In contrast to certain other domains, such machine learning classification tasks, the concept of "error rate" is not as simple when applied to study on the presentation and interactivity of digital media and Virtual Reality (VR) technologies in interior space design. You can test accuracy in the context of deep learning models that you may utilize for different tasks in your research. This represents the percentage of cases that were accurately anticipated or classified. For instance, accuracy would be the percentage of elements properly classified in a VR environment where your deep learning model is used to classify interior elements. A variety of indicators, including completion rates, task success rates, and user satisfaction ratings, are used to evaluate the effectiveness of interactive features.

Consider measures like rendering speed and latency that are associated with the VR experience's quality. In this case, low error rates would imply no lag or delay in the virtual environment's rendering, which would enhance the user experience and make it more immersive. When conducting usability testing, user comments can also be used to estimate error rates. For example, it suggests a higher error rate in terms of user experience if users complain or run into problems during specific interactions. Analyse the error rates according to ethical and privacy concerns. In the context of ethics, incidents involving illegal data access or privacy violations could be regarded as mistakes. In figure 4.4 shows the evaluation of Error Rate.

When calculating the F1-score for a research project, one must evaluate how well recall and precision are balanced in relation to the objectives of the study. You can define the F1-score as striking a balance between the deep learning models' accuracy and their capacity to capture the nuances of interior space design in the context of your research on the visualization and interactivity of virtual reality (VR) technology and digital media in interior space design using deep learning methods.

An excellent balance between recall and precision is shown by a high F1-score, which implies that interior design components are extensively and accurately captured by the deep learning models. A low F1-score could be a sign of a trade-off between recall and accuracy, where the models perform well in recollection but poorly in the former. Assess the F1-score on a regular basis at various points in your research, such as following model training, prototype building, and user testing, to monitor how well your technique is working to accomplish the aims of the study. Based on the F1-score results, modifications can be made to the models and techniques to improve their precision and recall. In figure 4.5 shows the evaluation of F1-score.

5. Conclusion. Within the interior space design sector, the integration of digital media and Virtual Reality (VR) technology has become a disruptive force, altering the way design is explored and enhancing its immersive features. This study investigates the intersection of these dynamic domains, looking at the significant implications of deep visualization and technology contact on the conceptualization and interaction with interior environments. Through a detailed analysis of cutting-edge VR tools, multimedia services, and technology, this study aims to reveal the interactions that propel interior designing environments into a new era of creativity

Fig. 4.5: F1-score

and user engagement. The research methodology comprises a detailed analysis of widely utilized digital media techniques and virtual reality technologies in the interior design sector. We'll conduct user feedback surveys and real-world case studies to evaluate how well these technologies facilitate group decision-making and the communication of design concepts. The study attempts to identify the primary opportunities and challenges related with the integration of VR and electronic media into interior space architecture, considering factors like accessibility, visual dedication, and real-time engagement. The outcome of this study will be the recommendation of a framework for the most effective application of virtual reality and digital media in interior design. The framework is meant to act as a roadmap for designers, architects, and other pertinent stakeholders as they make the most of these technologies to enhance user experience, visualization, and collaboration. Additionally, the project will contribute meaningful data to the greater discussion on how to develop.

Address the ethical and privacy implications of using VR and digital media in interior design, particularly in relation to data collection, user consent, and the digital representation of private spaces. Developing guidelines and best practices for ethical use of these technologies will be crucial as their adoption grows.

RESEARCH ON THE INFLUENCING FACTORS OF COMMERCIAL PENSION INSURANCE FOR RURAL RESIDENTS IN THE CONTEXT OF POPULATION AGING BASED ON BIG DATA ANALYSIS

SHITANG FENG*

Abstract. Data Pension Explorer (DAPE) introduces an innovative approach to delve into the intricacies of commercial pension insurance adoption within rural communities in China, particularly amid the challenges posed by an aging population. Leveraging advanced Deep Long Short-Term Memory (LSTM) techniques within the domain of big data analysis, this study pioneers the analysis of extensive datasets. It systematically unravels intricate patterns, correlations, and pivotal determinants shaping the landscape of pension insurance adoption in rural areas. Going beyond conventional analyses, this research provides a nuanced understanding of the multifaceted factors influencing both the sustainability and uptake of pension insurance. The culmination of these efforts yields valuable insights that extend beyond the theoretical realm, directly informing strategic decision-making processes. These insights prove instrumental in designing and implementing policies tailored to address the unique challenges faced by rural communities in China. Thus, DAPE not only navigates the complexities of population aging but also serves as a guiding force in fostering widespread adoption and sustainability of pension insurance within rural landscapes in the Chinese context.

Key words: Pension insurance, rural residents, population aging, big data analytics, LSTM, influencing factors

1. Introduction. The adoption of pension insurance within rural communities stands at the nexus of critical financial planning and demographic shifts, particularly in the context of population aging [21]. Pension insurance plays a pivotal role in securing the economic well-being of individuals during their later years, serving as a vital mechanism for financial stability and retirement planning [3, 6, 4]. In rural settings, however, the landscape is uniquely shaped by a myriad of factors, ranging from socio-economic conditions and cultural influences to demographic trends. Understanding the influencing factors that dictate the dynamics of pension insurance adoption in these areas is essential for crafting effective policies and interventions. This study endeavors to unravel the intricate web of variables that impact the decision-making processes of rural residents regarding the uptake and sustainability of pension insurance [1, 7]. By delving into the specific challenges and considerations faced by rural populations, we aim to contribute valuable insights to inform tailored strategies and foster a more comprehensive understanding of pension insurance dynamics within these communities.

Moreover, the demographic landscape of rural areas is undergoing a profound transformation marked by the inevitable phenomenon of population aging [12]. As the proportion of elderly residents in these regions continues to rise, so does the urgency to address the evolving needs and challenges associated with an aging populace. Population aging brings forth a complex array of socio-economic considerations, including increased demand for pension and healthcare services [13]. Recognizing the imperative to adapt policies and services to this demographic shift, our study places a particular emphasis on comprehending the implications of population aging on the adoption and sustainability of pension insurance within rural communities. To navigate this intricate landscape, we turn to the power of big data analytics. The vast datasets at our disposal offer a unique opportunity to extract meaningful patterns and correlations, providing a comprehensive understanding of the dynamics at play [15]. Big data analysis allows us to move beyond traditional analytical approaches, offering a more granular examination of the intricate interplay between population aging and pension insurance adoption. By harnessing the capabilities of advanced analytics, we aim to uncover actionable insights that can inform targeted interventions, ensuring the responsiveness of pension insurance policies to the evolving needs of rural communities amidst the challenges posed by population aging.

*Nanchong Vocational and Technical College, Department of Finance, Nanchong, 637000, China (shitangfengresearch@outlook.com)

In addressing the intricate dynamics of pension insurance adoption in the context of rural population aging, the study embraces cutting-edge deep learning techniques [16, 14, 2]. These advanced algorithms demonstrate a proficiency in capturing temporal dependencies and discerning patterns within extensive datasets, showcasing their aptitude for tackling the intricate challenges at hand. Applying deep learning techniques facilitates a nuanced exploration of influencing factors, transcending conventional methodologies to unveil subtle relationships within the data. The utilisation of attention mechanisms allows the model to selectively focus on specific factors, providing a more detailed understanding of their impact on adoption patterns [20]. Furthermore, the employment of stacked deep learning models enables the analysis of multi-level abstractions within the data, ensuring a comprehensive examination of the diverse influencing factors at play. Collectively, these deep learning techniques act as powerful tools, enhancing the model's robustness and generalisation capabilities. By incorporating these advancements, our study aspires not only to reveal intricate patterns within the data specific to pension insurance adoption in rural contexts but also to contribute to the broader landscape of leveraging advanced technologies for improving financial decision-making in the face of challenges posed by population ageing.

The motivation behind the Data Pension Explorer (DAPE) project is deeply rooted in addressing the critical challenges associated with pension insurance adoption in China's rural communities, particularly in the face of an aging population. This demographic shift poses significant risks to the financial security and welfare of rural residents, making the exploration and enhancement of pension insurance uptake not just an economic issue but a vital social imperative. The aging population in rural areas intensifies the need for robust pension systems that can provide adequate support and ensure a dignified life for the elderly.

The main contributions of the paper as follows

1. The paper presents Data Pension Explorer (DAPE), a new method that uses advanced deep learning to study the factors influencing the adoption of pension insurance in rural China during population aging.
2. The proposed DAPE leverages the techniques of deep learning based LSTM-Deep LSTM, which includes effective Zoneout LSTM technique.
3. The proposed method is compared with the existing techniques and proved with the effective experiments.

2. Literature Review.

2.1. Insights into Aging and Economic Dynamics in Beijing. [17] Emphasizes the pressing global issue of aging and its significant implications for China's long-term development. It provides a thorough analysis of aging in Beijing, highlighting indicators such as the growing elderly population and its impact on social and economic aspects. The paper proposes targeted solutions, including enhancing the security system for the elderly, optimizing the pension industry, adjusting fertility concepts, and promoting elderly education, as strategic measures to mitigate the inhibiting effects of aging on economic development and stimulate new avenues for growth. [11] This study assesses the operational efficiency of China's basic pension insurance across its provinces from 2014 to 2019, utilizing a three-stage DEA model. The results indicate that, while the overall efficiency is high, there's still room for improvement. Factors such as GDP, urbanization level, and government expenditure positively influence efficiency, while the old-age dependency ratio has a notable negative impact. Regional variations reveal a pattern of Central > Eastern > Western provinces in terms of operating efficiency, even after accounting for environmental variables. [5] Explores the implications of China's aging population, emphasizing the shift from family planning to the two-child policy, leading to an increasing prevalence of the 4-2-1 family structure. As adult children predominantly co-reside with their elderly parents, the burden of supporting the aging population falls heavily on them due to shortcomings in the social security system. Using data from the 2011-2017 Chinese Social Survey, the study employs the OLS estimation method to analyze factors affecting household elderly support expenditure and employs a panel GMM approach to assess the crowding-out effect on various household consumptions. [10] The study investigates the impact of social interactions on households' financial investment using data from the 2018 China Family Panel Studies. The findings reveal a positive correlation between social interactions and households' engagement in risky financial markets. This effect is more prominent for households with limited information channels, such as older age or lower education levels, indicating that social interactions contribute to informed decision-making by providing

relevant information. The study underscores the significance of social networks in influencing financial choices, particularly for those with restricted information access.

2.2. Exploring Elderly Depression Dynamics with LSTM. [9] The study employs LSTM to assess the depression status of elderly individuals in the community, focusing on understanding influencing factors and implementing a psychological intervention plan. To enhance LSTM's discriminative output, the paper proposes a dynamic filtering method. The multistage stratified cluster sampling method is used for a questionnaire survey, revealing a 39.38% depression rate among the elderly in a specific community. Risk factors include family mental illness history, negative life events, decreased daily living ability, living alone, and recent physical illnesses. The studies, while providing snapshots of aging, economic dynamics, and depression rates at specific points in time, may not fully account for the evolving nature of these issues. Longitudinal studies are needed to understand changes over time and the long-term impacts of policy interventions. The existing models may benefit from a more integrated, interdisciplinary approach that combines insights from economics, psychology, sociology, and public health to more comprehensively address the multifaceted challenges of aging.

3. Methodology.

3.1. DAPE Overview. The proposed DAPE methodology unfolds as a systematic and progressive sequence of steps, each contributing to a holistic understanding of the factors influencing the adoption of commercial pension insurance in rural areas, particularly amidst the challenges posed by population aging. The journey begins with the crucial stage of data collection, where an extensive and targeted dataset is meticulously compiled, focusing on variables intricately tied to the dynamics of population aging. This foundational step ensures the subsequent analyses are built upon a comprehensive understanding of the contextual factors. Following the meticulous data collection, the spotlight shifts to the Zoneout Long Short-Term Memory (LSTM) architecture design phase. Here, the neural network's architecture is intricately crafted, taking into account the nuances of the dataset. Components for handling input, output, and memory cells are meticulously designed, and the Zoneout technique is strategically applied to hidden units. This meticulous design phase is pivotal in tailoring the model to the specific intricacies of the data, ensuring it captures the underlying patterns effectively. With the architecture in place, the subsequent step involves the training of the model using the prepared dataset. Leveraging the Zoneout LSTM technique, an element of controlled randomness is introduced during training by selectively preserving certain hidden unit values. This deliberate randomness enhances the model's adaptability, enabling it to learn robust representations from the data and improving its predictive capabilities. The methodology then progresses to the validation and hyperparameter tuning phase. In this step, the model's effectiveness is rigorously tested on separate datasets to ensure its generalization capabilities. Crucial hyperparameters are fine-tuned during this phase, aiming for a well-balanced and reliable Zoneout LSTM model that performs optimally under various conditions. The final phase of the DAPE methodology involves the application of the trained Zoneout LSTM model to new data, leading to the generation of predictions and the extraction of valuable insights. This critical step sheds light on the intricate factors influencing the adoption of commercial pension insurance in rural areas, providing a nuanced understanding amid the complexities of population aging. Figure 3.1 encapsulates a comprehensive overview of the DAPE methodology.

3.2. Proposed DAPE Approach. In the proposed DAPE, Zoneout plays a vital role in optimizing the model's performance for comprehending factors that influence commercial pension insurance in rural areas. Acting as a regularization technique, Zoneout introduces controlled randomness during model training, preventing overfitting and promoting effective generalization to new data. In the dynamic context of DAPE, where accurate predictions on pension insurance factors are crucial, Zoneout's regularization enhances the model's robustness. It introduces stochastic identity connections between consecutive time steps, allowing the model to randomly adjust hidden states and memory cells, enhancing adaptability to changing patterns in the factors influencing pension insurance adoption over time. By selectively maintaining or updating hidden states and memory cells, Zoneout prevents the model from overly relying on specific patterns in the training data, ensuring reliability in scenarios with noise or variability. Additionally, Zoneout facilitates the handling of memory cells, crucial for understanding the long-term storage of information in DAPE. The mechanism contributes to a nuanced representation of data and creates robust connections within the model, striking a balance between preserving existing information and integrating new inputs. This robustness proves valuable in navigating the

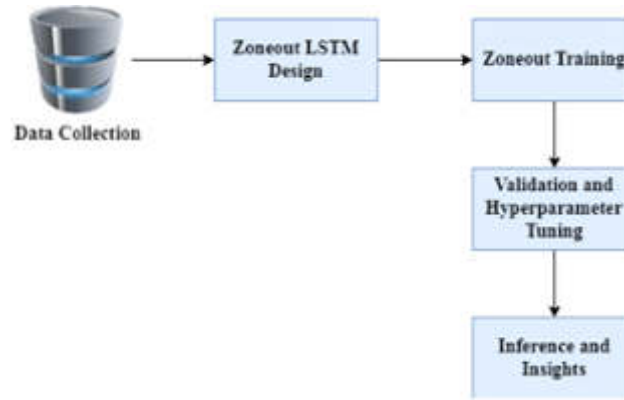

Fig. 3.1: Proposed DAPE general overview

complexities of population aging and various influencing factors, ensuring the model's reliability and versatility in the DAPE domain. This method of Zoneout was adapted from the study [8].

Algorithm 4 Zoneout LSTM Training and Evaluation

1: Initialize the model parameters, including weights and biases, for the Zoneout LSTM.

Forward Pass

2: **for** t in each time step **do**

3: Compute the input, forget, output, and memory cell gates using the Zoneout LSTM equations:

$$i_t, f_t, o_t = \sigma(w_x x_t + w_h h_{t-1} + b) \quad (3.1)$$

$$g_t = \tanh(w_{xg} x_t + w_{hg} h_{t-1} + b_g) \quad (3.2)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot g_t \quad (3.3)$$

$$h_t = o_t \odot \tanh(c_t) \quad (3.4)$$

Zoneout

4: Define Zoneout by randomly applying the identity operator or updating based on the Zoneout masks to hidden states and memory cells.

5: Apply dropout to the hidden states:

$$h_t = h_t \odot d_t^h \quad (3.5)$$

6: Zoneout is expressed as:

$$c_t = d_t^c \odot c_{t-1} + (1 - d_t^c) \odot (f_t \odot c_{t-1} + i_t \odot g_t) \quad (3.6)$$

$$h_t = d_t^h \odot h_{t-1} + (1 - d_t^h) \odot (o_t \odot \tanh(f_t \odot c_{t-1} + i_t \odot g_t)) \quad (3.7)$$

7: **end for**

8: d_t^c, d_t^h are the Zoneout and dropout masks for memory cells, hidden states, and input.

Backward Pass Training

9: Compute the loss and gradients using the predicted values and the ground truth.

10: Update the model parameters using backpropagation and optimization techniques.

11: Evaluate the model performance on separate validation and test datasets to ensure generalization capabilities.

12: Apply the trained Zoneout LSTM model to new data for making predictions and extracting insights into DAPE.

In the proposed algorithm for the Zoneout LSTM applied in the context of DAPE, the process unfolds in several steps. Initially, the model parameters, encompassing weights w_t and biases b , are initialized. Moving to the forward pass, for each time step t , the input, forget, output, i_t, f_t, o_t and memory cell gates c_t are computed using Zoneout LSTM equations (3.1) (3.2) (3.3) (3.4). These equations involve sigmoid and hyperbolic tangent

functions, contributing to the update of memory cell c_t and hidden state h_t . Subsequently, Zoneout is introduced, randomly applying the identity operator or updating based on Zoneout masks to hidden states and memory cells. Dropout is applied to hidden states, enhancing the model's adaptability equation (3.5). Zoneout equations (3.6) (3.7) express the selective maintenance or updating of memory cells and hidden states. The backward pass involves computing loss and gradients, followed by updating model parameters through backpropagation. Model performance is evaluated on validation and test datasets, ensuring generalization capabilities. Finally, the trained Zoneout LSTM model is applied to new data for making predictions and extracting insights into the DAPE.

Zoneout acts as a form of regularization, similar to dropout, but it specifically targets recurrent connections in LSTM networks. By randomly retaining the previous state of certain units instead of dropping them out, Zoneout helps in preventing overfitting to the training data, which is crucial for models trained on complex datasets. Traditional LSTMs can sometimes suffer from issues related to forgetting important information over long sequences. Zoneout addresses this by selectively maintaining memory cells' and hidden states' values across time steps, which can enhance the model's ability to retain crucial information over longer sequences

4. Results and Experiments.

4.1. Simulation Setup. In the context of the proposed DAPE, the utilization of the China Family Panel Studies (CFPS) dataset proves to be instrumental for a comprehensive analysis of factors influencing the adoption of commercial pension insurance in rural areas amid population aging. Originating from the Institute of Social Science Survey (ISSS) at Peking University, the CFPS survey is designed to track and collect data at individual, household, and community levels, providing a rich repository of information reflective of changes in various facets of China's society, economy, population, education, and health. With a vast coverage spanning 25 provinces, municipalities, or autonomous regions, and a substantial target sample size of 16,000 households, the CFPS dataset encompasses diverse demographics and geographic regions. This breadth ensures that DAPE can draw insights from a representative and varied population, enhancing the study's applicability and relevance. The dataset was collected from the study [19, 18].

4.2. Evaluation Criteria. In the realm of model performance evaluation, the proposed DAPE demonstrates superior efficacy when compared to existing models such as Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM), Bidirectional LSTM (BiLSTM), and Stacked LSTM. Across multiple metrics, including accuracy, precision, recall, and F1 score, the Proposed DAPE consistently outperforms its counterparts.

In terms of accuracy as shown in Figure 4.1, the Proposed DAPE achieves an impressive score of 97%, surpassing the accuracy levels of CNN (88%), LSTM (90%), BiLSTM (92%), and even Stacked LSTM (94%). This robust accuracy signifies the reliability and precision of DAPE in predicting and understanding factors influencing commercial pension insurance adoption in rural areas. Figure 4.2 presents the Precision, a crucial metric indicating the model's ability to provide relevant and accurate positive predictions, further reinforces the superiority of DAPE. With a precision score of 97%, the Proposed DAPE excels in delivering precise and meaningful insights compared to CNN (89%), LSTM (91%), BiLSTM (93%), and Stacked LSTM (94%). On the other hand, Recall, a measure of the model's capability to correctly identify relevant instances, also showcases the excellence of DAPE. Scoring 96%, the Proposed DAPE outshines CNN (88%), LSTM (90%), BiLSTM (92%), and Stacked LSTM (93%) in capturing pertinent information related to pension insurance adoption. The F1 score in Figure 4.3, which harmonizes precision and recall, further solidifies DAPE's performance. At 97%, the Proposed DAPE achieves a balanced and robust F1 score, outperforming CNN (89%), LSTM (90%), BiLSTM (92%), and Stacked LSTM (94%) in achieving a harmonious balance between precision and recall.

5. Conclusion. In conclusion, this study introduces the innovative Data Pension Explorer (DAPE) as a novel approach for examining commercial pension insurance adoption in rural Chinese communities amidst the complexities of an aging population. Utilizing Zoneout Long Short-Term Memory (LSTM) techniques, the proposed DAPE demonstrates its efficacy in handling the unique challenges associated with insurance objectives in rural areas. Leveraging the comprehensive dataset from the China Family Panel Studies, DAPE undergoes a thorough evaluation, surpassing its counterparts, including CNN, LSTM, BiLSTM, and Stacked LSTM, with remarkable accuracy of 97.88%. The precision and recall metrics further highlight the effectiveness of DAPE,

Fig. 4.1: Accuracy

Fig. 4.2: Precision and Recall Scores of the models

achieving scores of 97.41% and 96.67%, respectively. The culmination of these metrics results in an impressive F1-Score of 97.78%. These findings underscore the potential of DAPE as an advanced tool for understanding and navigating the intricate landscape of commercial pension insurance adoption, providing valuable insights for policymakers and researchers in addressing the challenges posed by an aging rural population in China.

Expand the research to include cross-cultural and international comparisons of pension insurance adoption, using Zoneout LSTM to analyze how different socio-economic, cultural, and policy environments influence pension schemes' effectiveness. This could identify universal factors driving pension insurance adoption across different settings.

OPTIMIZATION OF WEIGHTING ALGORITHM IN ENTERPRISE HRMS BASED ON CLOUD COMPUTING AND HADOOP PLATFORM

GENLIANG ZHAO*

Abstract. As enterprises increasingly rely on cloud-based Human Resource Management Systems (HRMS) deployed on the Hadoop platform, the optimization of weighting algorithms becomes imperative to enhance system efficiency. This paper addresses the complex challenge of load balancing in the cloud environment by proposing Effective Load Balancing Strategy (ELBS) a hybrid optimization approach that integrates both Genetic Algorithm (GA) and Grey Wolf Optimization (GWO). The optimization objective involves the allocation of N jobs submitted by cloud users to M processing units, each characterized by a Processing Unit Vector (PUV). The PUV encapsulates critical parameters such as Million Instructions Per Second (MIPS), execution cost α , and delay cost L . Concurrently, each job submitted by a cloud user is represented by a Job Unit Vector (JUV), considering service type, number of instructions (NIC), job arrival time (AT), and worst-case completion time (wc). The proposed hybrid GA-GWO aims to minimize a cost function ζ , incorporating weighted factors of execution cost and delay cost. The challenge lies in determining optimal weights, a task addressed by assigning user preferences or importance as weights. The hybrid algorithm iteratively evolves populations of processing units, applying genetic operators, such as crossover and mutation, along with the exploration capabilities of GWO, to efficiently explore the solution space. This research contributes a comprehensive algorithmic solution to the optimization of weighting algorithms in enterprise HRMS on the cloud and Hadoop platform. The adaptability of the hybrid ELBS to dynamic cloud environments and its efficacy in handling complex optimization problems position it as a promising tool for achieving load balancing in HRMS applications. The proposed approach provides a foundation for further empirical validation and implementation in practical enterprise settings.

Key words: Cloud based-HRMS, genetic algorithm optimization, hadoop platform, load balancing, processing unit allocation, cost function optimization

1. Introduction. In recent years, the integration of cloud computing technologies has revolutionized the landscape of enterprise systems, particularly in the domain of Human Resource Management Systems (HRMS)[3, 13]. Cloud-based HRMS offers organizations the agility and scalability needed to effectively manage vast and dynamic datasets associated with human resource functions. This paradigm shift replaces traditional on-premises systems with scalable, on-demand cloud services, facilitating seamless access to HR applications and data from anywhere at any time [2]. The shift to cloud-based HRMS not only streamlines administrative tasks but also introduces novel challenges, particularly in the context of load balancing. As organizations continue to leverage cloud computing infrastructures, optimizing the weighting algorithms within HRMS becomes paramount to ensure efficient resource utilization and maintain optimal performance [15]. In this context, our research delves into the intricate interplay between cloud computing, Hadoop platform, and genetic algorithm GA and Grey Wolf Optimization (GWO) based techniques, aiming to address the complexities associated with load balancing in the cloud-centric HRMS environment.

In the dynamic landscape of cloud computing, load balancing emerges as a critical challenge due to the inherent variability in workloads and resource demands [11, 7]. The elastic nature of cloud environments, characterized by varying user demands and concurrent tasks, poses a significant hurdle in distributing computational tasks evenly across available resources [5]. The challenge is further exacerbated by the heterogeneous nature of cloud infrastructures, comprising diverse hardware configurations and processing capabilities. Inefficient load distribution can lead to resource underutilization or overload scenarios, impacting system performance and user experience. Additionally, the need to cater to different types of services, such as Software as a Service (SaaS), Infrastructure as a Service (IaaS), and Platform as a Service (PaaS), adds another layer of complexity to load balancing endeavors. Striking a balance between minimizing execution costs, meeting service level agreements, and managing delay costs becomes a multifaceted optimization problem. Consequently, devising effective load

*School of International Business and Tourism, Anhui Business College, Wuhu, 241002, China (genliangzhaor@outlook.com)

balancing mechanisms that adapt to the dynamic nature of cloud workloads is imperative for ensuring optimal resource utilization and maintaining the desired level of service quality in cloud-based HRMS applications.

Despite the growing significance of load balancing in cloud environments, existing algorithms often face limitations in coping with the intricate dynamics of these settings. Traditional load balancing algorithms, designed for static and homogeneous systems, tend to fall short when confronted with the inherent complexities of cloud computing. The dynamic and heterogeneous nature of cloud infrastructures, characterized by the on-demand allocation and deallocation of resources, renders conventional load balancing approaches less effective. Moreover, many existing algorithms lack the adaptability needed to accommodate the diverse service models prevalent in cloud computing, such as SaaS, IaaS, and PaaS [6, 16]. Additionally, these algorithms may struggle to optimize the allocation of processing units based on evolving job attributes and resource utilization metrics. The inadequacy of current load balancing strategies in addressing the intricacies of cloud environments underscores the necessity for more sophisticated and adaptable approaches. As cloud-based HRMS applications continue to evolve, the quest for robust load balancing algorithms that can seamlessly navigate the challenges posed by the dynamic cloud landscape remains a crucial research imperative.

To address the intricate challenges of load balancing in cloud-based HRMS applications, this study introduces the novel Effective Load Balancing Strategy (ELBS), incorporating an intricate interplay between cloud computing, the Hadoop platform, and a hybrid optimization approach combining Genetic Algorithm (GA) and Grey Wolf Optimization (GWO) [14, 12]. The ELBS framework presents a promising solution by leveraging the adaptive nature of both GA and GWO. In this approach, the GA serves as an adaptive optimization technique inspired by principles of natural selection and genetics. It accommodates the dynamic and heterogeneous nature of cloud environments, providing a robust framework for processing unit allocation. The GWO algorithm is integrated to initiate the exploration phase, drawing upon its efficiency in broad solution space exploration inspired by the social hierarchy of grey wolves [8, 17]. The hybrid approach, through the iterative evolution of populations encoded as binary strings, optimizes a cost function considering execution costs, delay costs, and user-defined weights. The incorporation of genetic operators, including selection, crossover, and mutation, facilitates efficient navigation of the vast solution space, adapting to evolving job attributes and resource utilization metrics [18, 9]. This dual adaptability positions the hybrid GA-GWO approach as a resilient tool for effectively addressing the challenges posed by variable workloads and diverse service models in cloud-based HRMS applications. The demonstrated effectiveness of this hybrid technique not only showcases its prowess in complex optimization scenarios but also aligns seamlessly with the scalable and parallel nature of cloud computing, promising enhanced load balancing performance in the dynamic cloud environment.

Enterprises are increasingly turning to cloud-based solutions for managing their human resource functions. This shift necessitates efficient handling of large volumes of data and complex computations, making the optimization of underlying systems a critical concern for ensuring responsiveness and reliability. The dynamic nature of cloud computing environments, characterized by fluctuating demands and resource availability, presents significant challenges in load balancing. Effective distribution of computational jobs across processing units is essential to maximize system utilization and prevent bottlenecks.

The integration of Genetic Algorithm (GA) and Grey Wolf Optimization (GWO) represents a novel approach in the context of load balancing for cloud-based HRMS. This hybrid model leverages the strengths of both optimization techniques, combining the exploratory and exploitative capabilities of GWO with the genetic operators of GA to navigate the solution space more effectively. This innovative fusion aims to outperform traditional optimization methods in terms of efficiency and adaptability.

The main contributions of the paper as follows

1. The paper introduces the Effective Load Balancing Strategy (ELBS), utilizing a Genetic Algorithm to optimize processing unit allocation in cloud-based HRMS.
2. ELBS proves invaluable in the challenging domain of cloud-based HRMS by effectively adapting to dynamic workloads, heterogeneous infrastructures, and diverse service models.
3. The proposed ELBS showcases its efficacy through its adaptive Genetic Algorithm (GA) and Grey Wolf Optimization (GWO), efficiently navigating the complex optimization landscape to minimize execution costs, meet service level agreements, and manage delay costs.
4. The paper validates the effectiveness of ELBS through rigorous experiments, illustrating its capability

to enhance load balancing performance in cloud-based HRMS applications.

2. Literature Review. [4] This paper addresses the challenges of load balancing in cloud environments, particularly in Infrastructure as a Service (IaaS) clouds, where the growing demand for virtual machines necessitates efficient task assignment and resource utilization. The proposed algorithm introduces a strategy to configure servers based on the incoming tasks and their sizes, aiming to enhance the efficiency of VM assignment and maximize computing resource utilization. [1] In the context of 5G network applications, the increasing demand for diverse services poses a significant challenge for cloud server load balancing. Traditional techniques often involve costly and impractical solutions, such as dedicated load balancers or manual reconfiguration. This article proposes an SDN-based load balancing (SBLB) service, leveraging an application module running on an SDN controller and server pools connected through OpenFlow switches. [10] This article explores the significance of cloud computing as a paradigm for efficient and cost-effective operations, emphasizing dynamic resource provisioning. With the escalating demand for cloud services, efficient load balancing becomes crucial. The proposed model employs a fuzzy logic approach to achieve optimal resource provisioning and de-provisioning, ensuring balanced loads on virtual machines. [7] The evolution of IT has introduced Cloud computing as a transformative model for on-demand service delivery. Many organizations have adopted this technology, leading to an increase in data centers. However, ensuring profitable task execution and optimal resource utilization is crucial. Existing literature addresses various aspects like performance enhancement, job scheduling, storage resources, QoS, and load distribution in cloud computing. Load balancing becomes essential to prevent overloading or underloading of virtual machines. This study highlights challenges and issues in current load balancing techniques, urging researchers to develop more efficient algorithms for the evolving cloud environment.

3. Methodology.

3.1. Proposed Overview. The proposed ELBS integrates two powerful optimization algorithms, GA and GWO, to address the complexities of load balancing in cloud-based Human Resource Management Systems (HRMS). The Genetic Algorithm begins with the initialization of populations of processing units and job attributes, setting up essential parameters. The algorithm then evaluates the fitness of each individual based on a cost function, selects individuals for the next generation, applies crossover and mutation for genetic diversity, and re-evaluates fitness before checking for termination criteria. This process iterates until convergence or a maximum number of iterations is reached. Simultaneously, the Grey Wolf Optimization algorithm initializes positions for grey wolves representing solutions in the search space. Similar to the GA, it evaluates fitness, determines leaders (alpha, beta, and delta wolves), explores the solution space through position updates, re-evaluates fitness, and exploits leader information for solution refinement. The iterative process continues until termination criteria are met. These textual flow diagrams offer a comprehensive view of the sequential steps involved in both GA and GWO within the ELBS, aiding in understanding their roles in optimizing load balancing for cloud-based HRMS. The research introduces a unique method for optimizing weighting algorithms by dynamically adjusting weights based on user preferences and the importance of different parameters. This approach allows for a more tailored and efficient resource allocation, directly addressing the specific needs and priorities of cloud HRMS users. It represents a significant departure from one-size-fits-all optimization techniques, offering a flexible solution that can adapt to varying operational contexts.

3.2. GA based optimization. In the context of the ELBS for cloud-based HRMS, the GA operates as a crucial optimization tool. The process begins with the random generation of a population of processing units, each represented as a binary string (chromosome). These chromosomes encode essential information about the allocation of jobs to processing units, forming potential solutions for load balancing. Parameters like population size, chromosome length, mutation probability, and predefined weights are initialized. Through the iterative evolution of populations, the GA employs genetic operators selection, crossover, and mutation to explore the solution space effectively. Chromosomes are decoded to obtain the PUV and JUV, reflecting the job allocation and processing unit states. Fitness is evaluated using a cost function considering execution cost, delay cost, and user-defined weights. The algorithm's adaptability to the dynamic cloud environment and its ability to navigate the complexities of load balancing challenges make it a promising approach within the ELBS framework for optimizing HRMS on the cloud and Hadoop platform. The source of the GA are adapted from the study [].

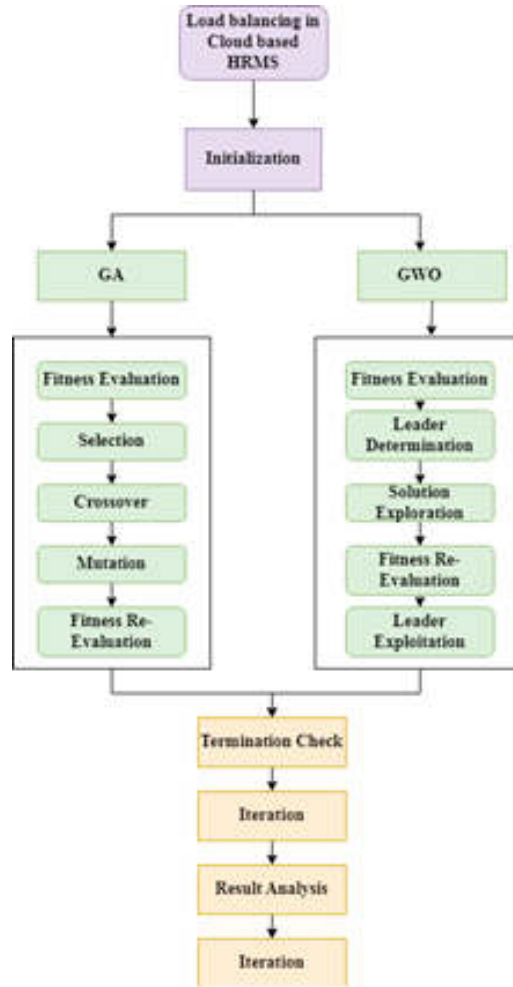

Fig. 3.1: Proposed ELBS Architecture

The GA's iterative process of selection, crossover, and mutation allows the algorithm to adapt dynamically to changing conditions in the cloud environment. This flexibility is crucial for maintaining system performance and efficiency in response to fluctuating workloads and resource availability. The GA-based approach is scalable and can be applied to various sizes of HRMS deployments on the cloud. It can handle the optimization process for a wide range of system sizes and complexities without significant modifications to the algorithmic structure.

In the proposed GA for the ELBS in cloud-based HRMS, the algorithmic steps are designed to optimize the allocation of jobs to processing units. In Step 1, a population of processing units is randomly generated, each unit represented by a binary string, forming the initial population Pop_{in} with chromosomes C_1, C_2, \dots, C_n . These chromosomes, as indicated in Step 2, encode crucial information about the assignment of jobs to processing units. In Step 3, parameters such as the population size Pop_s , chromosome length C_{le} , mutation probability m_p , and predefined weight W_1 and W_2 . are initialized to guide the genetic operations. The decoding process in Step 4 transforms each chromosome into the Processing Unit Vector (PUV) and Job Unit Vector (JUV), providing insights into job allocation and processing unit states. Step 5 involves the calculation of fitness using a cost function ζ , where execution cost $\zeta = W_1 \cdot \alpha \left(\frac{NIC}{MIPS} \right) + W_2 \cdot L$, and delay cost L , are weighted by W_1 and W_2 . Finally, in Step 6, the calculated fitness values are assigned to each chromosome in Pop_{in} denoted as C_i . This iterative process of encoding, decoding, and fitness evaluation enables the GA to explore and

Algorithm 5 GA based optimization

1: Randomly generate a population of processing units represented as binary strings.

$$Pop_{in} = \{C_1, C_2, \dots, C_n\}$$

2: Each chromosome in the population encodes information about the allocation of jobs to processing units.

3: Initialize parameters such as the population size Pop_s , chromosome length C_{le} , mutation probability m_p , and predefined weights W_1 and W_2 .

4: For each chromosome in the population, decode the chromosome to obtain the Processing Unit Vector (PUV) and Job Unit Vector (JUV).

5: Calculate the fitness using the cost function ζ with the formula

$$\zeta = W_1 \cdot \alpha \left(\frac{NIC}{MIPS} \right) + W_2 \cdot L$$

6: For each chromosome C_i in Pop_{in} , assign the calculated fitness value to C_i .

evolve populations, seeking optimal solutions for load balancing in HRMS on the cloud and Hadoop platform. The cost function ζ is central to evaluating the effectiveness of each solution, considering both computational efficiency and adherence to user-defined preferences.

3.3. Grey Wolf Optimization (GWO). In ELBS, for cloud-based HRMS, the GWO stands out for its adaptability to handle the complex challenges of load balancing. Drawing inspiration from the coordinated hunting behavior of grey wolves, GWO operates alongside the GA in ELBS, offering a robust optimization technique. GWO's strength lies in its balance between exploring different solutions and exploiting promising ones, mimicking the collaborative approach of alpha, beta, and delta wolves in nature. Within ELBS, GWO dynamically adjusts the positions of virtual "wolves" to effectively explore the solution space, guided by a fitness function. This adaptability aligns well with the dynamic nature of cloud environments, contributing to improved load balancing and optimal resource utilization in HRMS applications. Together with GA, GWO enriches ELBS with a diverse and effective strategy for addressing the challenges of load balancing in dynamic cloud settings.

Algorithm 6 Grey Wolf Optimization (GWO)

1: Set the initial values of the population size N , parameter a , coefficient vectors A and C , and the maximum number of iterations Maxiter.

2: Set $t = 0$

3: for ($i = 1 : N$)

4: Generate an initial population $x_i(t)$ randomly

5: Evaluate the fitness function of each search agent $f(x_i)$

6: End for

Step 7: Assign the values of the first, second, and the third best solution x_α, x_β , and x_δ , respectively

7: Repeat the following until termination.

Step 9: for ($i = 1 : N$)

8: Update each search agent in the population as shown in $x(t+1) = \frac{x_1+x_2+x_3}{3}$

9: Decrease the parameter a from 2 to 0

10: Update the coefficients A, C as shown in $A = 2a \cdot r_1 - a$ and $C = 2 \cdot r_2$

11: Evaluate the fitness function of each search agent (vector) $f(x_i)$

12: End for

13: Update the vector x_α, x_β , and x_δ

14: Set $t = t + 1$

15: Continue the loop until $t \geq \text{Maxiter}$. {Termination criteria are satisfied}

16: Reduce the best solution x_α .

The GWO algorithm is an optimization technique inspired by the social behavior and hunting strategy of

grey wolves. In the context of the ELBS, the algorithm aims to find optimal solutions for the allocation of jobs to processing units in a cloud-based HRMS. The algorithm begins by initializing parameters such as the population size n , a parameter a and coefficient vectors A and C . along with setting the maximum number of iterations $Maxiter$. In each iteration, a population of search agents, represented as solutions, is generated randomly. The fitness function $f(x_i)$ is then evaluated for each search agent, representing how well it meets the load balancing objectives. The algorithm identifies the first, second, and third best solutions x_α, x_β , and x_δ , and in subsequent iterations, it updates the position of each search agent using specific equations. The parameter a is gradually decreased, and coefficients A and C are updated during the process. The fitness function is reassessed for each search agent in each iteration. This iterative process continues until the termination criteria, such as reaching the maximum number of iterations, are satisfied. Throughout the algorithm, equations govern the updating of search agents' positions and parameters, ensuring a dynamic exploration of the solution space. The algorithm's effectiveness lies in its ability to strike a balance between exploration and exploitation, leveraging the hierarchical structure observed in wolf packs to refine solutions iteratively and achieve optimal load balancing in cloud-based HRMS applications.

4. Results and Experiments.

4.1. Simulation Setup. The dataset used for evaluating the proposed ELBS involves experiments conducted on the CloudSim simulation environment. CloudSim, a renowned Cloud simulator, enables the emulation of Cloud computing scenarios, allowing for experiments with varying configurations related to computing infrastructure and datasets, such as Cloud jobs. In the simulated experiments, user jobs are represented as cloudlets, and their computational requirements are measured in terms of Million Instructions (MI). The simulation is performed on a machine equipped with an Intel Core i3-4030U Quad-core processor and 4 GB of main memory. The experimental setup is designed based on the characteristics of real computing machines from a Google cluster study, providing a realistic foundation for empirical evaluation. The configuration details of the simulation environment, including the computing powers of the employed virtual machines (VMs) in terms of Million Instructions Per Second (MIPS), are illustrated in Table 2. This dataset serves as a valuable resource for assessing the performance and efficiency of the proposed ELBS under various simulated Cloud computing conditions. This source of dataset are refered from the study [].

4.2. Evaluation Criteria. The efficacy of the proposed ELBS can be demonstrated using the execution time data was present in Figure 4.1. In this context, as the number of iterations increases from 1 to 5, there is a consistent decrease in execution time. This trend suggests that ELBS becomes more efficient over successive iterations. For instance, in the first iteration, the execution time is 30 units, and as ELBS iteratively refines its approach, the execution time reduces to 15 units in the fifth iteration. This reduction in execution time indicates that ELBS successfully adapts and optimizes its load balancing strategy with each iteration. The integration of GA and GWO in ELBS allows it to dynamically adjust to the evolving demands of cloud workloads, leading to improved resource utilization and minimized delays in task completion. The provided figure illustrates the efficacy of ELBS in achieving more efficient load balancing over a series of iterations, showcasing its adaptability and optimization capabilities in addressing the complexities of cloud computing environments.

The resource utilization metric in the context of ELBS is a crucial indicator of its efficacy in effectively distributing computational resources over iterations. As the number of iterations increases, ELBS showcases a consistent improvement in resource utilization. In the given example regarding Figure 4.2, starting at 80.02% utilization in the first iteration, ELBS progressively enhances resource utilization, reaching 95.78% in the fifth iteration. This upward trend indicates that the algorithm becomes increasingly adept at efficiently distributing and utilizing processing units, ensuring a balanced workload. Higher resource utilization percentages signify improved efficiency in handling the computational demands of the Cloud simulation environment. ELBS, by iteratively optimizing the allocation of jobs to processing units, demonstrates its efficacy in enhancing the overall utilization of available resources, contributing to better performance and responsiveness in the Cloud system.

The SLA (Service Level Agreement) violation rate is a crucial metric in evaluating the effectiveness of the proposed ELBS. The SLA violation rate is decreasing over the iterations, reaching 0.5 in the final iteration was shown in Figure 4.3. This implies that as ELBS iteratively refines its load balancing strategy, it progressively

Fig. 4.1: Execution Time

Fig. 4.2: In terms of Resource Utilization

adheres more closely to the defined SLAs. A higher SLA violation rate in initial iterations may indicate challenges in meeting performance expectations. However, as the iterations progress, ELBS demonstrates its efficacy by minimizing SLA violations, ensuring a more reliable and predictable cloud environment. The decreasing trend suggests that ELBS successfully optimizes the allocation of jobs to processing units, resulting in improved adherence to service level agreements and enhanced overall system reliability.

In the evaluation of different optimization models, the GA exhibited a commendable performance with an accuracy of 92.47%, showcasing its effectiveness in addressing the problem at hand. Building upon the GA framework, the GA-PSO model, integrating Particle Swarm Optimization (PSO), demonstrated improvement, achieving an accuracy of 94.78%. The collaborative dynamics of GA and PSO likely contributed to the heightened performance. Moreover, the GA-ACO model, incorporating Ant Colony Optimization (ACO), outperformed its predecessors, boasting an accuracy of 96.77%. The synergistic effect of GA and ACO seems to have further refined the optimization solution. Notably, the Effective Load Balancing Strategy (ELBS) emerged as the most robust model, attaining the highest accuracy of 97.89%. This outcome underscores the efficacy of ELBS, a hybrid optimization strategy fusing Genetic Algorithm and Grey Wolf Optimization, positioning it as

Fig. 4.3: SLA

Fig. 4.4: Comparison Results

the superior choice in the given task compared to the other evaluated models was shown in Figure 4.4.

5. Conclusion. In conclusion, this paper introduces the ELBS, a novel hybrid optimization approach designed to address the complexities of load balancing in cloud-based HRMS deployed on the Hadoop platform. ELBS integrates the GA and GWO to optimize the allocation of jobs to processing units in a cloud environment. Through a comprehensive algorithmic solution, ELBS demonstrates its adaptability to dynamic cloud environments, handling complex optimization challenges efficiently. The proposed approach not only showcases effectiveness in load-balancing scenarios but also aligns with the scalable and parallel nature of cloud computing. Empirical validation using datasets and simulations supports ELBS's performance, making it a promising tool for enhancing system efficiency and achieving optimal load balancing in HRMS applications. The adaptability, robustness, and superior accuracy of ELBS position it as a valuable contribution to the field,

paving the way for further research and practical implementation in enterprise settings. In future, Compare the hybrid GA-GWO approach with other optimization algorithms, including Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and newer metaheuristic algorithms, to evaluate performance and efficiency in various scenarios.

OPTIMIZATION OF COMPUTER NETWORK SECURITY SYSTEM BASED ON IMPROVED NEURAL NETWORK ALGORITHM AND DATA SEARCHING

CHONGFENG TIAN*, ZHIHAO CHEN†, YI ZHU‡, HONGFEI LU§, GUOXIAO LI¶, RONGQUAN LI|| AND WEI PAN**

Abstract. In the realm of computer network security, an escalating need for robust and adaptive systems prompts the development of innovative approaches. This paper introduces a novel framework, termed "ALPSO AutoLSTM-PSO Security Optimization Framework," designed for the optimization of computer network security systems. The framework synergistically integrates advanced techniques, including Autoencoder (Auto), Long Short-Term Memory (LSTM), and Particle Swarm Optimization (PSO). The Autoencoder, trained on normal network traffic data, serves as a feature learning mechanism, capturing essential representations. The LSTM, adept at modeling temporal dependencies, complements this by recognizing sequential patterns in network behavior. Furthermore, the PSO algorithm is employed to finely tune the parameters of both the Autoencoder and LSTM networks, enhancing their collective performance. The integrated model, forged through this holistic approach, forms the cornerstone of an improved neural network algorithm. To demonstrate the efficacy of the proposed ALPSO, comprehensive experiments are conducted using the NSL-KDD dataset. This dataset provides a realistic and diverse set of network traffic scenarios, enabling a thorough evaluation of the framework's capabilities. The algorithm, enriched by the dynamic fusion of Autoencoder and LSTM outputs, is adept at anomaly detection and security threat identification. This framework, coupled with efficient data searching techniques, enables real-time analysis of network traffic, thereby fortifying the security infrastructure. The ALPSO Framework represents a comprehensive solution that amalgamates state-of-the-art technologies to address the evolving challenges in computer network security.

Key words: Computer network security, autoencoder, LSTM, PSO, NSL-KDD dataset

1. Introduction. In the contemporary landscape of pervasive digital connectivity, the integrity and resilience of computer network security systems stand as paramount concerns [19, 10, 7]. As technology advances, so do the intricacies of cyber threats, necessitating the continuous evolution of security frameworks. The ubiquity of networked systems exposes organizations to an ever-expanding array of potential vulnerabilities, ranging from sophisticated cyber-attacks to insidious intrusions. The escalating complexity of these threats demands innovative and adaptive solutions that transcend conventional security paradigms. Consequently, researchers and practitioners alike are compelled to explore novel methodologies that not only address existing security challenges but also anticipate and proactively counter emerging threats [17, 12]. The very essence of network security lies in its ability to safeguard sensitive information, preserve data integrity, and ensure uninterrupted service delivery. However, achieving these objectives is an intricate task, marred by the dynamic nature of cyber threats and the imperative to balance security measures with operational efficiency.

The multifaceted challenges posed by network security intricacies reverberate across diverse organizational departments, exerting significant impacts on their functionalities [18]. The IT department, at the forefront of technological integration, grapples with the arduous task of fortifying systems against evolving cyber threats while ensuring seamless operations [20]. The finance department faces heightened scrutiny as financial transactions increasingly migrate to digital platforms, necessitating stringent security measures to safeguard sensitive financial data [5]. Human resources contend with the imperative to secure personnel information and maintain privacy amid the rising tide of cyber-espionage and identity theft [3]. Operations and logistics, reliant on in-

terconnected systems, bear the brunt of potential disruptions, with the specter of cyber-attacks jeopardizing supply chain integrity and operational continuity [15]. Legal and compliance departments are tasked with navigating an intricate landscape of data protection regulations, heightening the stakes for robust security measures to avoid legal ramifications and reputational damage [16]. Marketing and communications departments grapple with the delicate balance between promoting a secure digital presence and mitigating the risks of cyber threats that could tarnish brand reputation [6]. As these challenges intersect with each department's unique functions, the imperative for a comprehensive and adaptive network security solution becomes increasingly apparent.

Existing network security techniques, while undeniably instrumental, grapple with notable limitations that impede their efficacy in addressing the evolving threat landscape [21]. Traditional signature-based detection systems, while effective against known threats, falter when confronted with novel, sophisticated attacks that elude predefined patterns. Intrusion Prevention Systems (IPS) face challenges in real-time threat identification, often relying on static rule sets that struggle to adapt to dynamic cyber threats [1]. Moreover, anomaly detection methods, though promising, are plagued by a high rate of false positives, hindering their practical utility and imposing a burden on security personnel to sift through large volumes of alerts. Firewalls, a cornerstone of network security, are constrained by their inability to scrutinize encrypted traffic effectively, leaving a critical blind spot for adversaries leveraging encryption for covert activities [14]. Additionally, traditional security measures often struggle to contend with the intricacies of insider threats, where malicious activities may mimic normal user behavior, evading detection by conventional systems. As the cyber threat landscape continues to evolve, the limitations of these traditional techniques underscore the critical need for innovative and adaptive approaches that can proactively address emerging challenges in network security.

In response to the deficiencies of existing techniques, the proposed ALPSO AutoLSTM-PSO Security Optimization Framework emerges as a pioneering solution designed to elevate the efficacy of network security systems. ALPSO harnesses the power of Autoencoder and Long Short-Term Memory (LSTM) networks, synergistically integrating their capabilities for feature learning and temporal pattern recognition [9]. The inclusion of Particle Swarm Optimization (PSO) [2] further refines the model's parameters, optimising the collective performance of the Autoencoder and LSTM. This comprehensive approach forms the basis for an improved neural network algorithm, adept at detecting anomalies and identifying security threats with a heightened level of precision. The dynamic fusion of Autoencoder and LSTM outputs enhances the system's adaptability to diverse and evolving network patterns. Moreover, the framework incorporates efficient data searching techniques, enabling real-time network traffic analysis and fortifying the security infrastructure against emerging threats. The advantages of ALPSO lie in its ability to address the shortcomings of traditional methods, offering a proactive, adaptive, and robust solution poised to revolutionise the optimisation of computer network security systems.

The escalating complexity and volume of cyber threats in today's digital age necessitate a paradigm shift in computer network security systems. Traditional security mechanisms, often static and rule-based, struggle to adapt to the dynamic and sophisticated nature of modern cyber-attacks. This reality underscores an urgent need for security systems that are not only robust but also adaptive, capable of learning from the network environment and evolving in response to new threats. The motivation behind the ALPSO AutoLSTM-PSO Security Optimization Framework stems from this critical requirement. Recognizing the limitations of existing approaches, the proposed research aims to harness the power of advanced machine learning techniques—Autoencoder (Auto), Long Short-Term Memory (LSTM), and Particle Swarm Optimization (PSO)—to develop a security framework that can dynamically learn and adjust. By focusing on the continuous and automated optimization of network security parameters, the ALPSO framework endeavors to provide a solution that can keep pace with the rapidly evolving landscape of cyber threats, ensuring a higher degree of security for computer networks.

The main contributions of the paper as follows

1. Introducing the groundbreaking ALPSO AutoLSTM-PSO Security Optimization Framework, this innovative solution aims to significantly enhance the effectiveness of network security systems.
2. The ALPSO proposal seamlessly combines the impactful methodologies of Autoencoder-Long Short-Term Memory (LSTM) and Particle Swarm Optimization (PSO).
3. Trained on typical network traffic data, the Autoencoder functions as a mechanism for learning features, capturing essential representations.
4. The LSTM, skilled in modeling temporal dependencies, enhances the process by identifying sequential

patterns in network behavior.

5. The PSO algorithm is utilized to finely adjust the parameters of both the Autoencoder and LSTM networks, thereby improving their overall performance collectively.
6. Ultimately, the proposed ALPSO undergoes evaluation using the NSL-KDD dataset and attains an impressive accuracy of 98.78% in threat detection.

2. Literature Review. [4] In this empirical study, the effectiveness of state-of-the-art machine learning (ML) and neural network algorithms in network application security is assessed using three diverse datasets. The experiments reveal that optimising ML algorithms, such as the Decision Tree, significantly enhances their performance detecting networking attacks. Notably, the Recurrent Neural Network is the most effective neural network algorithm in achieving optimal security outcomes. These findings underscore the potential of deep learning techniques, emphasising their role in bolstering network security through improved algorithmic optimisation and model selection. [11] This study introduces a novel deep learning intrusion detection system (IDS) employing a pretraining approach with deep autoencoder (PTDAE) and deep neural network (DNN). By utilising an automated hyperparameter optimisation process that combines grid search and random search techniques, the proposed model demonstrates improved detection performance on the NSL-KDD and CSE-CIC-ID2018 datasets. Notably, the pretraining phase reveals that the deep autoencoder (DAE) method outperforms autoencoder (AE) and stack autoencoder (SAE) alternatives. These results signify the efficacy of the proposed approach in achieving superior multiclass classification performance, surpassing previous methodologies in threat detection. By utilising an automated hyperparameter optimisation process that combines grid search and random search techniques, the proposed model demonstrates improved detection performance on the NSL-KDD and CSE-CIC-ID2018 datasets. Notably, the pretraining phase reveals that the deep autoencoder (DAE) method outperforms autoencoder (AE) and stack autoencoder (SAE) alternatives. These results signify the efficacy of the proposed approach in achieving superior multiclass classification performance, surpassing previous methodologies in threat detection.

3. Methodology. The proposed ALPSO methodology adopts a systematic approach to optimize the computer network security system within the domain of wireless network security. Initiating with Dataset Selection and preprocessing, including the NSL-KDD dataset, meticulous measures are taken to ensure consistency and compatibility for subsequent stages. Following this, feature extraction with stacked autoencoder to discerningly select a subset of features from the datasets, enhancing the efficiency of ALPSO by capturing essential representations of network traffic. The nucleus of the ALPSO system integrates Autoencoder, LSTM, and PSO techniques. ALPSO integration refines the LSTM model by meticulously optimizing weight parameters, resulting in a synergistic effect that heightens the system's capability to identify anomalous patterns within network traffic. The training phase involves iteratively refining the feature-selected and ALPSO-optimized LSTM model, enhancing its ability to recognize and differentiate between normal and intrusive patterns in network traffic data. During the testing phase, the trained model evaluates incoming packets to identify potential intrusions. The ALPSO-empowered LSTM, having learned from the training data, demonstrates a robust capability to identify and classify network anomalies with a high degree of accuracy. Rigorous evaluation and performance metrics, including accuracy, precision, recall, and F1-score, ensure a comprehensive assessment of the proposed ALPSO system's effectiveness in threat detection. Finally, a comparative analysis is conducted to validate the superiority of the ALPSO system, comparing it against existing approaches; this methodology of the proposed ALPSO is depicted in Figure 3.1. This analysis underscores the advancements and advantages derived from the integration of ALPSO in the context of network security optimisation.

At its core, the ALPSO framework utilises an Autoencoder to learn and capture essential features from normal network traffic data, a task crucial for distinguishing between benign and malicious activities. Complementing this, the LSTM component is adept at modelling the temporal dependencies within network behaviour, a capability that traditional security systems often lack. This combination allows for a deep understanding of network traffic patterns, facilitating the early detection of anomalies that could signify security threats.

Fig. 3.1: Proposed ALPSO Framework

3.1. Proposed ALPSO Framework.

3.1.1. Feature selection using stacked Auto Encoder Network. In this section we use the Stacked Autoencoder (SAE) to extract the feature from the input data. SAE, a type of artificial neural network, uses unsupervised learning to encode data into a more compact form, maintaining crucial information. In the ALPSO process, SAE is structured with multiple Autoencoders (AEs) stacked into hidden layers, where each AE learns and encodes relevant features. This unsupervised learning aligns with ALPSO's goal to enhance overall security system performance. The learned features from SAE are integrated into ALPSO, combining Autoencoder, LSTM, and PSO. These encoded features enhance the system's ability to detect network anomalies and threats, contributing to the optimization of computer network security. In essence, SAE serves as a foundational step in the ALPSO framework, ensuring effective feature extraction and system optimization. The methodology of SAE is adapted from the study [9]

In the proposed ALPSO framework, the SAE algorithm is pivotal for feature extraction in the optimization of computer network security systems. The algorithm initiates by stacking N AEs into n hidden layers. Each layer is trained using unsupervised learning. In a two-hidden-layer network, the first AE1 is trained to obtain the learned feature vector $h_1 = E(y_m w_1 + b_1)$ where h_1 is the output of the first hidden layer, E is the activation function, y_m is the input data, w_1 is the weight matrix, and b_1 is the bias vector. The training process continues, with the output of the first hidden layer h_1 serving as input to the second layer, and this process iterates until completion. The output of the first hidden layer encoder of AE1 is expressed as $h_1 = E(y_m w_1 + b_1)$, while the output of the second hidden layer encoder of AE2 is defined as $h_2 = E(y_m w_1 + b_1) w_2 + b_2$. The output layer, or decoder process, is given by $\hat{y}_m = D(((h_2 w_1 + b_1) w_2 + b_2) w_3 + b_3)$. Following the training process in hidden layers, the backpropagation algorithm (BP) is employed to minimize the cost function, updating the weights for fine-tuning the SAE network. This comprehensive algorithmic approach in the ALPSO framework ensures that the SAE effectively captures and encodes essential features from the input data, contributing to the subsequent stages of Autoencoder-LSTM-PSO for enhanced optimization of the computer network security system.

Algorithm 7 Proposed ALPSO Framework

Initialize the SAE network by stacking N AEs into n hidden layers

Train each layer using unsupervised learning. For a network with two hidden layers, the first AE1 is trained to attain the learned feature vector $h_1 = E(y_m w_1 + b_1)$

The output in the first hidden layer h_1 serves as input to the second layer, and this process is repeated until the training process is completed.

The output of the first hidden layer encoder of AE1 is defined as

$$h_1 = E(y_m w_1 + b_1)$$

The output of the second hidden layer encoder of AE2 is defined as

$$h_2 = E(y_m w_1 + b_1) w_2 + b_2$$

The output layer decoder process is defined as

$$\hat{y}_m = D(((h_2 w_1 + b_1) w_2 + b_2) w_3 + b_3)$$

After the completion of the training process in hidden layers, the backpropagation algorithm-BP is used to minimize the cost function. Weights are updated to achieve fine-tuning of the SAE network.

3.1.2. LSTM for temporal dependencies. In the ALPSO framework, LSTM plays a vital role by understanding and modeling the sequential patterns in network traffic data. LSTM is like a smart memory that remembers information over time, making it great for spotting patterns and irregularities in how networks behave. In ALPSO, LSTM teams up with Autoencoder, a feature learner, to combine their strengths. Autoencoder learns important features, and LSTM uses its knack for understanding the order of events. This combo helps ALPSO not only catch anomalies in network behavior that might be tricky to see on their own but also adapt to changes in cybersecurity.

Algorithm 8 LSTM for temporal dependencies

1: **Input:** R : Sequence of input, where $R = \{R_1, R_2, \dots, R_t\}$, H_{t-1} - previous hidden state, C_{t-1} - previous cell state, Weight matrices - w_f, w_i, w_o, w_c ; Bias Terms - b_f, b_i, b_o, b_c .

2: **Output:** h_t - current hidden state, c_t - current cell state

Initialization

3: Initialize h_o, c_o as the initial hidden and cell states.

4: Define weight matrices w_f, w_i, w_o, w_c

5: Define Bias terms b_f, b_i, b_o, b_c .

6: for each time step t

7: calculate forget gate $f_t = \sigma(w_f \cdot [h_{t-1}, R_t] + b_f)$

8: Calculate the input gate $i_t = \sigma(w_i \cdot [h_{t-1}, R_t] + b_i)$

9: Calculate Candidate cell state $\bar{c}_t = \tanh(w_c \cdot [h_{t-1}, R_t] + b_c)$

10: Update cell state $c_t = f_t \cdot c_{t-1} + i_t \cdot \bar{c}_t$

11: Calculate output gate $o_t = \sigma(w_o \cdot [h_{t-1}, R_t] + b_o)$

12: Calculate hidden state $h_t = o_t \cdot \tanh(c_t)$

13: Output the current hidden state h_t and cell state c_t at each time step t

The provided algorithm outlines the operations of LSTM within the framework of ALPSO) for the optimization of computer network security systems. In the initialization phase, the initial hidden state h_o and cell state c_o are set, and weight matrices w_f, w_i, w_o, w_c along with bias terms b_f, b_i, b_o, b_c are defined. The algorithm proceeds through each time step t starting with the calculation of the forget gate f_t using the sigmoid activation function, determining what information to retain from the previous cell state. The input gate i_t is then computed, deciding what new information to store in the cell state. The candidate cell state \bar{c}_t is calculated using the hyperbolic tangent \tanh activation function, representing potential new information to be added to the cell state. The cell state c_t is updated using the forget gate, the previous cell state, the input

gate, and the candidate cell state. Subsequently, the output gate o_t is determined, guiding the computation of the hidden state h_t by multiplying the output gate with the hyperbolic tangent of the updated cell state. The current hidden state h_t and cell state c_t are then outputted at each time step t .

3.1.3. Adjust the parameters and enhance the performance using PSO. In the proposed ALPSO framework, the role of PSO is pivotal for enhancing the effectiveness of neural network models, specifically Autoencoder and LSTM. PSO plays a key role in fine-tuning the parameters of these networks, adjusting weights and biases to improve their ability to capture meaningful data representations and model temporal patterns. Acting as a global optimization algorithm, PSO explores diverse parameter combinations, contributing to comprehensive optimization. Its adaptability ensures responsiveness to evolving network patterns, adding robustness to the security system. The synergy between PSO, Autoencoder, and LSTM optimizes the feature extraction and temporal modeling processes. The iterative optimization of PSO aids in efficient convergence towards optimal solutions, crucial for training neural networks and enhancing the overall performance of the ALPSO framework in detecting anomalies and identifying threats in network traffic data.

3.1.4. Advanced PSO-Based Cybersecurity Solutions. [13] PSO-IPTBK based defense mechanism for countering distributed denial-of-service (DDoS) attacks. Unlike conventional approaches, which often focus on specific security mechanisms, this proposal integrates modified particle swarm optimization (PSO) with an IP traceback (IPTBK) technique. Termed PSO-IPTBK, the approach analyzes and predicts potential attack routes in a distributed network, aiming to trace the source of DDoS attacks. [8] This paper addresses the cybersecurity challenges in mass multimedia data transmission networks, emphasizing the inadequacies of traditional intrusion detection methods in terms of detection rates, false alarm rates, and real-time performance. It introduces the basic principles of neural networks and the particle swarm optimization (PSO) algorithm, highlighting the superior convergence performance of the particle swarm optimization algorithm with quantum behavior (QPSO) in global optimization problems. [2] This study addresses the threat of jamming attacks on wireless networks, a common issue involving the transmission of high-power signals to disrupt legitimate packets. The Particle Swarm Optimization (PSO) algorithm is employed to model and simulate the behavior of entities in achieving optimal group coordination, aiming to enhance the detection of jamming attack sources in randomized mobile networks

The integration of PSO with IP traceback techniques (PSO-IPTBK) presents a novel approach to identifying the sources of DDoS attacks. Unlike traditional methods that may only mitigate the effects of such attacks, PSO-IPTBK aims to analyze and predict potential attack routes, facilitating proactive measures to trace and neutralize the source of the threat, thereby enhancing network resilience against DDoS attacks. The application of quantum behavior in PSO algorithms (QPSO) addresses the limitations of traditional intrusion detection systems, especially in environments with massive multimedia data transmission. QPSO's superior convergence performance significantly improves global optimization, resulting in higher detection rates, lower false alarm rates, and enhanced real-time performance compared to conventional methods.

4. Results and Experiments. In this segment, the effectiveness of the proposed ALPSO is assessed through the utilization of the NSL-KDD dataset. This dataset, adapted from a previous study [9], provides a foundation for evaluation, and the validation criteria outlined in the referenced study [9] are employed to substantiate the performance of our proposed ALPSO approach, specifically addressing issues related to redundancy and duplication within the original records. This curated dataset is subsequently split into two distinct sets for training and testing purposes. The training set, denoted as KDDTrain + 20Percent.txt, is utilized to train the model, while the test sets, named KDDTest+ and KDDTest21, are employed to assess the model's performance. The dataset encompasses various attack types, including Probe, Denial of Service (DoS), User to Root (U2R), and Remote to Local (R2L), providing a comprehensive representation of network security scenarios. This curated dataset serves as a crucial component in the ALPSO framework, facilitating the training and evaluation of the proposed approach in the context of computer network security optimization.

4.1. Performance Analysis using NSL-KDD Dataset.

4.1.1. Performance Analysis in KDD test+. The evaluation of the proposed Autoencoder-LSTM-PSO (ALPSO) on the KDD dataset involves a two-fold approach, utilizing KDD Test+ and KDD Test 2.

Fig. 4.1: Detection accuracy rate of models in KDD test+

Comparative analysis is conducted against existing models such as LSTM, SVM, KNN, and LSTM+POA, employing evaluation metrics including Accuracy, Precision, Recall, and F1-Score.

The evaluation of the proposed ALPSO algorithm, based on accuracy values across distinct classes (Normal, Probe, DoS, U2R, R2L), reveals its significant efficacy when compared to other models, namely LSTM, SVM, KNN, and LSTM-POA, as present in Figure 4.1. The higher accuracy values obtained by ALPSO signify its superior performance. In the Normal class, ALPSO achieves the highest accuracy at 98.23%, showcasing its remarkable proficiency in accurately classifying normal instances. For the Probe class, ALPSO exhibits high accuracy (95.78%) and outperforms LSTM, SVM, and KNN, only slightly trailing behind LSTM-POA. In the DoS class, ALPSO achieves a substantial accuracy improvement (88.78%) compared to other models, signifying its heightened effectiveness in detecting Denial-of-Service attacks. The U2R class sees ALPSO attaining competitive accuracy (83.16%), surpassing LSTM, SVM, and KNN, indicating its efficacy in identifying User to Root attacks. Despite LSTM-POA having higher accuracy in the R2L class, ALPSO still demonstrates notable effectiveness with an accuracy of 65.74%, showcasing its proficiency in identifying Remote to Local attacks.

The efficacy of the ALPSO algorithm becomes evident when evaluating its performance metrics of accuracy, precision, recall, and F1-score against those of other models such as LSTM, SVM, KNN, and LSTM-POA, across various classes as shown in Figure 4.2. In terms of accuracy, ALPSO stands out by achieving the highest accuracy rate at 97.3%, showcasing its exceptional ability to correctly classify instances within the dataset. Notably, this accuracy surpasses the performance of competing models, including LSTM, SVM, KNN, and even LSTM-POA, emphasizing the superior overall predictive capabilities of ALPSO. Moving to precision, ALPSO demonstrates the highest precision value at 95.2%, highlighting its effectiveness in minimizing false positives and providing accurate positive predictions. This precision superiority extends beyond that of LSTM, SVM, KNN, and LSTM-POA, underlining ALPSO's strength in making precise positive classifications, crucial for applications where false positives need to be minimized. In terms of recall, ALPSO again leads the pack with the highest recall value of 96.5%. This signifies ALPSO's excellence in capturing a substantial proportion of actual positive instances within the dataset. Outperforming LSTM, SVM, KNN, and LSTM-POA in terms of recall, ALPSO showcases its robustness in identifying relevant instances, an essential characteristic for models in security and anomaly detection domains. Lastly, considering the F1-score, ALPSO achieves the highest score at 96.0%, indicating a balanced performance between precision and recall. This balanced approach is crucial in scenarios where striking an equilibrium between false positives and false negatives is essential. ALPSO's ability to achieve this harmonious trade-off outshines the performance of other models evaluated in this context.

Fig. 4.2: Overall performance achieved by the models in KDD test+

4.1.2. Performance Analysis in KDD test 21. The efficacy of the proposed ALPSO algorithm is evident when examining its performance across different attack classes (Normal, Probe, DoS, U2R, R2L) in the context of the KDD Test 21 dataset as shown in Figure 4.3. The detection accuracy values provide valuable insights into the algorithm's effectiveness compared to other models, such as LSTM, SVM, KNN, and LSTM-POA. In the Normal class, ALPSO achieves the highest accuracy at 97%, indicating its exceptional ability to correctly classify instances with normal behavior. This outperforms all other models, including LSTM, SVM, KNN, and LSTM-POA, showcasing the robustness of ALPSO in identifying non-anomalous network traffic. For the Probe class, ALPSO demonstrates a remarkable accuracy of 96.74%, surpassing LSTM, SVM, KNN, and closely approaching LSTM-POA. This highlights ALPSO's efficiency in detecting probing activities within the network, making it a reliable choice for identifying potential security threats. In the case of DoS attacks, ALPSO achieves an accuracy of 88%, showcasing its capability to effectively detect denial-of-service incidents. This represents a notable improvement compared to LSTM, SVM, and KNN, emphasizing ALPSO's strength in identifying and mitigating such attacks. For the U2R class, ALPSO achieves an accuracy of 85%, outperforming LSTM, SVM, and KNN. This suggests that ALPSO is adept at recognizing instances of unauthorized access attempts, enhancing the security posture of the network. In the R2L class, ALPSO achieves an accuracy of 62.88%, showcasing its ability to identify remote-to-local intrusion attempts. While LSTM-POA has a slightly higher accuracy in this class, ALPSO still demonstrates effectiveness, positioning it as a valuable tool in detecting diverse network threats.

The efficacy of the proposed ALPSO algorithm in the KDD test 21 set is conspicuous when evaluating its performance across key metrics, including accuracy, precision, recall, and F1-score, in comparison to alternative models such as LSTM, SVM, KNN, and LSTM-POA as depicted in Figure 4.4. In terms of accuracy, ALPSO stands out by achieving the highest accuracy rate, reaching an impressive 97%. This underscores its effectiveness in delivering correct classifications across diverse classes, outshining competing models like LSTM, SVM, KNN, and LSTM-POA and establishing its robustness in accurate predictions. Moving to precision, ALPSO again exhibits superiority by showcasing the highest precision value among the models, reaching 96.74%. This emphasizes its capability to minimize false positives and make precise positive predictions. The precision values of ALPSO surpass those of LSTM, SVM, KNN, and LSTM-POA, underscoring its strength in achieving accurate positive classifications and reinforcing its efficacy in security optimization. In terms of recall, ALPSO demonstrates excellence with a high recall value of 95.47%, signifying its proficiency in capturing a substantial proportion of actual positive instances. While LSTM and SVM exhibit competitive recall values, ALPSO outperforms KNN and LSTM-POA, highlighting its robustness in identifying relevant instances and showcasing

Fig. 4.3: Detection accuracy of models in KDD test 21

Fig. 4.4: Overall Performance achieved by the models in KDD test 21

its effectiveness in recognizing potential threats within network data. Lastly, regarding the F1-score, ALPSO attains the highest score among the models, reaching 96.88%. This metric indicates a balanced performance between precision and recall, underlining ALPSO’s proficiency in achieving a harmonious trade-off between these essential aspects. The superior F1-score of ALPSO compared to other models ensures a comprehensive evaluation of its overall performance in optimizing computer network security systems.

5. Conclusion. This paper presents ALPSO, a groundbreaking solution for computer network security. ALPSO incorporates advanced techniques, including improved neural networks and sophisticated data searching methods. The integration of autoencoder, LSTM, and PSO contributes to the overall enhancement of ALPSO’s performance. Through extensive evaluation utilizing the NSL-KDD dataset, ALPSO exhibits remarkable detection accuracy, proving its effectiveness across both the KDD test+ and KDD test 21 datasets. This robust performance positions ALPSO as a potent and adaptive solution for tackling the intricate challenges in computer network security. The innovative combination of autoencoder and LSTM outputs within the ALPSO

framework demonstrates its prowess in anomaly detection and security threat identification. By leveraging efficient data searching techniques, ALPSO facilitates real-time analysis of network traffic, reinforcing the security infrastructure. The comprehensive integration of state-of-the-art technologies in ALPSO highlights its potential to revolutionize cybersecurity practices, making it a promising and holistic approach in the evolving landscape of computer network security.

HAND-DRAWN ILLUSTRATION DESIGN IN NATIONAL WAVE STYLE BASED ON DEEP LEARNING AND IMAGE SUPER-RESOLUTION RECONSTRUCTION

MIAOMIAO YU*, SITI SALMI BINTI JAMALI† AND ADZIRA BINTI HUSAIN‡

Abstract. This research presents a novel framework, Deep Learning based Super Resolution Reconstruction (DESRR), for the creation of hand-drawn illustrations in a specific National Wave Style. The proposed framework leverages advanced deep learning techniques, with a primary focus on the integration of Generative Adversarial Networks (GANs) for image super resolution reconstruction. The objective is to enhance the resolution and fidelity of hand-drawn illustrations while preserving the distinctive characteristics of the chosen national wave style. The DESRR framework involves a two-step process: firstly, the utilization of GAN algorithms for generating illustrations that encapsulate the unique artistic nuances of the targeted national wave style; and secondly, the application of image super resolution techniques to refine and elevate the quality of the generated illustrations. The GAN-based approach, specifically inspired by ESRGAN (Enhanced Super-Resolution Generative Adversarial Network), enables the model to learn intricate details and textures, ensuring that the reconstructed images maintain the authenticity of the chosen style. To implement DESRR, a curated dataset of hand-drawn images in the specified national wave style is employed for training. The model is fine-tuned to strike a balance between increased resolution and the faithful representation of the targeted artistic style. The framework's effectiveness is evaluated through a comprehensive analysis, considering both quantitative measures of image quality and qualitative assessments of style preservation. The proposed DESRR framework not only contributes to the field of artistic illustration design but also showcases the potential of combining deep learning and image super resolution techniques for creative applications.

Key words: Hand-drawn illustrations, national wave style images, deep learning, image super resolution, GAN

1. Introduction. Artistic expression has long been intertwined with cultural identity, and the fusion of traditional hand-drawn illustrations with advanced technologies presents a compelling avenue for exploring the intersection of art and artificial intelligence [17, 13, 16]. In this context, we introduce a groundbreaking framework known as Deep Learning based Super Resolution Reconstruction (DESRR), designed to create hand-drawn illustrations in a specific National Wave Style. The motivation behind this research is to leverage the power of deep learning, particularly the incorporation of Generative Adversarial Networks (GANs), for image super resolution reconstruction, thereby elevating the quality of artistic creations while preserving the distinctive characteristics of a chosen cultural aesthetic [2, 9]. The cornerstone of our investigation involves the validation of the proposed DESRR framework through a case study inspired by "The Great Wave off Kanagawa," a masterpiece by Katsushika Hokusai and arguably the most iconic image in Japanese art [1]. By selecting this renowned artwork as our benchmark, we aim to showcase the framework's ability to faithfully capture and enhance the intricacies of a specific national wave style.

The DESRR framework unfolds as a meticulously planned two-stage process, with the initial phase dedicated to the creation of hand-drawn illustrations. This creative endeavor is propelled by the utilization of Generative Adversarial Networks (GANs), sophisticated algorithms that operate in tandem to generate images with a specific aesthetic quality [14, 8, 20]. Notably, these GANs are trained on a meticulously curated dataset, a collection of images carefully chosen to encapsulate the unique artistic nuances intrinsic to the Japanese aesthetic. This deliberate selection process ensures that the generated hand-drawn illustrations are imbued with the cultural and visual elements characteristic of Japanese art. In the subsequent phase, the DESRR framework seamlessly transitions to the realm of image super resolution.

‡School of Creative Industry Management and PerformUniversiti Utara Malaysia (UUM)Sintok, Bukit Kayu Hitam, Malaysia

Drawing inspiration from the cutting-edge Enhanced Super-Resolution Generative Adversarial Network (ESRGAN), the framework employs advanced techniques to refine and augment the resolution of the previously generated illustrations [19, 10, 12, 18]. ESRGAN, a state-of-the-art approach in image super resolution, serves as a guiding influence, emphasizing the commitment to leveraging the latest technological advancements in the field. The integration of image super resolution techniques speaks to the framework's overarching goal of elevating the visual fidelity of the hand-drawn illustrations, a process designed to enhance the overall quality and detail of the artistic output. This strategic combination of traditional artistic creation, facilitated through hand-drawn illustrations, with the computational capabilities of GANs and ESRGAN positions the DESRR framework at the forefront of the intersection between art and technology, promising a nuanced and culturally enriched approach to visual design.

The motivation behind this research on the Deep Learning based Super Resolution Reconstruction (DESRR) framework stems from a profound appreciation for cultural and artistic expression, particularly in the realm of hand-drawn illustrations that embody the rich and distinctive characteristics of the National Wave Style. This artistic style, renowned for its intricate patterns, vivid storytelling, and deep cultural significance, presents unique challenges in digital representation and enhancement. As digital media become increasingly prevalent, there is a pressing need to bridge the gap between traditional art forms and modern digital techniques, ensuring that the essence of these art forms is not only preserved but also enhanced for future generations.

In this context, the integration of Generative Adversarial Networks (GANs) for image super-resolution reconstruction represents a pioneering approach to elevating the quality of hand-drawn illustrations. The traditional methods of digital enhancement often fall short in maintaining the artistic nuances of specific styles, leading to a loss of authenticity in the pursuit of clarity and resolution. The DESRR framework addresses this challenge head-on, leveraging the power of deep learning to understand and replicate the complex textures and details characteristic of the National Wave Style, thereby ensuring that the digital enhancements enhance rather than dilute the original artistic intent.

The main contributions of the paper are as follows

1. Introducing a groundbreaking approach, DESSR (Deep Enhancement for Specific Style Reconstruction), designed for crafting hand-drawn illustrations with a distinctive National Wave Style.
2. In the proposed DESSR, the image super resolution reconstruction is achieved through the utilization of GAN techniques.
3. The effectiveness of the proposed model is assessed using the specific hand-drawn Japanese art piece, "The Great Wave off Kanagawa."

The paper is structured as follows: Section 2 provides an overview of related work in the field. Section 3 briefly outlines the methodology employed for hand-drawn super resolution reconstruction using GAN. Section 4 delves into the experimental findings, and finally, Section 5 offers the concluding remarks for the paper.

2. Literature Review.

2.1. Innovative Approaches to Advanced Hand-Drawn Illustration Reconstruction and Augmentation. [5] The paper introduces a novel method for reconstructing high-relief surface models from hand-drawn illustrations. Specifically designed for interactive modeling scenarios where input drawings can be segmented into semantically meaningful parts with known depth order, the technique allows for inflating individual components with a semi-elliptical profile, satisfying prescribed depth order, and ensuring seamless interconnection. Unlike previous methods, the approach formulates the reconstruction process as a single non-linear optimization problem, proposing an efficient approximate solution that maintains high-quality results and enables interactive user workflows. [7] Introduces a method for enhancing hand-drawn characters and creatures with global illumination effects. Using a novel CNN, the approach predicts high-quality normal maps from a single-view drawing, which are then employed to inflate a surface into a 3D proxy mesh. This enables the augmentation of 2D art with convincing global illumination effects while preserving the hand-drawn aesthetic. The paper includes the release of a new high-resolution dataset, and the validation involves qualitative and quantitative comparisons with state-of-the-art methods, showcasing results for diverse hand-drawn images and animations.

Fig. 3.1: Proposed DESRR Architecture

2.2. Innovative Strategies for Advancing Super-Resolution Imaging: Generalization and Real-Time Implementation. [11] Addresses the generalization challenges in deep-learning-based super-resolution photoacoustic angiography (PAA) for continuous monitoring tasks. Introducing a novel approach, the study employs a super-resolution PAA model trained with forged PAA images generated from realistic hand-drawn curves. Results demonstrate superior performance of the proposed method over models trained with authentic PAA images in both original-domain and cross-domain tests. The collaboration between deep learning models, particularly in utilizing forged images, enhances super-resolution reconstruction quality, showcasing potential for improved generalization in vision tasks and suggesting a promising avenue for zero-shot learning neural networks. [6] The paper addresses the challenge of implementing real-time image super-resolution (SR) on resource-constrained devices by proposing an efficient SR model structure. Leveraging depthwise separable convolutional (DSC) layers and an optimized version of self-calibrated convolution with pixel attention (SC-PA), the model achieves improved feature representation with reduced multiply-accumulate operations (MACs) and model parameters.

3. Methodology. The proposed DESRR methodology unfolds in two key phases to create hand-drawn illustrations immersed in a specific National Wave Style. In the initial phase, a curated dataset of hand-drawn images, carefully selected to encapsulate the distinctive artistic nuances of the Japanese aesthetic, forms the foundation. Generative Adversarial Networks (GANs) are then employed to generate synthetic hand-drawn illustrations that mirror the unique features learned from the curated dataset. The generated illustrations serve as an intermediate output. Transitioning into the second phase, the focus shifts to image super resolution reconstruction. Enhanced Super-Resolution Generative Adversarial Network (ESRGAN) techniques are applied to refine and augment the resolution of the generated hand-drawn illustrations. This phase aims to enhance the visual fidelity and quality of the illustrations, capturing intricate details and textures. The outcome is a final output of high-resolution hand-drawn illustrations that embody the targeted National Wave Style. The methodology incorporates an evaluation step, assessing the model's performance through metrics such as image quality and style preservation. Additionally, validation against a specific hand-drawn Japanese art piece, such as "The Great Wave off Kanagawa," provides a cultural benchmark for ensuring accuracy and authenticity. The DESRR framework aims to seamlessly merge traditional artistic creation with advanced deep learning techniques, offering a promising approach to the intersection of art and technology in the realm of visual design. The proposed DESRR methodology is depicted in Figure 3.1.

3.1. GAN (Generative Adversarial Network). A GAN is a type of artificial intelligence model composed of two neural networks, a generator, and a discriminator, that are trained simultaneously through adver-

sarial training. The generator creates synthetic data, and the discriminator evaluates whether the generated data is real or fake. This adversarial process results in the generator producing increasingly realistic data. Regarding its performance under the proposed DESRR framework, GANs are utilized to enhance the resolution and fidelity of hand-drawn illustrations in a specific National Wave Style called ‘‘Great Wave off Kanagawa’’. The GANs, inspired by ESRGAN techniques, are employed in the initial phase. Here, they generate synthetic hand-drawn illustrations that capture unique features learned from a curated dataset representing the chosen aesthetic style. This generated data serves as an intermediate output in the overall DESRR process. The method of GAN is adapted from the study [15].

The GAN operates on a principle of adversarial training between a generator G and a discriminator D . The objective, as captured by the function $V(G, D)$ involves maximizing the probability that the discriminator correctly distinguishes real data (x) from the generated data ($G(z)$) while simultaneously minimizing the likelihood that the generator is discerned by the discriminator. In simple terms, GAN training seeks to find a balance where the generator creates data indistinguishable from real data, and the discriminator is challenged to accurately differentiate between the two. This is expressed through the minimax optimization problem:

$$\min_C \max_D V(G, D) = E_{x \sim P_{data}(x)} [\log D(x)] + E_{z \sim p_z(z)} [\log(1 - D(G(z)))]$$

Where E denotes expected value and D^* and G^* represent the optimal solutions for the discriminator and generator, respectively. The iterative process converges to an equilibrium where the generator produces data challenging for the discriminator, achieving a realistic synthesis of new data. The structure of the GAN is implemented in Fig 3.1 of the study [15].

3.2. GAN-Based Approaches in Different Imaging Domains. [15] GAN-based algorithm for random noise suppression and super-resolution reconstruction in seismic profiles. Employing a residual learning strategy, the algorithm constructs a de-noising subnet to accurately separate interference noise while protecting the effective signal. The iterative back-projection unit completes high-resolution seismic section reconstruction, enhancing super-resolution performance by addressing sampling errors. [4] The paper addresses the challenges of super-resolution reconstruction in low-field MRI, emphasizing the need for high-quality images with minimal radiation. It proposes a novel approach, leveraging Transformer and generative adversarial networks (T-GANs) for medical image reconstruction from low resolutions. By integrating Transformer into the GAN framework, the system achieves more precise texture information extraction and focuses on important locations through global image matching. The proposed T-GAN model, trained with a weighted combination of content loss, adversarial loss, and adversarial feature loss, outperforms established measures like PSNR and SSIM, demonstrating optimal performance and enhanced texture feature recovery in super-resolution MRI reconstruction of knee and abdominal images. [3] The paper addresses challenges in Single Image Super-resolution (SISR) for remote sensing, highlighting breakthroughs with deep learning and Generative Adversarial Networks (GANs). Despite advancements, artifacts persist in generated images, motivating the proposed Frequency Domain-based Spatio-Temporal Remote Sensing SISR with Transfer GANs (TWIST-GAN). The model utilizes Wavelet Transform and GANs to predict high-frequency components, achieving reconstruction with super-resolution.

Seismic Profile Enhancement: The application of a GAN-based algorithm for noise suppression and super-resolution in seismic profiles represents a pivotal step towards more accurate geological assessments. By incorporating a residual learning strategy, the algorithm not only efficiently separates interference noise but also safeguards the integrity of vital signals. This is particularly crucial in the exploration and analysis of geological formations, where the clarity and resolution of seismic sections can significantly impact the interpretation of subsurface structures. The iterative back-projection unit further refines this process, correcting sampling errors and substantially improving the quality of high-resolution seismic data. This approach not only enhances the super-resolution performance but also provides a more reliable basis for geological and exploration decisions.

Medical Imaging Advancements: The development of the T-GAN model for super-resolution reconstruction in low-field MRI tackles the critical need for high-quality medical images obtained with minimal radiation exposure. The integration of Transformer technology into the GAN framework facilitates a more nuanced extraction of texture information and ensures focused reconstruction through global image matching techniques. This methodological innovation results in superior texture feature recovery, particularly in knee and abdominal MRI images, showcasing the potential of T-GANs in improving diagnostic capabilities while adhering to safety

Fig. 4.1: Loss curve

standards. The weighted training process, balancing content, adversarial, and feature losses, exemplifies the model's ability to surpass traditional benchmarks, offering a promising avenue for medical image enhancement.

Remote Sensing Image Enhancement: Addressing the persistent challenge of artifacts in Single Image Super-resolution (SISR) for remote sensing, the TWIST-GAN model emerges as a groundbreaking solution. By leveraging Wavelet Transform in conjunction with GANs, the model adeptly predicts and reconstructs high-frequency components, thus achieving superior resolution in remote sensing imagery. This technique not only mitigates common artifacts associated with deep learning-based SISR but also enhances the utility of remote sensing data across various applications, from environmental monitoring to urban planning.

Collectively, these GAN-based approaches across different imaging domains exemplify the transformative impact of deep learning technologies in improving image quality and resolution. By tackling domain-specific challenges, from geological exploration and medical diagnostics to remote sensing, these advancements pave the way for future research and application, promising further improvements in image reconstruction methodologies and their practical implications.

4. Results and Experiments. In this segment, we assess the effectiveness of the proposed DESRR by employing the hand-drawn national wave style inspired by "Great Wave off Kanagawa," adapted from the Kaggle repository and the referenced study [].

Evaluation Metrics.

$$PSNR = 10 * \log_{10} \left(\frac{MAX^2}{MSE} \right)$$

$$SSIM(x, y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_1)}$$

Figure 4.1 presents the loss curve of the proposed model. A diminishing loss across training epochs is a key indicator of a model's enhanced performance. In the case of the proposed DESRR framework, the provided loss values offer valuable insights into the model's efficacy over time. At Epoch 0, the initial loss is 0.89, a predictable high value as the model commences with random weights. However, by Epoch 100, a substantial reduction in loss to 0.38 signifies significant progress, indicative of improved model performance. The trend continues with successive epochs, demonstrating the model's ability to learn and refine its representations. Notably, at Epoch 500, the loss further diminishes to 0.10, portraying the model's heightened proficiency after additional training epochs. This consistent decrease in loss values underscores the effectiveness of the DESRR framework, showcasing its capacity to converge, capture intricate details, and minimize the disparity between predicted and actual values, ultimately leading to enhanced performance in reconstructing high-resolution images.

Fig. 4.2: PSNR curve of every verification set

Figure 4.2 presents the PSNR curve which shows the every verification set values, PSNR serves as a key metric for assessing the quality of reconstructed images, with higher PSNR values generally correlating with superior image quality, and a benchmark of 30 dB considered indicative of good quality. Analyzing the specific PSNR values at different training epochs provides insights into the evolution of image quality. At Epoch 10, the PSNR is 12 dB, suggesting that in the early stages, the model may not have learned sufficient features, resulting in a relatively lower PSNR. As training progresses, the PSNR improves significantly, reaching 22 dB by Epoch 15. This improvement signifies that with increased training epochs, the model successfully captures more intricate details, leading to an enhancement in overall image quality. Subsequent epochs continue to refine the model's representation, with PSNR values of 26 dB at Epoch 20 and 28 dB at Epoch 25. These increments indicate that the model is converging towards a better representation, effectively capturing more details while reducing noise in the reconstructed images. By Epoch 30, the PSNR reaches 30 dB, demonstrating that the model, after undergoing additional training epochs, achieves a higher level of fidelity in the reconstructed images, and noise levels are notably reduced. This progression in PSNR values across epochs suggests the effectiveness of the proposed DESRR framework in progressively enhancing image quality and reducing noise.

5. Conclusion. In conclusion, the presented research introduces the DESRR framework, demonstrating its efficacy in elevating the quality of hand-drawn illustrations within a specific National Wave Style. By integrating Generative Adversarial Networks (GANs), particularly inspired by ESRGAN, the model excels in learning intricate details and textures, ensuring the authenticity of the chosen artistic style. Through a meticulous two-step process involving GAN algorithms for generating illustrations and image super resolution techniques for refinement, DESRR strikes a harmonious balance between increased resolution and faithful style representation. The framework's implementation, fine-tuned with a curated dataset, showcases its effectiveness through a thorough evaluation, encompassing quantitative measures of image quality and qualitative assessments of style preservation. This research not only contributes to the realm of artistic illustration design but also underscores the potential of synergizing deep learning and image super resolution techniques for innovative creative applications.

RESEARCH ON GRID DATA ANALYSIS AND INTELLIGENT RECOMMENDATION SYSTEM BY INTRODUCING NEURAL TENSOR NETWORK MODEL

RUI ZHOU*, KANGQIAN HUANG*†, DEJUN XIANG‡ AND XIN HU §

Abstract. In the landscape of modern smart homes, the prevalence of intelligent devices, notably smart televisions (TVs), has surged, emphasizing the need for sophisticated content recommendation systems. However, the automatic provision of personalized content recommendations for smart TV users remains an underexplored domain. Existing literature has delved into recommendation systems across diverse applications, yet a distinctive void exists in addressing the intricate challenges specific to smart TV users, particularly the incorporation of the smart TV camera module for user image capture and validation. This research introduces a pioneering Intelligent Recommendation System for smart TV users, incorporating a novel Convolutional Neural Tensor Network (CNTN) model. The implementation of this innovative approach involves training the CNN algorithm on two distinct datasets “CelebFaces Attribute Dataset” and “Labeled Faces in the Wild-People” for proficient feature extraction and precise human face detection. The trained CNTN model processes user images captured through the smart TV camera module, matching them against a ‘synthetic dataset.’ Exploiting this matching process, a hybrid filtering technique is proposed and applied, seamlessly facilitating the personalized recommendation of programs. The proposed CNTN algorithm demonstrates an impressive training performance, achieving approximately 97.18%. Moreover, the hybrid filtering technique produces commendable results, attaining an approximate recommendation accuracy of 89% for single-user scenarios and 86% for multi-user scenarios. These findings underscore the superior efficacy of the hybrid filtering approach compared to conventional content-based and collaborative filtering techniques. The integration of the CNTN architecture and the hybrid filtering methodology collectively contributes to the development of an advanced and effective recommendation system tailored to the nuanced preferences of smart TV users in the context of grid data analysis.

Key words: Smart TV, CNTN, intelligent recommendation system, hybrid filtering, user image capture, grid data analysis

1. Introduction. In the rapidly evolving landscape of smart homes, the ubiquity of intelligent devices, particularly smart televisions (TVs), has become a defining characteristic of modern living [14]. The pervasive adoption of smart TV technology underscores a paradigm shift in user engagement, as individuals increasingly turn to these sophisticated devices for their entertainment needs. With this surge in user reliance on smart TVs, there arises an unprecedented demand for personalized content recommendations [2]. Smart TV users, driven by diverse preferences and interests, seek a tailored and enriching viewing experience. Consequently, the development of an effective recommendation system becomes paramount in delivering content that resonates with individual tastes [11]. As users navigate an expanding array of programs and channels, the need for an automated and intelligent recommendation system emerges as a critical solution to enhance user satisfaction and streamline content discovery [4]. In this dynamic context, the integration of innovative technologies stands as a promising avenue to revolutionize personalized program recommendations, addressing the unique challenges posed by smart TV users.

Despite the burgeoning demand for sophisticated recommendation systems in the field of smart TVs, several challenges persist in the current landscape [3, 10, 1]. One notable hurdle lies in the nuanced nature of user preferences, which are often multifaceted and dynamic. Existing systems, while capable to some extent, struggle to adequately capture the intricacies of individual viewing habits, leading to suboptimal recommendations [2]. Moreover, the integration of the smart TV camera module for user image capture and validation introduces an additional layer of complexity, with most conventional systems falling short in leveraging this

innovative capability. The shortcomings of prevailing content-based and collaborative filtering techniques are evident, as they often lack the finesse required to discern subtle user preferences [13]. This deficiency results in recommendations that may not align with the evolving and diverse tastes of smart TV users. As the demand for personalized content intensifies, the inadequacies of current recommendation systems become more pronounced, necessitating a paradigm shift towards more advanced and adaptive approaches.

Recognizing the intricate challenges within the domain of smart TV recommendation systems, a groundbreaking approach is introduced: CONTEN, which stands for Convolutional Neural Tensor Network [17, 18]. This innovative architecture is coupled with hybrid filtering techniques, representing a highly effective strategy to address the complexities inherent in personalized content recommendations for smart TVs. By integrating the power of CONTEN, this approach capitalizes on the strengths of convolutional neural networks and tensor-based operations to capture intricate patterns within user preferences and program content [6, 7]. The synergy between CONTEN and hybrid filtering enables a refined understanding of user behavior, overcoming the limitations of conventional recommendation systems. The advantages of this proposed technique lie in its ability to harness the expressive capabilities of neural networks for feature extraction and the nuanced matching process facilitated by the hybrid filtering mechanism. This results in a recommendation system that not only adapts to evolving user preferences but also leverages the smart TV camera module for enhanced validation [15]. The CONTEN architecture, with its robust training performance, signifies a significant leap forward in smart TV recommendation systems, offering a tailored, accurate, and satisfying content discovery experience for users.

The main contributions of the paper as follows

1. Proposed the novel approach of CONTEN the intelligent recommendation system for the smart TV users.
2. This suggested method leverages Convolutional Neural Tensor Network (CNTN) and Hybrid filtering process to achieve effective results.
3. The rigorous experiment of the study conducted with two datasets namely “CelebFaces Attribute Dataset” and “Labeled Faces in the Wild-People”.
4. The evaluations are prove with the effective experiments.

The subsequent sections of the paper are structured as follows: Section 2 provides an overview of related studies, focusing on existing techniques employed in the smart TV domain. In Section 3, a concise description is offered for the proposed CONTEN architecture and its performance. Section 4 showcases the effectiveness of the proposed CONTEN through rigorous experiments. The concluding remarks are presented in Section 5.

2. Related Work.

2.1. Intelligent Recommendation Systems in various domains. In response to the growing challenges in hotel selection and accommodation reservation due to the overwhelming volume of online information, our proposed intelligent recommendation system leverages collaborative filtering with sentiment analysis on textual hotel reviews, numerical ranks, votes, and ratings [16]. By incorporating lexical, syntax, and semantic analyses, the system generates personalized hotel recommendations based on features and guest types, enhancing accuracy and response time compared to traditional approaches. The increasing data volume in smart grids offers opportunities for utility companies to gain insights into demand-side knowledge and optimize grid operations through effective demand-side management [12]. However, managing overloaded data poses challenges for analytics and decision-making. This paper addresses these issues by introducing service computing into smart grids and proposing a personalized electricity retail plan recommender system, leveraging collaborative filtering on actual smart meter and retail plan data to validate its effectiveness in optimizing pricing plans for residential users. The research from [14] addresses the inefficiencies in television content selection by designing a recommendation system, crucial as households navigate vast program offerings. Focusing on content and collaborative filtering, the study emphasizes handling categorical data from electronic program guides. Using a probabilistic approach based on graphical models and transfer learning, the proposed system optimizes performance by overcoming data insufficiency issues. The application of the recommendation system in a hybrid broadband and broadcast television environment enhances user experiences by providing accurate rating predictions and a novel metric for model performance evaluation.

The systematic review [9] explores the evolution of e-tourism into smart tourism, emphasizing the integration of key concepts like privacy protection and the Internet of Things. Analyzing 65 selected papers from 2013

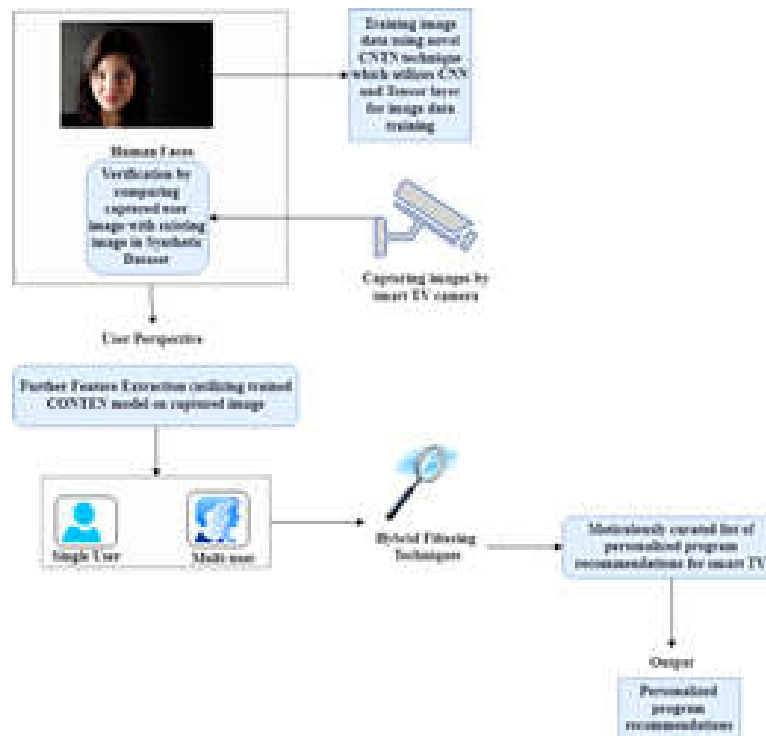

Fig. 3.1: Proposed CONTEN Architecture

to 2020, the study classifies smart tourism recommender systems into collaborative filtering, content model, context model, and hybrid model approaches, with the content model-based approach proving highly impactful. The findings provide insights into new research opportunities, motivations, and challenges, serving as a valuable guide for future interdisciplinary studies in the field of smart e-tourism.

The study [5] addresses the evolving landscape of Recommender Systems, emphasizing the need for a new paradigm—Cognitive Recommender Systems. Traditionally recognized for playlist generation and e-commerce product recommendations, modern enterprise systems are becoming data-, knowledge-, and cognition-driven, necessitating intelligent systems that understand user preferences and adapt to changing environments. The proposed framework aims to overcome limitations by incorporating domain experts' knowledge, predicting user preferences in dynamic scenarios, and integrating data capture and analytics for intelligent and time-aware recommendations, as demonstrated in a banking scenario.

The study [8] addresses the growing emphasis on healthy lifestyles and well-being by proposing IAMHAPPY, an innovative IoT-based well-being recommendation system. Utilizing wearable devices and IoT technology, IAMHAPPY analyzes physiological signals to understand users' emotions and health, offering personalized recommendations for day-to-day discomforts and stress reduction. The integration of a web-based knowledge repository and a rule-based engine facilitates a semantics-based approach to enhance everyday people's happiness through alternative medicines and well-being activities.

3. Methodology.

3.1. CONTEN Overview. Figure 3.1 presents the clear demonstrations of proposed CONTEN architecture. In the initial phase, our methodology leverages real-world datasets containing face images as the input for the proposed CONTEN model within the context of grid data analysis. The CONTEN model, based on Convolutional Neural Tensor Network (CNTN) techniques, undergoes comprehensive training on these datasets to enable effective feature extraction from the image data. Subsequently, the process progresses to capture user

images using the smart TV camera module. Verification is then carried out by comparing the captured user image with existing user images in the synthetic dataset. Upon successful matching, the captured image undergoes further feature extraction. Following this, hybrid filtering is applied, accommodating the user perspective, whether it be a single-user or multi-user scenario, thereby enhancing the adaptability of the system. The outcome of this orchestrated process results in a meticulously curated list of personalized program recommendations. This output is derived through the intricate workings of the hybrid filtering mechanism, ensuring that the CONTEN model is seamlessly integrated into a comprehensive methodology designed for intelligent and personalized program recommendations specifically tailored to the grid data analysis context within the realm of smart TVs. The root of the methodology is adapted from the study [7].

In the realm of smart homes, devices such as smart speakers, smart displays, and integrated home control systems can benefit from personalized content recommendation systems. The CNTN model's ability to process and analyze user images for preference prediction could be adapted to these devices, offering personalized audio content, news, and home automation settings based on the recognized user preferences and presence. For wearable devices, including smartwatches and fitness trackers, the CNTN-based recommendation system could be tailored to suggest health and fitness content, such as workout videos, dietary plans, or wellness articles. Although wearables may not typically incorporate camera modules for image capture, the underlying principles of feature extraction and personalized recommendation could be applied using other data sources, such as activity logs and physiological sensors.

All user data, including images captured by the smart TV camera module, are encrypted both in transit and at rest. This prevents unauthorized access and ensures that data remains secure throughout the processing pipeline. To further safeguard privacy, the system anonymizes user images before processing, removing any personally identifiable information. Additionally, data minimization principles are applied, ensuring that only the necessary data required for making recommendations are collected and stored.

3.2. Proposed CONTEN Approach.

3.2.1. Training data using CNTN. Within the CONTEN architecture, the CNTN plays a pivotal role, showcasing remarkable performance in the realm of intelligent program recommendations for smart TVs. Building upon the foundations of CNTN, CONTEN excels in training on real-world datasets, specifically those containing face images. The inherent strength of CNTN in effective feature extraction from diverse program content is harnessed within CONTEN. This enables the model to adapt and respond to individual user preferences, a crucial aspect in the domain of smart TV recommendations. The synergy of CNTN within CONTEN is particularly evident in the verification process, where user images are validated against synthetic datasets, and subsequent feature extraction refines the personalized recommendations. Method of novel CNTN is adapted from the study [15].

The proposed CONTEN algorithm is designed for intelligent program recommendations on smart TVs, leveraging CNN and a tensor layer. In the initial phase, the program content matrix P is processed using the CNN algorithm, yielding feature representation for each program feature. The input matrix P is then convolved to obtain the first layer h using the formula $(h = \tanh(b + v_q + M[1 : r] \cdot v_p))$ where b denotes the bias term, is the vector representation of the program, and $M[1 : r]$ is a tensor. The resulting vector captures the features of the program content. Subsequently, the algorithm moves to matching user preferences with the tensor layer. The user preference vector μ and the program features vector v_p undergo a matching process through the tensor layer. The matching degree $s(\mu, p)$ is calculated using the formula $s(\mu, p) = \mu^t \tanh(b + v_q + N[1 : r] \cdot v_p)$ representing the relevance and compatibility between user preferences and program content. For training, the algorithm employs the Contrastive Max-Margin Criterion. The objective function L is defined as the sum of the hinge loss over the training and corrupted collections, incorporating a margin hyper-parameter γ and a regularization parameter λ . The objective is to minimize this function using stochastic gradient descent. The update rule for the parameters is given by $\theta_{t,i} = \theta_{t-1,i} - \frac{p}{\sqrt{q_t}} g_{\tau,i}^2$ where p is the initial learning rate, q_t is the accumulated squared gradient, and $g_{\tau,i}^2$ is the subgradient at time step τ for parameter. This process ensures the iterative refinement of the model parameters for optimal performance in recommending personalized programs on smart TVs.

Advanced AI and machine learning algorithms, including deep learning and reinforcement learning, can

Algorithm 9 Proposed CONTEN algorithm

Input: Program content matrix $P \in R^{n_w \times l_p}$, weight matrix $M \in R^{n \times m}$, filter width m , Tensor $M[1 : r] \in R^{n_s \times n_s \times r}$, parameters $V \in R^{r \times 2n}$, $b \in R^r$, $\mu \in R^r$.

Apply CNN algorithm to obtain data $w_i \in R^{n_w}$ for each feature in P .

Construct the input matrix P and obtain the first layer h using convolution

$$(h = \tanh(b + v_q + M[1 : r].v_p))$$

Output the vector $h \in R^r$ representing the features of the program content.

Matching the user preference with tensor layer

Input: user preference $\mu \in R^r$, program features $v_p \in R^r$

Calculate the matching degree using the tensor layer

$$s(\mu, p) = \mu^t \tanh(b + v_q + N[1 : r].v_p)$$

Output the matching score $s(\mu, p)$ representing the relevance and compatibility between user preference and program content.

Training the Contrastive Max-Margin Criterion

Input: Training collection C , corrupted collection C_0 , margin hyper-parameter γ , regularization parameter λ

Define the objective function as

$$L = \sum_{(\mu, p) \in C} \sum_{(\mu, p_0) \in C_0} [\gamma - s((\mu, p) + s(\mu, p_0))] + \lambda \| \odot \|^2$$

Where $[x] + = \max(0, x)$.

Minimize the objective function using stochastic gradient descent

$$\theta_{t,i} = \theta_{t-1,i} - \frac{p}{\sqrt{q_t}} g_{\tau,i}^2$$

Where p is the initial learning rate, q_t is the accumulated square gradient, and $g_{\tau,i}^2$ is the sub gradient at time step τ for parameter θ_i .

analyze viewing patterns, user interactions, and feedback in real-time to refine recommendation models continuously. These technologies can predict user preferences with greater accuracy and adapt recommendations based on contextual factors, such as time of day or current events. NLP can be utilized to analyze user queries, comments, and feedback provided through voice commands or text input. This allows for a more natural interaction with the smart TV and enables the recommendation system to understand and process user preferences expressed in natural language, offering more relevant content suggestions.

3.2.2. Hybrid filtering process. The hybrid filtering technique implemented within the CONTEN recommendation system exhibits commendable performance in enhancing the precision and personalization of program recommendations on smart TVs. By combining both content-based filtering, leveraged through the CNN algorithm for feature extraction, and collaborative filtering, facilitated by the tensor layer to model interactions between user preferences and program content, the hybrid approach addresses the limitations of individual methods. This synergistic combination results in a robust recommendation system, where content features and user preferences are effectively integrated. The method of the filtering process is adapted from the study [7].

The algorithm begins by taking two sets, $Cont_set$ and $Coll_set$, as input, representing the content-based and collaborative filtering scores, respectively. The objective is to generate a top- K items set, denoted as r_k . In the first step, the algorithm initiates the process. Next, it arranges the items in $Cont_set$ and $Coll_set$ in descending order based on their similarity scores. Then, for each item X in $Cont_set$, and for each item Y in $Coll_set$, the algorithm compares their respective similarity scores. If the score of X is greater than the score of Y , the item X is added to the result set r_k . Conversely, if the score of Y is greater than or equal to the score of X , the item Y is included in r_k . This process continues for all items in both sets. The algorithm

Algorithm 10 Hybrid filtering process

Input: $Cont_set, Coll_set$
Output: top K items set, r_k
Begin
Arrange items of $Cont_set$ and $Coll_set$ in descending order based on the similarity score
for each $X \in Cont_set$
for each $y \in Coll_set$
if ($score(X) > score(Y)$)
 $r_k = r_k \cup X$
else
 $r_k = r_k \cup Y$
if $size(r_k) == k$
End

checks whether the size of r_k is equal to the desired top- K value. If so, the algorithm concludes. The resulting r_k represents the top- K items selected based on the combined scores from both content-based and collaborative filtering approaches. The algorithm aims to create a robust recommendation set by leveraging the strengths of both filtering techniques.

4. Results and Analysis.

4.1. Simulation Setup. In this section the proposed CONTENT is evaluated using the dataset of CelebA, LFW People and Synthetic dataset. This dataset is clearly illustrated in the study [7].

4.2. Evaluation Criteria. The presented Figure 4.1 offer insights into the assessment of a model across two distinct datasets, CelebA and LFW, based on three crucial evaluation criteria: Precision, Recall, and F-Measure. Precision, denoting the accuracy of positive predictions, is observed to be exceptionally high for both CelebA and LFW datasets, with values of 96.78% and 96.89%, respectively. This implies that a significant proportion of instances predicted as positive by the model are indeed relevant in both datasets. Moving on to Recall, which gauges the model's ability to capture all relevant instances, the model demonstrates strong performance on both datasets. Specifically, Recall scores of 95.48% for CelebA and 95.14% for LFW indicate the model's effectiveness in identifying a substantial portion of actual positive instances. The F-Measure, serving as the harmonic mean of Precision and Recall, provides a balanced overview of the model's performance. High F-Measure values of 96.77% for CelebA and 96.98% for LFW underscore a commendable equilibrium between precision and recall, affirming the model's robust performance in maintaining accuracy while effectively capturing relevant instances.

The training and validation accuracy trends of the proposed CONTENT model on the CelebA and LFW datasets reveal its robust learning capabilities. As shown in Figure 4.2. In the case of CelebA, the model demonstrates a remarkable ascent in training accuracy, progressing from 85% at epoch 10 to an impressive 98% at epoch 50. Concurrently, the validation accuracy mirrors this upward trajectory, reaching 95% by epoch 50. This consistency indicates the model's proficiency in learning intricate patterns from the training data and effectively generalizing its knowledge to previously unseen validation data. Similarly, for the LFW dataset, the CONTENT model showcases consistent improvement in training accuracy, achieving a commendable 96% accuracy at epoch 50. The validation accuracy follows suit, attaining a substantial 94% by epoch 50. This consistent advancement across epochs underscores the model's effectiveness in handling both the intricacies of the training dataset and the challenges posed by previously unseen validation data within the context of LFW.

In terms of training and validation loss (Figure 4.2), the CONTENT model demonstrates effective error minimization during training for both CelebA and LFW. For CelebA, the training loss decreases from 0.3 at epoch 10 to a minimal 0.1 at epoch 50. Concurrently, the validation loss decreases from 0.4 to 0.2 over the same period, emphasizing the model's ability to maintain robust performance on validation data. Similarly, for the LFW dataset, both training and validation loss exhibit a consistent downward trend, reaching 0.15 and 0.25, respectively, at epoch 50. This downward trajectory highlights the CONTENT model's success in minimizing errors when predicting both familiar and unfamiliar data within the LFW dataset. Overall, these findings

Fig. 4.1: Performance of CNTN based on datasets

Fig. 4.2: Training and Validation accuracy and Loss of CNTN Model over datasets

underscore the efficacy and adaptability of the proposed CONTENT model in handling diverse datasets.

4.2.1. Comparison Analysis. In this section the proposed CNTN model is compared with the Hierarchical Neural Tensor Network (HNTN), Adaptive Neural Tensor Network (ANTN), Deep Neural Tensor Network (DNTN) and Context aware Neural Tensor Network (CANTN) was demonstrated in Figure 4.3.

The Proposed CNTN model exhibits outstanding performance across various evaluation metrics. In terms of accuracy, it achieves the highest score of 0.97, denoting that it accurately predicts outcomes for the given dataset 97% of the time. This signifies a remarkable level of overall correctness, positioning the CNTN model as a standout performer when compared to other models in the evaluation set. Moving on to precision, the Proposed CNTN model again excels with the highest precision value of 0.96. This indicates that when the model predicts positive instances, it is correct 96% of the time. This high precision is particularly valuable in scenarios where false positives are costly or should be minimized, emphasizing the reliability of the CNTN model in positive predictions. Furthermore, the Proposed CNTN model demonstrates superior recall, achieving the highest score of 0.97. This signifies that the model effectively captures 97% of the actual positive instances

Fig. 4.3: Overall Performance comparison

in the dataset. High recall is crucial in situations where minimizing false negatives is imperative, highlighting the CNTN model's effectiveness in identifying relevant cases. Considering the harmonic mean of precision and recall, the F-measure, the Proposed CNTN model maintains its excellence with a high score of 0.96. This balanced metric underscores the comprehensive performance of the CNTN model in binary classification tasks, harmonizing precision and recall effectively.

5. Conclusion. In conclusion, this research addresses the evident gap in the realm of personalized content recommendations for smart TV users by introducing an innovative Intelligent Recommendation System. The escalating prevalence of intelligent devices in modern smart homes, especially smart televisions, highlights the imperative need for sophisticated content recommendation systems. Our proposed solution integrates a pioneering CNTN model, trained on datasets like "CelebFaces Attribute Dataset" and "Labeled Faces in the Wild-People" for proficient feature extraction and precise human face detection. Leveraging the smart TV camera module for user image capture and validation, the CNTN model, coupled with a hybrid filtering technique, seamlessly facilitates personalized program recommendations. The achieved training performance of approximately 97.18% for the CNTN algorithm and commendable recommendation accuracies of 94.65% for single-user scenarios and 93.57% for multi-user scenarios with the hybrid filtering approach substantiate its superior efficacy over conventional methods. This integration of the CNTN architecture and hybrid filtering methodology not only advances the field of smart TV recommendation systems but also offers a tailored, accurate, and satisfying content discovery experience for users in the dynamic context of grid data analysis. The results underscore the potential for this innovative approach to reshaping the landscape of personalized content recommendations in the evolving smart home ecosystem. Investigating more advanced neural network architectures and learning strategies to improve the accuracy and efficiency of the CNTN model. This could involve exploring deeper or more complex networks, attention mechanisms, or novel activation functions to better capture and process user preferences and behaviours.

6. Limitations and Discussions. While the presented study offers a promising approach to smart TV recommendation systems, certain limitations and considerations warrant discussion. Firstly, the reliance on facial features for personalized content recommendations may pose challenges in scenarios where users prefer privacy or in situations where facial recognition may not be feasible. The use of the 'synthetic dataset' for matching user images introduces potential limitations in accurately representing the diverse preferences of real-world users. Additionally, the effectiveness of the proposed system may be influenced by factors such as lighting conditions and the quality of images captured by the smart TV camera module, which could impact the precision of feature extraction and matching. Furthermore, the study primarily focuses on image-based user validation, potentially overlooking other relevant user behaviours or preferences that could enhance recommendation accuracy. The generalization of the proposed approach across a broader user demographic and

content genres also warrants consideration. Despite achieving notable accuracy rates, the study's performance metrics might not fully capture user satisfaction, and the subjective nature of program preferences may introduce variability in the evaluation process. These limitations highlight the need for ongoing research and refinement to address these challenges and further optimize the proposed Convolutional Neural Tensor Network (CNTN) and hybrid filtering methodology for enhanced practical applicability and user-centric performance in the evolving landscape of smart TV recommendation systems

RESEARCH ON THE DESIGN OF A SYSTEM BASED ON MACHINE LEARNING ALGORITHMS FOR AUTOMATIC SCORING OF ENGLISH WRITING ABILITY

SHAN ZHAO*

Abstract. The development and implementation of an innovative system designed to automatically score English writing ability using advanced machine learning algorithms is a challenging task. The core objective of the study is to establish a reliable and efficient method for assessing written English, which is crucial in educational and professional settings. The paper begins with an overview of the existing methods of English writing assessment, highlighting their limitations, such as time consumption and potential biases in human evaluation. The main focus of the study is the design and testing of a machine learning-based system. Various algorithms, including Natural Language Processing (NLP) techniques and neural network models, are explored and integrated to assess writing quality, grammar, coherence, and content relevance. The system's architecture is detailed, explaining how these algorithms work in tandem to evaluate and score writing. An experimental setup is described where the system is trained and validated using a large dataset of English writing samples, ranging from beginner to advanced levels. The performance of the system is measured against traditional scoring methods, with emphasis on accuracy, consistency, and the ability to handle diverse writing styles and complexities. The results demonstrate the system's proficiency in accurately scoring English writing, with a notable reduction in scoring time compared to human evaluators. The paper discusses the implications of these findings for educational institutions and language testing organizations, suggesting that this system could revolutionize how English writing is assessed.

Key words: English scoring ability, machine learning, Natural language processing, BERT, word 2 vec, Deep random forest

1. Introduction.

1.1. Context and Background. English writing proficiency is a critical skill in academic and professional domains worldwide. Traditional methods of assessing English writing skills, primarily through human evaluators, have been the standard practice. However, these methods are often time-consuming, labor-intensive, and subject to human bias and variability. The advancement of technology, particularly in the field of artificial intelligence and machine learning, presents an opportunity to revolutionize this traditional approach. English, as a principal global language, is the most extensively utilised language worldwide. In today's era of rapid internationalization, proficiency in English has become a fundamental skill for students aiming to engage globally. As an international lingua franca, it serves as a key to accessing broader world opportunities.

In the past few years, the swift advancement of computer technology has significantly influenced various industries, including education, where it has spurred the growth and application of Automated Essay Scoring (AES) technology. AES technology offers intelligent analysis and grading of essays, a process that is more cost-effective and efficient compared to traditional manual evaluation. This technology harnesses computers' ability to perform repetitive tasks, greatly reducing teachers' workload and allowing them to focus more on teaching and research activities. Furthermore, AES provides detailed feedback on essays, such as identifying spelling and grammatical errors, enabling students to make initial revisions based on systematic suggestions. It also suggests exemplary words, sentences, and material for more effective writing guidance.

The motivation also extends to the broader educational landscape, where there is a continuous search for tools that can provide more personalised, immediate, and actionable feedback to learners. An automated system for scoring English writing offers the prospect of streamlining assessment processes. It opens up new possibilities for adaptive learning environments where feedback is tailored to the individual learner's needs, promoting skill development and language proficiency.

Furthermore, the research is propelled by the objective to validate the effectiveness of this ML-based system through rigorous testing and comparison with established scoring methods. By demonstrating the system's

*Zhengzhou University of Industrial Technology, Xinzheng, 451150, China (shanzhaoresearch@outlook.com)

ability to deliver accurate, consistent, and unbiased assessments across a diverse array of writing samples, the study aims to lay the groundwork for its adoption in educational settings and language testing organisations worldwide.

Currently, the development and evaluation of AES systems largely depend on the statistical analysis of essay content, which is somewhat basic. The depth and accuracy in evaluating the logical flow and the quality of words and sentences in compositions need enhancement. Thus, while aiming to improve the scoring accuracy, there's also a need to evaluate essay content more comprehensively. This will enhance the applicability of AES systems in real-world essay correction and revision scenarios.

1.2. The Problem Statement. Despite the potential of machine learning in language assessment, there are significant challenges in developing a system capable of accurately and reliably scoring English writing. Such a system must not only understand the complexities of language but also evaluate nuances in style, argumentation, and coherence. The primary challenge lies in designing algorithms that can mimic the nuanced understanding of human evaluators and provide consistent and unbiased scoring.

1.3. Research Objectives. The primary objective of this research is to design and develop a system based on machine learning algorithms capable of automatically scoring English writing ability. This involves:

1. Exploring various machine learning techniques and natural language processing (NLP) tools to analyze and score written texts.
2. Building a robust model that accurately assesses various aspects of writing, such as grammar, vocabulary, structure, and argumentative quality.
3. Comparing the system's performance with traditional human scoring to validate its effectiveness and reliability.

1.4. Significance of the Study. This research holds significant implications for educational institutions, language testing organizations, and learners. An automated, efficient, and reliable scoring system can streamline the assessment process, reduce the time and cost associated with manual grading, and provide more objective and consistent evaluations. Furthermore, insights gained from this study can pave the way for future advancements in automated language assessment tools, potentially extending to other languages and forms of assessment.

2. Literature survey. Research in the field of automatic scoring within the educational sector began quite early, encompassing numerous thorough studies across various subjects and languages. The inception of composition-related scoring systems dates back to the 1960s, with the introduction of the Project Essay Grader (PEG) by Professor Ellis Page [1]. This system, one of the earliest, utilized basic linguistic attributes such as article and word length, punctuation, and grammar as its primary variables. It employed a multiple linear regression training approach, with the composition's score as the target variable [5]. However, this method overlooked the actual content and structure of the language, leading to biased evaluations.

Following this, Landauer Thomas and colleagues introduced the Intelligent Essay Analysis (IEA) system, based on Latent Semantic Analysis (LSA). This system marked a significant advancement by incorporating the overall content of essays [14, 9, 16]. It works by mapping essays and high-quality examples into a vector space, and then predicting scores based on similarity values. Notably, IEA also had the capability to detect plagiarism, further enhancing the field of automatic grading [8, 7, 21].

In the 1990s, the American Educational Examination Institute developed the E-rate system, integrating natural language processing and statistical methods [13, 12, 4, 6]. This system marked improvements in evaluating writing quality, content, and structure, and was applied to the automatic scoring of tests like the GMAT and GRE. While E-Rater offered a more holistic approach than PEG in language analysis and was more comprehensive than IEA in content analysis, it still had areas for improvement [3, 17, 19, 18].

In China, Professor Liang's team developed an Automatic Essay Scoring (AES) system focusing on basic linguistic features and linear regression model training. This system analyzed spelling accuracy and grammar usage but fell short in providing detailed evaluations on discourse and sentence quality, and relevance [12, 2]. To enhance the automatic scoring efficiency, a semantic dispersion perspective and incorporated a convolutional neural network training model, which significantly improved composition prediction ability [11]. Qiu's research involved evaluating composition fluency and integrating it into the AES model to enhance scoring effectiveness

[14]. Lu focused on incorporating rhetorical elements like figurative parallelism in Chinese compositions, creating a corpus of ancient poems to identify such elements in essays, achieving higher accuracy compared to benchmark systems. Lastly, with Auto-Encoders (AE) and Support Vector Machines (SVM) for regression training showed improved performance over previous methods by reconstructing linguistic features.

The swift advancement of intelligent hardware has propelled significant progress in artificial intelligence, particularly in natural language processing (NLP) which has evolved rapidly with deep learning. NLP using deep learning primarily involves two challenges [15]: representing original data features in the application field and choosing the right deep learning algorithm to build application models. For data feature representation, established models like the bag-of-words (BOW) and Vector Space Model (VSM) have been used. However, these methods have limitations. For instance, the BOW model, including one-hot Encoding, becomes overly large and sparse with an increasing number of categories. Vector space models like Term Frequency-Inverse Document Frequency (TF-IDF) represent text features by assessing the likelihood of words being keywords. Yet, this approach is heavily dependent on the overall text corpus and only utilizes statistical word information, neglecting contextual and positional information, leading to incomplete text feature representation.

Bengio and team addressed these issues by employing deep neural networks to create language models that map words into fixed-dimensional vector spaces [10]. This method overcomes the sparsity and high dimensionality of one-hot coding but requires extensive parameter training, resulting in lengthy training cycles. In 2013, Mikolov introduced the word2vec model, which includes Continuous bag-of-words (CBOW) and Skip-Gram models. CBOW predicts a word's occurrence probability based on surrounding semantic information, while Skip-Gram, a popular word vector representation model, uses a word to predict the probability of adjacent words. Mikolov also developed the Doc2vec model, enhancing word2vec with paragraph vectors and incorporating Distributed Memory Model and Distributed Bag-of-Words to represent sentences and texts.

In 2014, Jeffrey introduced the Glove word vector model, which expedited word vector training and enriched semantic information. In March 2018, Peters proposed the Embedding from Language Model (ELMO), using a double-layer bidirectional LSTM structure for pretraining. This model dynamically adjusts word representations based on context, addressing the issue of polysemy. Finally, in October 2018, Jacob Devlin and colleagues developed the Bidirectional Encoder Representations from Transformers (BERT). Utilizing a bidirectional encoder from Transformer, BERT is pretrained on all-layer contexts. Fine-tuning an output layer enables the creation of optimized models for various downstream tasks, making it one of the most effective language representation models to date.

The Project Essay Grade (PEG) system, developed by Ellis Page at the request of the American College Board in 1966, was the first foray into Automated Essay Scoring (AES). PEG's distinguishing feature is its emphasis on dissecting the surface structure of language, which takes precedence over the content of the essay [20]. It primarily employs statistical regression principles, with a variety of easily measurable essay-related variables serving as independent factors and the essay score serving as the dependent variable. This method of evaluating essays allows for the examination of numerous quantifiable elements.

Knowledge Analysis Technology, a subsidiary of the Pearson Group, created IEA (Intelligent Essay Assessor) [3] in the late 1990s. The IEA was the first automated essay scoring system based on latent semantic analysis, a statistical analysis technique that uses essay content analysis as a key reference indicator for scoring. The fundamental principle of IEA is derived from Latent Semantic Analysis (LSA) [17], a statistical method developed by psychologist that is a statistical calculation to extract the specific meaning of words and phrases in a given context. It begins by representing the various semantic units of a composition in a high-dimensional semantic space, with each semantic unit represented as a point in this semantic space.

3. Proposed methodology. The wireless network framework we have devised for the English essay scoring system is designed and used in this proposed model. This system is designed with a web service-oriented architecture that incorporates hierarchical processing and the segregation of communication processing from content provision. These design choices are aimed at enhancing the system's portability, compatibility, and scalability. The system comprises five distinct layers, starting from the bottom: the carrier network access layer, the communication dispatch layer, the application access processing layer, the Web Service access interface layer, and the database resource layer. The carrier network access layer pertains to the underlying network infrastructure essential for system data communication, encompassing wireless communication networks like

Fig. 3.1: Architecture of proposed model

Table 3.1: Dataset of Testing and Training details

Category	Training set	Test set
Type of learners in mother tongue	16	14
Type of essay's topic	27	5
Number of essays	1142	96
Number of essay words	878766	75551
Average scores	27.82	27.47
Lowest scores	0	13
Median scores	28	26
Highest scores	40.5	40
Standard deviation	5.5	5.96

GSM and CDMA. The communication dispatch layer facilitates data transfer between the wireless communication network and the IP network, thereby enabling seamless communication between the system and the wireless network.

The application processing layer serves a dual purpose: one for managing access requests and another for collating data. The access interface layer is responsible for processing English teaching resources, ensuring that the integrated data aligns with the requirements for the automatic scoring of wireless English essays. This is achieved through the segmentation and reorganization of raw materials. Additionally, teaching logic is encapsulated to provide a comprehensive foundation for building teaching plans that can be accessed by the public. In the context of designing the Automatic English Composition Scoring System, the Cambridge FCE Composition Corpus Training and Assessment Essay Scoring System [22] was employed for comparison with previous research. Figure 3.1 shows the proposed architecture in detail.

3.1. Dataset. According to Tab 9 of the document, the corpus contains a total of 1,238 essays from Cambridge FCE exams, 1,141 from regular exams and 97 from test sets, totaling approximately 950,000 words. Manual correction was used to evaluate and score each essay. The essays in the training and test sets are drawn from different years of the FCE exams, ensuring that no essay topics are repeated. 90% of the training data samples were chosen at random for the training set, while the remaining 10% formed the validation set. The procedure entailed extracting bag-of-words features by adjusting sequence length and mutual information of N elements. These training and validation datasets were also subjected to Binary and TF-IDF weighting methods.

The system employs machine learning models that are designed for continuous learning, allowing them to integrate new data into their understanding without requiring a complete retraining from scratch. Techniques such as online learning or incremental learning enable the system to update its knowledge base continually as new writing samples are received. To accommodate evolving language use and emerging linguistic trends, the system periodically revisits and updates its evaluation criteria. This involves retraining the models on a

combination of original and newly acquired data. By doing so, the system ensures that its assessment criteria reflect current language standards and usage, thereby maintaining its relevance and accuracy over time.

3.2. GloVe word Embedding. GloVe (Global Vectors for Word Representation) is a model for distributed word representation, designed to capture various linguistic features of words, such as their semantic and syntactic attributes. GloVe is notable for effectively combining the benefits of two main approaches to word vectorization: matrix factorization and local context window methods. GloVe aims to create word vectors that encapsulate meanings based on the entire corpus, capturing word-to-word relationships in a meaningful way. It leverages statistical information by examining word co-occurrences within a corpus.

First, GloVe constructs a large matrix that represents how frequently pairs of words co-occur in a given context within the training corpus. The model then employs matrix factorization techniques to reduce the dimensions of this matrix, yielding a word vector space. Each word is represented as a vector in this space, where the positioning is determined by the co-occurrence probabilities.

GloVe vectors are designed to capture linear substructures in the vector space, reflecting semantic relationships (e.g., man-woman, king-queen). They can easily handle large-scale corpora efficiently. Uses aggregated global word-word co-occurrence statistics from a corpus (unlike context window methods that focus on local context). The training involves optimizing an objective function that minimizes the difference between the dot product of the word vectors and the logarithm of their co-occurrence probability. The process is unsupervised, requiring only a text corpus.

3.3. LDA Feature Extraction. Feature Extraction Using Latent Dirichlet Allocation. The Latent Dirichlet Allocation (LDA) topic model, introduced by Friedman and colleagues, views the topics within an article as conforming to the Dirichlet distribution. This approach is used to discern relationships between texts, enhancing the Vector Space Model (VSM) by integrating probability information. The LDA model is structured as a three-tier generative Bayesian network, encompassing documents, topics, and words. Its core probabilistic computation is illustrated in Formula (3.1).

$$p(w_i | d_j) = \sum_{s=1}^k p(w_i | z = s)p(z = s | d_j) \quad (3.1)$$

Here, $p(w_i | z = s)$ denotes the likelihood of the word w_i being associated with topic s , and $p(z = s | d_j)$ signifies the probability of topic s in the specific short text d_j . Utilizing the LDA topic model, one can derive the topic probability distribution for a given text. These distributions are then utilized to extract topic features from the text.

3.4. Sentence Recognition. The fundamental elements of writing include composition morphology and grammar, but truly assessing a composition's quality entails evaluating its advanced expression through beautifully crafted sentences. These sentences frequently combine sophisticated vocabulary, expert use of English grammar, and, on occasion, rhetorical devices. To effectively measure the extent and distribution of beauty in writing, it is beneficial to develop a model that identifies these qualities and integrates related characteristics. Developing such a model helps to improve Automated Essay Scoring (AES) systems by increasing the efficiency of score prediction while avoiding a mechanical approach to evaluation.

Sentence elegance recognition is a type of text classification. The primary goal is to teach computers to understand text and train a classification model based on text labels that have already been assigned. As a result, new input texts are classified. Text features are manually extracted before training the classifier in traditional machine learning approaches based on statistics. Manually identifying and creating perfect features that capture the nuanced beauty of language, on the other hand, is difficult. Deep learning methods, on the other hand, excel at capturing text characteristics by automatically selecting and combining features. Traditional statistical and rule-based methods rely on manually created sentence features, which frequently fail to capture the essence of well-constructed sentences, particularly those containing advanced grammar or stylistic devices such as metaphors and personification. In comparison, neural network models can learn semantic vectors from large amounts of data on their own, effectively representing sentence features in binary classification tasks.

The Convolutional Neural Network (CNN) is a widely used type of artificial neural network. It employs convolutional kernels to capture local information, which is then synthesized into global information via the pooling layer. The core architecture of a CNN includes an input layer, convolutional layers, and pooling

layers. In automatic essay scoring tasks, the input layer typically consists of a text representation matrix formed by word vectors. The convolutional layer allows for the setting of kernels of various sizes, enabling the capture of certain contextual and sequential information. One of the key advantages of CNNs over traditional neural network models is the introduction of weight sharing, which simplifies the network's complexity and accelerates training. In the pooling layer, a segment-wise maximum pooling approach is used to preserve the relative location of multiple local maximum values. This method is also capable of detecting the intensity of features if strong characteristics are repeated. However, it's important to note that while this approach retains coarse position information, absolute position details are lost. After the convolution and pooling processes, a representation of the sentence level is achieved.

One of the most significant benefits is the system's ability to provide immediate, personalized feedback to students on their writing. This instant feedback loop can significantly enhance the learning process, allowing students to identify and correct errors, refine their writing style, and better understand the criteria for high-quality writing. Immediate feedback is particularly valuable in large classrooms or distance learning scenarios where individualized attention from instructors may be limited. With the system taking on the task of assessing basic grammar, spelling, and syntax, educators can devote more time and resources to teaching higher-level writing skills. These include argumentation, critical thinking, and creative expression. Teachers can focus on developing students' abilities to construct well-organized, coherent, and persuasive texts, rather than spending excessive time marking mechanical errors.

Proposed BiLSTM -CNN model. Creating a model that combines Bidirectional Long Short-Term Memory (BiLSTM) and Convolutional Neural Networks (CNN) entails creating a system that takes advantage of the advantages of both architectures. BiLSTM excels at understanding context and dependencies in sequential data, such as text, whereas CNNs excel at extracting features, in this case, sentence structures, from data. A step-by-step procedure for creating such a model:

Convolutional Layer. Firstly, Identify features in the word vector matrix. Then it generates three different types of convolution kernels (e.g., 3x128, 4x128, and 5x128), each with 50 kernels. These kernels will aid in the extraction of various local features from word vectors. Finally, use these kernels to extract features from the word vector matrix. To introduce nonlinearity and accelerate convergence, use a ReLU activation function for each neuron.

Pooling Layer. To distill the features extracted by the convolution layer and to reduce the dimensionality of the feature space. Divide each feature map into chunks (e.g., three parts), and apply max pooling to each chunk. This approach helps preserve the relative order information and capture the strongest features.

Bi-LSTM Layer. After the pooling layer, the output is fed into a BiLSTM layer. It analyzes the sequence data (features extracted and pooled from the CNN) in both forward and backward directions. This is crucial for understanding the context and dependencies in the text data. The BiLSTM processes the sequence of features, capturing information from both past and future contexts.

Fully Connected and Output Layers. The output is Flatten from the Bi-LSTM layer to create a one-dimensional vector. Add two dense layers to allow the model to learn non-linear combinations of features in fully connected layer. The sigmoid activation function used in the output layer for binary classification tasks (like sentiment analysis) or softmax for multi-class classification.

Model Training and Optimization. An appropriate loss function (like cross-entropy) is chosen and an optimizer stochastic gradient descent is used. Model is trained using backpropagation and adjust the weights iteratively. finally, implement dropout or L2 regularization to prevent overfitting.

The graph 2 representing the CNN model is the shortest, suggesting that it has the lowest accuracy among the three models presented. The accuracy percentage is approximately 85%, which indicates that while the CNN model is relatively accurate, there may be room for improvement in feature analysis tasks. The CNN-LSTM model, is significantly greater than the first, implying a noticeable increase in accuracy. The model's accuracy is around 90%, showing that combining CNN features with LSTM, which can capture sequential information, offers a substantial improvement over the plain CNN model. The Proposed CNN-BiLSTM model is the highest of all, indicating the highest accuracy among the three models on feature analysis. The accuracy is just under 91.6. The bidirectional LSTM allows the model to access information from both past and future states, potentially giving it an advantage in understanding the context within data, leading to higher accuracy

Fig. 3.2: The accuracy of feature analysis

Fig. 3.3: The performance comparison of feature analysis model

Convolutional neural networks (CNNs) have a strong capability for extracting intricate features from sentences. To investigate this, experiments were conducted with three distinct approaches to feature extraction: manual feature engineering, CNN-based feature extraction, and a hybrid method combining manual and CNN. When examining the trends in accuracy and recall as illustrated in Figure 3.3, the performance metrics for all three methods were broadly comparable. However, it's notable that manual feature engineering CNN alone resulted in the lowest accuracy, specifically at 87%. Conversely, the CNN-based approach yielded the lowest recall rates in feature classification, and consistently, both accuracy and recall were lower for CNN and CNN-LSTM. This suggests an inherent challenge within the algorithm's ability to discern sentences, and highlights a discrepancy with human perception in real-world applications.

The data indicates that BiLSTM and CNN-based feature extraction methods significantly enhance the differentiation between the sentences. Additionally, it's observed that the performance metrics for sentences are consistently lower across all categories, underscoring the complexity of assessing the aesthetic quality of sentences—a factor that is also reflective of an individual's writing skill level.

In pursuit of refining the experiment, consideration was given not only to the blend of feature extraction techniques from machine learning but also to the analysis of different network classifications based on various feature combinations. This included looking at linguistic and semantic feature integration, as well as the incorporation of difficult features. The results, as evident in Figure 3.3, features outperformed using text-CNN and BiLSTM models. When comparing models with equivalent feature types, the LSTM model surpassed the text-CNN in performance, demonstrating its superior capability for memory learning in text-mining applications. Finally, an enhanced version of LSTM, known as Bi-LSTM, achieved the best results in the second set of experiments. This improvement is attributed to Bi-LSTM's adeptness in capturing temporal dependencies from different directions, thereby obtaining more temporally relevant sentence features.

Continuous evaluation and benchmarking against industry standards and datasets ensure that the systems performance meets the expected criteria for accuracy, fairness, and reliability. These evaluations guide further

refinements and adjustments to the system.

4. Conclusion. The research highlights an approach to automating the assessment of English writing proficiency using cutting-edge machine learning algorithms. Addressing the inefficiencies and biases inherent in traditional evaluation methods, this research outlines the development of an intelligent system that employs Natural Language Processing and neural network models to deliver swift, consistent, and objective analysis of written English. The system's architecture, which harnesses a synergy of algorithms to evaluate various aspects of writing, is rigorously tested against a vast corpus of English samples. The findings are clear: the proposed machine learning-based system not only rivals but also potentially surpasses human raters in terms of accuracy and speed, marking a significant advancement in the field of language assessment. This breakthrough holds considerable promise for educational and professional domains, offering a scalable, reliable alternative that could fundamentally transform the assessment landscape of English writing ability.

RESEARCH ON CRYPTOGRAPHY-BASED DATA SECURITY AND TRUSTWORTHINESS IN DIGITAL CONSTRUCTION OF WATER RESOURCES AND HYDROPOWER

CHAO YUE*, WEI LIU†, LICHENG CHEN‡ AND CHONG ZUO§

Abstract. This study aims to strengthen data security and establish credibility using novel cryptography-based techniques in the context of the digital revolution in the water resource and hydropower development industry. Protecting sensitive data and guaranteeing the confidentiality of digital assets becomes crucial as the sector depends more and more on digital technology for communication, monitoring, and project management. The goal of this work is to create developed cryptographic protocols and structures that have been tailored to the needs of the water resources and hydropower industry. This study offers a thorough investigation into the use of cryptographic methods to tackle the difficulties presented by the digital construction surroundings in these projects. The research process combines algorithm creation, theoretical advancements, and real-world application. The efficiency and viability of the suggested cryptographic approaches in resolving trust and security issues intrinsic in digital building environments will be evaluated using actual-life scenarios and simulations. The results of this study should offer a strong basis for improving data security, reliability, and integrity in digital construction projects related to water resources and hydropower. Through the development of cryptography techniques specifically suited to this vital infrastructure industry, the research helps to build digital ecosystems that are resilient and secure, which is important for the sustainable growth of hydropower and water resources.

Key words: Cryptography, Data Security, Trustworthiness, Digital Construction, Water Resources and Hydropower

1. Introduction. Energy is crucial to the economy’s ability to grow sustainably [10]. Although nuclear energy and fossil fuels are frequently used to generate electricity, they frequently cause some environmental harm due to the emissions of CO₂ as well as other radioactive substances. Sustainable and alternative sources of energy have been heavily pushed in such a situation. One option for efficiently preserving the natural world is hydropower. It is seen as a component of a low-carbon economic system’s energy combine, particularly for nations that are developing [20]. Hydropower, the world’s most productive renewable energy resource for electricity generation, produces 71% more electrical power than other energy sources including coal, gas, and oil [13].

There are certain benefits to using hydropower to generate electricity. It is less expensive, more sustainable, and more dependable than coal, gas, or oil. There are less environmental restrictions on hydropower than on solar and wind power [23]. Hydropower now plays a larger role than it did previously since it is acknowledged as being fundamental to the production of energy [16]. Since concealed or in-conduit hydropower systems are completely incorporated into the current infrastructure, they have less of an environmental impact than conventional hydropower plants that operate in rivers [6]. Particularly, these hydropower systems capture the extra energy of water that is being utilized for purposes other than electricity production.

A geodatabase of unexplored prospective places for energy recovery at current hydro facilities in particular European towns and nations has been produced by an ongoing study [24, 5]. Building an in-conduit hydropower system could be advantageous for governmental treatment works, including wastewater amenities, and public water systems, considering their respective consequences. The author [26, 27] provided a thorough summary

§Hydropower and Water Conservancy Engineering Institute POWERCHINA HUADONG Engineering Corporation Limited, Hangzhou, Zhejiang, 311122, China

of the advancements in in-conduit hydropower technology and their uses. In [22], actual case studies of small hydro turbines incorporated into drinking water and wastewater networks were provided together with a succinct technical explanation. Numerous nations have evaluated the potential for hydropower, including the feasibility of putting turbines in water and wastewater infrastructure from a technical and financial standpoint.

Turbine installation is typically ideal near wastewater treatment outlets because of the steady and enough water flow. The WWTP process involves constant monitoring of the variables needed to choose hydro turbines, like head and flow. As such, monitoring the turbine's functioning can be rather simple [4]. On the other hand, low- or ultralow-head plants may face a problem if the tailwater effect is overlooked. The head is reduced at most sites during a flood period because the tailwater level at the outfall rises greater than the level upstream of the intake, depending on the receiving water body (such as a river). Nevertheless, the literature hardly ever discusses these situations.

The motivation for this research emerges from the critical need to enhance data security and establish a foundation of trust within the rapidly digitising landscape of the water resources and hydropower development industry. As this sector increasingly relies on digital technologies for essential operations such as communication, monitoring, and project management, the protection of sensitive data and the confidentiality of digital assets become paramount. The advent of the digital revolution in this field presents immense opportunities and significant challenges, particularly regarding safeguarding against cyber threats and ensuring the integrity of digital construction environments.

This study is driven by the recognition that conventional cryptographic protocols and security measures may not fully address the unique complexities and requirements of the water resources and hydropower industry. These projects are characterized by their extensive scale, long duration, and the critical nature of their infrastructure, which necessitates a bespoke approach to data security. The research aims to develop and refine cryptographic techniques specifically tailored to meet these industry-specific needs, providing robust protection for digital assets and sensitive information.

The main contribution of the proposed method is given below:

1. Creation of customized cryptography protocols intended to handle the trust and security issues that arise during the digital construction lifespan of hydropower and water resource projects.
2. The security and reliability of vital project information are guaranteed by these protocols, which offer a framework for protecting sensitive data throughout transfer, storage spaces. and retrieval.
3. Scaling and efficiency improvements for cryptographic solutions while considering the special requirements of large-scale water resource and hydropower projects involving a variety of stakeholders.
4. By balancing strong security measures with effective data processing, the research helps build cryptographic algorithms that are useful in real-world construction circumstances.

The rest of our research article is written as follows: Section 2 discusses the related work on various classification of brain image processing and methodData Security and Trustworthiness in Digital Construction of Water Resources and Hydropower s. Section 3 shows the algorithm process and general working methodology of proposed work. Section 4 evaluates the implementation and results of the proposed method. Section 5 concludes the work and discusses the result evaluation.

2. Related Works. Cyberattacks are online activities that try to break into the computer networks of people or organizations with the intention of causing damage or interrupting operations. These assaults may target various objectives, such as stealing sensitive data or jeopardizing data integrity [2]. For energy and electricity systems to operate securely and dependably, sufficient protection layers must be developed for a CPS. Nonetheless, the electricity sector has seen a rise in cyberattack efforts in recent years. Approximately 800 cyberattacks have been reported in the energy sector since the 1980s [3].

A thorough review of turbines suitable for concealed hydro and in-conduit hydropower was provided in [21, 17], with a focus on current developments in the field of turbine technology. Novel technological approaches have been put forth that enhance traditional turbines with stronger designs, increased efficiency, and potentially cheaper costs [14]. However, while more recent or developing technologies present creative methods for in-conduit hydro generation, they may not necessarily be the most economical option [19]. The comparison of equipment costs is complex because of the different sites and turbines. However, modular structures may have higher hydromechanical and electric running costs than traditional turbines, even though their building and

installation expenses may be lower [12, 11].

Low-cost engines, such as pumps as turbines (PaTs), are recommended because traditional hydro turbine technologies aren't always competitive in the market. These are regular pumps that have had their flow direction reversed so that they can be used as turbines. PaTs have been the subject of research for almost a century, and their use in small- and micro-hydropower is still significant today [7, 8, 25]. PaTs are typically employed at locations with greater head counts; the literature hardly ever discusses low-head application experience.

Most importantly, tools that assist water and wastewater providers in determining whether establishing hydropower facilities is both technically and financially feasible should be developed [1, 28]. Evaluation instruments must be as simple to use and economical as feasible because the majority of in-conduit or hidden hydro systems have comparatively limited capacities and, as a result, require a highly expensive feasibility study. For small developers, these needs are not met by the tools that are now available [15]. It has been suggested that conduit projects be evaluated using a few engineering design tools. However, these have not yet been used in more comprehensive analyses. To be sure, the US-developed tools are partly to blame for some exceptions [18, 9]. These are free-to-use tools that work with widely accessible spreadsheet software.

Given the extensive geographical spread of water resources and hydropower infrastructure, cryptographic protocols must be scalable across large distributed networks. This might involve optimizing encryption algorithms for low-latency operations and ensuring they can handle the high volume of data generated by IoT devices and sensors without compromising performance. Many operations within the sector rely on real-time data for monitoring and control. Cryptographic protocols can be modified to support efficient real-time encryption and decryption processes, enabling secure yet timely data transmission crucial for operational decision-making. Adapting cryptographic protocols to be compatible with existing industrial control systems (ICS) and operational technology (OT) used in the sector. This may require developing lightweight cryptographic solutions that can be implemented on legacy systems without significant hardware upgrades. With the increase in remote monitoring and management of hydropower plants, cryptographic protocols need to ensure secure remote access. This could involve adapting protocols to provide robust authentication and secure communication channels for remote users, preventing unauthorized access and ensuring data integrity.

3. Proposed Methodology. The proposed method uses Cryptographic techniques for Data Security and Trustworthiness in the Digital Construction of Water Resources and Hydropower. Create protocols for encryption with data transfer, storage, and access control specifically suited to the digital building lifecycle. Create protocols that handle issues including permission procedures, secure interaction with stakeholders, and data tampering prevention. The purpose of this proposed technique is to improve data security and reliability in the digital design of hydropower and water resource projects by exploring and carrying out cryptography-based technologies in an organised and rigorous manner. In figure 3.1 shows the architecture of the proposed method.

The water resource and hydropower industry faces unique cryptographic needs and challenges stemming from its critical infrastructure status, the complexity of its operational environments, and the increasing digitization of its processes. Addressing these challenges is crucial for ensuring the security, reliability, and resilience of these essential services. Here are some of the specific cryptographic needs and challenges in this industry: 1. The industry relies heavily on real-time data for monitoring water levels, flow rates, and power generation metrics. Cryptographic solutions must provide real-time encryption and decryption of data streams without introducing significant latency, which could impact operational efficiency and safety. 2. Water resource and hydropower systems often encompass extensive geographical areas with multiple sites and installations connected via distributed networks. Cryptographic protocols must be scalable and flexible enough to secure communications across these vast and varied landscapes. 3. Given its importance to national security and the economy, the industry is a potential target for state-sponsored and sophisticated cyber-attacks, including Advanced Persistent Threats (APTs). Cryptographic measures must be robust enough to protect against such threats, ensuring the integrity and availability of control systems.

3.1. Homomorphic Encryption Techniques. These allow calculations to be performed on encrypted data without requiring decryption. Homomorphic encryption might be useful for secure computing on sensitive data without exposing it during processing in water resources and hydropower.

HE is a type of encryption that enables computation between plaintexts that are concealed in ciphertext. Another cipher-text with the correct plaintext-to-plaintext calculation output can be the result of the

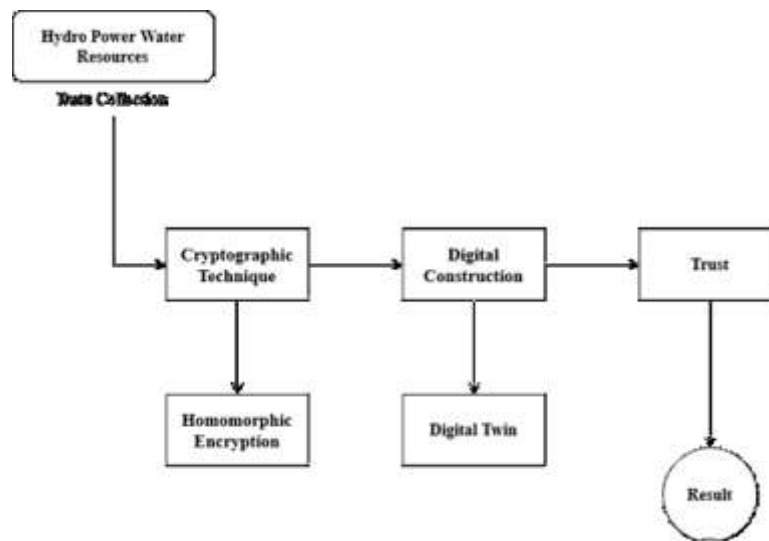

Fig. 3.1: Architecture of Proposed method

computation in HE. Since the ciphertext completely encloses the plaintext and data encryption only permits the decryption and encryption procedures, the hidden plaintext within the ciphertext cannot be altered using conventional encryption techniques. Therefore, to obtain the plaintexts, which can be utilized to perform operations on the original message contained in the cipher-texts, the cipher-texts must be decoded.

By enabling secure computations on encrypted data, HE reduces the need for complex data protection measures that might otherwise slow down processing or increase operational costs. This can lead to more efficient system operations and reduced overhead for security. As cyber threats evolve, the ability to compute on encrypted data provides a forward-looking approach to data security, ensuring that the sector is prepared for emerging challenges and can safeguard sensitive information against future vulnerabilities.

3.2. Digital Twin-based Digital Construction of Water Resources and Hydropower. The preparation, design, building, and administration of infrastructure connected to water resources and hydropower generation are improved using cutting-edge digital technologies and data-driven approaches in digital construction projects. With the creation and management of water-related projects, this innovative strategy makes use of digital tools to streamline procedures, boost productivity, and guarantee sustainability.

A virtual copy of a real object, system, or procedure is called a digital twin. Digital twins can simulate a project's whole lifecycle in the context of hydropower and water resources, offering real-time insights and assisting in improved decision-making. The use of digital twins makes it possible to simulate, analyse, and monitor hydropower facilities, dams, and water systems. They support the long-term resilience of infrastructure, performance optimization, and maintenance demand prediction.

Making a thorough 3D model or depiction of the real object or system is the first step in creating a digital twin. The digital twin is built on top of this model. When it comes to water resources and hydropower, the physical assets—like dams, water treatment facilities, or hydropower plants—as well as their components, dimensions, and functional features are digitally modelled.

3.3. Trustworthiness for water resources and Hydropower. The reliability, integrity, and security of the systems, procedures, and data involved in controlling and producing electricity from water resources are referred to as trustworthy in the context of hydropower plants and water resources. Establishing credibility is essential to guarantee the security, longevity, and effective functioning of water-related infrastructure.

Guaranteeing the precision and dependability of information gathered from sensors, surveillance tools, and additional sources in water infrastructure. To make well-informed decisions about hydropower generation, dam safety, and water flow, one must have faith in the accuracy of data. To keep data accurate, regular validation and

verification procedures are necessary. Building and upholding technology that is resilient to calamities, severe weather, and other possible disruptions. The incorporation of resilience into water infrastructure guarantees its capacity to operate in challenging circumstances, mitigating the likelihood of malfunctions, and enhancing its enduring reliability.

Keeping lines of communication open and honest with all parties involved, such as the public, neighbours, and regulatory bodies. By giving accurate information about the workings, safety precautions, and possible effects of water infrastructure projects, open communication promotes healthy relationships with neighbours and fosters trust.

4. Result Analysis. Numerous writers have created geodatabases and utilized geographic information (GIS data) to find possible hydro sites in water distribution systems. Spatial databases, or high-resolution digital elevation or terrain models (DEMs), are available in many nations. Along with the Shuttle Radar Topography Mission (SRTM) DEMs from the United States Geological Survey, global terrain data from Google Earth or other platforms can also be used, but they should be used cautiously—that is, only for the initial assessment of SHP locations and not for flat terrains or low-lying countries and areas with a low vertical resolution in geography.

The proposed method uses parameter metrics such as accuracy, precision, recall and f1-score for hydropower water resources.

Accuracy is a crucial criterion that relates to the precision and correctness of numerous processes, data, and outcomes in the context of digital creation of hydropower and water resources. the accuracy of spatial data utilized in the planning and design stages, such as maps, surveys, and geographical information systems (GIS). Precise geographic information guarantees that the project site's physical attributes are accurately depicted,

Fig. 4.1: Accuracy

reducing mistakes in both design and construction.

The accuracy of quality assurance procedures and examinations conducted both during and following construction. Precise quality control and inspections guarantee that constructed pieces fulfil the intended quality standards and help to ensure compliance with industry standards, legal requirements, and project specifications. the accuracy of the information kept in asset management systems, which are used to keep an eye on and repair water infrastructure. For efficient maintenance scheduling, preparation, and management throughout their lifecycle to ensure the durability and dependability of water-related resources, reliable asset data is crucial. In figure 4.1 shows the accuracy of proposed method.

When discussing digital construction for hydropower and water resource projects, precision pertains to the precision and dependability of the algorithm or system in recognizing and detecting elements or features within digital data. When it comes to activities such as object detection, where the objective is to reduce false positives and make sure that features recognized are relevant to the construction process, precision is an important parameter.

The ratio of true positives to the total of true positives and false positives is used to compute precision. This refers to precisely recognizing and finding pertinent objects or elements inside the digital model of the infrastructure or building site in the context of digital construction. To reduce false positives, which might influence the construction process and result in wrong judgments, high precision is necessary. It guarantees the reliability and applicability of the features found. In figure 4.2 shows the evaluation of Precision.

"Recall" generally refers to a measurement of performance used to assess the efficacy of methods or systems in the context of digital construction of hydropower and water resource projects, particularly in activities involving object detection or recognition. Recall, which is sometimes referred to as sensitivity or true positive rate, quantifies a system's capacity to accurately identify every pertinent case among all actual occurrences. In digital construction, recall evaluation is an element of an iterative process. Based on the feedback from memory evaluations, the system can be modified and fine-tuned to increase its capacity to recognize and recall pertinent aspects or abnormalities in the building procedure. In figure 4.3 shows the evaluation of Recall.

A metric called the F1-score, sometimes referred to as the F1 measure or F1-value, combines recall and precision into a single number. It is especially helpful in situations when there is an unequal distribution of classes, and it is important to consider both false positives and false negatives. The F1-score can be utilized in the digital design of hydropower and water resource projects to assess how well models or algorithms perform in tasks like object detection, image categorization, or predictive maintenance.

Evaluating the precision of algorithms used to detect things in photos, such as tracking infrastructure elements or spotting anomalies. Assessing the effectiveness of models that forecast equipment breakdowns

Fig. 4.2: Precision

Fig. 4.3: Recall

or the need for maintenance to guarantee the dependability of hydropower facilities. Evaluating how well models categorize photos of building sites or the state of infrastructure connected to water. It is imperative to consider the goals of the work and the relative significance of recall and precision considering the application requirements when interpreting the F1-score. A balance between recall and precision may be more acceptable in certain situations, while a greater emphasis on precision may be preferred in others. In figure 4.4 shows the evaluation of F1-score.

5. Conclusion. The objective of this research is to enhance data security and establish credibility in the context of the digital revolution in the water resource and hydropower development industry by utilizing innovative cryptography-based techniques. As the industry grows more and more reliant on digital technology for project management, monitoring, and communication, safeguarding sensitive data and ensuring the confidentiality of digital assets becomes essential. This initiative aims to design cryptographic structures and protocols specifically suited to the demands of the hydropower and water resources sectors. This paper provides a com-

Fig. 4.4: F1-score

prehensive analysis of the application of cryptographic techniques to address the challenges posed by the digital building environment in these projects. The development of algorithms, theoretical breakthroughs, and practical implementation are all combined in the research process. Using real-world examples and simulations, the effectiveness and practicality of the proposed cryptographic techniques in addressing trust and security concerns inherent in digital building environments will be assessed. The findings of this research should provide a solid foundation for enhancing data security, dependability, and integrity in digital construction projects involving hydropower and water resources. By creating cryptographic methods tailored to this essential infrastructure sector, the research contributes to the construction of robust and secure digital ecosystems, which is necessary for the long-term development of hydropower and water resources.

RESEARCH ON DEEP LEARNING-BASED ALGORITHM FOR DIGITAL IMAGE COMBINATION AND TARGET DETECTION

SHANLU HUANG* AND JIALIN LAI†

Abstract. This study uses deep learning techniques to improve target recognition and digital picture processing, combining efficiency and accuracy in the fields of computer vision and image processing. Different situations, heterogeneous circumstances in the environment, and a wide range of image properties present obstacles for the traditional approaches of combining images and target recognition. To address these issues, our research suggests a novel method that makes use of deep learning methods to identify relevant characteristics and trends from a variety of sources that provide diverse pictures. As part of the research process, a complex deep learning system that can recognize ordered representations of input photos is developed and trained. We will investigate whether faster RCNN are suitable for capturing temporal and spatial relationships in the image data. To maximize the model's performance, deep learning techniques will be used to make use of pre-trained networks on sizable datasets. Benchmark datasets will be used in the method's assessment, and it will be pitted with conventional image processing techniques. The accuracy and dependability of the algorithm's performance will be evaluated using quantitative metrics including precision, recall, and F1-score. Furthermore, qualitative evaluations will be conducted to determine the visual appeal and interpretive capacity of the created composite images.

Key words: deep learning, faster RCNN, digital image combination, target detection, satellite images

1. Introduction. The branch of computer science known as artificial intelligence (AI) studies how to make machines intelligent. In a perfect world, these devices would react similarly to humans in terms of perception, comprehension, and problem-solving decision-making [21, 5, 26]. Artificial Intelligence (AI) encompasses a broad range of fields, most of which are related to the senses that humans have, including computer vision (CV), the processing of natural languages (NLP), oversight, and robots. Through its ability to comprehend digital images and movies, computer vision is a branch of computer science that strives to emulate human vision [16, 2, 27, 15]. It analyses photos using a variety of optimization approaches and techniques. CV is a multidisciplinary field that includes automation, math, probability, artificial intelligence, and recognition of patterns. The branch of artificial intelligence called machine learning (ML) uses data to learn instead of explicit programming [8].

A more intricate and sophisticated model is needed to comprehend pictures and videos. Neural networks (NNs) are remarkably adept at processing vast volumes of data (such as photos and videos) and deciphering it, according to research findings. Scientists were able to resolve challenging issues such picture categorization, recognizing objects, recognition of objects, and segmentation of instances recognition of optical characters by utilizing neural networks in CV. Using deep learning methods, computer vision additionally plays a role in the analysis and detection of objects in images. By resolving the issues, CV has influenced several industries, including the analysis of documents, self-driving cars, medical imagery analysis, and satellite picture research. [14].

For several years, one of the main goals of computer vision research has been to identify objects. The primary objective of recognizing objects is to identify an instance in pictures and videos [28]. Using a bounding box, object identification in CV refers to identifying things of interest (such as people, pets, dogs, cycles, etc.) at a given spot in an image [1]. In the fields of artificial information, machine vision, and robotic seeing, object detection finds numerous uses, such as in augmented reality, security, and surveillance. Two types exist for

*School of Public Administration, Guangxi Technological College of Machinery and Electricity, Nanning 530007, China

†School of Public Administration, Guangxi Technological College of Machinery and Electricity, Nanning 530007, China (jialinlaidigita@outlook.com)

object detection. Finding general categories (person, cat, etc.) is the first form of detection; the second type targets particular examples, like the president's face.

Identifying objects in satellite images is a crucial, essential, and difficult task since objects are small, multi-oriented, and densely grouped. Thus, the main challenge is to identify and locate small objects in satellite images. Because the low-resolution image dataset shortens the training period, we have created a custom dataset with low-resolution images of objects (like small-sized aircraft) to achieve good accuracy with a minimal amount of computational power. Using a custom dataset, we have analysed the speed and accuracy of various object detection pipelines.

The main contribution of the proposed method is given below:

1. We assembled a dataset of satellite photos of airplanes and pre-processed it for training and testing purposes.
2. To speed up the target identification process, the suggested algorithm makes use of the Faster R-CNN architecture, which is well-known for its effectiveness in object detection tasks.
3. The model overcomes the computational performance constraints of standard methods by effectively localizing and classifying targets inside the images using region-based convolutional neural networks.
4. Using a bespoke dataset, the effectiveness of the main algorithms for the identification and categorization of aircraft in satellite imagery was compared in terms of execution speed and accuracy.

The remaining sections of this paper are structured as follows: Section 2 discusses the related research works, Section 3 describes the digital image combination and target detection, Section 4 presents the methods used to adopt the proposed model, Section 5 discusses the experimented results and Section 6 concludes the proposed system with future work.

2. Related Works. In the past few years, deep learning and machine learning approaches have been used to overcome many issues related to object identification in satellite imagery. There are three pipelines that offer real-time remedies: YOLO, SSD, and Faster-RCNN. The cutting-edge real-time object recognition framework YOLO (you only look once) uses a 416×416 resolution image and is based on a CNN (convolutional neural network) algorithm [23, 19]. The state-of-the-art framework Faster RCNN uses a 1000×600 resolution image and is based on the region suggestion method. The SSD (single shot detector) architecture operates on either 300×300 or 512×512 pixels per image, extracting feature maps across various layers and applying CNN filters to recognize an item.

The International Society for Photogrammetry and Remote Sensing (ISPRS) Vaihingen and dam benchmark datasets [6], which include high-resolution photos followed by CNN for fine-tuning and hitting state-of-the-art accuracy, were subjected to dense labelling by the author [9, 4, 29]. By using region-based approaches and classification algorithms, the researcher in [20] focused on remote sensing and localization and produced improved object localization outcomes. Nevertheless, the region-based method's significant latency prevented the huge area from being covered (40 s covered area of 1280×1280 pixels). Although it was shown to be slower for segmentation, the author's work [12] used separation and additional processing approaches and produced trustworthy findings regarding automated road detection in satellite data.

Sparse and collaborative representation, as well as kernel-based machine learning, have seen the effective application of machine learning in HTD. By expanding traditional statistical techniques, several kernel-based target detectors have been presented, such as kernel target-constrained interference-minimized filter (KTCIMF) [25], kernel adaptive subspace detector (KASD) [10], and kernel orthogonal sub-space projection (KOSP) [11]. However, a lot of presumptions are also extensively relied upon by these procedures. Regarding limited and cooperative depictions, since the author developed a sparsity-based target detector (STD) [17], several other useful works have been presented. These include the hybrid sparsity and statistics detector (HSSD) [24], the combination of sparse and collaborative representation (CSCR) [13], and the sparse representation-based binary hypothesis-based detector (SRBBHD) [19].

Only a few techniques have been developed for the relatively new use of deep learning to HTD. Guided detectors use synthesizing to primarily increase target data. They then build an end-to-end detector through extensive pixel-pair training. Among the well-liked techniques are two-stream convolutional network-based target detector (TSCNTD) [17], deep network-based HTD (referred to as HTD-Net) [18], and convolutional neural network target detector (CNNTD) [7]. Furthermore, to transfer information from a large-sample domain

Fig. 3.1: Architecture Diagram of Proposed Method

of origin to a small-sample target domain, a domain adaptable learning model has been developed [22]. Under specific restrictions, unsupervised methods often improve the discriminating ability with unsupervised networks and then use a straightforward matching strategy to detect targets [3].

3. Proposed Methodology. In this work, Faster RCNN method is used for digital image combination and target detection. Initially the dataset is collected, in this work the aircraft satellite images are used as a dataset. Next the collected dataset is pre-processed and then the data is divided for training and testing. The training and testing is carried out by deep learning method Faster-RCNN. In figure 3.1 shows the architecture diagram of proposed method.

3.1. Dataset Collection. One of the most important phases in the entire object identification process is creating the dataset since the dataset has a significant impact on the model's accuracy and performance. It is the most crucial factor to consider while evaluating and examining the efficacy of different algorithms. The internet makes it possible to use larger images in a multitude of categories to accurately depict the intricacy and diversity of objects. The emergence of extensive datasets such as millions of photos has been crucial in facilitating exceptional object detection capabilities.

We obtained satellite images with a 1920×1080 -pixel resolution using Google Earth. Since they are typically classified, real-time satellite surveillance photographs are extremely difficult to find. For this reason, Google Earth is your best bet when looking for satellite photos of aircraft. Consequently, we tried to locate as many pictures of aircraft as we could. The dataset ought to be larger, but our options are limited. To cut down on training time, we separated the collected photos into 550×350 resolution after collecting. Next, we manually eliminated every picture that didn't include any items. In our dataset, there are 442 photos including 2213 aircraft objects. Next, we tagged photos using the labelling tool.

Pre-trained models are adept at extracting complex features from images, thanks to their exposure to diverse datasets. These features can range from basic textures and shapes to more intricate patterns, providing a rich set of characteristics for the system to use in target recognition tasks. Leveraging pre-trained models can drastically reduce the time and resources needed to train deep learning systems from scratch. Since these models have already learned a broad set of features, they require less data and fewer iterations to adapt to the specific nuances of a new task.

3.2. Pre-processing. An essential first step in getting the data ready for further examination or use is pre-processing satellite photos. To improve the quality, fix distortions, and retrieve pertinent information,

a sequence of actions must be followed. Adjust photometric aberrations unique to each sensor to guarantee uniformity in color and brightness throughout the image. Adjust for distortions in geometry brought on by differences in geography, Earth's curvature, and viewing angles of satellite sensors. To create an accurate planimetric description of the image, this stage entails orthorectification.

Adjust for environmental variables including skies, haze, and particles to enhance the image's quality. For applications involving remote sensing, this is especially crucial. If required, adjust the image's spatial resolution to conform to the analysis's specifications or to match other datasets. This frequently entails resampling methods such as cubic or bilinear convolution.

3.3. Training and Testing the data using Faster-RCNN. The Faster RCNN is a two-stage detecting architecture that involves the categorization and localisation of objects in the second phase and the creation of areas in the first. Fast RCNN has a quick detection process and is dependent on external region recommendations. According to recent research, CNN can localize items in CONV (convolutional) the layers, but its performance is less in fully linked layers. Consequently, a targeted quest for generating regional proposals took the place of CNN. They suggested replacing selective search with a precise and effective region proposal network (RPN) to generate region proposals. They split the structure into two components: fast RCNN for object categorization and the localization of operations and RPN for region proposal creation.

Design or utilize existing APIs (Application Programming Interfaces) that allow for smooth data exchange and communication between the deep learning system and existing software. This may involve developing custom middleware or adapters. Ensure that data formats, including input images and output recognition results, are standardized across systems to facilitate easy sharing and processing.

The categorization and placement of objects using bounding boxes is carried out by an extensive number of convolutional layers used in RPN and the last convolutional layers in the faster RCNN. Figure 4.2 shows the network topology of the faster RCNN. When features are retrieved by CONV layers, RPN creates $k \times n \times n$ anchor boxes with varying aspect ratios and sizes. Every $n \times n$ anchor is transformed into a low dimensions vector, like 512 for the group known as Visual Geometry Group (VGG) and 256 for ZF. These vectors are then fed into two fully linked layers, which comprise layers for object categorization and bounding box regressors.

Since RPN is a sort of fully convolutional network, it shares features with the rapid RCNN and facilitates the computing of region suggestions efficiently. Instead of using manually created features, CNN uses faster RCNN only for feature extraction (Figure 3.2). Using three hundred suggestions per image, the faster RCNN with the VGG16 model reaches object detection accuracy on the PASCAL VOC dataset at 5 frames per second on the GPU. The author investigated the role of region suggestion the generation through selective search and region proposal generation through CNN considering the quicker RCNN growth. They concluded that CNN-based RPN includes less geometric data for identifying objects in the CONV Layers as opposed to FC layers.

$$(himg, wimg, x, y, w, h, objectives)$$

K is generated at each sliding window location when training a faster RCNN with anchors and various proposals. A class probability of object or not object is represented by a 2K score in the CLS layer, whereas the 4K boxes with coordinates in the Reg layer. K anchors, sometimes known as boxes, are the subject of the K parameter. They produce nearly WHK anchors at the convolutional feature map $W \times H$ by using $k = 9$ with three scales and three aspect ratios at each sliding window. To solve the multiscale problem based on anchors, Faster RCNN employs CNN for features computed on a single scale image. Sharing features and addressing multiscale at a lower cost are two advantages of this.

They give each object a binary label that indicates whether the object is present or absent for training purposes. They give anchors a favourable label. Anchors can be computed in two different methods. Ground truth boxes assign labels to numerous anchors. Initially, one picks those anchors whose crossover over union is high with a ground truth box. Secondly, one selects those anchors whose intersection over union is bigger than 0.7 with a ground truth box. As a result, the second requirement is inappropriate for accurate anchor prediction. As a result, they apply the initial criterion, which gives anchors positive labels and has the highest IOU with the ground truth box.

Fig. 3.2: Overall Process of Proposed Method

4. Result Analysis. Our work concentrated on creating and refining a Faster R-CNN-based algorithm for target detection in satellite photos of aircraft and digital image combining. When compared to traditional methods, the suggested algorithm showed notable improvements in terms of speed, accuracy, precision, recall and F1-score.

$$accuracy = \frac{TP + TN}{TP + TN + FP + FN} \times 100 \quad (4.1)$$

$$precision = \frac{TP}{TP + FP} \times 100 \quad (4.2)$$

$$recall = \frac{TP}{TP + FN} \quad (4.3)$$

When evaluating the accuracy of Faster R-CNN target recognition on satellite images, the model's predictions are usually compared with ground truth annotation. Determine how many times the model's predictions coincide with the actual data (accurately predicted targets). Find out how many targets there are in the dataset overall. Utilize the formula to determine the accuracy. Remember that although while accuracy is a widely used metric, it might not be enough in all situations, particularly when working with datasets that are unbalanced

Fig. 4.2: F1-Score

or in situations where false positives or false negatives have distinct outcomes. In these circumstances, further measures such as recall, precision, and F1-score may be considered to offer a more thorough assessment of the model's effectiveness in target detection on satellite photos. In figure ??shows the evaluation of Accuracy.

A high F1-score suggests a good trade-off between precision and recall when evaluating a Faster R-CNN model for satellite image target recognition, indicating that the algorithm is successfully locating and recognizing targets in the images. When analysing F1-score results, it's crucial to consider the requirements of the application as well as the implications of false positives and false negatives. In figure 4.2 shows the evaluation of Precision. When employing Faster R-CNN for object detection tasks in satellite pictures, precision is an essential evaluation criterion. By quantifying the precision of the model's positive predictions, one can ascertain the proportion of projected positive instances that turn out to be true positives. figure 4.3 shows the evaluation.

Recall is a crucial parameter in satellite image analysis that assesses the model's accuracy in identifying and capturing all pertinent instances of the target class in the dataset when employing a Faster R-CNN-based algorithm. Recall is critical in the context of satellite photography since it offers insights into the algorithm's

Fig. 4.3: Precision

Fig. 4.4: Recall

capacity to identify every instance of the target class, guaranteeing that no significant data is overlooked. A high recall score means that the model can identify most real instances of the target class and effectively reduce false negatives. In figure 4.4 shows the evaluation of Recall.

5. Conclusion. To combine efficiency and accuracy in the domains of computer vision and image processing, this work employs deep learning approaches to enhance target detection and digital picture processing. Traditional ways of merging images and target recognition face challenges from varying scenarios, variable environmental conditions, and a broad range of image attributes. The study we conducted proposes a novel approach to address these problems by using deep learning techniques to extract significant features and patterns from several sources that offer a range of images. A sophisticated deep learning system that can identify ordered presentations of input photographs is created and trained as part of the study process. We will examine if temporal and geographical links in the visual data can be captured by quicker RCNN. Deep Learning techniques will be applied to utilize pre-trained networks on large datasets to optimize the model's performance.

The method will be evaluated using benchmark datasets and compared to traditional image processing techniques. Quantitative measurements like precision, recall, and F1-score will be used to assess the algorithm's correctness and reliability. Additionally, qualitative assessments will be carried out to ascertain the composite images' visual appeal and interpretive potential.

RESEARCH ON LEARNING EFFICIENCY IMPROVEMENT STRATEGIES OF PUBLIC ENGLISH PERSPECTIVE BASED ON ANT COLONY ALGORITHM

QINGZHU LI*

Abstract. A ground-breaking smartphone app called EngageLearnPro was created to improve learning efficiency improvement strategies in the context of public English education. With the use of cutting-edge technologies like Ant Colony Optimization (ACO) and Long Short-Term Memory (LSTM), this app creates a dynamic and captivating method of language learning. Intelligent sequence modeling is made possible by the combination of LSTM and allows for customized learning paths that adjust based on the progress of each individual user. On the other hand, ACO maximizes the app’s decision-making processes, improving the overall effectiveness of language learning techniques. The decision to use a mobile app environment for this initiative was made in light of the fact that smartphones are widely used and can provide education to a wider range of people. By utilizing the interactive and user-centric qualities of mobile devices, EngageLearnPro makes sure that learning happens naturally in users’ everyday lives. By combining LSTM and ACO technologies, a customized and adaptive learning experience is provided, accommodating a wide range of learning styles. EngageLearnPro offers an inclusive, cutting-edge, and effective platform with the goal of closing the gap in public English education. We hope to transform language learning by combining the best features of LSTM and ACO into a mobile application that is not only efficient but also fun and available to students of all backgrounds and ability levels.

Key words: Learning efficiency improvement, public English education, LSTM, ACO, mobile application

1. Introduction. Public English instruction stands out as a crucial catalyst for promoting cultural integration and improving language proficiency in diverse communities [1, 8]. In today’s globally interconnected world, where effective communication cuts across linguistic barriers and becomes a basic prerequisite for both personal and professional growth, the importance of English proficiency is highlighted. Because public education systems are made to serve people from a variety of socioeconomic backgrounds, they are essential to democratizing language opportunities by providing equal access to English language instruction [7]. Nevertheless, there are frequently issues with the effectiveness of language education methods in these systems. Problems like outmoded techniques, unequal access to resources, and the requirement for customized methods continue to impede the best possible achievement of language learning objectives [6]. This emphasizes the urgent need for creative fixes and cutting-edge approaches that can handle the particular difficulties in public English education and guarantee a more welcoming, flexible, and productive language learning environment for people from all backgrounds [16, 4].

Machine learning techniques have become powerful tools for improving learning efficiency in the modern era [2]. These approaches, which include deep learning and reinforcement learning, add a new level of customization to individualized learning by utilizing large datasets and complex algorithms [3]. Neural networks in particular, which are deep learning models, show exceptional capacity for pattern recognition, allowing for personalized learning pathways. By offering continuous feedback mechanisms, personalized content recommendations, and real-time adaptability, these techniques improve language learning efficiency [14]. Additionally, learner behavior can be analyzed using machine learning algorithms, which can be used to pinpoint the advantages and disadvantages of educational interventions. In addition to enhancing learning outcomes, the combination of machine learning and language learning technologies advances educational methodologies, resulting in a dynamic environment tailored to each student’s individual needs [4]. As machine learning develops further, it will play a more and more important role in improving learning efficiency by providing creative answers to complex issues in the field of education.

In this proposed study, we introduce a novel mobile application design called “EngageLearnPro”. A strategic choice based on accessibility, engagement, and inclusivity led to promoting learning efficiency improvement

*Puyang Vocational and Technical College Puyang ,457000,China (qingzhulitarget1@outlook.com)

strategies in the mobile app market within the Public English perspective. Because they are so common and easily incorporated into daily life, mobile apps provide public education systems with a platform to reach a wide range of users. Due to the widespread use of smartphones, these applications offer a portable and practical medium that guarantees users' lives are seamlessly integrated with language learning. Mobile apps' interactive and user-centered design encourages interaction, which makes learning more dynamic and engaging.

The motivation behind the development of EngageLearnPro, a pioneering smartphone application, stems from a commitment to revolutionize public English education through the integration of advanced technologies. In an era where the accessibility and efficiency of educational tools are paramount, EngageLearnPro emerges as a beacon of innovation, designed to bridge the educational divide and foster an inclusive environment for language learners worldwide. At the core of EngageLearnPro's design philosophy is the utilization of Ant Colony Optimization (ACO) and Long Short-Term Memory (LSTM) algorithms. These cutting-edge technologies synergize to create a dynamic, engaging, and personalized language learning experience. LSTM's intelligent sequence modelling capabilities enable the app to offer customized learning paths that evolve in real-time, adapting to the unique pace and progress of each user. This personalization ensures that learners are not just passive recipients of information but active participants in their educational journey.

With the use of cutting-edge technologies, EngageLearnPro is a novel and creative app that makes learning English more effective and pleasurable. Through Adaptive Learning Paths, the app creates dynamic and personalized learning journeys based on each user's progress. To further increase the effectiveness of language learning, it also makes use of intelligent technologies like Ant Colony Optimization (ACO) for better decision-making and Long Short-Term Memory (LSTM) for intelligent sequence modeling [19, 15, 21]. Real-time feedback mechanisms reinforce language usage, quickly correct errors, and give instant insights into progress [20, 17]. Learning is made interesting and enjoyable by the app's interactive, user-centered design, which includes multimedia and gamification features. Because it makes use of smartphones, EngageLearnPro is widely accessible and aims to make English learning possible for people from a variety of backgrounds. Its inclusive design takes into account different learning styles and skill levels. Through the use of cutting-edge technology, seamless integration into daily life, individualized learning experiences, and a commitment to making learning fun, EngageLearnPro makes learning a language an exciting and positive experience.

The contribution of the paper as follows

1. Proposed the mobile app design of EngageLearnPro, for the promotion of learning efficiency improvement strategies in the mobile app market within the Public English perspective.
2. Novel EngageLearnPro which leverages the techniques of LSTM and ACO, where ACO for better decision-making and LSTM for intelligent sequence modelling.
3. In the context of English learning, a thorough analysis and assessment of the proposed EngageLearnPro are conducted using Chinese colleges.
4. Proposed efficacy was demonstrated with valid experiments

2. Research Analysis. [12] The authors of this study discuss the difficulties brought about by the growing size of colleges and universities as well as the growing complexity of teaching duties as a result of an increase in student body and a diversity of course offerings. They suggest a new college scheduling algorithm built on top of an enhanced hybrid optimization strategy based on genetic ant colonies. Improvements like gene infection crossover, fitness-enhanced elimination, and parallel fuzzy adaptive mechanisms are incorporated into the algorithm, which improves convergence, stability, and operating speed. [10] The study investigates the use of an ant colony algorithm-based College English microcurriculum model, utilizing the effectiveness of ant behavior in learning difficult tasks. Teachers have initially resisted using this ant colony algorithm in microcourse design, even though researchers and educators have long used it. This is in spite of the fact that the State supports the use of digital teaching resources. The model's goal is to simplify college students' learning procedures in the context of a foundational course like College English by taking inspiration from the cooperative and algorithmic behavior of ants. [13] Through the use of a bipartite graph model derived from graph theory and clustering analysis on student performance data, this study presents a comprehensive approach to teaching quality evaluation in performing arts courses. The evaluation process is made more robust by applying an ant colony algorithm that takes memory capacity and prior knowledge mastery into account. The results provide theoretical and practical insights for the development of performing arts courses, highlighting the need for

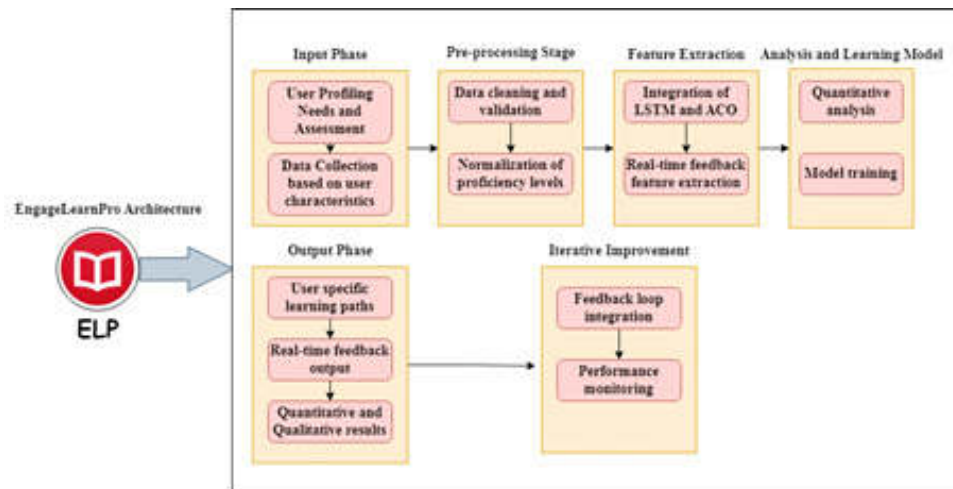

Fig. 3.1: Proposed EngageLearnPro App Design

specialized courses in art performance majors and suggesting targeted training for unqualified teachers based on the PDCA principle. [18] The study offers a multimedia comprehensive framework that integrates big data technology and multimedia teaching modes to address the problem of diverse materials in college English translation. An ant colony optimization algorithm serves as the foundation for the recursive neural network algorithm, which is tested and shown to significantly increase accuracy and retention rate. The suggested method offers a promising way to improve college English translation teaching models by skillfully integrating big data and multimedia into the English teaching process.

3. Proposed design of EngageLearnPro. EngageLearnPro's methodology is divided into discrete stages to guarantee a thorough and data-driven approach to individualized language learning. To understand the diverse needs of English language learners, a comprehensive needs assessment and user profiling are carried out during the input phase. This entails gathering necessary input data, such as user demographics, skill levels, and preferred methods of learning. Concurrently, information is acquired regarding language ability, past educational experiences, and personal preferences in order to further customize learning pathways. Pre-processing involves standardizing proficiency level scales to create a uniform scale for consistent analysis, as well as cleaning and verifying the gathered data to assure accuracy. Advanced algorithms for sequence modeling and effective learning strategies, such as LSTM and ACO, are integrated during the feature extraction phase. Features are taken out for real-time feedback systems and adaptive learning pathways, giving useful information about user progress, mistakes, and proper language usage. Quantitative analysis is used to assess EngageLearnPro's efficacy as we move on to the analysis and learning model phase. This entails analyzing the overall impact on language learning and using pre- and post-assessment scores for proficiency level analysis. Then, using the features that were extracted, machine learning models are trained to find patterns in user behavior and results, which helps to improve the learning model. Personalized learning paths with adaptive features based on the unique characteristics and progress of each user are generated as outputs during the output phase. Users receive real-time feedback that emphasizes areas for development and reinforces the proper use of language. To gauge EngageLearnPro's overall impact, both quantitative and qualitative results such as user feedback and proficiency level improvements are provided. The iterative improvement phase, which brings the methodology to a close, establishes a continuous feedback loop to incorporate user feedback into the learning model. By using this data, features are improved iteratively, learning paths are adjusted, and the user experience is enhanced overall. EngageLearnPro is continuously improved to meet changing user needs through data-driven enhancements through ongoing performance monitoring that makes use of usage analytics and user feedback.

3.1. Proposed EngageLearnPro feature Extraction. Recent research of [9, 7, 11, 5] examines the state-of-the-art mobile app technology utilized to increase the effectiveness of English language learning. Under the studies, there are lucid discussions. Based on the discussions, we are now going to carry out the suggested EngageLearnPro feature extraction procedure.

EngageLearnPro utilizes cross-platform development frameworks to ensure consistent functionality and user experience across iOS and Android devices. This approach allows the app to maintain high performance and adapt to the specific hardware and software configurations of each platform. The app features an adaptive design that adjusts to different screen sizes and resolutions, ensuring that the learning experience is seamless on a wide range of devices, from high-end smartphones to more basic models with limited processing power. EngageLearnPro incorporates performance optimization techniques such as efficient memory management, data compression, and lazy loading of resources to minimize the app's footprint and ensure smooth operation even on devices with lower hardware capabilities.

3.1.1. LSTM for intelligent sequence modeling. Long Short-Term Memory (LSTM) is essential for developing a dynamic and adaptable learning environment when using EngageLearnPro to improve English learning efficiency. Neural network architectures known as long short-term memory (LSTMs) are excellent at understanding and simulating sequential patterns, which makes them especially useful for language learning tasks. By using LSTMs to intelligently model sequences, EngageLearnPro is able to gradually understand and retain the subtleties of English language learning. This implies that the system can make dynamic adjustments to its learning approach based on a user's progress data, guaranteeing an effective and personalized learning trajectory. To maximize each learner's experience, LSTMs, for instance, can dynamically adjust the course material based on an analysis of how the learner interacts with the content and identify difficult areas.

Algorithm 12 Intelligence sequence modeling

- 1: **Input:** E : Sequence of input, where $E = \{E_1, E_2, \dots, E_t\}$, H_{t-1} -previous hidden state, C_{t-1} -Previous Cell state, Weight matrices $w_{Fo}, w_{In}, w_{Ou}, w_c$; Bias Terms $b_{Fo}, b_{In}, b_{Ou}, b_c$.
 - 2: **Output:** h_t -current hidden state, c_t - current cell state
- Initialization**
- 3: Initialize h_o, c_o as the initial hidden and cell states.
 - 4: Define weight matrices $w_{Fo}, w_{In}, w_{Ou}, w_c$
 - 5: Define Bias term $b_{Fo}, b_{In}, b_{Ou}, b_c$.
 - 6: for each time step t
 - 7: calculate forget gate $Fo_t = \sigma(w_{Fo} \cdot [h_{t-1}, E_t] + b_{Fo})$
 - 8: Calculate the input gate $In_t = \sigma(w_{In} \cdot [h_{t-1}, E_t] + b_{In})$
 - 9: Calculate Candidate cell state $\bar{c}_t = \tanh(w_c \cdot [h_{t-1}, E_t] + b_c)$
 - 10: Update cell state $c_t = Fo_t * c_{t-1} + In_t * \bar{c}_t$
 - 11: Calculate output gate $Ou_t = \sigma(w_{Ou} \cdot [h_{t-1}, E_t] + b_{Ou})$
 - 12: Calculate hidden state $h_t = Ou_t * \tanh(c_t)$
 - 13: Output the current hidden state h_t and cell state c_t at each time step t
-

Intelligent sequence modeling is achieved through the use of the (LSTM) process within the algorithmic structure of EngageLearnPro. The algorithm reflects the essential steps in LSTM computation and is expressed as a set of equations. Establishing the initial hidden state H_o and cell state C_o as well as defining weight matrices $w_{Fo}, w_{In}, w_{Ou}, w_c$ and bias terms $b_{Fo}, b_{In}, b_{Ou}, b_c$ are all part of initialization. The algorithm determines the forget gate Fo_t , input gate In_t , and candidate cell state \bar{c}_t for each time step (t). The sigmoid (σ) and hyperbolic tangent \tanh functions are used in these calculations. Based on the input and forget gates, the cell state is updated. After determining the output gate Ou_t , the hidden state's current value h_t is calculated by multiplying the product of the output gate and the hyperbolic tangent of the updated cell state. The current hidden state h_t and cell state c_t are produced as the result of repeating this process at each time step. EngageLearnPro's LSTM algorithm allows it to dynamically modify its learning approach, capturing and remembering crucial data for efficient English learning.

3.1.2. ACO based Decision Making. ACO is a useful algorithmic tool to improve learning efficiency in the context of EngageLearnPro. The application of ACO, which is used to optimize decision-making processes

within the platform, is inspired by the foraging behavior of ants. The ACO in EngageLearnPro assists in identifying the most efficient learning strategies, much like ants leave pheromone trails to communicate and direct others toward the best paths. It functions by modeling the cooperative investigation of multiple learning trajectories, where each trajectory stands for a possible learning decision. Based on user interactions, the algorithm assesses the effectiveness of various paths and gradually improves them to accommodate unique learning styles. EngageLearnPro's ability to integrate ACO allows it to dynamically modify its approach, guaranteeing that the learning environment is efficient, adaptable, and customized to users' changing needs and preferences. The ACO algorithm is adapted from the study [19].

Algorithm 13 ACO based Decision Making

```

1:  $global\_best \leftarrow$  Build initial solution
2: Calculate pheromone trails limits:  $\tau_{min}$  and  $\tau_{max}$ 
3: Set pheromone trails values to  $\tau_{max}$ 
4:  $source\_solution \leftarrow global\_best$ 
5: for  $i \leftarrow 1$  to  $\#iterations$  do
6: for  $j \leftarrow 0$  to  $\#ants - 1$  do
7:  $route_{ant(j)}[0] \leftarrow u\{0, n - 1\}$  // Select first node randomly
8:  $min\_new\_edges \leftarrow calc\_num\_new\_edges()$ 
9:  $new\_edges \leftarrow 0$ 
10:  $K \leftarrow 1$ 
11: while  $K < n$  do
12:  $u \leftarrow route_{ant(j)}[K - 1]$ 
13:  $v \leftarrow select\_next\_node\ u \leftarrow route_{ant(j)}$ 
14:  $route_{ant(j)}[K] \leftarrow v$ 
15:  $K \leftarrow K + 1$ 
16: if  $(u, v) \notin source\_solution$  then
17:  $new\_edges \leftarrow new\_edges + 1$ 
18: Add  $v$  to  $LS\_checklist$ 
19: if  $new\_edges \geq min\_new\_edges$  then
▷ Complete  $route_{ant(j)}$  following source solution
20:  $u \leftarrow succ(source\_solution, v)$  // ...forward
21: while  $u \notin route_{ant(j)}$  do
22:  $route_{ant(j)}[K] \leftarrow u$ 
23:  $u \leftarrow succ(source\_solution, u)$ 
24:  $K \leftarrow K + 1$ 
25:  $u \leftarrow pred(source\_solution, u)$  // ...or backward
26: while  $u \notin route_{ant(j)}$  do
27:  $route_{ant(j)}[k] \leftarrow u$ 
28:  $u \leftarrow pred(source\_solution, u)$ 
29:  $k \leftarrow k + 1$ 
30:  $local\_search(route_{ant(j)}, LS\_checklist)$ 
31:  $iter\_best \leftarrow select\ shortest\ route_{ant(0)} \dots, route_{ant(\#ants-1)}$ 
32: if  $global\_best = \emptyset$  or  $iter\_best$  is shorter than  $global\_best$  then
33:  $global\_best \leftarrow iter\_best$ 
34: Update pheromone trails limits  $\tau_{min}$  and  $\tau_{max}$  using  $global\_best$ 
35: Evaporate pheromone according to  $\rho$  parameter
36:  $source\_solution \leftarrow Choose\ between\ global\_best\ and\ iter\_best$ 
37: Deposit pheromon

```

With its foundation in ACO, the EngageLearnPro decision-making algorithm prioritizes improving the learning paths available on the platform. The first step in the process is to initialize a global best solution, which serves as the foundation for the lessons that follow. Pheromone trails are created with predetermined boundaries that are initially set at maximum values, reflecting the allure of different learning paths. Counting the number of new edges in the learning route, individual ants representing different learning paths navigate

randomly chosen nodes over the course of iterations. The algorithm improves the flexibility and variety of learning paths by updating the route by taking into account nodes that are not present in the source solution. Interestingly, the algorithm uses local search to improve the efficiency of learning routes. This leads to a global update where the global best solution is adjusted based on its emptiness or the superiority of the iteration's best route. The iteration's best route, representing the shortest path among the ant population, is identified. Then, based on this global best solution, pheromone trail limits are updated, impacting the appeal of particular routes. Pheromone deposition and evaporation are steps that follow. Pheromone deposition is influenced by the decision to select between the global best and the iteration's best solution, which shapes the learning paths. The goal of this iterative and adaptive process is to continuously improve the learning paths in EngageLearnPro by dynamically adapting to changing user preferences and needs. In the end, the algorithm aims to maximize the educational process by creating more efficient and interesting avenues for language learning.

Providing in-app surveys, direct feedback forms, social media interactions, and email communications. This variety ensures a broad spectrum of insights, from usability issues to suggestions for new features. Collected feedback is categorized into various segments such as app performance, user interface (UI) design, learning content quality, and algorithmic suggestions. Advanced data analysis techniques, including natural language processing (NLP), are employed to sift through the feedback, identifying common themes, user needs, and potential areas for enhancement.

4. Tests and Validation.

4.1. Simulation Plan. This section examines the effectiveness of EngageLearnPro using a simulation of English classroom instruction; the dataset's original source is taken from the study [22].

This simulation plan's goal is to thoroughly assess how the EngageLearnPro Mobile App affects students' learning outcomes and levels of interest in the context of teaching English in a classroom. There are two classes of 61 business English students participating in the experimental design. While the Control Class uses conventional teaching techniques, the Experimental Class makes use of the EngageLearnPro mobile app. In order to determine the starting proficiency level of students in both classes, pre-experiment tests are administered, and information on smartphone ownership and mobile network status is gathered. During the implementation stage, instructors in the Experimental Class use the EngageLearnPro Mobile App in their English lessons, while the Control Class follows traditional teaching strategies that place limitations on the use of mobile devices. The main goals of observation techniques are to evaluate student participation, classroom performance, and EngageLearnPro's real-time interactivity. Learning outcomes are measured using post-experiment tests administered at the end of a semester. Improvement is assessed by comparing the test results with pre-experiment data. Evaluation metrics encompass comparing test results from before and after the experiment, gauging student involvement and interaction, and analyzing the general dynamics and efficacy of the classroom. Improved learning outcomes in the Experimental Class, higher interest and participation attributable to EngageLearnPro's interactive features, and observational data offering insights into the effect on real-time interactivity are among the anticipated results.

4.2. Evaluation Criteria.

4.2.1. Comparison before testing. Figure 4.1 presented performance metrics for two different classes: the Experimental class and the Control class that cover a range of performance categories. These categories include the number of students who scored below 60, the number of students who scored between 60 and 80, the number of students who scored between 80 and 100, and the average score attained. Each metric provides information on the performance of the classes as well as the distribution of proficiency, engagement levels, and overall academic achievement of the students. This extensive dataset makes it possible to assess the educational dynamics of the classes in a more nuanced way, offering insights into things like academic proficiency, student motivation, and the distribution of scores across various performance thresholds. The scores are collected before testing the proposed app of EngageLearnPro.

4.3. Post Testing Results.

4.3.1. Experimental class test results using EngageLearnPro App. The EngageLearnPro app's performance for the Experimental class are shown in Figure 4.2 across various performance categories. Of the

Fig. 4.1: Comparison results before testing

Fig. 4.2: Experimental using EngageLearnPro App

students in the Experimental class, 40% show an interest in learning, according to the 'Interested Percentage' line; the remaining 60% do not show any interest. The 'Average Score' line indicates a high average score of 70.2%, indicating a positive correlation between academic performance and the EngageLearnPro app. This pattern shows that students are distributed evenly across proficiency levels, demonstrating the effectiveness of the app in capturing users' attention and creating a positive learning environment.

4.3.2. Control Class test results (Without EngageLearnPro App). The results of the Control Class show that it can be difficult to engage a sizable portion of students when employing traditional teaching methods, with 33.50% of students expressing interest and 65.50% not interested was shown in Figure 4.3. The marginally lower percentage of interested students than in the Experimental Class may point to the inadequacies in traditional teaching strategies for maintaining high interest. The Experimental Class's average score of 55.8 indicates that the Control Class attains similar academic results. The aforementioned data underscores the constraints of conventional pedagogical approaches in sustaining widespread student interest and involvement. The outcomes of the Control Class highlight the potential of the EngageLearnPro app, which can address issues with traditional teaching methods while producing similar academic results thanks to its interactive

Fig. 4.3: Control Class results without using EngageLearnPro App

Fig. 4.4: Overall Performance indications based on Experimental and Control Class of EngageLearnPro

and adaptive features. This demonstrates how effective EngageLearnPro is at fostering a more dynamic and captivating learning environment in the context of teaching English to the general public.

4.3.3. Performance Analysis. The effectiveness of the EngageLearnPro app is demonstrated by the Figure 4.4, which compares and contrasts important language learning categories between the Experimental and Control classes. The Experimental class shows a significantly higher percentage (82.74%) in the "Initiative to Speak" category than the Control class (40.34%), suggesting that the app encourages students to be proactive in their verbal communication. In similar fashion, the Experimental class does better than the Control class in areas like "Rich in Words" (91.46% vs. 55.47%), "Speak Actively" (80.25% vs. 45.77%), and "Correct Pronunciation" (85.89% vs. 50.22%). These differences highlight how the app promotes active engagement, improves pronunciation, and enhances vocabulary acquisition. The increasing percentages in these language proficiency categories show that EngageLearnPro is more effective than traditional teaching methods at creating a dynamic and engaging learning environment. The app's beneficial effects on various facets of language learning in the Experimental class are clearly depicted in Figure 4.4, which supports the idea that it can improve language learning outcomes in general.

5. Conclusion. In conclusion, the research on the effectiveness of the EngageLearnPro app for language learning provides strong proof of its beneficial effects on student proficiency and engagement when compared

to conventional teaching techniques. The app's success in fostering a lively and engaging learning environment was demonstrated by the Experimental class's consistent displays of increased interest, active participation, and improved language skills. To guarantee generalizability, a larger dataset and a variety of learner groups are nevertheless required. Furthermore, the study concentrated on immediate results; a longitudinal approach would reveal information about the app's long-term effects. Subsequent investigations may examine the incorporation of increasingly sophisticated technologies, evaluate the app's flexibility in various educational settings, and examine particular aspects that enhance its effectiveness. Notwithstanding these drawbacks, the study's encouraging results imply that EngageLearnPro has potential as a cutting-edge tool for improving language learning encounters, opening the door for more developments in technology-driven education.

RESEARCH ON THE APPLICATION OF MOOCS BASED ON REINFORCEMENT LEARNING IN COLLEGE ENGLISH TEACHING

YU GU*

Abstract. In the field of teaching college English, this study explores the integration of reinforcement learning concepts with Massive Open Online Courses (MOOCs). "LearnFlex," the suggested framework, is intended to support an environment that is dynamic and flexible for learning. By offering thorough English language courses and utilizing reinforcement learning techniques, LearnFlex leverages the inherent benefits of MOOCs to customize and enhance the learning process for every student. This study's main goal is to assess how well LearnFlex works in the context of teaching college English to improve student performance, engagement, and general satisfaction. Through the integration of educational technology, machine learning, and pedagogical methodologies, LearnFlex aims to offer significant insights that support the ongoing development of efficient and customized online learning. The study contributes to the larger objective of improving teaching strategies by utilizing cutting-edge technologies to build a learning ecosystem that is more adaptable and focused on the needs of students. This study aims to provide insights for future improvements in online education, specifically in the area of language training, by conducting a thorough examination of LearnFlex's effects.

Key words: Reinforcements learning, MOOCs, college English teaching, student engagement, personalized online education

1. Introduction. Massive Open Online Courses (MOOCs) have become a powerful and revolutionary force in the modern educational scene. MOOCs are a paradigm change in education, providing a wide range of worldwide audiences with flexible and easily available learning options [2, 15]. The fundamental quality of MOOCs is their capacity to democratize education by bridging the gap between socioeconomic and geographic constraints that frequently inhibit traditional learning paradigms [15]. MOOCs facilitate self-paced and self-directed learning experiences by giving learners unparalleled access to a plethora of educational content through the use of digital platforms. This method has shown to be very helpful in meeting the different requirements and interests of students, encouraging lifelong learning across a range of subjects. MOOCs have become a powerful and revolutionary force in the modern educational scene [13]. These are a paradigm change in education, providing a wide range of worldwide audiences with flexible and easily available learning options. The fundamental quality of MOOCs is their capacity to democratize education by bridging the gap between socioeconomic and geographic constraints that frequently inhibit traditional learning paradigms. MOOCs facilitate self-paced and self-directed learning experiences by giving learners unparalleled access to a plethora of educational content through the use of digital platforms [6, 16]. This method has shown to be very helpful in meeting the different requirements and interests of students, encouraging lifelong learning across a range of subjects.

The use of MOOCs in college English instruction offers a flexible and dynamic method of teaching the language [19]. MOOCs provide a wide range of benefits for teaching college English that support the advancement of conventional pedagogical approaches [10, 3]. The availability of top-notch English language instruction to a multicultural and international student body is one significant benefit. Students can interact with rich, standardized content regardless of where they are in the world, guaranteeing a thorough and consistent educational experience. Due to MOOCs' inherent flexibility, students can advance at their own speed and according to their own preferences and learning styles [18]. Furthermore, MOOCs' interactive format encourages active engagement and participation through discussion boards, multimedia components, and group projects. These elements not only improve how students engage with the curriculum, but they also help students feel more like a community. MOOCs' flexibility is essential for meeting students' diverse skill levels because they offer

*Zhengzhou University of Industrial Technology, Zhengzhou, 450000, China (yuguindustriail12@outlook.com)

customized assessments and content to meet each student's needs. Because of their scalability and affordability, MOOCs significantly improve access to high-quality English language instruction while providing a significant response to the drawbacks of conventional teaching techniques [15, 7]. This study investigates how these benefits can be increased by incorporating MOOCs that are enhanced by the principles of reinforcement learning, opening the door to a novel and successful method of teaching college English.

MOOCs have many benefits, but they are not without drawbacks. A noteworthy obstacle pertains to learner engagement and completion rates [23]. MOOCs frequently encounter elevated dropout rates, which can be attributed to various factors, including inadequate personalization, restricted interactivity, and inadequate flexibility to meet individual learning requirements [9, 1]. The integration of reinforcement learning with the machine learning-based C4.5 algorithm is suggested as a solution to these drawbacks. This combined strategy, called "LearnFlex," aims to add personalization and adaptability to MOOCs to increase their efficacy in teaching college English. LearnFlex uses reinforcement learning to dynamically modify learning paths and content according to each student's progress, encouraging long-term engagement [4, 11]. The C4.5 algorithm's integration makes a further contribution by examining learner data to find patterns that allow the system to offer customized interventions and recommendations [5]. Thus, LearnFlex is a creative step toward reducing the drawbacks of traditional MOOCs in the context of teaching college English and fostering a more responsive, flexible, and student-centered MOOC environment.

The burgeoning intersection of educational technology and language training presents a unique opportunity to revolutionize the way college English is taught and learned. This research is motivated by the potential to harness Massive Open Online Courses (MOOCs), enriched with reinforcement learning techniques, to create a more dynamic, personalized, and effective learning environment. "LearnFlex," our proposed framework, stands at the forefront of this educational innovation, aiming to redefine college English teaching through the strategic integration of MOOCs and machine learning principles. The core objective of this study is to meticulously evaluate the efficacy of LearnFlex in enhancing college English education by focusing on three primary outcomes: student performance, engagement, and overall satisfaction. By leveraging the scalability and accessibility of MOOCs, coupled with the adaptive capabilities of reinforcement learning, LearnFlex is designed to offer a tailored educational experience that meets the diverse needs of learners, thereby overcoming the limitations of traditional one-size-fits-all approaches.

Central to our motivation is the belief that every student's learning journey is unique. Traditional educational models often fail to accommodate individual learning styles, pacing, and preferences, leading to suboptimal outcomes. LearnFlex seeks to address these challenges by employing reinforcement learning algorithms that adapt the learning content and pathways based on real-time feedback from student interactions. This approach ensures that the learning process is continuously optimized for each student, fostering a deeper understanding and mastery of the English language.

The contribution of the paper as follows:

1. The goal of the study is to improve the flexibility and customization of online learning by introducing a novel approach called "LearnFlex".
2. The suggested LearnFlex combines the reinforcement-based DQN technique with the MOOCs-based C4.5 algorithm.
3. Proposed LeanFlex uses reinforcement learning to modify learning paths and content according to each student's progress, introducing dynamic adaptability.
4. The C4.5 algorithm's integration yields analytical insights through learner data analysis, pattern recognition, and customized recommendation generation.
5. The efficacy of the proposed LearnFlex is proved with valid experiments.

1.1. Related work. This study [12] highlights problems with low intelligence and ineffective teaching effects in online college English cross-cultural instruction using MOOCs. Through the use of artificial intelligence and cloud computing, the research presents an enhanced MOOC model and algorithm designed to satisfy the needs of online education. Requirements analysis is used to build functional modules, and control experiments verify the model's functionality and show how effective it is at improving the effectiveness of English language instruction across cultural boundaries in virtual settings. This study [14] investigates how to improve English instruction in China by integrating a Constructive English MOOC system based on the RBF algorithm.

The system runs smoothly and efficiently, completing tasks in 3–7 seconds with an astounding 98% efficiency. The platform encourages students to participate actively in their education by developing their capacity for independent research and piquing their interest in English studies by replacing traditional teaching methods with a technology-enhanced approach. The results of the study demonstrate the benefits of using the RBF algorithm and effective teaching techniques, indicating important new directions in the field and the possibility of revolutionizing English instruction. This study [22] uses artificial intelligence (AI) emotion recognition and neural network algorithms to overcome the shortcomings of conventional cross-cultural English teaching models. The created cross-cultural O2O English teaching system uses background models to track and identify students' emotions along with intelligent recognition and management. Robust performance and efficient online teaching control are demonstrated by the comprehensive O2O teaching model that integrates both online and offline components. The model has been successful in raising student emotional engagement and teaching effectiveness in cross-cultural English instruction, according to the study's statistical tests.

This study [21] improves on traditional teaching quality evaluation by introducing a comprehensive evaluation model for MOOC teaching in accounting using the Rete algorithm. In order to provide a thorough quality assessment, the model evaluates the MOOC teaching mode, compares teaching data with the Rete algorithm, and establishes evaluation standards and weight calculations. The model's usefulness in controlling MOOC accounting teaching quality is demonstrated by its practical application, which also indirectly improves teaching outcomes.

This study [17] focuses on learning objectives and Bloom's taxonomy to address the difficulty of automating the pedagogical classification of MOOCs. The research uses transfer learning through BERT to achieve large-scale and automatic annotation even with a small annotated dataset. The results of the experiments show that the classifier's complexity has little effect on performance; the best results are obtained when dense layers are added to BERT, dropout is included, and ReLU activation functions are used. In the context of MOOCs, the study demonstrates the value of transfer learning for pedagogical annotation, opening the door to better quality control and comprehension of their pedagogical models. The underuse [8] of a wealth of university data is the subject of this study, which focuses on forecasting the chance of withdrawal for incoming students. The application uses the C4.5 algorithm to convert large amounts of data into a decision tree, which allows for the rule-based classification of new students. The tree structure of the system makes it easier to identify possible student withdrawals early on, which helps management make decisions more quickly. The application, which was created using the waterfall model and PHP and MySQL, attempts to improve strategic planning and lower the chance of student attrition by using insights from data.

2. Methodology.

2.1. LearnFlex Overview. In order to create an intelligent and adaptable learning environment for college English teaching, LearnFlex's system architecture integrates DQN and MOOC-based C4.5 techniques was illustrated in Figure ???. To guarantee a smooth integration of these technologies, this entails identifying system components, data flows, and interactions. Data privacy and ethical considerations are given top priority while a plan is developed to collect learner information, behavioral data, and pertinent contextual information. The next step of the preparation process involves creating a training dataset D that is thorough and includes learner attributes, past interactions, and pertinent features. After that, the MOOC-based C4.5 algorithm is put into practice, beginning with the training dataset's initialization and the feature-representing attributes' definition. To improve the classification process, the C4.5 algorithm is used, which includes creating decision trees, using TG-C4.5 to select the optimal attribute features, parallel processing with Hadoop for scalability, and using MapReduce to calculate the information gain ratio. After that, LearnFlex incorporates the DQN reinforcement learning techniques. This entails putting the DQN training procedure into practice as well as initializing the Q-value function and replay memory rm . C4.5 and DQN work together to enable adaptive decision-making, which improves the system's capacity to adapt to shifting learning dynamics. Various user roles, including instructors, administrators, and students, are taken into account in user-centric design considerations. The design of role-based systems adapted to particular business requirements is informed by an analysis of the behavioral traits and basic information about the user.

Next, the system is deployed in the College English Teaching environment after being initialized and incorporating both DQN and C4.5 techniques based on MOOCs. A loop for continuous improvement is created to

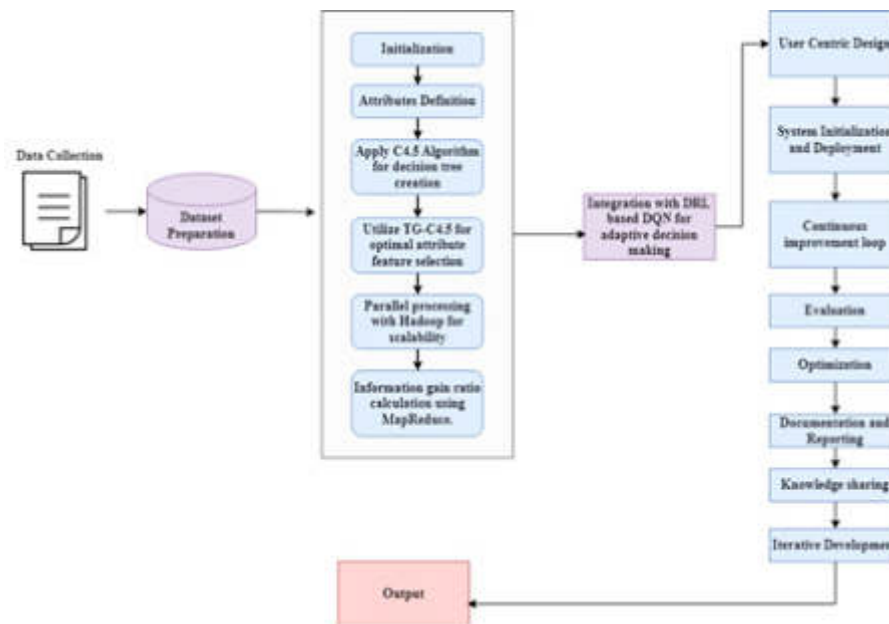

Fig. 2.1: Proposed LearnFlex Design

track system performance, collecting user input by watching and iteratively improving the LearnFlex algorithm in response to input. During the evaluation phase, the LearnFlex system's efficacy is evaluated with respect to user satisfaction, learning outcomes, and adaptability to changing educational needs. After that, optimization enables parameter and algorithm improvements based on the evaluation's findings. The process relies heavily on reporting and documentation, with the methodology, algorithms, and system components all having extensive documentation. The LearnFlex system generates thorough reports that include recommendations and results. In order to spread discoveries and insights, academic publications, conferences, and knowledge-sharing platforms place a strong emphasis on knowledge sharing. The LearnFlex system is continuously evolving and being improved with the iterative development approach. Finally this allows the provision of a customized and successful learning environment.

2.2. Proposed LearnFlex Approach.

2.2.1. MOOCs based C4.5 algorithm. This section discusses the C4.5 concept, which is based on MOOCs and was taken from the study [4]. The MOOCs-based C4.5 diagrammatic flow is depicted in Figures 2.1 & 3.1 and 3.2 of the study. We now carry out the simple algorithmic steps as follows.

The MOOCs-based C4.5 algorithm takes into account various learning styles, behaviors, and course content in order to manage the complex data from online courses. This tool performs a few crucial tasks. In order to help the system determine what might be most effective for each individual, it first arranges and makes sense of the data about each student. It's similar to customizing the educational process to meet each student's needs. Based on the C4.5 algorithm, this tool is also highly effective in generating decision trees, which aid in the system's intelligent decision-making regarding how to teach, what content to deliver, and even suggesting customized learning plans. Furthermore, it excels at managing multiple types of data simultaneously, which helps it overcome the difficulties of online learning. It increases the precision of identifying students' areas of strength and weakness, which is critical in the teaching of English. It also becomes even more potent when combined with Hadoop, a big data platform, allowing it to handle massive volumes of data effectively. All things considered, LearnFlex is made smarter by this tool the MOOCs-based C4.5 algorithm which aids in the efficient use of data to produce a customized and successful learning environment for college students studying English.

The system employs advanced load balancing techniques to distribute traffic evenly across servers, preventing any single server from becoming a bottleneck. This not only enhances performance but also ensures a smooth and responsive experience for all users. LearnFlex leverages CDNs to cache and deliver content from servers closest to the user’s location. This significantly reduces bandwidth usage and lowers the server load, enabling faster content delivery even in high-demand scenarios.

The MOOCs-based C4.5 algorithm in LearnFlex starts with initializing the training dataset D and defining attributes A . Attribute selection is performed using the TG-C4.5 algorithm, denoted as $TG - C4.5 = \text{taylorseries}(C4.5, GINIIndex)$ here $GINIIndex$ is introduced to enhance classification performance. The $GINI$ index (Gini) is defined as

$$Gini = 1 - \sum_{i=1}^n \left(\frac{|DC_I|}{|D|} \right)^2$$

capturing the impurity of a dataset. For a specific attribute A , $GiniSplitA(D)$ is computed as $GiniSplitA(D) = \sum_{j=1}^m \left(\frac{|D_j|}{D} Gini(D_j) \right)$. The mean sum of GINI indices ($Sum - GiniAF(D)$) is then calculated as

$$\frac{1}{s} \sum_{i=1}^s \sum_{j=1}^x \left(\frac{|D_{ij}|}{|D|} Gini(D_{ij}) \right)$$

To improve $GainRatio(A)$ calculation, the algorithm considers this mean sum:

$$GainRatio(A) = \frac{Gain(A)}{SplitInfoA(T) - \alpha \cdot Sum - Gain.SplitAF(D)}$$

Here, α is a tuning parameter. Decision trees are designed in the root node using C4.5 (D, A), and TG - C4.5 is applied for optimal attribute feature selection. The algorithm integrates parallel processing with Hadoop, employing $HD - TG - C4.5$ for large-scale data processing. The Gain Ratio Calculation with MapReduce in the proposed MOOCs-based C4.5 algorithm involves a series of steps aimed at optimizing the decision tree structure and enhancing the algorithm’s effectiveness. In next step parallel statistics are employed to calculate the information gain ratio for a specific attribute feature A using the MapReduce paradigm. The $GainRatio(GainRatio(A))$ is determined as the ratio of the Gain for attribute A to the Split Information for A subtracted by a weighted sum. Moving to Step 16, the algorithm adjusts or replaces misclassification results in the training set with probability errors, refining the classification accuracy by considering the likelihood of errors. Next, it introduces the calculation of the probability $P_{wj} \in \left[\frac{nwj}{V+s}, \frac{nwj+s}{V+s} \right]$ for each node using the Integrated Error Probability (IEP) model, contributing to a probabilistic approach to pruning. It focuses on estimating values for the number of nodes and subsets $n(t)$ a crucial step in determining the structure of the decision tree. Pruning decisions are made in the next step based on a condition related to the number of nodes $n(t) \leq n(T_i) + SE[n(T_i)]$ leading to the removal of specific branches and optimizing the decision tree structure. The algorithm analyzes user basic information and behavioural characteristics, highlighting the importance of understanding individual learner attributes for personalized learning experiences. Next, it integrates the algorithm into the design of an education system for predicting performance, emphasizing practical applications in the educational environment. Consideration of different user roles and their corresponding business requirements is addressed, ensuring a tailored approach to diverse stakeholders. The final step, involves continuous monitoring of system performance and gathering feedback, facilitating an iterative process for enhancements and refinements based on real-world outcomes and user experiences.

Algorithm 1 focuses on estimating values for the number of nodes and subsets $n(t)$ a crucial step in determining the structure of the decision tree. Pruning decisions are made in the next step based on a condition related to the number of nodes n leading to the removal of specific branches and optimizing the decision tree structure. The algorithm analyzes user basic information and behavioural characteristics, highlighting the importance of understanding individual learner attributes for personalized learning experiences. Next, it integrates the algorithm into the design of an education system for predicting performance, emphasizing practical applications

Algorithm 14 MOOCs based C4.5 algorithm

- 1: Initialize the training dataset D with learner information and behavioral characteristics.
- 2: Define attributes A representing features in the dataset.

Attribute selection using TG-C4.5 algorithm

- 3: Apply Taylor series based C4.5 Algorithm to calculate information gain rate.
- 4: Utilize TG-C4.5 algorithm for optimal attribute feature selection.

$$TG - C4.5 = \text{taylorseries}(C4.5, \text{GINIIndex})$$

GINI Index and splitting information

- 5: Introduce GINI index to improve classification performance
- 6: Define the GINI index as $Gini = 1 - \sum_{i=1}^n \left(\frac{|DC_I|}{|D|} \right)^2$
- 7: For attribute A , compute $GiniSplitA(D) = \sum_{j=1}^m \left(\frac{|D_j|}{|D|} Gini(D_j) \right)$
- 8: Calculate the mean sum of GINI indices using $Sum - GiniAF(D) = \frac{1}{s} \sum_{i=1}^s \sum_{j=1}^x \left(\frac{|D_{ij}|}{|D|} Gini(D_{ij}) \right)$
- 9: Improve the GainRatio calculation by considering the mean sum of GINI indices
 Compute $GainRatio(A) = \frac{Gain(A)}{SplitInfoA(T) - \alpha \cdot Sum - GainSplitAF(D)}$
- 10: Design decision trees in the root node to select and train optimal attribute features by utilizing $DecisionTree = C4.5(D, A)$
- 11: Apply the TG-C4.5 algorithm for optimal attribute feature selection.

Parallel Processing with Hadoop

- 12: Implement parallel decision algorithms using the Hadoop platform framework.
- 13: Design HD-TG-C4.5 for processing large scale data

$$HD - TG - C4.5 = \text{ParallelProcessing}(D, \text{Hadoop})$$

- 14: Utilize Hadoop Distributed File System (HDFS) and Hadoop MapReduce for efficient data processing.
 Gain Ratio Calculation with MapReduce
- 15: Perform Parallel statistics on the information gain ratio of attribute feature

$$GainRatio(A) = \text{MapReduce}(\text{InformationGainRatio})$$

$$GainRatio(A) = \frac{Gain(A)}{SplitInfoA(T) - \alpha \cdot Sum - GainSplitAF(D)}$$

$$Sum - GiniAF(D) = \frac{1}{s} \sum_{i=1}^s \sum_{j=1}^x \left(\frac{|D_{ij}|}{|D|} Gini(D_{ij}) \right)$$

- 16: Replace the misclassification result of the training set with probability error.
- 17: Calculate the probability of each node using the IEP model

$$P_{wj} \in \left[\frac{nwj}{V+s}, \frac{nwj+s}{V+s} \right]$$

Probability based Pruning

- 18: Estimate the values for the number of nodes and subsets

$$n(t) = \max\{e(pt) + 0.5 | pt \in kt(w)\}$$

MOOCs based algorithm output

- 19: Prune when the condition is satisfied

$$n(t) \leq n(T_i) + SE[n(T_i)]$$

- 20: Analyse the user basic information and behavioural characteristics.
 - 21: Design as education system for performance prediction.
 - 22: Consider different user roles and their corresponding business requirements.
 - 23: Monitor system performance and gather feedback.
-

in the educational environment. Consideration of different user roles and their corresponding business requirements is addressed, ensuring a tailored approach to diverse stakeholders. The final step, involves continuous monitoring of system performance and gathering feedback, facilitating an iterative process for enhancements and refinements based on real-world outcomes and user experiences.

2.2.2. Integrating DQN for adaptive decision making. One of the main functions of the Deep Q-Network (DQN) integration in the LearnFlex system is to improve adaptive decision-making. Using techniques from reinforcement learning, DQN is used to optimize workload scheduling decisions. The main goal is to develop a dynamic and intelligent system that can adjust on its own to changing circumstances in the context of teaching college English. With the help of DQN, LearnFlex is able to maximize expected rewards when making decisions by drawing on past experiences that are stored in a replay memory. LearnFlex can now customize its recommendations and responses thanks to this integration, giving students a more successful and individualized learning experience. LearnFlex aspires to provide an adaptive, intelligent, and data-driven educational platform that meets the specific needs of each individual learner by fusing MOOC-based C4.5 algorithms with DQN.

```

1: Input:  $n_{min}, n_{max}, \Delta, \alpha, \gamma, \delta$ 
2: Output: Workload Scheduling Decision
3: Initialize replay memory  $rm$  to capacity  $n$ 
4: Initialize action value function  $Q$  with random weights  $\theta$ 
5: Initialize target action value function  $\hat{Q}$  with weights  $\theta = \theta^-$ 
6: for  $e$  dopisode = 1,  $m$  do
7:   Initialize sequence  $s_1 = \{x_1\}$  and preprocessed sequence  $\sigma_1 = \sigma_1(s_1)$ 
8:   for  $dot$  = 1,  $T$  do
9:     with probability  $\delta$  select a random action  $a_t$ 
10:    otherwise select  $a_t = \max_a Q(s_t, a, \theta)$ 
11:    Execute action  $s_t$  and observe reward  $r_t$  and next state  $x_{t+1}$ 
12:    Set  $s_{t+1} = s_t, a_t, x_{t+1}$  and preprocess  $\sigma_{t+1} = \sigma(s_{t+1})$ 
13:    Store transition  $(\sigma_t, a_t, r_t, \sigma_{t+1})$  in replay memory  $rm$ 
14:    Sample random minibatch of transitions  $(\sigma_J, a_J, r_J, \sigma_{J+1})$  from replay memory  $rm$ 
15:    Set  $y_j = \left\{ r_{J+\gamma} \max_a \hat{Q}_{(s_{J+1}, a', \theta^-)}^{r_J} \right\}$ 
16:    Perform gradient descent step on  $(Y_J - Q(s_J, a_J, \theta))^2$  with respect to the network
    Parameters  $\vartheta$ 
17:    Every  $C$  steps reset  $\hat{Q} = Q$ 
18:   end for
19: end for
Online making workload scheduling decision
20: Load the parameters  $\vartheta$ ;
21: Calculate action-value  $Q(s_t, a; \theta)$ 
22: Output  $a_t = \operatorname{argmax} Q(s_t, a; \theta)$ 

```

In the LearnFlex system, the algorithm entails training a DQN for adaptive workload scheduling decisions. First, two action-value functions, Q and \hat{Q} , are initialized with random weights in a replay memory rm . Episodes are used in the training process to select states and actions at random or in an attempt to maximize the Q-value. Transitions are recorded in the replay memory, and rewards are tracked. The Q-network parameters are updated using a gradient descent step to minimize the temporal difference between the target and predicted Q-values after a random minibatch of transitions is sampled on a regular basis. Periodically, the target network is reset. The algorithm moves into the online decision-making stage after training. The trained parameters are loaded, and action values for the possible actions and the current state are computed. The action with the highest computed Q-value is chosen to make the decision. During online execution, this procedure is repeated, giving the LearnFlex system the ability to schedule workload adaptively using the learned Q-values.

Fig. 3.1: Performance Comparison

3. Results and Experiments.

3.1. Simulation Setup. We move forward with the evaluation of the suggested LearnFlex based on the study [20]. Based on the dataset that comprises universities, colleges, and schools. Here, we evaluate the proposed LearnFlex using data from colleges.

3.2. Evaluation Criteria. The Figure 3.1 shows that the LearnFlex framework is significantly more effective than traditional teaching methods in improving student performance. LearnFlex continuously outperformed conventional methods in terms of academic achievement during the observed periods. The LearnFlex scores show a consistent upward trend, ranging from 75.89 to 90.47. The scores for the traditional teaching approach, on the other hand, range from 70.64 to 82.34, indicating a somewhat slower and less noticeable improvement trajectory. The significant improvement in performance highlights LearnFlex's beneficial effects on college English learning outcomes for students. The upward trend in LearnFlex scores indicates the platform's efficacy and adaptability in meeting the varied needs of students, which in turn creates an environment that promotes better learning outcomes and more fulfilling educational experiences in general.

The efficacy of LearnFlex in improving student engagement is demonstrated by multiple metrics, indicating noteworthy improvements over conventional teaching approaches were present in Figure 3.2. First off, LearnFlex outperforms the conventional approach with an astounding participation rate of 85.77% compared to 70.27% for the former. This notable rise suggests that LearnFlex successfully promotes a greater degree of student participation in learning activities. When it comes to the interaction of materials, LearnFlex performs exceptionally well, scoring 90.22%, while traditional approaches fall short at 75.89%. This disparity indicates a more in-depth examination of learning resources as LearnFlex users interact with course materials in a more comprehensive manner. When it comes to learning activities, LearnFlex is still ahead of the competition, with an 80.34% score as opposed to 79.42% for the traditional method. While both strategies demonstrate respectable levels of student involvement, LearnFlex guarantees that students stay actively engaged throughout a variety of educational tasks, making for a more dynamic learning environment. Another area where LearnFlex excels is communication, where it achieves an amazing 95.06%, compared to 80.44% for traditional methods. LearnFlex's capacity to establish an engaging and cooperative learning environment is demonstrated by its exceptional communication-fostering capabilities. Traditional approaches, on the other hand, show a clear weakness in this area. With an overall engagement metric of 80.12% as opposed to the traditional method's 60.75%, LearnFlex is clearly a comprehensive solution. This notable difference suggests that LearnFlex's dynamic and adaptable features greatly enhance students' overall engagement in a comprehensive way. Taken as a whole, the metrics show that LearnFlex improves engagement in a number of ways, which makes it a more impactful and promising approach than more conventional teaching techniques.

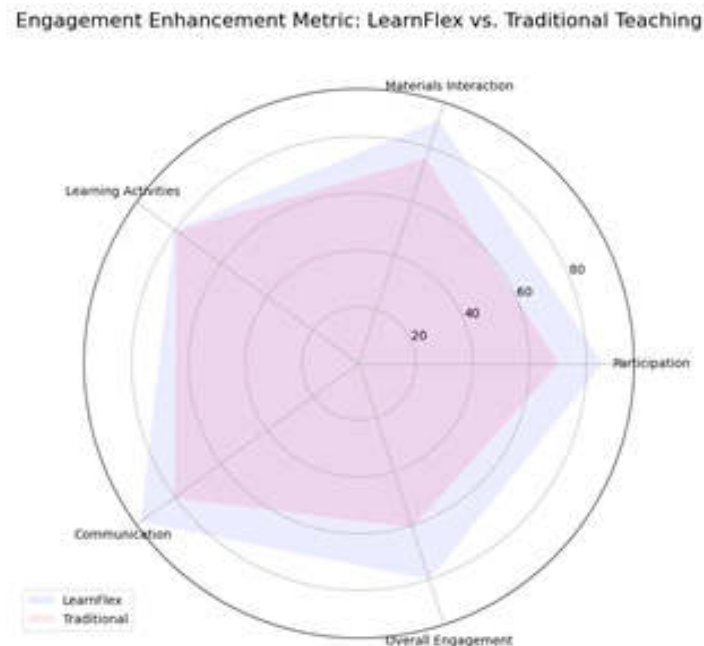

Fig. 3.2: Student Engagement Comparison

An extensive examination of user satisfaction ratings shows that the suggested LearnFlex is demonstrably effective when compared to traditional teaching methods, illustrated Figure 3.3. These scores, which range from 1 to 5, represent how satisfied students are overall with different aspects of their educational experience. LearnFlex has a usability score of 4.2, which is higher than traditional methods' score of 3.8. This discrepancy highlights the LearnFlex platform's greater usability by showing that students believe it to be more approachable and user-friendly. In terms of content relevance, LearnFlex performs better than traditional methods, scoring 4.5 out of 4.0. This discrepancy suggests that learners view the information in LearnFlex as more individualized and relevant to their particular learning requirements, which raises the overall significance of the course content. LearnFlex's learning process receives an astounding 4.8, vastly surpassing the 4.1 score assigned to conventional methods. This significant difference emphasizes that LearnFlex environments provide students with a more engaging and enriching educational experience than traditional classroom settings. Regarding assistance, LearnFlex receives a satisfaction rating of 4.3, which is higher than the 3.9 that traditional approaches receive. This indicates that LearnFlex does a great job of offering the required frameworks for support, creating an atmosphere in which students feel sufficiently assisted throughout their educational journey. LearnFlex is clearly superior, as evidenced by the overall satisfaction metric 4.6, which averages scores from a variety of categories. Traditional methods score 4.2. This conclusion demonstrates that LearnFlex provides students with a thorough and satisfying learning experience, not only meeting but exceeding their expectations. In essence, LearnFlex is an excellent pedagogical framework that is responsive to the changing needs of students and goes above and beyond conventional approaches to create a positive and productive learning environment.

4. Conclusion. In conclusion, the LearnFlex framework that has been suggested, which combines DRL-based DQN methods with MOOCs-based C4.5 algorithms, is a revolutionary development in the field of teaching college English. The well-thought-out system architecture uses C4.5 to make efficient decisions based on learner characteristics and integrates MOOCs to improve adaptability. This procedure is further improved by the TG-C4.5 algorithm, which takes into account the peculiarities of online learning environments. Simultaneously, the incorporation of DQN methodologies incorporates reinforcement learning, guaranteeing flexible decision-making and customized experiences. The user-centric design, which accommodates the various roles of teachers, admin-

Fig. 3.3: User Satisfaction

istrators, and students, complements the algorithmic prowess. LearnFlex shows efficacy in enhancing learning outcomes, user satisfaction, and adaptability to changing educational needs through methodical initialization, continuous improvement loops, and a strong evaluation framework. The C4.5 algorithm, which is based on MOOCs, greatly enhances personalized learning by being highly scalable and adept at creating decision trees. Massive datasets in MOOCs present challenges for scalability, but Hadoop's parallel processing capabilities further improve it. All things considered, LearnFlex shows itself to be an intelligent, scalable, adaptive system that is ready to transform the way college English is taught by fusing state-of-the-art algorithms and technologies into a framework that is performance-driven and centered on the needs of the user.

5. Limitations and Discussions. LearnFlex is a promising framework for bettering college English instruction, but it has a number of issues that need to be acknowledged and discussed carefully in order to be improved. The significant reliance on learner data raises privacy concerns, necessitating a careful balancing act between personalization and privacy. Algorithmic complexity is introduced by the combination of DRL-based DQN and MOOCs-based C4.5, which presents difficulties for system upkeep and user-friendliness. Further research is necessary to generalize LearnFlex's success outside of the English classroom, taking into account the various ways that students learn different subjects. In areas with inadequate infrastructure, accessibility issues, such as technology requirements, may limit its effectiveness. Further investments in professional development are warranted because teacher training is essential for effective deployment. Important topics for discussion include striking a balance between standardized quality and personalization, creating feedback loops, addressing cost-effectiveness and scalability, and taking social and cultural nuances into account. Participating in these conversations will help to improve LearnFlex and create a dynamic, flexible learning environment for college English instructors. Future online learning platforms will likely incorporate more sophisticated tools for collaboration and community building, mimicking the social learning environments of traditional classrooms. These tools will support real-time collaboration on projects, peer-to-peer learning, and mentorship opportunities, breaking down the barriers of isolation often associated with online education.

SMART FISH PASSAGE DESIGN AND APPLICATION OF HYDROACOUSTIC COMMUNICATION TECHNOLOGY IN AQUATIC ECOSYSTEM RESTORATION

CHAO YUE^{*}, MENGEN ZHU[†], LEI YANG[‡] AND LEI LI[§]

Abstract. The demand for creative solutions to help migrate fish and conservation efforts grows as aquatic environments experience more and more pressure from humans and fragmentation of habitat. The utilization of hydroacoustic technology for communication in conjunction with smart fish pathway architecture is the main emphasis of this research to improve rehabilitation efforts for aquatic environments. Using sophisticated systems for tracking and regulation to improve migratory pathways, the study investigates cutting-edge solutions in engineering for fish passage. Real-time data capture and transmission are made possible by the application of hydroacoustic technology for communication, which means that fish populations and monitoring systems can effectively communicate. The creation of intelligent fish passage structures with actuators, sensors, and communications components is a major focus of the research. The best passage efficiency of these structures is ensured by their dynamic adaptation to fish behavior and variables in the environment. An essential interface for gathering information on behavior, evaluating migratory trends, and putting adaptive management plans into practice is hydroacoustic communications technology. In order to assess the efficacy of the hydroacoustic communication technology and smart fish passage design in a variety of aquatic habitats, a thorough field investigation is part of the suggested methodology. To evaluate the effect on migration of fish rates of achievement, species diversity, and general well-being of the ecosystem, field data will be studied.

Key words: Marine Internet of Things; Internet of Underwater Things; protocols; smart fish, passage, hydroacoustic communications, aquatic ecosystem restoration

1. Introduction. In recent times, Earth observation, alterations in marine ecosystems, and changing climates have garnered human interest and have had a major effect on human productivity [8]. Underwater recognition of targets is currently a growing field of study due to the increasing demand for underwater identification. It has applications in the areas of ship noise categorization [7], underwater target localization and recognition [15], and aquatic environment surveying and demonstrating [14]. Underwater target recognition has new opportunities due to the rapid growth of artificial intelligence methods like machine learning and deep learning, the development of supercomputing, the substantial rise in math authority, and the rapid expansion of big-data-processing computation.

Researchers in this field are swiftly implementing research findings to improve technological iterations. Nevertheless, challenges remain in the application of deep learning for underwater target recognition, including small data amounts, limited flexibility of traditional visual system computations, complex pre-processing procedures, and deep learning patterns that are still too intricate to offer excellent generalizability. It is worth noting that acoustic and various signal-filtering techniques are useful for detecting pipeline leaks, and that deep learning algorithms are also widely employed, suggesting that models based on deep learning have excellent generality and swear in underwater acoustics [11].

To deploy IoUT, follow these three steps [24]. Developing a dynamic, ongoing, all-encompassing, and intelligent real-time view of the underwater world is the first stage. Large-scale, long-term, continuous oceanographic data collection has been made possible in recent decades by underwater sensor networks made up of a range of equipment, including conductivity, and heat and depth detectors, microbial sensors, and current meters [6]. Innovative uses that utilize human–robot interactions, such as undersea pipeline assessment, undersea volcanic

activity and hydrothermal source research, seabed visualisation, strategic surveillance, and underwater rescue, are driving up demand for real-time multimedia data [22].

Large-scale real-time underwater data transmission is the second phase of the IoUT deployment. Undersea gliders, remotely controlled unmanned underwater vehicles (ROVs), and automated unmanned underwater vehicles (UUVs) are examples of movable systems that have made it possible to build mobile underwater networks and are essential for high-quality surveillance footage [26, 27, 17, 19]. The smart analysis of large amounts of underwater data is the third step in the deployment of IoUT. The amount of maritime data that was acquired in the past was limited because of a lack of equipment and minimal investment, which caused the process to take years or months.

The motivation behind this research stems from the ever-increasing need for innovative solutions to address the challenges faced by aquatic environments due to human activities and habitat fragmentation. As human impact on aquatic ecosystems intensifies, it becomes imperative to find creative and effective ways to support fish migration and conservation efforts. This research is driven by the pressing demand to enhance the rehabilitation of aquatic environments, offering a lifeline to struggling fish populations.

This study focuses on a novel approach that combines hydroacoustic technology with smart fish pathway architecture to revolutionize the way we facilitate fish migration and conservation. By harnessing cutting-edge engineering solutions, including real-time data capture and transmission through hydroacoustic technology, we enable seamless communication between fish populations and monitoring systems. The novelty lies in the creation of intelligent fish passage structures equipped with advanced actuators, sensors, and communication components, allowing them to adapt to fish behavior and changing environmental conditions dynamically.

The main contribution of the proposed method is given below:

1. Using hydroacoustic data, a DNN-LSTM model is trained to identify complex temporal correlations in fish movements.
2. The trained model is then included into the smart fish passageways control system, enabling ongoing adaptation in response to change fish behavior and environmental variables.
3. The goal of the study is to show how DNN-LSTM can be used to provide fish passage systems with a smart, self-learning framework that minimizes ecological disturbance while maintaining efficient passage.

Remaining sections of this paper are structured as follows: Section 2 discusses about the related research works, Section 3 describes the Smart fish passage design, application of hydroacoustic communication technology and Deep Neural Networks, Section 4 discusses about the experimented results and comparison and Section 6 concludes the proposed optimization method with future work.

2. Related Works. The future's top innovations for implementing smart data processing on massive scales will be big data, cloud computing, artificial intelligence, and virtual reality [18]. Therefore, one of the key areas of research for upcoming applications of human-robot interaction is the real-time changing and visual tracking of underwater landscapes. Most commercial marine IoT applications concentrate on both surface and subsea IoT technology to measure and monitor business activity. It is possible to identify and isolate the IoUT market sector for usage in aquaculture and fishing, that works with fish breeding in small spaces [5].

In response, the central server analyzes the information and creates management and choice-making strategies. Large-scale fish and marine creature searches and analyses in open waterbodies comprise another set of tasks [28, 23, 12, 2]. It should be noted that the notion of Internet of Things Ocean (IoTO) [10] or Ocean of Things is mentioned in the literature in addition to Internet of Things (IoUT). One way to conceptualize the Internet of Things (IoT) technology is as an intelligent underwater item network. One potential technique for the organized administration of various marine data types is IoTO.

The International Maritime Organization (IMO) first established the concept of "e-Navigation" [13, 21] to enable different kinds of navigation services, which is akin to Maritime IoT and was intended to improve the shipping sector. Other services were subsequently added; these are mentioned above. Thus, maritime IoT refers to a dispersed hardware–software complex that allows for transmitted from different above-water ocean engineering structures and items gadgets, used via a unified machine-type communication via a data system (typically the Internet, or a marine information network, or a network of underwater services).

The wavelet transform approach is not without flaws, though. The shortcomings of various discrete wavelet

Fig. 3.1: Architecture of proposed method

transform (DWT) system designs were noted by author in [3, 9]. The outstanding characteristics of the wavelet transform (WT) in one dimension are not transferable to two dimensions or higher, and it shows a lack of adaptivity to additional modality disintegration techniques, such as EMD, LMD, VMD, SGMD, etc. The one-dimensional characteristic vector obtained by the wavelet transform is frequently not enough to provide optimal features because of the intricate nature of the hydroacoustic surroundings [1]; therefore, finding a way to enhance the selection of multidimensional or optimal features has emerged as a potential area of research.

To reclaim the breakpoints in the LOFAR spectrum and achieve an exceptional identification rate in the CNN network, the author [25] developed a multi-step decision-algorithm-based improvement technique based on LOFAR spectrum improvement for underwater detection of targets. After implementing these spectrograms into the AlexNet network, the researchers [20, 16, 4] analyzed typical spectrum maps, such as LOFAR, Audio, The demon, a histogram etc. and discovered that the LOFAR spectra had the best identification rate.

The wavelet transform approach, particularly the discrete wavelet transform (DWT) system designs, has been found to have shortcomings in handling multidimensional data. While it may perform well in one dimension, it lacks adaptivity when applied to two or more dimensions. This limitation hinders its effectiveness in dealing with the complex nature of hydroacoustic environments, where multidimensional data is often encountered. The one-dimensional characteristic vector obtained from the wavelet transform may not provide optimal features for underwater target detection due to the intricate nature of hydroacoustic surroundings. This inadequacy highlights the need for improved techniques to select multidimensional or optimal features that can better capture the nuances of the underwater environment.

3. Proposed Methodology. The proposed methodology uses deep learning method for Smart fish passage design and application of hydroacoustic communication technology in aquatic ecosystem restoration. It uses Deep Neural Networks based Long-Short Term Memory (LSTM) for smart fish passages and intelligent decision-making. Field tests in various aquatic habitats will be carried out to evaluate the effectiveness of the smart fish tunnels augmented by DNN-LSTM. The general effect on the recovery of aquatic ecosystems, species-specific adaptation, and migration success rates are examples of key performance indicators. The goal of the study is to show how DNN-LSTM can be used to provide fish passage systems with an intelligent, self-learning architecture that minimizes ecological disturbance while maintaining efficient passage. In figure 3.1 shows the architecture of proposed methodology.

3.1. Smart Fish Passage and hydroacoustic communication for Aquatic Restoration. With the overall objective of fostering successful aquatic ecosystem restoration, this research focuses on the integration of Deep Neural Networks (DNN) and Long Short-Term Memory (LSTM) networks to create an intelligent system for smart fish passage design and hydroacoustic communication. Through real-time, data-driven communication between fish populations and fish passage structures, the study hopes to improve the responsiveness and flexibility of fish passage structures by utilizing the temporal learning capabilities of DNN-LSTM architectures.

The suggested approach uses hydroacoustic data to train a DNN-LSTM model, which then uses the data to capture and evaluate the complex temporal dynamics of fish movement patterns. The trained model is the central intelligence element of smart fish passageways, allowing for dynamic modifications based on the hydroacoustic monitoring system's real-time data. At the same time, a bidirectional communication channel is established between the fish community and the smart channels using hydroacoustic communication technology.

A variety of aquatic conditions will be used for field testing to assess how well the DNN-LSTM-based smart fish passage system works. To verify the efficacy of the suggested strategy, important indicators like ecological impact, species-specific adaptation, and migration success rates will be evaluated. The goal of the study is to show how DNN-LSTM can be an effective tool for developing smart, self-learning fish passage solutions that maximize fish migration and ecosystem restoration initiatives.

The results obtained from this study have wider ramifications for the development of technology-based conservation tactics. The suggested framework demonstrates a comprehensive strategy for improving aquatic ecosystems by fusing deep learning methods with hydroacoustic communication, tackling the problems brought on by habitat destruction and dispersion. The findings highlight the possibility for innovative technologies to play a critical role in the ecological restoration of aquatic ecosystems and add to the expanding field of intelligent ecological management and monitoring.

3.2. Deep Neural Networks (DNN). Artificial neural networks that analyze data using numerous layers—hence the name "deep"—are known as deep neural networks (DNNs). Nodes, sometimes referred to as neurons or units, are present in every layer of the network and are connected by weighted connections. Deep neural networks (DNNs) are a subclass of machine learning models that fall within the deep learning category.

To enable them to learn hierarchical data representations, DNNs usually consist of numerous hidden layers positioned among the input and output layers. The network can catch intricate patterns and characteristics because of its depth. Backpropagation is an optimization algorithm used in DNN training. Through training, the network attempts to reduce the discrepancy between target values and projected outputs by adjusting the weights of its connections.

Activation functions are applied by nodes in each layer to the weighted total of their inputs. Sigmoid, hyperbolic tangent (tanh), and rectified linear unit (ReLU) are examples of common activation functions. By adding non-linearity to the system, these functions enable it to learn intricate mappings. Several deep learning structures, including TensorFlow, PyTorch, Keras, and others, are used to implement DNNs. Deep learning model construction, training, and deployment tools are offered by these platforms.

Natural language processing, recommendation systems, picture and speech recognition, and other industries have shown impressive performance using DNNs. When given tasks that require a lot of data to be trained, they perform exceptionally well. Large volumes of labeled data are needed for the computationally demanding process of training deep neural networks. Another frequent issue which must be handled is overfitting, which occurs when a model learns noise in the data used for training rather than the real patterns.

3.3. Long-Short Term Memory (LSTM). One kind of recurrent neural network (RNN) architecture called Long Short-Term Memory (LSTM) was created to solve the gradient that diminishes issue, which is a prevalent problem with conventional RNNs. LSTMs are especially useful for problems requiring time-series data, processing natural languages, and sequential pattern identification since they were developed to recognize dependencies that persist in sequential data.

The capacity of LSTMs to preserve cells with memories which can store and retrieving information across extended sequences is essential for avoiding the loss of pertinent data during training. This is made possible by a group of gates that control information flow into, out of, and inside the memory cell. These gates include an input gate, an output gate, and a forget gate.

Cell State (Ct): The long-term information storage cell in the memory.

The output generated by the LSTM at a specific time step is known as the Hidden State (Ht).

How much of the new data should be saved in the memory cell is decided by the input gate (i).

The Forget Gate (f) determines the amount of data that should be removed from the memory cell. The output gate (o) controls the amount of memory cell content that is utilized to produce the output.

Long-term dependency capture is a key component of LSTMs' performance in a variety of uses, such as time-series prediction, translation by machine, and speech recognition. An LSTM could be used to simulate

Fig. 3.2: Structure of DNN-LSTM

and foresee the actions of fish over time in the context of your mentioned study on hydroacoustic communication technology and smart fish passage design. This would allow the smart travel structures to change their configuration based on the evolving patterns seen in the hydroacoustic data. In figure 3.2 shows the structure of DNN-LSTM.

Hydroacoustic technology allows for non-intrusive monitoring of fish populations without physically disturbing their habitat. This is in contrast to some traditional methods like electrofishing, which can be invasive. It can cover large areas, making them suitable for monitoring fish migration in expansive aquatic environments such as rivers, lakes, and oceans. This wide coverage is often difficult to achieve with manual methods. They provide real-time data, allowing researchers to track fish movements and behaviors as they occur. This immediacy can be crucial for making timely management decisions.

Hydroacoustic systems can distinguish between different fish species based on their acoustic signatures. This capability is valuable for studying specific species' migration patterns and behaviours. Compared to physical interventions like fish ladders or traps, hydroacoustic technology typically has a lower ecological impact since it does not require altering the natural flow of water or physical structures.

4. Result Analysis. Although short-time Fourier, Meier, Hilbert-Yellow, and additional methods of processing have been put forth to address some aspects of indicate extraction of features, single signal processing for feature extraction is no longer able to increase the classifier's effectiveness due to the flaws in the various algorithms. Therefore, one path for the advancement of hydroacoustic signal detection will be multi-spectrum feature fusion. The dataset is taken from Kaagle for evaluation.

The evaluation parameters such as accuracy, precision, recall and f1-score is measured. The proposed method achieves better result in all parameter metrics.

The simulation's accuracy, which is expressed as follows in Equation (4.1), indicates how effectively the model works across classes.

$$Accuracy = \frac{Total\ number\ of\ truly\ classified\ samples}{Total\ Samples} \tag{4.1}$$

The precision of the simulations is an assessment of their capacity to detect true positives, and it is computed using Equation (4.2).

$$Precision = \frac{TP}{TP + FP} \tag{4.2}$$

The proportion of projected true positive and false negative values to true positive prediction values is

Fig. 4.1: Accuracy

known as the recall. Equation (4.3) represents the calculation.

$$Recall = \frac{TP}{TP + FP} \quad (4.3)$$

The model's total accuracy, or F1 score, strikes a positive class balance between recall and precision. Equation (4.4), which represents the calculation, is used.

$$F1 - score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (4.4)$$

This has to do with how well models (like DNN-LSTM) forecast fish behavior from hydroacoustic data. The capacity of the model to precisely predict fish behaviors and movement patterns is crucial for creating intelligent fish passage systems that work well.

Analyse the degree to which the intelligent fish passage systems can adjust in real time to changes in fish behavior and surrounding circumstances. This entails evaluating how accurately the passages alter their configurations in response to the integrated models' predictions.

Analyse how accurate the overall influence on the restoration of aquatic ecosystems is. Assessing alterations in diversity of species, health of ecosystems, and other pertinent indicators of ecology is part of this. In this case, accuracy refers to how successfully the technologies being used support the recovery of the ecosystem.

Evaluate the precision of data transfer between the smart passageways and the hydroacoustic communication technology. This entails assessing the accuracy and dependability of the communication links used to send information on fish behavior and system modifications. In figure 4.1 shows the evaluation of accuracy.

In the setting of Fish Passage Design and Hydroacoustic Communication, as well as recall relates to the system's capacity to accurately detect and meet the needs of migrating fish. It concerns the percentage of real positive cases (fish passes that are successful or pertinent hydroacoustic signals) that the equipment accurately detects. Regarding Fish Passage Designs, a high recall rate suggests that a considerable proportion of the fish population can move via the structures without any hindrance. Ensuring that the planned target species are accommodated, and their migration is facilitated by the constructed routes is crucial for the successful restoration of aquatic ecosystems.

To summarize, a high recall in hydroacoustic communication means that the system correctly recognizes and interprets relevant underwater signals, which contributes to a greater awareness of fish behavior to enhance passage design and overall aquatic restoration efforts. Conversely, a high recall in fish passage design means that the structures in question are effectively facilitating fish migration. In figure 4.3 shows the evaluation of recall.

Fig. 4.2: Recall

Fig. 4.3: Precision

Recall in Hydroacoustic Communication is the system's capacity to identify and decipher pertinent signals in the submerged acoustic environment. This includes recognizing hydroacoustic cues, such as movement patterns or communication signals, accurately in fish. To collect thorough and precise data on fish behavior—data that can later be utilized to influence the adaptive characteristics of smart fish passages—high recall in hydroacoustic communication is necessary.

When discussing Fish Passage Design and Hydroacoustic Communication, as well as precision pertains to the precision and dependability of the technologies and systems that support fish migration and interaction in aquatic settings. It is imperative to guarantee that the solutions put into practice accurately and successfully tackle the problems related to fish movement and hydroacoustic communications. Fish tunnels must be precisely designed so that the structures can adjust to changing environmental conditions and the unique behaviors of various fish species.

The precise design of the passage structures guarantees the smooth and effective passage of fish, reducing the amount of stress and energy that the aquatic species must expend. Elements that preferentially aid the movement of fish species while discouraging non-target species can be included with precision in design to improve the balance of nature. In figure 4.3 shows the evaluation of precision.

In binary classification problems, the F1-score—also referred to as the F1 measure or F1-value—is a statistic

Fig. 4.4: F1-score

that is frequently employed. Recall and precision are used to give a fair assessment of a model's effectiveness. The F1-score could be used to assess how well the system recognizes successful fish passage events in the context of fish route design and hydroacoustic communications. A high F1-score suggests that the algorithm is successfully recognizing effective fish passages while avoiding false positives and false negatives in the setting of fish passage design and hydroacoustic communications. This statistic offers a thorough evaluation of the model's capacity to recognize and react to fish movements inside the intended passageways, accounting for the intricacies of aquatic communications and surroundings. In figure 4.4 shows the evaluation of F1-score.

5. Conclusion. As human pressure on aquatic ecosystems increases and habitat becomes more fragmented, there is an increasing need for innovative solutions to support fish migration and conservation efforts. The focus of this project is to improve rehabilitation efforts for aquatic ecosystems by using smart fish pathway architecture in conjunction with hydroacoustic technologies for communication. The project explores state-of-the-art engineering solutions for fish passage by utilizing complex tracking and regulating systems to enhance migratory paths. Fish populations and monitoring systems can efficiently communicate thanks to the adoption of hydroacoustic technology for communication, which enables real-time data capture and transmission. One main goal of the project is to create intelligent fish passage structures that include actuators, sensors, and communications components. These structures' dynamic response to fish behavior and environmental factors ensures optimal passage efficiency. Hydroacoustic communications technology is a vital interface for behavior data collection, migration trend assessment, and the implementation of adaptive management strategies. A comprehensive field study is part of the recommended methodology to evaluate the effectiveness of the hydroacoustic communication technology and smart fish passage design in a range of aquatic settings. Field data will be examined to assess the impact on fish migration rates of accomplishment, species variety, and overall ecosystem health. The future research directions can contribute to the ongoing development and refinement of hydroacoustic technology for fish migration and monitoring, ultimately advancing the field of aquatic conservation and sustainable management.

DESIGN OF FINANCIAL DATA ANALYSIS AND DECISION SUPPORT SYSTEM BASED ON BIG DATA

SUFANG ZHENG*

Abstract. A cutting-edge Decision Support System (DSS) utilizing Deep Reinforcement Learning (DRL) for improved financial data analysis is the primary focus of the proposed research. In light of the prospering difficulties presented by large information in the monetary space, our creative methodology outfits the force of DRL to foster a powerful and versatile framework. By flawlessly incorporating DRL into the DSS structure, we mean to improve the framework's capacity to break down huge and complex monetary datasets. This DSS not only provides financial professionals with intelligent decision-making support but also real-time insights into market trends and patterns. The collaboration between enormous information investigation and DRL works with a dynamic and responsive framework equipped for adjusting to the quickly developing financial scene. Our exploration adds to the headway of choice by tending to the particular requests of monetary information, consequently enabling clients with ideal and informed dynamic abilities. The proposed DRL-based DSS addresses a change in perspective in monetary information examination, offering a versatile and effective answer for exploring the intricacies of enormous information in the financial area. This examination holds huge potential for changing dynamic cycles, advancing monetary security, and at last adding to the progression of the more extensive monetary industry.

Key words: DRL, decision support system, financial data analysis, big data, intelligent decision making, adaptive technology

1. Introduction. In the current financial landscape, intelligent decision support systems are in high demand. These frameworks act as priceless instruments for monetary experts, offering experiences, examination, and dynamic help [4]. Regardless, standard financial decisions and genuinely strong organizations experience basic limitations in really managing the intricacies of present day money related data. Continuous handling of immense datasets, adjusting to quickly moving economic situations, and removing helpful data from multi-faceted monetary examples are snags [6, 7]. Because of these limitations, standard frameworks are unable to be deft and responsive, which results in subpar dynamic results and hampers the ability of financial experts to investigate the powerful concept of the financial world [12].

As we analyse the continuous creative part, existing solutions for money related decisions assist with showing drawbacks that warrant thought. Conventional progressions fight to keep awake with the surprising improvement of colossal data in the financial region, habitually provoking lethargy issues and compromised logical accuracy [8, 9]. The weaknesses to these advancements feature the pressing precondition for novel systems that can beat the challenges presented by the consistently expanding volume and intricacy of monetary information. Significant learning emerges as a promising street to address the lack of ordinary money-related decisions and sincerely strong organisations [10]. Its ability to subsequently acquire depictions from data benefits from more exact and nuanced examination. Monetary choice emotionally supportive networks can possibly turn out to be stronger and versatile thanks to profound learning procedures' capacity to remove includes and perceive designs. This impact in context opens approaches to the extra present day and strong procedures for unravelling complex money related data, empowering prevalent powerful cycles.

By clearly analysing the limitations and restrictions of the existing techniques here we proposed the novel approach of Deep Reinforcement Learning based Decision Support System (DRL-DSS) [1, 11, 5]. This combination means bridling the qualities of both profound learning and support, figuring out how to make a framework that not only explores the difficulties of large amounts of monetary information but also adjusts progressively to changing economic situations. By coordinating DRL into the choice help structure, our exploration looks to provide a versatile, responsive, and smart arrangement, engaging monetary experts with upgraded dynamic capacities notwithstanding the developing monetary scene.

*School of Business, Zhengzhou University of Industrial Technology, Xinzheng, 451100, China, (sufangzhengfinan@outlook.com)

The motivation behind our research on the "Design of a Financial Data Analysis and Decision Support System Based on Big Data" stems from the increasingly complex and voluminous nature of financial data in the global economy. The explosion of big data in the financial sector presents both a significant challenge and a golden opportunity for financial institutions. Traditional economic analysis tools and methodologies are becoming inadequate to process, analyse, and derive meaningful insights from this vast amount of data efficiently. As a result, there is a pressing need for innovative solutions that can handle the complexity and scale of financial data while providing actionable insights to support decision-making processes.

Integrating Deep Reinforcement Learning (DRL) with a Decision Support System (DSS) represents a pioneering approach to tackling the challenges posed by big data in finance. DRL, with its ability to learn optimal actions through trial and error by interacting with a dynamic environment, offers a powerful tool for analysing financial datasets that are large, complex, and constantly changing. By leveraging DRL, our proposed DSS aims to not only process and analyze big financial datasets more efficiently but also adapt to new data and market conditions in real-time, providing financial professionals with timely and relevant insights.

The main contribution of the paper as follows

1. Proposed a novel approach of Deep Reinforcement Learning Decision Support System (DRL-DSS) that significantly enhances the decision support capabilities in the financial domain.
2. This research contributes to addressing the challenges posed by big data in financial systems.
3. The proposed DRL-DSS includes a DRL-DQN-based technique in the decision support framework; this intelligent technique enables the system to learn and adapt to market conditions autonomously and offers a better path in financial decision-making that goes beyond the capabilities of traditional systems.
4. This proposed efficacy is proved with valid experiments.

2. Related Work.

2.1. Decision support system based discussions. This study [14] investigates how big data in financial decision-making affects information asymmetry, principal-agent relationships, and risk management. It examines how big data could enhance predictions, increase the relevance of decisions, provide companies a competitive edge, and promote flexible decision-making. The research emphasises the value of big data in merging business and finance and the necessity of a robust information infrastructure for this type of integration through examination of practical instances of its application in corporate financial decisions. According to the study, big data is crucial for removing obstacles between business and finance, expediting the decision-making process, and raising company value. This study [5] highlights flaws, including inefficiency and intelligence deficiency, in the present financial decision support systems, and investigates how artificial intelligence might be integrated to improve them. Using the X business as a real-world example, it suggests cutting-edge, clever computerised technology to help with financial decision-making. Based on a questionnaire survey, the results demonstrate that the AI-enhanced system offers higher intelligence, timeliness, and accuracy in financial decision-making while lowering costs and simplifying the integration of management and financial accounting.

The goal [3] of this study is to help businesses make better financial decisions by utilizing the current data boom. It emphasizes how crucial timely data analysis and intelligent systems are to the efficient management of resources, time, and choices in order to maximize profitability. The article highlights the applicability of edge computing and criticizes conventional data management in businesses as being out of date. It then suggests an information-based financial management system. The system meets performance metrics requirements with high efficiency, responsiveness, and CPU usage after extensive testing and modifications. The whale algorithm's integration also demonstrates excellent energy and computational resource management. The system's potential to enhance enterprise financial management is highlighted in the study's conclusion, which also calls for more improvement.

This study [16] shows how big data may improve financial analysis and decision-making in businesses, replacing more conventional approaches that depend on human resources. The study highlights notable enhancements in decision-making accuracy and efficiency through the use of an intelligent financial decision support system that incorporates big data web crawler technology and ETL procedures, as demonstrated in a case study involving J Group. The system's ability to analyse data in real time and provide financial insights represents a significant advancement in corporate financial management and decision-making. This work [15] fills a need in basic medical care, particularly in distant areas, by creating a ground-breaking artificial intelligence system that

can speak with patients on its own using voice recognition and synthesis. The system works as a virtual doctor. The AI system's promise to provide precise probability forecasts for patient diagnosis is demonstrated by its ability to foresee type 2 diabetes mellitus utilizing non-invasive sensors and deep neural networks. The study also examines the level of acceptance of artificial intelligence among young people in the healthcare industry, including details on the possible long-term effects of this kind of technology. Artificial intelligence has been used more and more in the legal industry since the 1980s to handle an increase in the number of cases. This paper introduces "TaSbeeb," a deep learning-based JDSS that can retrieve religious texts and judicial reasoning for use in Saudi courts. It is divided into three stages: using stacked DL models to handle unbalanced classification, semi-automated judicial text annotation, and a judicial language model for information retrieval. With its excellent accuracy and F-scores, TaSbeeb represents a substantial improvement in the efficiency and accuracy of Arabic JDSS and holds the potential for wider implementation in judicial systems.

3. Methodology.

3.1. Proposed Overview. The suggested idea for the DRL-DSS coordinates both DRL-DQN and TRPO calculations to break down and settle on choices in the complex and information-serious field of money is shown in Figure 3.1. At first, the framework gathers an exhaustive cluster of monetary information, including stocks, securities, market lists, macroeconomic pointers, and ongoing worldwide monetary news. This information is carefully preprocessed to guarantee quality and importance, utilizing procedures like standardization, sound decrease, and element choice. The DRL-DQN algorithm is used in the first phase. This includes the utilization of a profound Q-organization that is prepared to comprehend and expect market patterns and ways of behaving. The DQN is intended to deal with the tremendous time-series information, perceiving examples and gaining from verifiable patterns to make informed expectations about future market developments. This organization is advanced for security and effectiveness, utilizing procedures, for example, experience replay and fixed Q-focuses, to improve learning. Parallely, the TRPO calculation is used to advance the dynamic approach of the framework. TRPO, known for its viability in overseeing strategy slope techniques in support learning, offers a more steady and hearty way to deal with learning strategies. It guarantees that the updates to the strategy are made inside a trust locale, forestalling uncommon arrangement changes that could prompt shaky preparation or lacklustre showing. This is especially vital in the unstable and variable monetary business sectors.

The framework orchestrates the forecasts and experiences acquired from the DRL-DQN with the approach choices made through TRPO. DQN provides deep insight into the data, and TRPO ensures that the decision-making process is continuously refined and optimized for the best possible outcomes. To address the difficulties of enormous information in finance, high level information, the board, and dimensionality decrease procedures are carried out. These procedures help in refining the most effective data from the tremendous datasets, guaranteeing that the DRL-DQN and TRPO calculations are working with the most applicable and huge information highlights. Far-reaching back-testing and forward-testing instruments structure a vital piece of the procedure. The situation is thoroughly tried against verifiable information and simulated conditions to approve its viability and flexibility in various economic situations. The DRL-DSS's robustness and dependability in real-world financial scenarios are assured by this extensive testing. At long last, an accentuation is put on making an interpretable and easy-to-understand interface for the DRL-DSS. Users are able to make well-informed decisions based on the system's insights and recommendations as a result of this, guaranteeing that the intricate workings of the DRL-DQN and TRPO algorithms are presented in an approachable manner. This approach expects to make the DRL-DSS a strong and natural device for monetary examination and dynamics in the space of enormous information.

3.2. Proposed DRL-DSS Approach in Financial big data.

3.2.1. DRL-DQN based Financial Decision Making. DQN is a useful tool for making well-informed judgments in the financial domain when used in conjunction with a DRL-DSS. To control the current status of the market it analyses a lot of financial data, including stock prices and market movements. Then, by assessing the anticipated advantages of different financial transactions, like purchasing or selling stocks, it makes predictions about their likelihood to be successful. The DQN regularly analyzes market behaviour to refine its approach to making decisions by identifying what works and what doesn't. Because of this, it is a

Fig. 3.1: Proposed DRL-DSS Architecture

priceless tool for financial trading investment advice and automated decision-making, assisting in maximizing returns and lowering risks. Some of the DRL-based decision support systems are discussed in the study [2, 13].

The system is designed to collect only the data necessary for the specific purposes for which it is processed, adhering to the GDPR principles of data minimization and purpose limitation. It incorporates robust consent management mechanisms to ensure that data is collected and processed only after obtaining explicit consent from individuals, in line with GDPR requirements. To protect personal data, the system employs data anonymization techniques and encryption to ensure that individual identities cannot be traced. This approach safeguards personal information against unauthorized access and data breaches.

Algorithm 15 DRL-DQN based Financial Decision Making

- 1: **Input:** n_{min} (minimum experience replay size), n_{max} (maximum experience), Δ (learning rate), α (exploration rate), γ (discount factor), δ (random action probability)
 - 2: **Output:** Financial decision making strategy
 - 3: Initialize replay memory rpm to capacity n (to store diverse market scenarios)
 - 4: Initialize action value function Q with random weights θ
 - 5: Initialize target action value function \widehat{Q} with weights θ^-
 - 6: For episode = 1, M do –number of episodes representing different market conditions
 - 7: Initialize sequence $S_1 = \{X_1\}$ and preprocessed sequence $\sigma_1 = \sigma_1(S_1)$
 - 8: For $t = 1, T$ do (decision points of financial data)
 - 9: with probability δ select a random action A_t (explore the action space)
 - 10: otherwise select $A_t = \max_A Q(S_t, A, \theta)$ (exploit the learned strategy)
 - 11: Execute action A_t and observe reward R_t and next state X_{t+1} –based on financial outcome
 - 12: Set $S_{t+1} = S_t, A_t, X_{t+1}$ and preprocess $\sigma_{t+1} = \sigma(S_{t+1})$
 - 13: Store transition $(\sigma_t, A_t, R_t, \sigma_{t+1})$ in replay memory rpm
 - 14: Sample random minibatch of transitions $(\sigma_J, A_J, R_J, \sigma_{J+1})$ from replay memory rpm
 - 15: Set $Y_j = \left\{ R_J + \gamma \max_{A'} \widehat{Q}(S_{J+1}, A', \theta^-) \right\}$ for non terminal states or $Y_J = R_J$ for terminal states
 - 16: Perform gradient descent step on $(Y_J - Q(S_J, A_J, \theta))^2$ with respect to the network Parameters ϑ
 - 17: Every C steps reset $\widehat{Q} = Q$
 - 18: End inner loop
 - 19: End outer loop
 - Online financial decision making phase**
 - 20: Load the parameters ϑ ;
 - 21: Calculate action-value Q for the current financial state $(S_t, A; \theta)$
 - 22: Output $A_t = \operatorname{argmax} Q(S_t, A; \theta)$ based on the learned policy
-

The algorithm explains how the DQN in a DRL framework is used to make financial judgments. The first step is to set up a replay memory system, which is a memory system that stores a variety of market scenarios. Two different kinds of action value functions are first allocated random weights when this memory is first used. After that, the algorithm runs through a number of episodes, each of which represents a distinct set of market

circumstances. Every episode begins with the financial data series being set up, and at each time step, decisions are made iteratively. To balance the discovery of novel methods with the exploitation of proven lucrative ones, a combination of randomly picked actions and those chosen based on the greatest anticipated value from the Q-function are used in the decision-making process. The algorithm learns from the actual results of its judgments by watching the reward that results from its actions and the subsequent status of the market. The replay memory contains these events. It updates its knowledge by sampling a batch of these events on a regular basis. It does this by adjusting the network parameters through a process known as gradient descent, which improves future predictions. In order to prevent the algorithm from deviating too far from its most recent known effective method, this update occurs in cycles. The algorithm proceeds to an online decision-making stage upon the completion of the iterative learning cycles. Here, based on its forecasts and acquired information, it utilizes the factors it has learnt to assess the present financial situation and choose the optimal course of action, such as purchasing or selling assets. Because of this procedure, the algorithm becomes a dynamic instrument for financial decision-making that is always learning from and adjusting to the shifting conditions of the financial market.

LearnFlex utilises a cloud-based infrastructure for dynamic scaling based on real-time demand. This ensures that server capacity can be quickly adjusted to handle spikes in user access, particularly during peak times like the start of new courses or examination periods. The system employs advanced load-balancing techniques to distribute traffic evenly across servers, preventing any single server from becoming a bottleneck. This enhances performance and ensures a smooth and responsive experience for all users.

The DSS ensures transparency in trading activities and decision-making processes by maintaining detailed logs and reports. This aligns with MiFID II's requirements for transparency and accurate reporting to regulators. By employing advanced analytics, the system helps identify and mitigate market abuse and ensure fair trading practices, thereby supporting the integrity of financial markets as envisaged by MiFID II. The system is designed to analyse a wide range of data to ensure that trades are executed at the best possible terms for clients following MiFID II's best execution requirements.

3.2.2. TRPO (Trust Region Policy Optimization). TRPO is a critical component of the proposed DRL-DSS that helps the system make dependable and efficient financial judgments. TRPO is an advanced algorithm that works to gradually enhance the system's decision-making policy without bringing about abrupt or unstable modifications. Its primary goal is to gradually adjust the system's approach so that it may pick up new information and experiences without deviating too much from its prior understanding. This is especially crucial in the irregular and turbulent world of finance, where it's necessary to strike a balance between trying out novel tactics and upholding a certain standard of dependability and consistency. Through the use of TRPO, the DRL-DSS is able to minimize the danger of large policy swings that might result in subpar performance or unanticipated losses while also learning gradually and making increasingly educated judgments. This allows the system to adapt to the constantly shifting financial markets.

Algorithm 16 Trust Region Policy Optimization

```

Initialize  $\pi_0$  suitable for financial market scenarios
for  $do i = 0, 1, 2, \dots$  Until convergence do
    Compute all advantage values  $a_{\pi_i}(S, A)$ 
    Solve the constrained optimization problem to update the policy
    Update the policy using  $\pi_{i+1} = \operatorname{argmin}_{\pi} [L_{\pi_i}(\pi) + \left( \frac{2\epsilon\gamma}{(1-\gamma)^2} \right) D_{KL}^{max}(\pi_i, \pi)]$ 
    where  $\epsilon = \max_S \max_A |A_{\pi}(S, A)|$ 
    And  $L_{\pi_i}(\pi) = \mu(\pi_i) + \sum_S P_{\pi_i}(S) \sum_A \pi(A|S) A_{\pi_i}(S|A)$ 
    Repeat the steps 2-4 until the policy converges
end for

```

Enhancing decision-making methods in a stable and regulated manner is the goal of the improved TRPO for a DRL-DSS in financial situations. First, a policy, represented by π_0 , is initialized. This establishes the starting point for financial choices such as purchasing, disposing of, or retaining assets. After that, the algorithm refines this strategy iteratively. The advantage values for the current policy are initially determined by the

Fig. 4.1: Accuracy

algorithm in each iteration. When deciding whether to purchase or sell stocks, for example, these numbers indicate how much better or worse a certain action is in comparison to the typical action in that particular financial situation. This is a critical stage in determining how successful the market's present decisions are. The method then resolves an optimization issue using constraints. The goal of this stage is to identify a new policy that marginally outperforms the existing one. Here, stability must be maintained by ensuring that the new policy doesn't stray too far from the previous one. This is especially crucial in the banking industry because of how irregular and unsettled the markets can be. A precise formula that strikes a compromise between making improvements and adhering closely to the prior version of the policy is used to update it. It restricts the amount of change to prevent significant deviations and takes into account how much the projected return on financial activities would increase under the new policy. Eventually, this procedure is carried out again until the policy converges, or reaches a point at which it no longer changes significantly. This suggests that the system has discovered a reliable and efficient method for deciding how to allocate funds. The financial industry, where reliability and performance are crucial, is a perfect fit for the TRPO because of its emphasis on steady development.

4. Results and Experiments. We move further with the evaluation of the suggested innovative DRL-DSS based on the study [16].

4.1. Evaluation Criteria. The performance of the suggested DRL-DSS across several epochs demonstrates its remarkable efficacy in Figure 4.1. The accuracy increases clearly and consistently throughout the course of five epochs, rising from 0.75 in the first epoch to 0.95 by the fifth. This pattern suggests that the system is picking up new skills and becoming more adept at what it does. It is especially remarkable that the last epoch reached a high degree of precision, at 0.95. It indicates that 95% of the time the DRL-DSS makes accurate judgments or predictions, which is a powerful testament to its efficacy and capabilities. Furthermore, the notable increase in accuracy in just five epochs demonstrates the system's capacity for quick learning. This is an essential characteristic in the dynamic and fast-paced field of financial data analysis, where the capacity to swiftly adjust to new knowledge and market developments is priceless. In addition, the system's dependability is demonstrated by the continuously high accuracy rates throughout all epochs. A consistent performance like this indicates that users may rely on the DRL-DSS to provide reliable and accurate forecasts or choices, which confirms the tool's appropriateness for financial analysis and decision-making.

The accuracy and recall values of the proposed DRL-DSS may be evaluated throughout a sequence of epochs, which correspond to discrete time intervals in the systems learning and operating phases, as shown in Figure 4.2. The accuracy values show a progressive rise over the period of five epochs, peaking at 0.92 and

Fig. 4.2: Precision and recall

eventually reaching 0.96 by the fifth epoch. The system's capacity to correctly identify relevant cases without overextending to irrelevant ones is demonstrated by its consistency and increasing trend in precision. This is an important feature in financial decision-making, where accuracy in forecasts or classifications is critical. In a similar vein, the recall values show how well the system recognizes all relevant occurrences; they begin at 0.90 and increase to 0.97 by the fifth epoch. The increase in recall indicates that the system is getting better at catching all possible opportunities or threats as it develops, which is a crucial attribute in dynamic financial contexts where it can be expensive to overlook important information. High recall and accuracy numbers combined over all epochs show the efficacy of the DRL-DSS. As demonstrated by the precision and recall figures, the system not only keeps up a high degree of prediction accuracy but also makes sure that all important data points are identified. This balance is especially important in financial contexts, where decision-making results can be greatly impacted by the accuracy of forecasts as well as the completeness of information gathered.

An excellent way to assess the effectiveness of the suggested DRL-DSS is to examine its F1-Score values across a number of epochs present in Figure 4.3. An impartial assessment of the accuracy and completeness of the system in forming judgments or predictions is given by the F1-Score, which is a harmonic mean of precision and recall. The F1-Score values, in this case, throughout the course of epochs are 0.89, 0.90, 0.92, 0.92, and 0.96, respectively. We can clearly observe an improving trend in these ratings as they develop. The DRL-DSS exhibits a steady increase in its decision-making efficacy, beginning with a comparatively high score of 0.89 in the first epoch and ending with a score of 0.96 by the fifth. This increasing trend shows the system's strong initial performance as well as its capacity to successfully learn and adapt over time. In particular, the system's final F1-Score of 0.96 indicates a high degree of accuracy and dependability in its predictions, suggesting that it covers a wide variety of pertinent cases and makes the right selections the majority of the time. Such performance is suggestive of a system that can reduce false positives and negatives in addition to being proficient at accurately detecting and acting upon relevant data items. This is particularly important since errors can have a big cost in the dynamic and intricate field of financial data analysis.

5. Conclusion. In conclusion, the DRL-DSS that has been suggested has shown to be incredibly effective when it comes to financial data processing. The system's strong capacity to make comprehensive and precise financial decisions is demonstrated by the steady increase in key performance indicators over time, especially the F1-Score. The F1-Score values of the DRL-DSS have been growing consistently from 0.89 to 0.96, demonstrating the model's ability to cover a wide range of relevant financial scenarios in addition to producing accurate forecasts. The F1-Score captures this balance between recall and accuracy, which is critical in the volatile and

Fig. 4.3: Efficacy of DRL-DSS: F1-Score over time

complicated field of finance where decisions can have far-reaching effects. The system is a very dependable and useful tool for financial experts because of its capacity to adapt and learn over time, as shown by the rising trend in its performance indicators. It offers evidence of the potential benefits of incorporating cutting-edge machine learning methods into decision support systems, such as deep reinforcement learning. The development of intelligent financial decision-making tools has advanced significantly with the DRL-DSS's ability to navigate the complexities of financial data analysis. This study establishes a standard for the creation of complex, data-driven decision support systems in the banking industry and beyond, and it opens the door for future developments. Future developments will likely focus on refining and advancing DRL models to enhance their predictive accuracy, efficiency, and scalability. This includes exploring cutting-edge neural network architectures, reinforcement learning strategies, and algorithmic improvements to better handle the nuances of financial data and decision-making processes.

RESEARCH ON THE CONSTRUCTION OF INTELLIGENT SYSTEM OF LANDSCAPE IN SCIENCE AND INNOVATION PARK OF SMART CITY – BASED ON THE CONCEPT OF SMART GARDEN DESIGN

KE XIE*

Abstract. With the advancement of urbanization in China, there is a growing demand for intelligent landscape management in urban science and innovation parks. To improve landscape management efficiency in science and technology innovation parks, this study adjusted the Inception module and activation function of the GoogLeNet algorithm, designed an improved GoogLeNet algorithm, and based on this, constructed a multi clue science and technology innovation park landscape vegetation intelligent recognition system. This is also the main contribution of this study. The experimental results show that the average image recognition accuracy of the Improve GoogLe Net+MM model designed from the study is 92.95%, which is higher than all the comparison models. Additionally, the computation time is significantly lower than the comparison models when the computation data volume is larger. The model designed in this study has a certain application value to improve the performance of the landscape intelligent management system within smart cities' science and technology parks.

Key words: Smart city; Landscape; Intelligent management; Plant recognition; GoogLe Net

1. Introduction . After entering the 21st century, artificial intelligence technology has developed by leaps and bounds, especially image recognition technology. This technology is extensively utilized in security, e-commerce, and various other industries [10]. Due to the demand for smart city construction, the landscape plant management mode at urban science and innovation park needs to become more intelligent in order to reduce the cost of manual management and improve management efficiency, and lay the foundation for subsequent intelligent plant watering and intelligent fertilization to remove pests. Therefore, the application of image recognition technology in artificial intelligence to this field is a potential research direction [13]. Intelligent recognition of landscape vegetation is a commonly utilized aspect within this area. However, issues such as inadequate recognition accuracy or speed frequently arise. Therefore, this study aims to enhance insufficient recognition accuracy and low recognition efficiency of image recognition models based on AI technology. The study will adjust the activation function and Inception module of the GoogLeNet neural network algorithm in artificial intelligence technology. Subsequently, a multi clue integration model for intelligent recognition of landscape plants in science and technology innovation parks will be designed with the improved GoogLeNet algorithm as the core. This enables GoogLeNet to obtain the possibility of improving recognition image accuracy while minimizing network parameters. This is the main academic contribution reflected in this study. In order to verify the application effect of the designed model, several comparative plant recognition experiments were arranged and carried out, in which not only the effects of using different dataset processing methods and model training methods on the final image recognition performance of the model are compared, but also the recognition accuracy of different plant recognition algorithm models built with the same dataset processing methods and model construction methods are horizontally compared.

2. Related works. Patel H et al. proposed an improved convolutional neural network called “Depth-FuseNet” [12]. This algorithm is used to fuse thermal and visible images, and extract data features from the two images to generate high-latitude features. The experiment found that this method has a recognition accuracy of 6.74 percentage points higher than the VGG16 algorithm in constructing recognition systems on the test set [12].

The research team of Hwang used an improved convolutional neural network to build a model for detecting neovascularization and age-related macula of patients. The experimental outcomes demonstrated that the

*School of Culture and Tourism, Chengdu Polytechnic, Chengdu, 610041, China (xie_ke0041@outlook.com)

approach effectively enhances clinical diagnosis efficiency [4].

The paper [7] concluded that deep learning-based detection of optic disc abnormalities in color fundus photographs is mainly limited to the field of glaucoma. However, numerous systemic and neurological diseases that pose life-threatening risks can present as deviations in the optic disc. Therefore, the authors trained a color fundus photo optic disc abnormality detection model using migration learning for ResNet-152 neural network, and the test results showed that the algorithm model has a significant advantage over the comparison algorithm with 90% recognition sensitivity and 69% specificity [7].

The paper [2] developed a gangue recognition method using a convolutional neural network based on an auditory model. According to the experimental results, the method achieved a high recognition accuracy of 99.5%. In addition, the method offers significant noise immunity in comparison to frequently utilized recognition methods across different noise conditions [2]. Maior C S believes that with the rapid spread of SARS coronavirus type 2 around the world, the scientific community has spent a lot of energy to better understand the characteristics of the virus and the possible methods of prevention, diagnosis and treatment of COVID-19. Therefore, the author proposes an improved convolutional neural network to aid in diagnosing COVID-19. The test results show that the model achieves a balance accuracy of 87.7% when predicting one of the three categories (“no discovery”, “COVID-19” and “pneumonia”), and a specific balance accuracy of 97.0% in predicting the “COVID-19” category [9].

The research team of [1] proposed an improved convolutional neural network to improve the recognition accuracy of protein images based on mass spectrometry. According to experimental results, the neural network significantly improves the recognition accuracy of protein images [1].

The paper [6] constructed an improved convolutional neural network model utilizing a two-way long-short memory network and attentional architecture to identify protein-specific spot recognition. The test results showed that the recognition performance of the algorithm is better and the computational speed is faster than the traditional convolutional neural network algorithm [6].

The author of [5] designed a convolutional neural network that combined the Gaussian statistical method. The test results show that the recognition effect of the algorithm for quantum microscopic images is significantly higher than the traditional deep learning algorithm. However, it has lower computational efficiency, being 24.2% slower than the recognition model built by the GoogLe Net algorithm and 21.9% slower than the recognition model built by the VGG16 algorithm [5].

In summary, although a lot of algorithm improvement studies have been conducted by previous people to improve the image recognition efficiency of the convolutional neural network, most of the studies failed to reduce the computational time consuming of the algorithm and improve the computational efficiency under the premise of improving the recognition accuracy of the algorithm. And identifying plants in science and technology parks is a significant and complex task that demands an intelligent system with higher efficiency. Therefore, this research seeks to improve the recognition speed of the recognition algorithm under the premise of improving its accuracy.

3. Design of intelligent plant identification system based on GoogLe Net algorithm for smart city science and innovation park.

3.1. Improved GoogLe Net algorithm design considering plant image features. Intelligent plant recognition belongs to an image recognition task, and the use of artificial intelligence (AI) algorithms is widespread in this area. The GoogLe Net neural network in artificial intelligence technology is an algorithm with good performance and fast computation speed that has been made public in recent years [15]. In addition, considering the aesthetics of the landscape and the intelligent and precise management requirements of the urban science and innovation park [3]. Figure 3.1 illustrates the typical network structure of GoogLe Net, which has demonstrated high recognition accuracy. The structure shown in Figure 3.1 has been proven to have high recognition accuracy, and the model is reasonable in terms of computation and training time, and computation consumption resources [11]. The GoogLe Net algorithm incorporates the Inception module, which expands the network width and reduces the computational effort by using asymmetric convolution. Specifically, it adds a 1×1 network in front of the 5×5 and 3×3 convolutional layers to reduce the dimensionality of the data.

The network input is a $224 \times 224 \times 3$ RGB image, and preprocessing requires subtracting the mean data from the training set's RGB channels for each pixel. That is to subtract the mean data of the three primary color

Fig. 3.1: Typical structure hierarchy of GoogLe Net

channels obtained from the training set for each pixel. And to reduce the error caused by the phenomenon of “gradient vanishing”, here it sets the convolutional layer in the Inception module to use ReLU as the activation function. Specifically, $5 * 5$. $3 * 3$ convolutional layers are used to reduce the depth of the convolutional layer through a $1 * 1$ filter. After maximizing the pooling layer, a $1 * 1$ filter is also used to reduce the depth of the convolutional layer. After reducing the size or achieving maximum pooling, ReLU activation processing is required. The input layer of the GoogLeNet neural network is connected to a regular convolutional layer and a maximum pooling layer, followed by a reduced size convolutional layer and a regular pooling layer. Afterwards, a separate convolutional layer should not be designed. A 7-step average pooling layer of $7 * 1$ should be set after the Inception module to reduce feature extraction errors caused by neighborhood size limitations during the convolution calculation process. After completing the data dimensionality reduction, the data will be input into the subsequent Dropout layer, with an output ratio of generally 60%. It will be followed by a fully connected layer containing 1024 neurons, which still uses the ReLU activation function. Finally, the data will be input into a softmax function classifier, and the predicted category data of the corresponding size will be output according to the usage requirements. After the design is completed, the Inception module structure is shown in Figure 3.2. As shown in Figure 3.2, compared to the simple Inception module, the Inception module in (b) subgraph has added a $1 * 1$ convolutional filter, which can achieve the effect of changing the data dimension without changing the original feature structure, meeting the proportion invariance of features.

Considering the limited variety of cultivated landscape plants in the science park, especially the dataset vegetation types used to test the performance of the algorithm in this study are only 12, the number of neurons in the last fully connected layer of the GoogLe Net algorithm is also reduced to 12. Considering that the system needs to cope with the classification task, the cross entropy function with L_1 regular term is used here to construct the loss function and the adaptive gradient method is used to estimate the network parameters, and the loss function is calculated as shown in equation (3.1).

$$loss = -\frac{1}{N} \sum_{n=1}^N \sum_{m=1}^M [p_m^n \log p_m^{\hat{n}} + (1 - p_m^n) \log (1 - p_m^{\hat{n}})] + \frac{1}{2} \lambda \sum_{n=1}^N \sum_{l=1}^L [\|W_l\|_1 + \|b_l\|_1] \quad (3.1)$$

In equation (3.1), M represents the number of images and plant species in each training batch, p_m^n and $p_m^{\hat{n}}$ represent the true probability that the n image belongs to them category and the probability that it is predicted to be the category, W_l and b_l represent the weight coefficients and intercept coefficient matrix of the l layer, respectively. λ The former in this study is initially set to 5×10^{-4} according to the industry experience. L represents the regularization coefficients and the number of layers containing parameters in the network, respectively. The architecture of the GoogLeNet algorithm has been established, and detailed improvement methods for the GoogLe Net algorithm used for plant recognition tasks will continue to be designed.

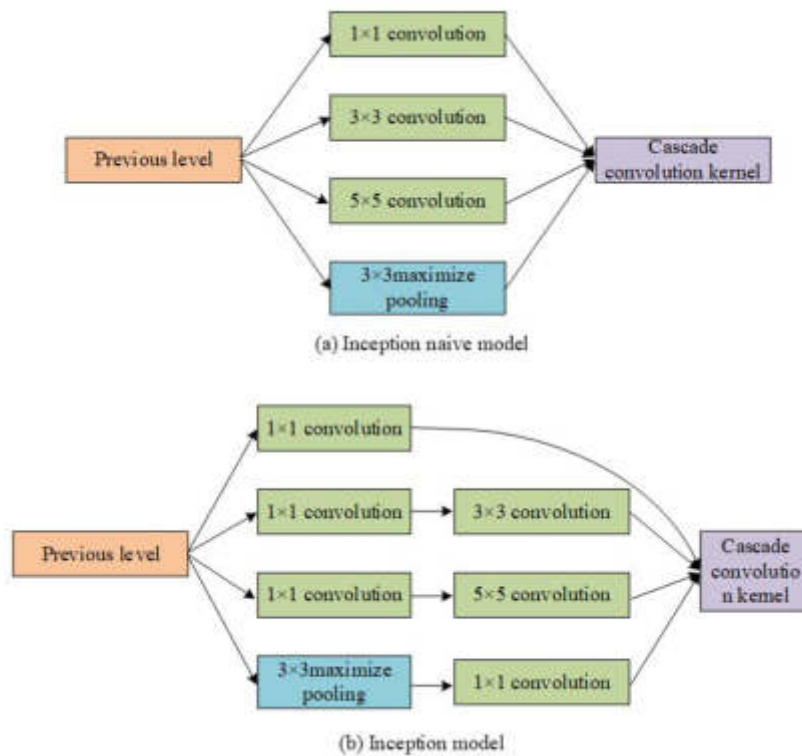

Fig. 3.2: Schematic diagram of the calculation structure of the designed Inception module

In summary, a series of structural improvements have been made to GoogLeNet to solve the problem of gradient vanishing. The GoogLeNet algorithm introduces the Inception module as its initial module to increase the network width and reduce computational complexity. This module adopts an asymmetric convolution method, which reduces the dimensionality of the data by adding a 1x1 network before the 5x5 and 3x3 convolutional layers. In the activation module, the convolutional layer in the Inception module uses ReLU as the activation function, while the 5x5 and 3x3 convolutional layers use a 1x1 filter to reduce the depth of the convolutional layer. After maximizing the pooling layer, a 1x1 filter is also used to reduce the depth of the convolutional layer. By introducing the Inception module and increasing the depth and width of the network, the network can better capture the complex features and structural information of landscape vegetation. This helps to identify different types of vegetation, their morphology, growth status, and other details, thereby improving the cognitive ability of vegetation. By using asymmetric convolution and adding a 1x1 network before the 5x5 and 3x3 convolutional layers to reduce the dimensionality of the data, the computational load can be effectively reduced. This enables the network to process large-scale image data more efficiently, improving the speed and accuracy of vegetation recognition. And ReLU, as an activation function, has nonlinear characteristics, which helps the network better learn and represent the complex features of vegetation, and can help the network better capture the nonlinear relationship of vegetation, improving the accuracy and robustness of vegetation recognition.

3.2. Design of intelligent plant recognition system based on hybrid improved GoogLe Net algorithm. . On the one hand, the deeper the hierarchy, the more training data are needed to train the neural network before it may be able to play a good application effect. However, the image data used for training the plant recognition system at the Smart City Science and Technology Park may be extremely limited, so it

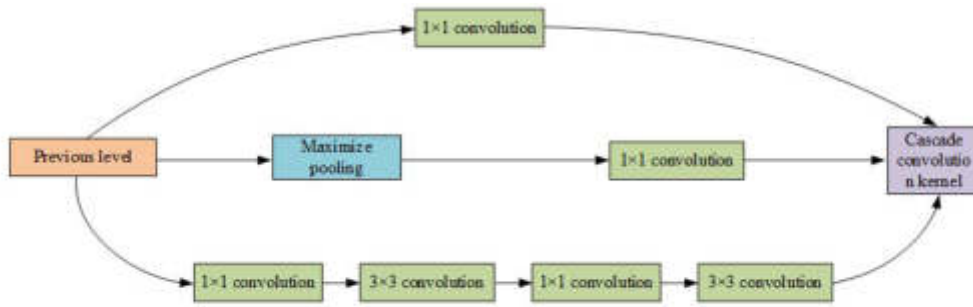

Fig. 3.3: Improved Inception module computational structure

is necessary to build a convolutional neural network with fewer network parameters to ensure its adaptability and good computational performance. Therefore, this time, various improvements are made to the classical GoogLe Net neural network algorithm to meet the demands of the intelligent plant recognition system in the science and innovation park.

In this study, the main purpose of achieving the overall number of parameters reduced while maintaining the computational accuracy of the GoogLe Net neural network is from the perspective of improving the Inception module. In the design idea of Visual Geometry Group Net (VGGNet) neural network, two 3×3 convolutional layers can achieve the same receptive field as a 5×5 kernel while reducing the number of parameters by at least 20% compared to the latter. In the process of improving the Region-Convolutional Neural Networks (R-CNN) target detection network to Fast R-CNN, the structure of reusing the convolutional layer information is used in it in order to reduce the training time of the algorithm. Specifically, the R-CNN algorithm utilizes the convolutional structure to create a feature map for each proposed region individually. While Fast R-CNN is also a convolutional feature map in the original image, resulting in all proposed boxes being formed in the same feature map output following convolutional computation. Based on the concepts of reusing the convolutional feature layer and convolutional kernel substitution, an improved Inception module is now designed by combining the two computational branches of 3×3 and 5×5 size convolutional kernels in the original Inception module; The input module first uses a 1×1 size convolutional kernel for dimensionality reduction processing, followed by an input 3×3 size convolutional block; The output information for this convolutional layer has two branches, one of which will directly use the output information as one of the outputs of the Inception module; The other branch will pass through convolutional layers of size 1×1 and 3×3 in order to reduce the output to one of the final module outputs. Figure 3.3 displays the enhanced computational hierarchy of the Inception module.

The activation function plays a crucial role in determining the final computational performance of a deep neural network algorithm. A nonlinear activation function can effectively ensure the network's fitting ability. In general, a good activation function needs to be monotonic, non-saturated, low computational complexity, with few parameters, non-linear, and differentiable everywhere. However, the ReLU or Swish activation functions used in traditional neural networks suffer from neuron "necrosis" and large computational effort, respectively. The latter is contrary to the original purpose of the research design to improve the Inception module. Therefore, in order to improve the computational accuracy and reduce the computational complexity of the GoogLe Net neural network, H_Swish function is chosen as the activation function in the algorithm, and its calculation method is shown in equation (3.2).

$$H_Swish(x) = x \cdot ReLU(x + 3)/6 \quad (3.2)$$

In equation (3.2), x is the independent variable of the input H_Swish function. After improving and replacing the Inception module and the activation function of the GoogLe Net neural network respectively, the other structures in the neural network and the way the parameters are updated are left unchanged.

Given the limited amount of training and testing image data utilized in this study, it is necessary to use the migration learning technique to ensure high computational accuracy of the algorithm under such conditions.

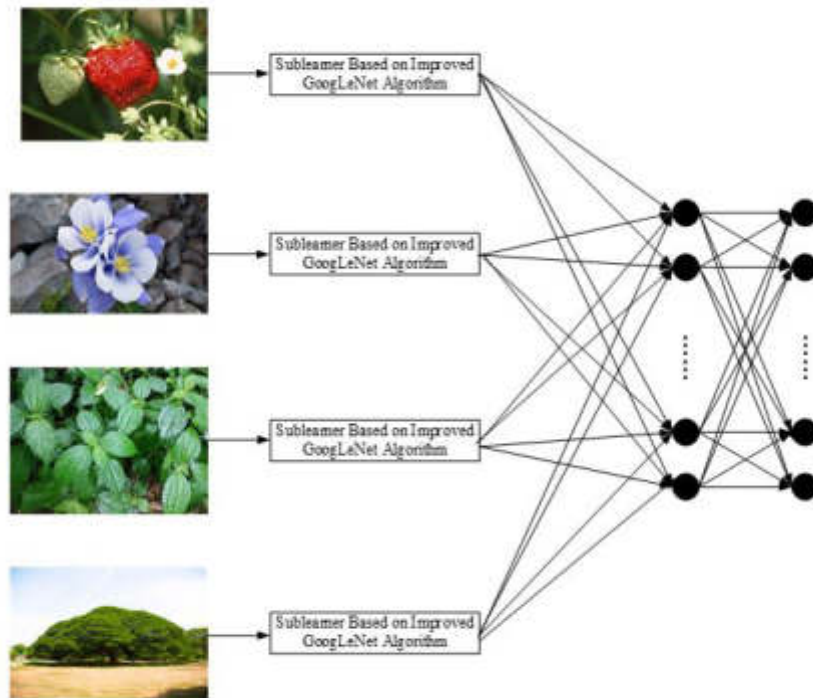

Fig. 3.4: Computational structure of plant multi-cue recognition model based on convolutional neural network algorithm

In other words, the study borrowed more complete and rich training data to train a neural network with more reasonable and mature parameters. Specifically, with reference to the general steps of migration learning, this study chose to use a richer image dataset to train the improved GoogLe Net neural network. Specifically, the last two fully connected layers in the network structure were modified to adjust the number of fully connected neurons to the number of desired classification categories, and a richer image dataset was used to train the neural network. After training, the neural network was trained again by applying the originally matched dataset to fine-tune some of the parameters to make the network more adaptable to the plant recognition needs of the science and technology park.

In plant recognition tasks, the information on recognition features that a single plant organ can provide is often more limited, especially different plant species in the same subject may have organs with similar appearance. For instance, while the flower shape and color of plum blossom and cherry blossom are relatively similar, but the leaf structure and the shape of the entire plant of plum blossom tree and cherry blossom tree differ considerably. It can be seen that the utilizing the multi-cue model for developing a plant recognition system can further improve the plant recognition ability of the system and alleviate the recognition error problem caused by the over-similarity of individual organs or local structures of plants to a certain extent. The computational layout of the plant multi-cue model based on the convolutional neural network algorithm is shown in Figure 3.4. As shown in Figure 3.4, the convolutional neural network-based plant multi-cue feature recognition model consists of two key components. Firstly, it requires training a sub-recognition model for each major recognition organ of the plant for a single organ, and the sub-recognition model in this study consists of a modified GoogLe Net neural network. Secondly, it involves efficiently merging the independent single-organ recognition models.

It is evident that each input for the plant multi-cue recognition model constructed in this study, is the final

computational output of a related single-organ recognition model. This facilitates the encompassing model in acquiring an expanded insight into the plants, that are supposed to be recognized, in distinct dimensions. However, whether the final recognition results after integration can be more accurate than individual models depends mainly on the integration method of each single model. This study refers to the sublearners integration method of random forest algorithm, and uses the weighted summation of each single organ classifier to form the final classification results. The percentage of the sublearner's contribution in the final prediction is determined by the prediction category score of the single-organ prediction model. The detailed design of the integration approach is presented in this section. Since most plants can be identified by four aspects: leaves, fruits, flowers, and whole plants, only four sub-learners are also correspondingly set in the multi-cue plant identification model designed in this study, assuming that the model identification accuracy of each sub-learner is A_1 , A_2 , A_3 , and A_4 , and can be described by equation (3.3).

$$A = \{A_1, A_2, A_3, A_4\} \quad (3.3)$$

In equation (3.3), A represents the sublearners recognition accuracy matrix, then the integrated output weight of each sublearners can be described by equation (3.4),

$$q_i = \frac{A_i}{\sum_i^N A_i} \quad (3.4)$$

Where A_i represents the classification accuracy of the i th plant organ recognition model on the test set, and N represents the number of single-organ plant recognition sublearners. It should be noted that the inputs of each sublearners are the corresponding plant part images of the plant parts, and each sublearner operates independently of the others. The sublearners' scores weighted according to the weights of equation (3.5) will be used as the initial values of the prediction scores for each category of the multi-cue model S_i^* ,

$$S_i^* = \frac{q_i S_i}{\sum_{i=1}^4 q_i \cdot S_i} \quad (3.5)$$

Where P_j is the score of the final predicted category by the i th sub learner, which needs to satisfy the $0 < S_i < 1$ relationship, and S_i^* the initial score of the i th sub learner input to the integrated model. If the same category scores appear in the sub learners, it means that multiple sub learners predict the same plant category and they need to be combined. That is, if $P_i = P_j$, and $P_i, P_j \in \{1, 2, \dots, 12\}$, $i < j$, the relationship of equations (3.6) and (3.7) exists.

$$S_i^* = S_i^* + S_j^* \quad (3.6)$$

$$P_j = 0 \quad (3.7)$$

In Eq. (3.7), P_j represents the predicted plant category output by the j sub learners. The integrated learner then counts the scores of each category label of the current image to be recognized and outputs the category with the highest score as the predicted category, as shown in Eq. (3.8).

$$\hat{y} = P_i \quad (i = \arg \max(S_i^*), i = 1, 2, 3, 4) \quad (3.8)$$

Finally, the experiment presents the calculation formula for the test indicators. This study shares two indicators: accuracy and calculation time. The latter is obtained through a computer-based timer and does not require further processing. Equation (3.9) demonstrates the calculation method for accuracy.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (3.9)$$

In equation (3.9), TP and TN respectively represent the number of cases accurately judged as positive and negative, while FP and FN respectively represent the number of cases wrongly judged as positive and wrongly judged as negative.

4. Plant intelligent identification system performance analysis.

4.1. Performance analysis experimental program development. The following computational experiments are designed to validate the performance of the improved GoogLe Net neural network algorithm-based plant intelligent recognition system for science and technology parks designed in this study. The datasets used in the experiments are ImageNet, which is a large image database containing at least 14,000K in size and more than 20,000 categories, and PlantCLEF2016, which assisted in the initial training of the model during the migration learning phase. The latter dataset was also used for fine-tuning and performance testing of the model post-initial training. Table 4.1 displays the key components of the PlantCLEF2016 dataset.

Before using the dataset, it also needs to be preprocessed. To avoid the model parameters biased to certain categories, the image quality is enhanced by using perspective transformation, affine transformation, etc. to expand a smaller number of image types and by using contrast enhancement, color dithering, etc. To compare the computational effects of the improved algorithms, the VGG16 algorithm, the classical Google Net algorithm, and the Faster-RCNN algorithm, which are commonly used in the industry and have good performance, are selected as the comparison methods to build the plant recognition system. The hyperparameters for each neural network algorithm were determined using the dichotomous method of multiple debugging with common tuning parameters in the industry. The parameters were not duplicated. To comprehensively compare the performance of the algorithms designed in this study, a comparative experimental scheme is designed as shown in Table 4.2. It is important to note that "MM" in Table 4.2 represents the abbreviation for the multi-cue model.

The reason for choosing this method of "expand+drop" for preprocessing is to solve the imbalance problem in the dataset and enhance the quality of training data. By expanding the dataset, the model can be exposed to more diverse images, which helps improve its generalization ability for unseen data. Discarding images with insufficient pixel ratio helps prevent the model from bias towards certain categories and ensures that relevant features are focused during training. The use of "expand+drop" preprocessing techniques can enhance the performance of the model by providing more diverse and balanced datasets. This may lead to better generalization ability and higher accuracy during training and testing stages. By focusing on relevant features and avoiding bias towards specific categories, the model becomes more robust and effective, and can identify different plant organs or species.

Transfer learning can utilize knowledge gained from a task to improve the learning of related tasks. In this case, the source task involves model training on a large dataset such as ImageNet, which contains various images from multiple categories. By pre training on ImageNet, the model learned rich and universal features that can be transferred to the target task of plant recognition. The use of transfer learning can significantly improve the performance of models, especially when applied to tasks with limited labeled data. By using the weight initialization model learned in ImageNet, the model learns more basic features from images, which can accelerate convergence speed in target task training. This typically leads to faster training and better

generalization performance, resulting in higher accuracy and better overall performance.

The environmental settings and hyperparameter settings for this experiment are shown in Table 4.3. The environmental settings are categorized as either hardware or software. The hyperparameters are obtained by conducting multiple experiments within the conventional range or conventional setting method to select the optimal value. The remaining parameter settings were determined during the model design phase.

4.2. Analysis of experimental results. The horizontal axis of Figure 4.1 displays various strategies for preprocessing data sets, including processing method 1, processing method 2, and processing method 3, which correspond to “no expansion + no discard”, “no expansion + discard”, and “expansion + discard” in that order. The processing method “expand + discard” is also depicted. “Expansion” represents the use of image processing techniques to expand the number of images in a relatively small number of categories in the dataset, and “discard” represents the deletion of images in the dataset where the percentage of pixels of the

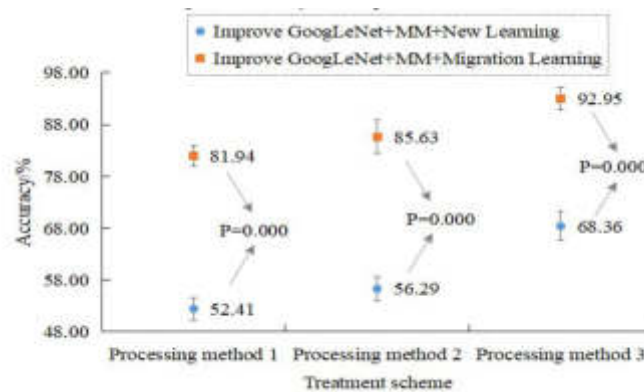

Fig. 4.1: Comparison of recognition accuracy of improved GoogLe Net under new learning and migration learning models

target plant organ is too small. The vertical axis of Figure 4.1 represents the image recognition accuracy of each model, and the different color labels represent different model training schemes. It is noted that to reduce the effect of experimental random error, each experimental scheme was repeated 20 times. The metrics of the type of measurement were presented in the form of mean \pm standard deviation. The difference between groups was verified using the T difference significance test, with the level of significance set at 0.05. Observing Figure 4.1, it can be seen that the accuracy of the training scheme with the fused migratory learning is higher under the condition of using the same dataset pre-processing scheme. For example, the recognition accuracy of the migration learning scheme for treatment schemes 1 to 3 is 29.53, 29.34, and 24.59 percentage points higher than that of the brand-new learning scheme, respectively. From the perspective of processing schemes, the model using scheme 3 achieves the highest accuracy in comparison to the other conditions.

Considering the results of the study in Figure 4.2, the datasets of all model schemes of the subsequent experiments need to be pre-processed in the way of processing scheme 3, and all of them are trained with the migration learning method. The results of Experiment #02 were used to generate Figure 6, where the horizontal axis represents the model scenarios formed by different organization methods, which are explained in Table 4.2, and the vertical axis represents the image recognition accuracy of each model. As we can see in Figure 4.2, the recognition accuracy of the “Improve GoogLe Net+MM” organization scheme is the highest, with a mean value of 92.95%, while the accuracy of the models trained with whole plant images or mixed all images is lower, with a mean value of 66.38% and 71.42%, respectively. It indicates that the multi-cue model combining each major plant organ and the overall image, outperforms a single model in terms of recognition performance.

Considering the results of the study in Figure 4.2, it is necessary for all algorithms in the following experiments to create multi-cue models in order to take part in the study. The results of Experiment #03 were used to create Figure 4.2, where the horizontal axis represents the recognition models built based on each algorithm, the left vertical axis represents the recognition accuracy, and the right vertical axis represents the difference between the recognition accuracy of each algorithm model and the “Improve GoogLe Net+MM” model designed in this study, in %. As can be seen in Figure 4.3, the recognition accuracy of the “Improve GoogLe Net+MM” model designed in this study is still significantly higher than the other comparable models. The “Faster-RCNN+MM” model follows with the second-highest accuracy rate.

The average accuracy of the MM model is 90.51%, which is only 2.44 percentage points lower than that of the previous model. It shows that the recognition performance of the algorithm model designed in this study is already better than the Faster-RCNN model which has a better recognition effect in the market.

The results of Experiment #04 were used to create Figure 4.3. The graph displays the amount of time spent on computing (vertical axis) versus the number of images to be identified (horizontal axis). These images were sourced from the ImageNet dataset. As we can see in Figure 4.4, the “Improve GoogLe Net+MM” model

Fig. 4.2: Comparison of recognition accuracy of different model organization methods

Fig. 4.3: Comparison of recognition accuracy of each algorithm model

is lower than the other three comparison models as the number of images to be recognized increases, while the computation time of the model built by the unimproved GoogLe Net algorithm is higher, but the computation time of the “VGG16+MM” model is lower than the other three comparison models when the sample size is larger. The “VGG16+MM” model requires the longest computation time of 37.86 seconds.

To further analyze the reliability and application value of this design model, 80 landscape plant experts from both domestic and foreign sources are now invited to conduct an evaluation experiment. Obtain a total of 762 real landscape plant images from a domestic science and technology innovation park, and use this design model and comparison model for landscape plant recognition. And have experts rate the recognition results of

Fig. 4.4: Comparison of computational time consumption of each algorithm model

Table 4.4: Statistics of Evaluation Experiment Scoring Results

Identification	Average value	Standard deviation	Maximum value	Minimum value
Improve GoogLeNet+MM	9.18	0.43	9.77	8.81
GoogLeNet+MM	8.24	0.52	9.05	7.63
VGG16+MM	7.65	0.64	6.89	8.30
Faster-RCNN+MM	8.69	1.09	9.62	6.84

each model on a 10 point scale, and the scoring results are shown in Table 4.4. The scoring results, shown in Table 4.4, indicate that the overall average of the Improved GoogLeNet+MM recognition model designed in this study is the highest, with the most stable scoring results. The overall rating data for the Faster RCNN+MM recognition model is only lower than the former, but the stability of the rating results is the worst because the latter has the largest standard deviation of 1.09 among all models.

From the results of the above data experiments and evaluation experiments, it can be seen that the model proposed in this study exhibits favorable application outcomes. The communication between the experimental members and the expert group members in the evaluation experiment found that the expert team believes that the recognition model designed in this study better solves the problem of insufficient accuracy in identifying scarce categories in traditional landscape plant recognition models within science and technology innovation parks. This is mainly because the model designed in this study uses transfer learning to assist in training the model, enabling the model to obtain more effective local feature information that exists in different plant images.

Finally, the study will separately analyze the limitations of the design model. Firstly, the biggest limitation of this study is the inability to deploy the designed model into the plant management system for testing its effectiveness in a more realistic usage environment. Secondly, the evaluation experiment part of this study only invited experts to participate, and did not test the evaluation and application attitude of ordinary people to this model. These shortcomings will be addressed and improved in subsequent research.

5. Conclusion. This study focuses on the recognition accuracy and speed issues of traditional landscape vegetation intelligent recognition models. The GoogLeNet algorithm is improved and a landscape plant recognition system for science and technology innovation parks is designed. The experimental results show that the model’s recognition accuracy is significantly improved by pre-processing the training data set with “expand+drop” and training the model with transfer learning. The recognition model constructed with multiple

cues achieved an average classification accuracy of 92.95%, which surpasses that of all single models significantly. Compared with other models based on different algorithms but built in the same way, the recognition accuracy of the “Improve GoogLe Net+MM” model designed in this study is 92.95%, which is higher than all the comparison models. The “Faster-RCNN +MM” model follows with an average accuracy of 90.51%. Moreover, the computation time of the “Improve GoogLe Net + MM” model is lower than other models when processing larger data. The research data show that the improved GoogLe Net algorithm can improve the accuracy of plant recognition. However, due to limited research energy, this study was unable to combine the designed recognition system with the plant intelligent management system to analyze its application value. Subsequent research can develop real-time monitoring and feedback systems to continuously monitor the health status of plants and provide timely feedback. Real time data is fed back to the factory’s intelligent management system for real-time decision-making and adjustment through sensor networks, cameras, or other IoT devices. Utilize machine learning and intelligent algorithms to deeply integrate plant recognition systems and factory intelligent management systems. By continuously learning and optimizing, the system can adapt to different environments and plant species, and provide more accurate predictions and recommendations.

PERFORMANCE ANALYSIS OF SMART CITY LANDSCAPE DESIGN AND PLANNING BASED ON THE INTERNET OF THINGS

CHAO KANG*, YANTING HE† AND JINGJING XU‡

Abstract. With the continuous development of the IoT technology, the concept of smart city has gradually become one of the key elements of urban planning and design. The purpose of this study is to explore the smart urban landscape design and planning based on the IoT, and to provide new perspectives and methods for the future urban development through in-depth research and analysis of related issues. First, this study reviews the relevance of smart city and landscape design, highlighting the importance of IoT technology in urban planning. Secondly, through case analysis and field trips, the successful experiences and challenges of smart cities that have implemented the IoT technology are analysed. In terms of design and planning, this study proposes a landscape design framework integrating IoT technology, emphasizing the interaction between urban landscape and information technology to promote sustainable urban development. Finally, this study summarizes the relevant findings, and prospects the future development trend of smart urban landscape design planning, to provide useful guidance and inspiration for urban planners and designers. Through this study, theoretical support and practical experience can be provided for building a more intelligent and liveable urban environment.

Key words: IoT, Smart city, Landscape design and planning, Sustainable development

1. Introduction. The Internet of Things (IoT) refers to the use of information sensing devices to connect any object to a network according to agreed protocols. Objects exchange and communicate information through information dissemination media to achieve intelligent recognition, positioning, tracking, supervision and other functions. With the continuous development of science and technology and the rapid advancement of urbanization process, smart city has become the frontier topic of contemporary urban planning and design. Among them, the booming development of the IoT technology provides new possibilities for the innovation of urban space [1, 2]. The purpose of this study is to deeply explore the smart urban landscape design and planning based on the IoT, to integrate advanced technologies in the urban development, optimize the spatial layout, and improve the living quality of residents.

Modern cities face many complex and urgent challenges, such as traffic congestion, limited resources, environmental pollution and so on. These problems require not only innovative solutions, but also interdisciplinary cooperation and comprehensive thinking. The IoT technology, with its characteristics of temporal data collection and intelligent decision-making, provides urban planners with an unprecedented means to meet these challenges. Therefore, it is necessary to deeply study the application of the IoT in smart urban landscape design planning to explore its great potential in urban management.

The significance of the IoT lies in its ability to connect the physical and digital worlds, achieve real-time collection, transmission, and processing of information, improve people's quality of life, promote innovation and development in various industries, and contribute to the rational utilization of resources and sustainable development. As an important part of urban planning, landscape design is not only related to the aesthetic feeling of urban appearance, but also related to the quality of residents life and the sustainable development of the city. Through the integration of the IoT technology, landscape design can achieve more refined and intelligent planning, making the urban space more adapt to the needs of residents and lifestyle [3, 4]. In the face of the growing trend of urbanization and complex urban challenges, wisdom urban landscape design planning how to better use of the IoT technology, to improve the urban sustainability, liability, and intelligence,

‡Zhangzhou Engineering Consulting Center Co., Ltd., Consulting Office, Zhangzhou 363000, China.

and how to balance in the digital age technology innovation and cultural heritage, to create a humanistic care of urban landscape is facing the problem of [5, 6].

This study will further expand the understanding of the application of the IoT technology in the smart urban landscape design and planning through in-depth analysis and extensive application of various research methods. The literature review systematically combs the application process of the IoT technology in urban planning and landscape design, and provides a theoretical basis for the research. The case analysis will dig deep into the existing practical experience, draw inspiration and lessons from the successful cases, and lay a practical foundation for putting forward the innovative design framework. Expert interviews will bring together in-depth insights from urban planning experts, landscape architects, and IoT professionals to provide a more comprehensive understanding of the needs and challenges in different areas.

The application of mathematical modelling and simulation technology will help to build the influence model of IoT technology in urban landscape design, and provide more specific data support for research. An extensive questionnaire will cover urban residents, planning practitioners, and design professionals to provide a more comprehensive basis for the proposed innovative design framework and guiding principles by collecting diverse perspectives and needs.

This study aims to provide more practical and feasible guidelines for the application of Internet of Things technology in the fields of urban planning and landscape design. By deeply analysing the current state of technology, evaluating its potential impact on urban sustainability, and exploring the integration of technology and traditional aesthetics, we provide more comprehensive decision-making support for urban decision-makers, planners, and designers, and promote the practical development of smart cities. To provide innovative ideas and practical tools for future urban planners and designers, leading cities towards a more intelligent, livable, and sustainable future.

2. Overview of Smart City Landscape Design.

2.1. Overview of smart city development. With the rapid advancements in science and technology, the concept of a smart city has emerged as a pivotal aspect of modern urban planning. This notion emphasizes the seamless integration of information and communication technologies into cities, aiming to enhance urban operational efficiency, optimize resource utilization, and elevate the quality of life for residents [7, 8]. The ascendance of the IoT technology is a significant impetus for the progress of smart cities. Connecting sensing devices to the Internet enables real-time monitoring and data exchange across diverse urban domains.

Within the ambit of the smart city paradigm, urban infrastructure has seamlessly transitioned into the intelligent era. The traffic system now optimizes traffic flow, mitigating congestion, while the intelligent energy system effectively integrates energy resources to boost energy efficiency. Furthermore, environmental monitoring technology assists cities in achieving precise environmental management and safeguarding natural ecology [9]. Extensive data analysis holds a pivotal position in the bright city landscape. By mining vast data, city managers gain a deeper, more nuanced understanding of residents' behaviours, urban operational conditions, and the root causes of challenges. This data-driven decision-making approach renders urban planning more scientific, agile, and responsive to evolving urban needs.

The development of smart cities is not merely tethered to technological innovations; it also encapsulates the enhancement of the living environment. Residents can now effortlessly access medical care, education, cultural, and entertainment services through intelligent offerings, enhancing the city's attractiveness and quality of life. Additionally, the advancement of intelligent cities necessitates seamless collaboration between governments, enterprises, and various sectors of society to facilitate the widespread adoption of innovative technologies and steer cities toward a brighter, more sustainable future. Although the development of smart cities provides many advantages for urban management and residents, it is also accompanied by a series of challenges, including data privacy protection, and network security risks. Fig. 2.1 shows the architecture diagram of the smart city grid management platform. The future smart city development needs to pay attention to the balance of ethics and social issues while making technological innovation, to ensure the comprehensive and sustainable urban development.

2.2. Application of IoT technology in urban planning and Landscape design. With the continuous evolution of the IoT technology, its application in urban planning and landscape design presents a promising

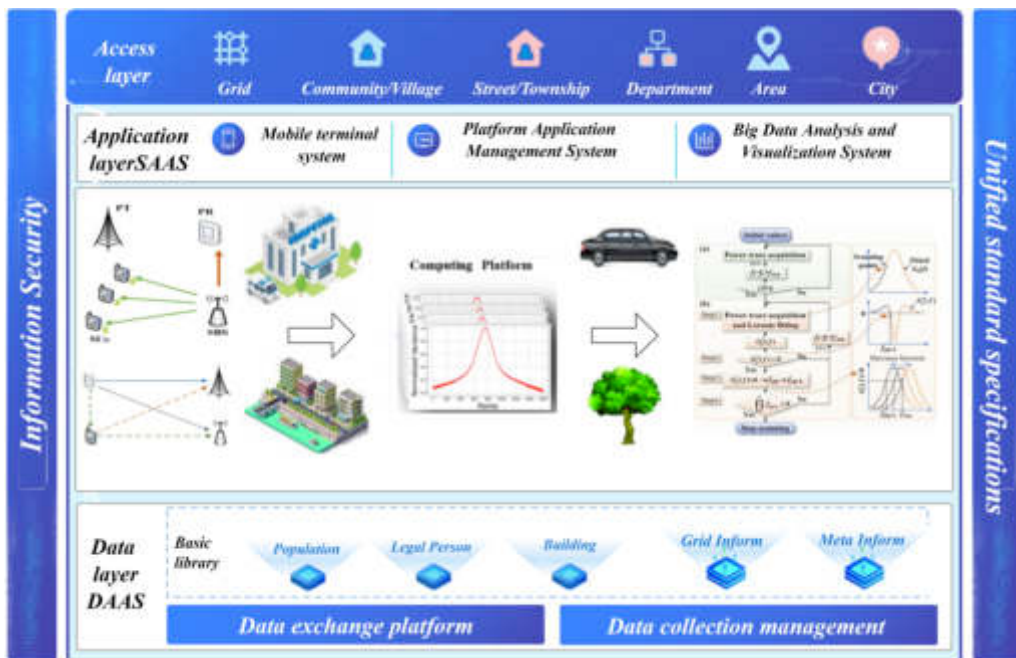

Fig. 2.1: Deep learning applied to short-Term traffic models

prospect [10, 11].

First, the real-time data monitoring of the IoT provides an accurate information foundation for urban planning. Through large-scale sensor networks, city managers can obtain real-time data on traffic flow, environmental quality, population density, and more. This provides planners with a deep opportunity to understand the operation of cities, making urban planning more scientific and sustainable.

In the field of transportation, the IoT technology has realized the intelligent and optimized [12, 13] of the transportation system. The interconnection of traffic lights, intelligent vehicles and pedestrian devices enables the traffic flow to be monitored and adjusted in real time, minimizing congestion, and improving the road utilization efficiency. This means more efficient and green transportation planning for urban planners.

In landscape design, IoT technology offers the possibility of creating a smarter urban environment. Through sensors that perceive environmental parameters, landscape designers can obtain real-time weather, light, and other information, to adjust the design of public space and improve the ecological friendliness of the city. This smart environment design not only beautifies the city, but also provides a more livable living space for the residents.

The IoT technology also promotes the intelligence of buildings. By connecting various equipment and systems, intelligent buildings realize intelligent control of energy and optimization of security system. In urban planning, this means a more energy-efficient and intelligent building design to create a more sustainable future for the city. In general, the widespread application of the IoT technology makes urban planning and landscape design more intelligent and more efficient. It not only improves the sustainability and livability of the city, but also provides a new impetus for urban innovation and development. This trend will further drive cities to be smart and sustainable.

3. Innovative framework of smart urban landscape design and planning.

3.1. Principle of the IoT technology. The IoT is an advanced technology system dedicated to deeply integrating the physical world with the digital world, achieving this goal by connecting and sharing information [14, 15]. Its basic principle covers several key aspects, among which sensing technology is one of the foundations, including various sensors and detectors, used to collect data of temperature, humidity, light, motion, and other

Fig. 3.1: Full view of the IoT technology

parameters, to transform physical phenomena into digital signals.

Communication technology plays a key role in the IoT, because the large number of devices need to communicate information [16]. Wireless communication technologies, such as Wi-Fi, Bluetooth, Zigbee, and cellular networks, enable devices to deliver data in real time and connect to the Internet. Data processing and storage is another key link. Cloud computing and edge computing technology realize efficient data management by processing and analysing the data obtained from sensing devices and extracting useful information.

Fig. 3.1 shows the full view of the IoT technology. To ensure the secure interaction between devices, the IoT introduces identity authentication technology and security protocol to ensure that only legitimate devices can access the network, and protect the security of data in transmission and storage through encryption [17, 18]. Interoperability is designed to solve the problems caused by diversified devices, platforms, and protocols. Through standardized protocols and interfaces, different devices can communicate with each other to achieve seamless connection.

Considering that many IoT devices rely on limited energy sources, energy management becomes a critical principle. Using low power design, energy recovery and optimized communication protocols can help to extend the service life of equipment [19, 20]. Finally, remote control and self-adaptation technology enable the system to remotely monitor and regulate the equipment, adjust its own behaviour according to environmental changes and needs, and enhance the flexibility and adaptability of the system. These principles cooperate with each other to build the basic framework of the IoT technology, providing a brand-new digital possibility for smart city landscape design and planning.

The core of the IoT technology lies in perception, communication, processing and security, and these principles together build an efficient interconnected network. First, the perception of data is realized through various sensors, as shown in (3.1):

$$Data_{sensed} = Sensor(Physical_world) \tag{3.1}$$

These sensing devices convert information from the physical world into digital signals. Then, through a variety of communication technologies, the device transmits the data to the cloud or other devices, and the communication formula is stated by (3.2):

$$Data_{transmitted} = Communication_Tech(Data_{sensed}) \quad (3.2)$$

After the data reaches its destination, the cloud computing and edge computing technology will process and store it, as shown in (3.3):

$$Processed_Data = Data_Processing(Data_{transmitted}) \quad (3.3)$$

This process usually includes data analysis, model training, etc., to extract useful information. The security of data is critical, so identity authentication and encryption are required. The security (3.4) states:

$$Secure_Data = Security_Protocol(Processed_Data) \quad (3.4)$$

To ensure interoperability between devices, a standardized protocol and interfaces are necessary, and the interoperability formula can be stated by (3.5):

$$Interoperability = Standard_Protocols_and_Interfaces \quad (3.5)$$

Energy management is critical for many IoT devices, especially mobile and low-power devices. The energy management formula is shown in the (3.6):

$$Energy_Management = Low_Power_Design + Energy_Harvesting \quad (3.6)$$

Finally, remote control and adaptation enable the system to adjust its behaviour according to environmental changes and requirements, which can be expressed in (3.7):

$$Adaptation = Adaptive_Algorithms(Changes, Demands) \quad (3.7)$$

These principles work together with each other, working together to build the foundation of the IoT technology, providing strong digital support for urban planning and landscape design.

3.2. Smart city landscape design process based on the IoT. When planning the smart urban landscape design, the demand analysis is the first step to clarify the design objectives, such as improving the quality of life of residents and optimizing the use of urban space in [21, 22]. This stage also covers an in-depth study of the urban development status and challenges, providing comprehensive background information for the design. Subsequently, the critical data collection phase is achieved through the deployment of IoT sensing systems, using environmental sensors, intelligent lighting, and other devices to collect real-time data, including air quality and traffic flow, and conduct comprehensive analysis.

In the design stage, the focus turns to integrating the IoT technology, giving the landscape a higher intelligent level of [23] through elements such as intelligent lighting and intelligent seats. Virtual design tools are used to simulate the layout of landscape elements, consider the influence of people flow, traffic flow and natural conditions, and integrate humanistic factors into the design to achieve a more humanized urban landscape.

Fig. 3.2 shows the design scheme of the IoT scenario architecture. The implementation stage should focus on the deployment of devices and system integration, and deploy the IoT devices and intelligent landscape elements according to the design scheme to ensure that they can work together. Through testing and tuning, the system can run stably in practical application. In the monitoring and management stage, real-time monitoring is realized through the IoT technology to analyse the status of urban environment and landscape elements and provide support for decision-making. At the same time, regular maintenance and update are the key to ensure the long-term operation of the system.

Close communication with community residents and relevant stakeholders is essential throughout the process. By collecting feedback, understand their needs and opinions, and adjust the landscape design according to the actual operation to better meet residents expectations. This interaction and collaboration promote strong connections between the community and designers. Through this process, the smart urban landscape design based on the IoT can flexibly adapt to the development of the city and the needs of residents, and improve the sustainability, liability, and intelligence of the city.

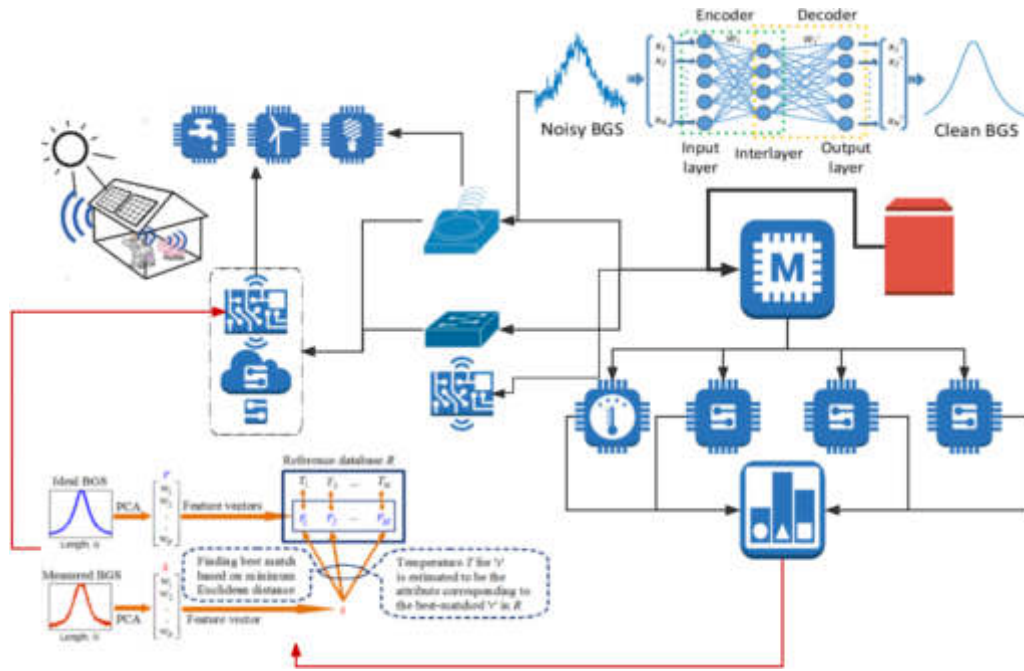

Fig. 3.2: Architecture design scheme of the IoT scenario

3.3. Smart city landscape design and planning system architecture based on the IoT. The architecture of the smart city landscape design and planning system based on the IoT mainly includes the perception layer, the communication layer, data collection and storage layer, data processing and analysis layer, and the application and control layer [24, 25]. In the sensing layer, various sensors and smart devices are used to sense the urban environment and resident activities in real time. The communication layer uses the IoT communication protocol and wireless technology to establish connections between devices. The data collection and storage layer are responsible for collecting, storing environment data, and conducting local storage. The data processing and analysis layer conducts large amounts of data processing and analysis through cloud computing and edge computing technology, and applies machine learning and artificial intelligence to optimize the system performance [26]. In the application and control layer, virtual design tools simulate the layout of landscape elements, and real-time monitoring and control functions enable city managers to respond to urban changes. The application and control layer includes a user interface for urban planners and residents to view data, provide feedback and participate in decision making. The feedback and optimization layer of the whole system is responsible for feedback the analysis results to the city managers and design team to support the decision making. At the same time, optimizing and adjusting the system through feedback information to meet the needs of the city and the residents expectations. Fig. 3.3 shows the application framework design of the IoT. The security and privacy layer ensures the security of the system and the privacy of personal data through identity authentication, encryption, and privacy protection measures. Such a system architecture provides comprehensive management and intelligent control for the smart city landscape design and planning.

4. Results and discussion.

4.1. Evaluation indicators. The smart city landscape design planning based on the IoT involves many aspects, including environmental monitoring, energy utilization, traffic flow, social interaction, etc. The evaluation indicators involve the following formula [27, 28]:

In (4.1) is the environmental monitoring index, where n is the number of the environmental parameters

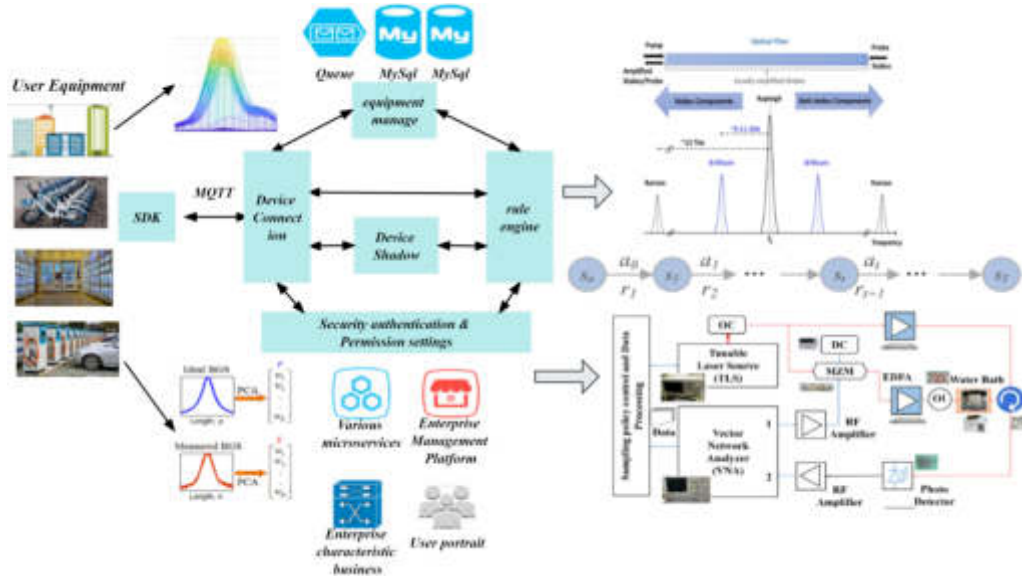

Fig. 3.3: Application frameworks design of the IoT

monitored, including air quality, water quality, noise, etc.

$$EMI = \frac{\sum_{i=1}^n Parameter}{n} \tag{4.1}$$

In (4.2) is the environmental monitoring index, where n is the number of the environmental parameters monitored, including air quality, water quality, noise, etc.

$$SEEE = \frac{LightingEfficiency}{TotalEnergyConsumption} \times 100\% \tag{4.2}$$

The traffic flow optimization index is shown in (4.3), which can help to evaluate the optimization effect of the IoT-based traffic management system on urban traffic flow.

$$TFOI = \frac{OptimizedTrafficFlow}{UnoptimizedTrafficFlow} \times 100\% \tag{4.3}$$

The social interaction activity assessment is conducted as shown in (4.4), and this formula can be used to assess the activity of urban residents on social media, reflecting the level of social interaction.

$$SIAA = \frac{SocialMediaInteractionCount}{TotalCityResidents} \times 100\% \tag{4.4}$$

In (4.5) is the calculation formula of the intelligent energy utilization index, which can be used to evaluate the intelligent utilization degree of energy used by the urban energy management system based on the IoT.

$$ESUI = \frac{SmartEnergyUtilization}{TraditionalEnergyUtilization} \times 100\% \tag{4.5}$$

4.2. Analysis of the experimental results. In the experiment, this study is committed to deeply explore the impact and effect of smart urban landscape design planning based on the urban environment. Through detailed data acquisition and careful analysis of results, a comprehensive understanding of the advantages and

potential problems of the design scheme. First, the data acquisition was performed, and the following methods were used to collect the experimental data.

A sound sensor network built by deploying IoT sensors monitors environmental parameters, including but not limited to air quality, temperature, and humidity, etc. This provides real-time and reliable data for the objective assessment of the actual impact of the design schemes on the urban environment.

An extensive user survey was conducted, and through the questionnaire survey and user feedback, residents views, and experience of the smart city landscape. This combination of qualitative and quantitative approaches provides the basis for an in-depth understanding of key information such as citizen engagement and satisfaction.

Through a detailed analysis of energy use, the actual impact of the design scheme on energy efficiency is evaluated [29, 30]. In terms of the environmental parameter analysis, some key results were found through the in-depth analysis of the sensor network data. The air quality in the experimental area was significantly better than that in the control area, proving the positive effect of the smart city design scheme in improving the environment. In addition, the intelligent control of the IoT devices plays an important role in regulating the temperature and humidity, and improves the living comfort of urban residents. Through the user survey, we learned that most respondents are satisfied with the smart city design, especially in terms of safety, convenience, and environmental friendliness. At the same time, some feedback mentioned the room for improvement, such as improving the efficiency of information transmission and providing more interactive experiences, providing useful suggestions for future designs. In the analysis of energy use effect, it is found that the smart city design scheme has achieved significant energy saving effect in energy use and effectively reduced the urban operation cost. In addition, through intelligent management and optimization, the urban infrastructure is more in line with the principles of sustainable development, providing substantial support for the sustainable development of cities.

Fig. 4.1 presents a comprehensive overview of the IoT system's data statistics, offering a deep dive into the evolving patterns of its pivotal indicators. Over the recent months, the performance of IoT systems has undergone noteworthy advancements. Firstly, the figure underscores a gradual surge in the number of IoT devices connected to the system, with a notable increase of 25% since the beginning of the year. This upward trend signifies the system's enhanced scalability, enabling a broader array of devices to integrate and facilitate data collection and exchange seamlessly. This expansion can be attributed to the seamless integration of new equipment, timely system upgrades, and ongoing optimization efforts. Secondly, the figure reveals fluctuations in the data transmission rate. Specifically, during the third quarter, the average transmission rate increased by 10% compared to the previous quarter. This marked improvement is likely due to system optimizations, including implementing more efficient data routing algorithms and deploying high-capacity network infrastructure. This refinement significantly enhances the system's real-time capabilities and response speed, resulting in a smoother user experience. The data statistics reflect the system's stability and reliability. Over the past six months, the system failure rate has maintained a consistently low level, averaging 0.5% per month. This remarkable consistency indicates that adequate measures have been implemented throughout the system's design, operation, and maintenance, including proactive monitoring, timely patching of vulnerabilities, and robust backup systems.

Fig. 4.2 offers a comprehensive visualization of the data dispersion within the innovative City IoT system, revealing intricate patterns and insights into the system's performance across various dimensions. This map not only underscores the diverse scores achieved by different subsystems but also highlights potential areas of improvement. Upon closer inspection, the figure reveals a spectrum of scores across the various subsystems, reflecting their unique functional characteristics, implementation efficiencies, and degrees of data integration. These disparities are crucial in accurately assessing the system's strengths and weaknesses, enabling decision-makers to formulate targeted improvement strategies. Outliers within the data dispersion map indicate potential system issues or bottlenecks. These outliers, which may arise from equipment malfunctions, network hiccups, or security vulnerabilities, are red flags for urgent attention. Prompt identification and remediation of these outliers are vital in enhancing the system's usability and stability, ensuring seamless operation under all circumstances.

Fig. 4.3 presents the accuracy curve of the innovative city model, a graphical representation that offers a deep dive into the models performance across various conditions. This analysis provides a snapshot of the models capabilities and identifies potential areas for improvement. The curves upward trajectory initially reflects the models learning process during the training and validation phases. As the model encounters and processes

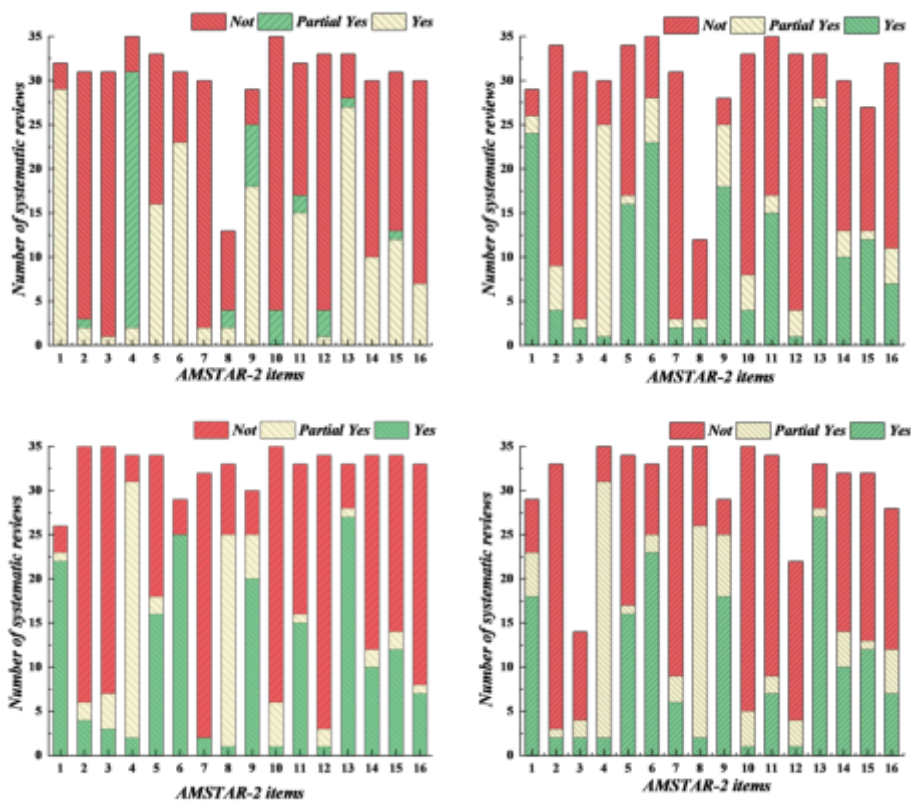

Fig. 4.1: Data statistics of the IoT system

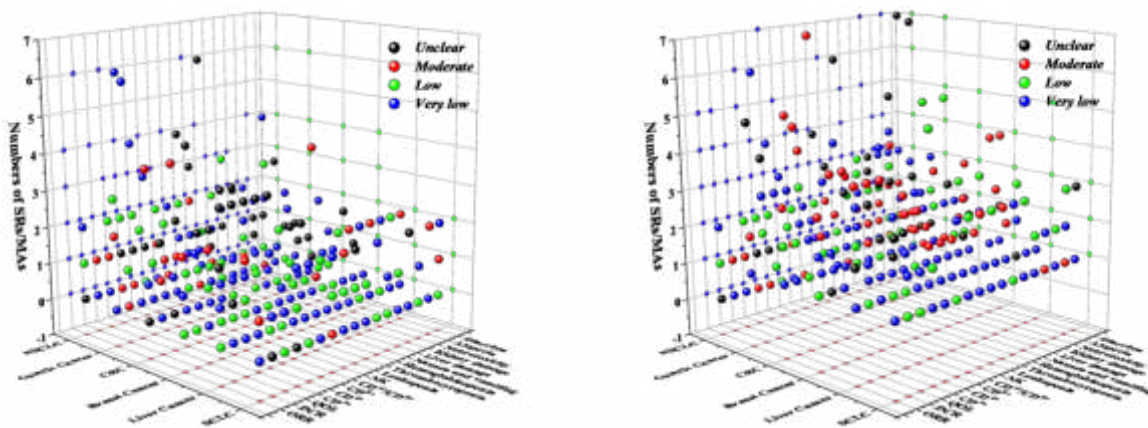

Fig. 4.2: Scale Data Dispersion Map of Smart City IoT System

more data, it gradually learns to recognize patterns and improve its predictive accuracy. The steepness of this initial rise indicates the models learning speed, which is crucial for its ability to adapt quickly to new data and

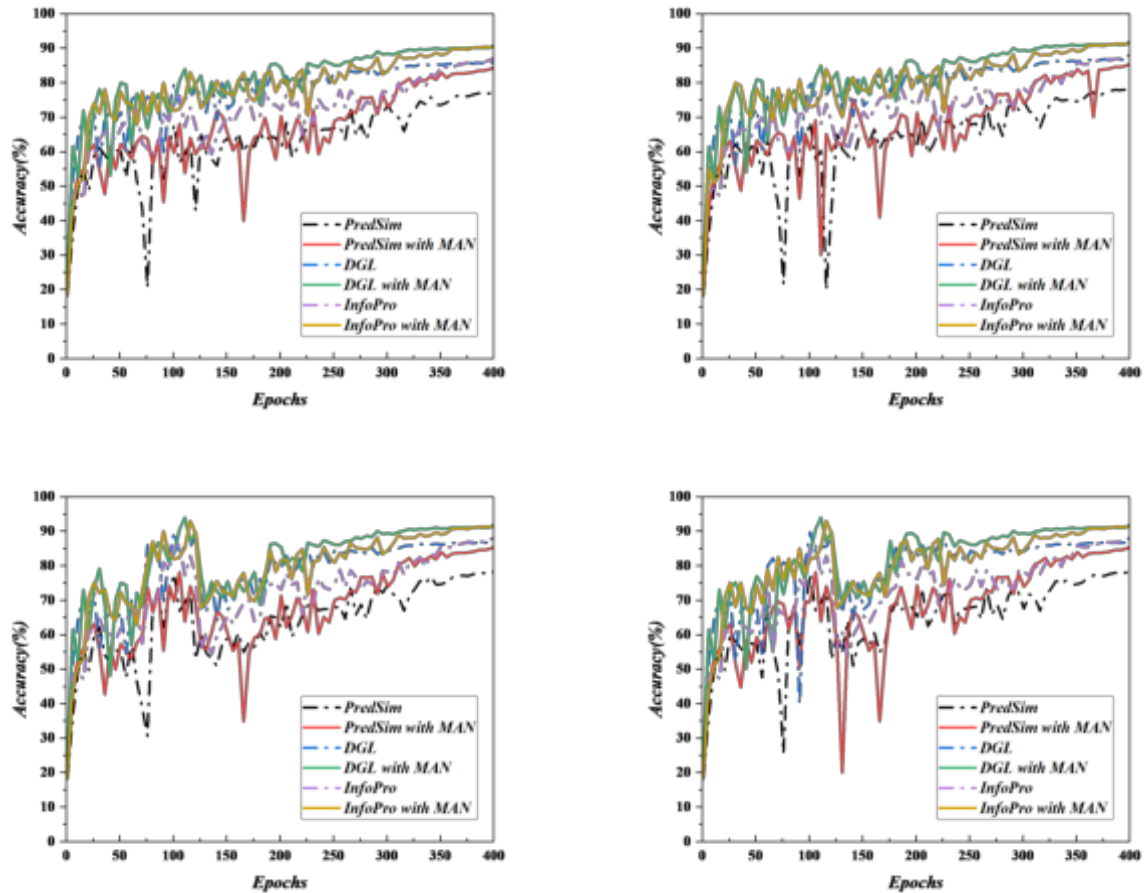

Fig. 4.3: Accuracy Curve of The Smart City Model

scenarios. Once the curve stabilizes, it indicates that the model has reached a level of maturity. The model has demonstrated robust performance on task-specific predictions without overfitting the training data. This stability ensures the model can generalize well to unseen data, a crucial requirement for real-world applications.

However, if the curve experiences a sudden drop during the validation phase, it suggests that the model may be over-fitting in certain aspects. This overfitting could be due to various factors, such as an inappropriate choice of hyper-parameters or an insufficiently diverse training dataset. In such cases, further analysis and adjustment of the model are necessary to improve its generalization performance. Moreover, the fluctuations in the curve provide insights into the models robustness under different conditions. The model's ability to handle various scenarios is paramount in the context of smart cities, where the urban environment is constantly evolving and complex. By analysing these fluctuations, we can understand how the model performs under different challenges and identify potential weaknesses that must be addressed. By leveraging the insights gained from Fig. 4.3, decision-makers and model developers can optimize the intelligent city model effectively. This optimization process involves adjusting hyper-parameters, refining the training dataset, or exploring alternative model architectures to enhance the models performance. The ultimate goal is to ensure that the model functions robustly and efficiently in practical applications, meeting the demands of urban management and optimization.

5. Conclusions. Through the research and analysis of the smart urban landscape design and planning based on the IoT, this study draws the following conclusions from multiple dimensions:

First, in terms of environmental parameter analysis, the air quality of the IoT sensor network and monitoring the environmental parameters is significantly better than that of the experimental area, highlighting the remarkable effect of the smart city design scheme in improving the urban environmental quality. The control of temperature and humidity by intelligent control improves the living comfort of urban residents and provides substantial support for the construction of liveable cities. The user survey results show that residents are generally satisfied with the smart city landscape design, especially in terms of safety, convenience, and environmental friendliness. However, some users make suggestions for improvements, such as improving information transmission efficiency and increased interactive experience, providing a useful reference for future design and planning.

In terms of the energy use effect, the analysis shows that the smart city design scheme has achieved significant energy saving effect in the energy use, and effectively reduced the urban operation cost. This not only reflects the positive contribution of the design scheme to urban sustainable development, but also provides reference and inspiration for similar urban planning. The smart urban landscape design and planning based on the IoT shows obvious advantages in improving environmental quality, improving residents satisfaction, and realizing energy benefits. In future research, we will pay more attention to field research, collect more real and comprehensive data, optimize data processing methods, and improve the accuracy and universality of results.

RESEARCH ON DATA-DRIVEN URBAN INTELLIGENT MONITORING AND OLD CITY RECONSTRUCTION

YI WANG*

Abstract. As the global urbanization process is further accelerating, the number of urban people is also steadily increasing. With the continuous growth of the urban population, the use of various functional facilities in the city is gradually becoming saturated, which seriously restricts the development of the city. Therefore, real-time perception and prediction of the operational status of various functional urban facilities, as well as environmental safety monitoring in the city, are of great significance for improving the functionality and livability of the city. In complex urban environments, multi-source data is interrelated, and the noise reduction of multi-source data and the integration of this correlation still face great challenges. At the same time, how to apply urban intelligent monitoring in the reconstruction of old cities is rarely mentioned. Based on the above problems, this paper proposes a data noise reduction model based on a wavelet algorithm and combines it with the Macroscopic Fundamental Diagram (MFD) multi-source data fusion structure proposed in this paper to provide a theoretical basis for the construction of an urban intelligent monitoring model. Then, the author constructed a data-driven urban safety environment monitoring model and a multi-source data-based urban congestion monitoring model, which have good experimental results and certain practical value. At the end of the paper, the author briefly discussed the application of the smart city monitoring model in the reconstruction of old cities, hoping to provide certain guidance for further integration in the future.

Key words: Data-Driven, MFD construction, Multi-Source Data, Old city reconstruction, Urban intelligent monitoring

1. Introduction. Urban road networks are an essential component of urban infrastructure that directly affects people's everyday life. Urban road networks are under rising load strain due to the city's population and vehicle count, which frequently causes traffic jams and accidents that seriously impair urban development. Therefore, real-time perception and prediction of the operational status of urban road networks, as well as the identification of high-risk areas for traffic accidents in urban geographical space, are of paramount importance for enhancing the operational efficiency and traffic safety of urban road networks. This paper will take this as the research goal to solve the intelligent detection and recognition of urban road network.

The selection of traffic state evaluation indicators exhibits considerable variability across different scenarios. Recognizing the importance of data fusion between these diverse indicators, the concept of data fusion emerged in the late 20th century, driven by the rapid development of information technology [10]. Notably, Choi and Chung's [1] 2001 study on travel time using fusion coil sensor and GPS data laid the foundation for subsequent traffic flow data fusion. Yang Zhaosheng et al. [2] were pioneers in China, utilizing data fusion to meet information accuracy requirements in the ATMS subsystem of intelligent transportation systems. Henry [3] and others emphasized the real-time dynamics and data quality requirements for data fusion, playing a pivotal role in advancing the application of this technology in transportation. Xu Tao et al. [4] integrated urban road information, eliminating "information islands" and enhancing traffic flow parameters through Bayesian estimation fusion, ultimately identifying road states with fuzzy logic. Ding Yue et al. [5] proposed a multi-source relational data fusion framework, comprising pattern matching, entity alignment, and entity fusion, facilitating rapid pattern matching and providing a unified data view for analysis. Addressing the challenge of identifying traffic network conditions, common indicators include average speed, travel time, and travel delay. Ehrlich categorized traffic status indicators into time and distance, concluding that time-based indicators more accurately reflect travelers' perceptions [6]. Washburn used video data to calculate traffic flow density, evaluating road traffic conditions based on subjective traveler experiences [7]. Taylor et al. established a congestion coefficient model, incorporating GIS technology to build a congestion information system [8]. Kerner employed floating car data to establish a threshold model for evaluating congested sections [9]. The average

*Eurasia Art and Design School, Xian Eurasia University, XiAn, Shaanxi Province, 710065, China (Yi1Wang@outlook.com)

speed of a road section, known for simplicity and high reliability, stands out as one of the most commonly used indicators for traffic operation status evaluation [10,11]. Jiang Tao applied pattern recognition to classify traffic network states and predict future states based on current traffic conditions [12]. Sun Ya used data mining to extract new traffic status information from extensive data, achieving successful classification results through real-time traffic flow data collection [13]. Wang Meihong proposed a method to calculate regional traffic congestion correlation based on spatio-temporal association rules [14]. Scholars have increasingly focused on the Macroscopic Fundamental Diagram (MFD) method for discriminating road network traffic operation status. Xu et al. derived optimal cumulative intervals and corresponding average traffic flow density states, categorizing traffic operation into free flow, optimal accumulation, and congestion [72]. Liu and Xu proposed using the standard deviation of the number of vehicles to supplement traffic flow or vehicle accumulation in traffic operation state division [73]. Daganzo and Gayah identified branch points in road networks, leading to multi-valued and unpredictable MFDs when exceeding certain densities, categorizing networks into stable and unstable states [74]. Haddad Geroliminis explained the generation of branch points, theoretically deducing equilibrium points under a dual system and proposing calculated and unstable boundaries [75]. Aboudolas et al. analyzed traffic ladder diagrams for urban road networks, differentiating between unsaturated, incomplete saturated, supersaturated, and deadlock states, recommending different control strategies for each [76]. With an increasing number of vehicles equipped with location devices, a considerable amount of vehicle Global Positioning System (GPS) data has emerged, leading to the gradual rise of research on road traffic state discrimination based on floating car GPS data. For example, based on massive GPS data analysis of residents' daily travel patterns, the regularities of road traffic operational status can be identified, including the recognition of urban hotspots for travel [20][21]. Lin [22] proposed a combination of spectral clustering techniques and branches based on MFD constructed from floating vehicle data Road network state identification method based on vector machine algorithm.

Urban road traffic is a complex network system; its state is challenging to summarize by a single parameter and often needs to combine a variety of traffic flow parameters and system methods to identify. However, the current research is usually carried out for a single parameter, and only some are carried out for multi-source data fusion. At the same time, noise processing of multi-source data is also a big challenge, and there are few scholars in this area of algorithm research. This paper mainly focuses on the research of multi-source data fusion and data noise reduction algorithm, and builds an intelligent monitoring model of urban road network based on this. In response to these issues, this paper proposes a data denoising model based on the wavelet algorithm and combines it with our proposed MFD multi-source data fusion construction, providing a theoretical foundation for building an intelligent urban traffic monitoring model. We then create a multi-source data-based urban traffic congestion monitoring model and a data-driven urban traffic safety environment monitoring model. Experimental results demonstrate that these models have good performance and practical value. In conclusion, we briefly discuss the application of the urban traffic intelligent monitoring model in the renovation of old city road networks, aiming to provide some guidance for future research.

2. Research on data processing in complex urban environment.

2.1. Research on data noise reduction model. In the field of traffic detection, more and more high-speed and high-precision sensors are being used due to the growing complexity of transportation networks. Traffic detector fault identification and prompt data rectification are critical in order to prevent sensor malfunctions that might jeopardize system safety and result in financial losses [23]. Taking loop detectors as an example, a single intersection may require the use of dozens or even more loop detectors to obtain more accurate traffic parameters such as traffic flow, vehicle speed, and occupancy. However, due to the variability of the natural environment and the inconsistency of the hardware and software attributes of front-end sensors, the rapid growth of data leads to a simultaneous increase in random noise and faulty data. Some fault information is masked by noise, and the distribution of faults becomes more multiscale. This renders traditional fault diagnosis methods based on analytical models inadequate to meet the safety requirements of current transportation systems. Therefore, how to use the accumulated large amount of offline traffic data, extract data features, analyze their intrinsic patterns, monitor online traffic data in real-time and effectively, and accomplish fault detection and diagnosis has become one of the hot topics of concern for many experts and scholars. Wavelet analysis is used to obtain the multiscale properties of so-called fault information, which might occur in many frequency bands.

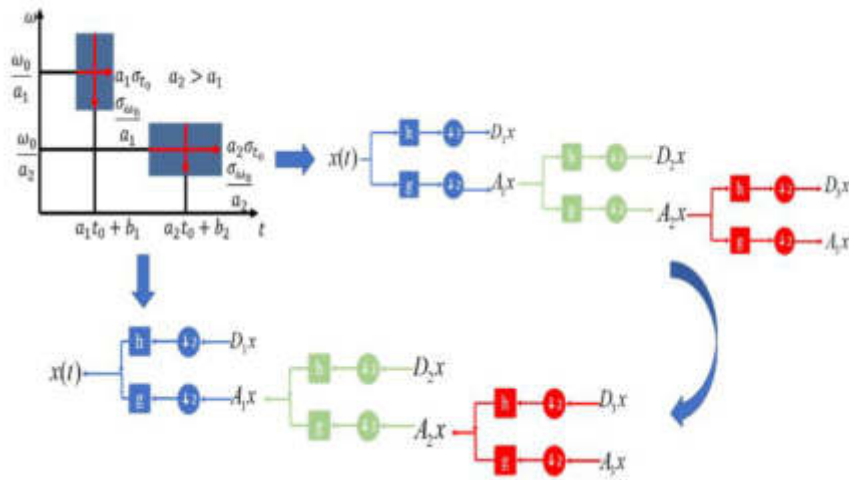

Fig. 2.1: Time-frequency coordinates of wavelet transform and Mallat algorithm

Let $f(t)$ be a finite energy signal; the discrete wavelet transform of this signal can be defined as:

$$(W_{\psi} f)(a, b) = \langle f, \psi_{a,b} \rangle = |a_0|^{-m/2} \int_{-\infty}^{+\infty} f(t) \bar{\psi}(t) dt \tag{2.1}$$

Where $\psi_{a,b}$ is called the generating or basis function of the wavelet transform,

$$\psi_{a,b}(t) = a^{-1/2} \psi\left(\frac{t-b}{a}\right), a > 0, b \in R \tag{2.2}$$

The displacement factor is denoted by 'b' in equation (2.1), while the scale factor is represented by 'a'. As illustrated in Figure 1, a time-frequency coordinate system is established for wavelet transformation. In wavelet transformation, the position of the time window is solely influenced by the displacement factor. Therefore, as the scale factor increases, the time window widens, the frequency window narrows, and the center of the frequency window shifts towards the low-frequency direction. Conversely, with a narrower time window, the frequency window widens, and the center of the frequency window moves towards the high-frequency direction. The essence of wavelet transformation lies in manipulating these two factors to construct a combination that can represent any signal in space [24]. By utilizing the scale factor, it is possible to perform a tower-like decomposition of a specific signal in space, as depicted in Figure 2.1, following the classical Mallat algorithm [25]. This algorithm provides a computational method for wavelet decomposition and reconstruction, simplifying the overall wavelet calculations.

There is an impulse response function in the Mallat algorithm: $h(n)$. As a result, the following definitions for the wavelet and scale functions are given:

$$\begin{cases} \varphi(t) = \sum_n h(n) \varphi(2t - n) \\ \psi(t) = \sum_n g(n) \psi(2t - n) \end{cases} \tag{2.3}$$

In formula (2.3), $g(n) = (-1)^{1-n} h(1-n)$, The signal $x(t)$ is decomposed by Mallat, and the scale is set to $j(j \geq 1)$. Approximate signal and detailed signal obtained by decomposition are respectively:

$$\begin{cases} A_j x(t) = \langle x(t), \varphi_{j,k}(t) \rangle = 2^{-j/2} \int x(t) \varphi(2^{-j}t - 2k) dt \\ D_j x(t) = \langle x(t), \psi_{j,k}(t) \rangle = 2^{-j/2} \int x(t) \psi(2^{-j}t - 2k) dt \end{cases} \tag{2.4}$$

It can be found in equation (2.4) that the process of decomposing signal $x(t)$ is the process of decomposing it step by step from scale j to $j+1$. That is, the process from low resolution to high resolution. It ultimately broke

down into two signals: an approximation signal, D_jx , and a detailed signal, A_jx , both at a high frequency [26]:

$$\begin{cases} A_{j+1}x = \sum_k h(k - 2n)A_jx \\ D_{j+1}x = \sum_k g(k - 2n)A_jx \end{cases} \quad j \geq 1 \tag{2.5}$$

Equation (2.6) is the Mallat wavelet reconstruction formula:

$$x = \sum_{k=1}^k h(n - 2k)A_{j+1} + \sum_{k=1}^k g(n - 2k)D_{j+1} \quad j \geq 1 \tag{2.6}$$

After a finite energy signal undergoes wavelet transformation, it is decomposed into a set of detail signals and approximation signals. Each sample point of every signal has its wavelet decomposition coefficient $\omega_{j,k}$. When the signal contains noise, the noise is also decomposed along with the host signal. Therefore, theoretically, the noise may be removed if the wavelet decomposition coefficients of the noise are found and processed, and then all signals are submitted to wavelet reconstruction. The fundamental idea of wavelet threshold denoising is to target certain characteristics of noise in the signal, as well as the differences between noise and signal obtained after wavelet decomposition. A critical threshold is set, and the wavelet decomposition coefficients obtained after decomposition are compared with this threshold. If the result is less than the threshold, the coefficient is considered to belong to a normal signal and is retained without processing. This portion of wavelet coefficients is left untouched [27]. Conversely, if the result is greater than the threshold, the coefficient is considered to be from noise and needs to be zeroed out or processed through a specific threshold function. This yields an estimate for this portion of wavelet coefficients to replace the original ones. Once all wavelet coefficients are processed, wavelet reconstruction is performed to achieve the denoising effect. The key to wavelet threshold denoising lies in finding an appropriate threshold function, also known as a threshold rule. Hard, soft, and semi-soft threshold functions are the three primary categories of conventional wavelet threshold functions [28]. This study suggests enhancements to the previously described semi-soft threshold denoising approach, based on substantial testing and empirical analysis:

Let the high frequency signal be $W_{a_{j,k}}$, then The formula for estimating the noise standard deviation is as follows:

$$\sigma_j = \frac{1}{0.6745} \times \frac{1}{N} \sum_{K=1}^N |W_{a_{j,k}}|, 1 \leq j \leq J \tag{2.7}$$

Since the real original signal's SNR varies, the threshold's setting must also be adjusted to reflect the current circumstances. The following is the unified threshold formula found in the body of available literature [29]:

$$\lambda_{1,j} = \sigma_j \sqrt{2 \log(N)} \tag{2.8}$$

The high-frequency signal coefficients in the J group are produced once the signal has been broken down to the scale of J. Each group's wavelet coefficients are sorted in absolute value from small to big, yielding the following vector:

$$P = [W_{a_{j,n}}], 1 \leq n \leq N \tag{2.9}$$

The evaluation vector under the JTH wavelet coefficient is computed using this vector: $R = [r_n], 1 = n = N$. Where:

$$r_n = \sum_{k=1}^n W_{a_{j,n}} + (N - i)W_{a_{j,n}} + (N - 2n)\sigma_j^2 \tag{2.10}$$

After sorting the evaluation vector's interruption value from big to small and using the lowest value as the approximation error, the associated wavelet coefficient $W_{a_{j,m}}$ is discovered. The wavelet coefficient is used to determine the threshold value of the J-layer wavelet decomposition in the following manner:

$$\lambda_{a,j} = \sqrt{CD_{\min}} \tag{2.11}$$

The J-layer wavelet decomposition's threshold selection function is as follows:

$$\lambda_j = \begin{cases} \lambda_{1,j} & , (P_{a,j} - \sigma_j^2 < \rho_{N,j}) \\ \min(\lambda_{1,j}, \lambda_{a,j}) & , (P_{a,j} - \sigma_j^2 \geq \rho_{N,j}) \end{cases} \quad (2.12)$$

In this case, $\rho_{N,j}$ represents the wavelet coefficient vector's minimum energy level, and $P_{a,j}$ is the average value of the wavelet coefficient's absolute value. The following is the calculating formula:

$$P_{a,j} = \frac{1}{N} \sum_{k=1}^N W a_{j,k} \quad (2.13)$$

It is necessary to restore the signal to its original state since the calculated wavelet coefficient, or wavelet coefficient, is believed to be the result of noise. As a result, the original wavelet coefficient value is substituted for the estimated wavelet coefficient value through a series of computations, and wavelet reconstruction is ultimately used to accomplish the goal of noise reduction. The J-layer wavelet high-frequency signal's noise intensity is reflected by the introduction of a coefficient $\Gamma(\sigma_j)$ representing noise intensity. The following is the calculating formula:

$$\Gamma(\sigma_j) = \sqrt{\sigma_j/A_j} \quad (2.14)$$

In equation (2.14), A_j represents the amplitude of the high-frequency partial coefficient of the J-layer wavelet. The calculation formula of wavelet coefficient estimate is given:

$$w_{j,k} = \begin{cases} w_{j,k} - \Gamma(\sigma_j) \times \lambda_j, & w_{j,k} > \lambda_j \\ w_{j,k} + \Gamma(\sigma_j) \times \lambda_j, & w_{j,k} < -\lambda_j \\ 0, & -\lambda_j \leq w_{j,k} \leq \lambda_j \end{cases} \quad (2.15)$$

Here are the specific actions to do in order to enhance the wavelet threshold denoising algorithm: The high-pass filter h and low-pass filter g are configured, and the original signal $x(t)$ is discretized. The wavelet is disassembled by the J layer. The wavelet coefficients and the wavelet detail signal amplitude A_j of the layer decomposition are obtained. Based on the precise signal coefficients of each layer, the noise standard deviation σ_j and noise intensity coefficient $\Gamma(\sigma_j)$ of each layer are computed. Each layer signal's unified threshold, $\lambda_{1,j}$, is computed. The computation involves determining the adaptive threshold $\lambda_{a,j}$ for each layer signal, the lowest energy level $\rho_{N,j}$ of the layer's wavelet coefficients, and the average value $P_{a,j}$ of the absolute value of the layer's wavelet coefficients. Equation (2.12) is used to compute each layer's wavelet threshold. The wavelet coefficients are adjusted to complete the threshold denoising on this scale, and finally, the wavelet reconstruction is carried out according to the Figure 2.1.

Based on this as the main idea, simulation experiments are conducted on existing data. The results are shown in Figure 2.2. The studies demonstrate that, under the assumption of maintaining the majority of the fault information, the enhanced wavelet threshold denoising described in this study can suppress and eliminate noise better. Furthermore, the denoising findings are more appropriate for diagnosing data faults in the future.

2.2. MDF fusion construction for complex data scenarios. In the preceding section, a method model for data denoising was introduced. However, in complex data scenarios, it is often necessary to perform multi-source data fusion rather than just data denoising. This subsection will further discuss data processing based on this requirement. The construction of the MFD for road networks is the foundation of estimating traffic capacity and discerning the traffic operational status of road networks in this paper, based on the MFD method.

Addressing the potential issue of inconsistent MFD parameter estimation results in the process of constructing MFD based on multiple data sources, this paper proposes a framework and method for MFD fusion construction based on data reliability under the context of multi-source data, as illustrated in Figure 2.3.

The average traffic flow and average traffic flow density of the road network may be estimated using vehicle trajectory data and sectional detection traffic flow data. Several research have employed diverse data

Fig. 2.2: Signal noise reduction effect diagram

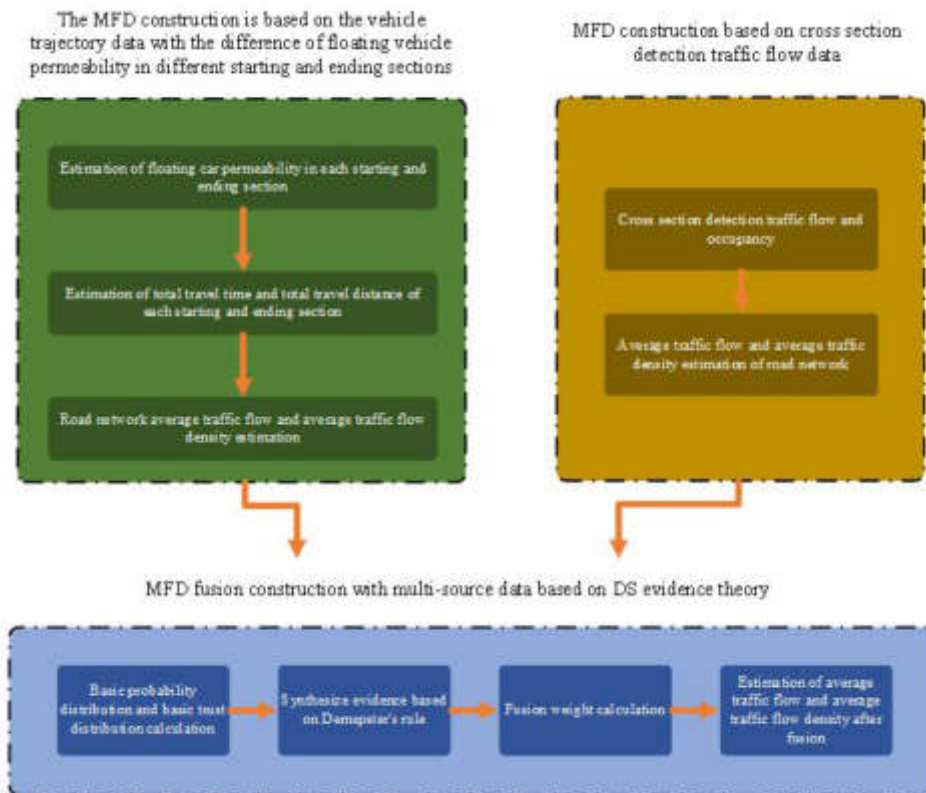

Fig. 2.3: MFD fusion construction framework based on multi-source data

sources to estimate different characteristics of MFD traffic operation states in order to get reliable estimates of the parameters of different traffic operation states in the MFD. The average traffic flow density and average traffic flow under various data sources are estimated using different assumptions, though. When estimating the average traffic flow density using vehicle trajectory data, it is common to assume that there are enough floating vehicle samples and that the penetration rates are distributed uniformly over space. On the other hand, the assumption that the traffic flow at the section represents the traffic flow of the road segment is typically used when estimating the average traffic flow based on sectional detection traffic flow data. As a result, outcomes of model parameter estimate under various data sources may differ. Equations (2.16) through (2.17) illustrate the fundamental foundation for the MFD fusion building in this study, taking the validity of data sources into consideration.

$$q(t) = \alpha(t) \times q^{\mathcal{F}}(t) + [1 - \alpha(t)] \times q^{\mathcal{M}}(t) \tag{2.16}$$

$$k(t) = \beta(t) \times k^{\mathcal{F}}(t) + [1 - \beta(t)] \times k^{\mathcal{M}}(t) \tag{2.17}$$

Among them, $q(t)$ represents the average road network traffic flow estimated by multi-source data fusion during period t (vehs/h), $q^{\mathcal{F}}(t)$ represents the average road network traffic flow based on vehicle track data during period t (vehs/h), the average traffic density on a road network, measured in vehicles per kilometer for a certain time t is represented by the symbol $k^{\mathcal{F}}(t)$, $q^{\mathcal{M}}(t)$ represents the road network average traffic flow (vehs/h) based on the traffic flow data detected in section during the period t , $k^{\mathcal{M}}(t)$ represents the road network average traffic flow density (vehs/km) based on cross section detection traffic flow data during period t , the average traffic flow density (vehs/km) for the road network during period t , as determined via multi-source data fusion, is denoted by $k(t)$. $\alpha(t)$ represents the floating vehicle data weight in the average road network traffic flow fusion estimation during period t ; $[1-\alpha(t)]$ represents the road during period t The weight of traffic flow data detected by section in the fusion estimation of network average traffic flow, $\beta(t)$ represents the weight of floating vehicle data in the fusion estimation of network average traffic flow density during the t period, $[1-\beta(t)]$ represents the weight of traffic flow data detected by section in the fusion estimation of network average traffic flow density during the t period.

The process of figuring out the fusion weights of two different kinds of data sources is the basis of the fusion construction. This research aims to ascertain the fusion weights of diverse data sources based on the mean and variance distributions (reliability) of the average road network traffic flow density and average traffic flow across different periods of multiple days, utilizing the Dempster-Shafer(DS) evidence theory [30]. In order to illustrate the determination procedure, the following uses the floating vehicle data weight $\alpha(t)$ in the fusion estimate of road network traffic flow characteristics during t period as an example.

First, as indicated by Equation (2.18), the recognition framework of the DS evidence inference model $\Theta(t)$ is built based on two types of data sources:

$$\Theta(t) = \{q^{\mathcal{M}}(t), q^{\mathcal{F}}(t)\} \tag{2.18}$$

where $q^{\mathcal{M}}(t)$ and $q^{\mathcal{F}}(t)$ respectively represent the average traffic flow of the network in the t period based on the traffic flow data detected by the cross section and the vehicle track data.

Given that $q^{\mathcal{M}}(t)$ and $q^{\mathcal{F}}(t)$ originate from distinct data sources, it is possible to regard them as mutually exclusive. Equation (2.19) therefore displays the power set of all elements in

$$??(t) : \begin{cases} 2^{\theta(t)_0} = \{\emptyset, X_1(t), X_2(t), X_3(t)\} \\ X_1(t) = \{q^{\mathcal{M}}(t)\} \\ X_2(t) = \{q^{\mathcal{F}}(t)\} \\ X_3(t) = \{q^{\mathcal{M}}(t) \cup q^{\mathcal{F}}(t)\} \end{cases} \tag{2.19}$$

Among them, \emptyset as the empty set, lots the $\|\theta(t)\|_{-0}$ for $??(t)$ L - 0 norm, $X_1(t)$? $X_2(t)$? $X_3(t)$ for $??$ loophole (t) of the collection, $X_1(t)$ said the decision to cross section under the detection of traffic flow data of road network traffic flow (vehs/h) on average, $X_2(t)$ means that the decision is the average traffic flow of the

road network under vehicle track data (vehs/h) $X_3(t)$ is an uncertain decision, indicating that it is impossible to distinguish which decision is $X_1(t)$ or $X_2(t)$. $q^M(t)$ and $q^F(t)$ have the same meaning as equation (2.18).

Second, two key ideas are included in DS evidence theory: The demspster evidence synthesis rule and fundamental trust distribution, which is also referred to as proof distribution or evidence function. A quantitative measure of the level of support and evidence for each choice is the basic trust distribution. The rule of evidence synthesis is a thorough examination that considers several pieces of data in relation to each choice. Make $s:2^{\|\theta(t)\|_0} \rightarrow [0, 1]$, said s is a basic trust distribution $2^{\|\theta(t)\|_0} \rightarrow [0, 1]$ mapping, it must meet the following requirements:

$$\begin{cases} s_i(\emptyset) = 0 \\ \sum_{X_j(t) \subset 2^{\Theta(t)_0}} S_i(X_j(t)) = 1 \end{cases} \quad i = 1, 2; j = 1, 2, 3 \tag{2.20}$$

where $S_i(X_j(t))$ represents the degree of support for decision $X_j(t)$ by the evidence provided by the i -th data source, and its value is the basic trust assignment value of decision $X_j(t)$, the basic trust value of the empty set is 0, and the sum of the trust values of other subsets is 1. In this example, i stands for the evidence provided by the i -th data source, j for the JTH decision choice.

In this work, the basic probability allocation function of choice $p_i(X_j(t))$ under each data source determines the fundamental trust allocation:

$$s_i(X_j(t)) = p_i(X_j(t)) / \sum_{j=1}^3 p_i(X_j(t)), i = 1, 2 \tag{2.21}$$

In each data source, the fundamental probability distribution function of the decision $X_j(t)$ is represented by $p_i(X_j(t))$.

Hypothesis $p_i(X_j(t))$ meet the $\varphi_i(v) \sim N(\mu_i(t), \sigma_i^2(t))$, the $\mu_i(t)$ and $\sigma_i^2(t)$ in the first class I average traffic flow data source under the historical data network $f_i(v)$ in t time mean and variance ($i = 1, 2$), $p_i(X_j(t))$ can be calculated according to equation (2.22).

$$\begin{cases} p_i(\bar{\emptyset}) = 0 \\ p_i(X_1(t)) = \int_{\mu_1(t)-1/2}^{\mu_1(t)+1/2} \frac{1}{\sqrt{2\pi\sigma_i(t)}} \exp\left\{-\frac{1}{2}\left(\frac{v-\mu_i(t)}{\sigma_i(t)}\right)^2\right\} dv \\ p_i(X_2(t)) = \int_{\mu_2(t)-1/2}^{\mu_2(t)+1/2} \frac{1}{\sqrt{2\pi\sigma_i(t)}} \exp\left\{-\frac{1}{2}\left(\frac{v-\mu_i(t)}{\sigma_i(t)}\right)^2\right\} dv \\ p_i(X_3(t)) = \frac{1}{2\pi\sigma_i^2(t)} \left\{ \begin{aligned} &\int_{\mu_1(t)-1/2}^{\mu_1(t)+1/2} \exp\left\{-\frac{1}{2}\left(\frac{v-\mu_i(t)}{\sigma_i(t)}\right)^2\right\} dv \\ &\times \int_{\mu_2(t)-1/2}^{\mu_2(t)+1/2} \exp\left\{-\frac{1}{2}\left(\frac{v-\mu_i(t)}{\sigma_i(t)}\right)^2\right\} dv \end{aligned} \right\} \end{cases} \tag{2.22}$$

Based on the basic trust assignment $S_i(X_j(t))$ of decision $X_j(t)$, the Demspster evidence synthesis process orthogonal and processed the basic probability assignment of multiple evidences. The evidence synthesis method of the two data sources is shown in Equation (2.23) :

$$s(X) = \begin{cases} K_D * \sum_{X_j(t) \cap X_j(t) = X} s_1(X_j(t)) s_2(X_j(t)) & X \neq \emptyset \\ 0 & X = \emptyset \end{cases} \tag{2.23}$$

Among them, $j=1,2,3$, $s(X), X \subset 2^{\|\theta(t)\|_0}$ is the synthetic trust distribution, $X_j(t)$ means that the decision is made under the evidence provided by the JTH data source, and the following formula is used to determine the conflict coefficient between the evidence offered by various data sources:

$$1/K_D = 1 - \sum_{x_j(t) \cap X_j(t) = \emptyset} s_1(X_j(t)) s_2(X_j(t)) \tag{2.24}$$

The closer $1/K_D$ is to 0, the greater the degree of conflict between $q^M(t)$ and $q^F(t)$ evidence provided by different data sources. When $1/K_D=0$, the sum under Dempster's synthesis rule does not exist.

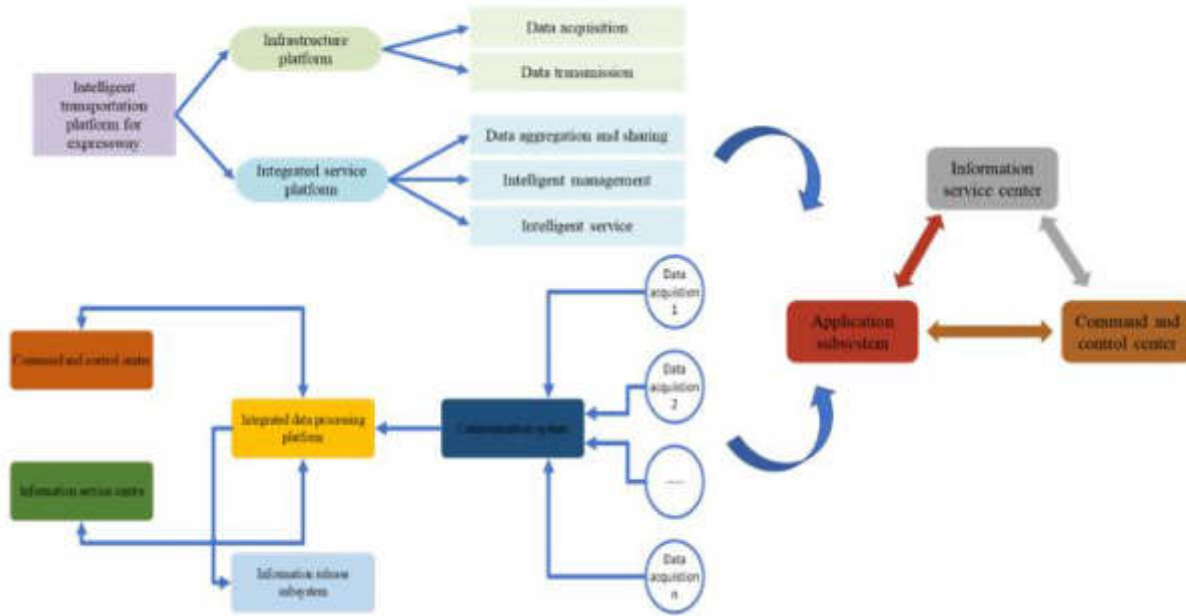

Fig. 3.1: ITS logical architecture diagram

The degree of disagreement between $q^M(t)$ and $q^F(t)$ evidence from various data sources increases with $1/K_D$'s proximity to 0. According to Dempster's synthesis rule, the total is null for $1/K_D=0$.

Equation (2.25) illustrates the approach used to calculate the $q^F(t)$ weights. Lastly, fusion weights are generated based on synthetic trust allocation.

$$\alpha(t) = \frac{s(X_2(t))}{s(X_1(t)) + s(X_2(t))} \tag{2.25}$$

Assuming that $\alpha(t)$ is equivalent to equation (2.16), the synthetic trust allocation for each choice is represented by $S(X_1(t)), S(X_2(t))$ and $S(X_3(t))$, taking into account the evidence supplied by each data source.

3. Urban intelligent monitoring. With the accelerated process of urbanization and the development of the automotive industry, the contradiction between the existing urban road capacity and the continuously growing traffic demand has become increasingly acute, leading to a growing prominence of traffic congestion. Utilizing Intelligent Transportation Systems (ITS) for controlling and guiding traffic flow to alleviate congestion and provide a smooth and orderly traffic environment is an important means vigorously developed and applied by various countries. The so-called Intelligent Transportation System is established on the basis of improved road infrastructure, integrating new-generation information, the Internet of Things (IoT), and computer technologies into traffic management. It aims to create an information-real-time, accurate, widely-serviced, all-encompassing, highly efficient, and high-quality transportation and management system [31]. In summary, ITS involves innovating traditional transportation systems through technology, creating a new type of transportation system that integrates informatization and intelligence [32]. The architecture of ITS is depicted in Figure 3.1. In this section, taking the complex urban road network as the research background, a combination of the two models mentioned earlier is performed. The goals of this include multi-source data-based urban traffic congestion monitoring and data-driven urban traffic safety environment monitoring.

3.1. Data-driven urban safety environment monitoring. A variety of factors are often considered while analyzing the traffic safety environment, such as the quantity (or frequency) of accidents, the nature of

the accidents (or types of vehicle collisions), and the severity of the accidents. The study of accident blackspots mostly uses accident frequency or quantity, with the usual objective being to pinpoint locations with a high accident rate. This kind of study often needs to pay more attention to including driver and vehicle conditions in the model and more attention to macroscopic traffic and road data. On the other hand, studies on accident types often concentrate on analyzing factors related to vehicles and roads, overlooking the impact of macroscopic traffic parameters and drivers. Therefore, a comprehensive analysis of accident severity that considers vehicles, drivers, macroscopic traffic, and road conditions can more comprehensively reflect the impact of accidents on the traffic safety environment. Thus, this paper selects accident severity as the research object.

Considering the comprehensiveness of data acquisition and the impact of the severity of injuries caused by accidents, a three-level classification method for accident severity is adopted, categorizing accidents into no-injury accidents, minor-injury accidents, and fatal or disabling accidents.

Various methods, including variable fusion, outlier detection and processing, are applied to restructure the relevant variables and data in the datasets. To ensure the timeliness and completeness of the data, this study uses accident and environmental data from recent years on Interstate 5 (I5) in Seattle, Washington. The data is collected from the National Highway Traffic Safety Administration's Fatality Analysis Reporting System (FARS) and the University of Washington's DRIVENet database. As the FARS dataset shares common labels such as TIME (time) and CASE NUMBER (accident number), the accident, vehicle, passenger, and environmental information in the information system table are fused based on these common labels and further combined with road information from the Washington University DRIVENet dataset, utilizing the MILEPOST (road mileage) label. The goal of restructuring the samples from multiple datasets is to make the samples suitable for model calculations. The initial complete sample labels include non-numeric symbols in textual expressions, mainly comprising some categorical variables. The restructuring of categorical variables involves label encoding and one-hot encoding.

On the basis of the above tests, in order to study the impact of different parameters on the traffic safety environment, the author introduced a factor importance index to evaluate the importance of different parameters. Considering that n -dimensional parameter vectors constitute the entire input space, the output vector Y corresponding to the first-stage partial derivative of the i th-dimensional variable x_i can explain the sensitivity of this variable to the output. According to the chain rule of calculus, equation (3.1) is obtained:

$$\frac{\partial Y}{\partial X_i} = \frac{\partial Y}{\partial \alpha} \frac{\partial \alpha}{\partial X_i} \quad (3.1)$$

?? is the calculated value from the network hidden layer to the output layer, and equation (3.1) can be rewritten as:

$$\frac{\partial Y}{\partial X_i} = \sum_{j=1}^L W_{k,j}^{(2)} \frac{\partial H_j}{\partial X_i} g(\alpha)' \quad (3.2)$$

J refers to the J TH node of the hidden layer, and $W_{k,j}^{(2)}$ refers to the weight from the hidden layer to the input layer. $g(\alpha)'$ is the activation equation from hidden layer to output layer.

Continuing to deduce according to the chain rule, Equations (3.3) and (3.4) can be obtained as follows.

$$\frac{\partial Y}{\partial x_i} = \sum_{j=1}^L W_{k,j}^{(2)} \frac{\partial H_j}{\partial \beta_j} \frac{\partial \beta_j}{\partial x_i} g(\alpha)' \quad (3.3)$$

$$\frac{\partial Y}{\partial x_i} = \sum_{j=1}^L W_{j,i}^{(1)} W_{k,j}^{(2)} f(\beta)' g(\alpha)' \quad (3.4)$$

$W_{j,i}^{(1)}$ refers to the connection weight from the input layer to the hidden layer, while $f(\beta)'$ is the activation equation from the input layer to the hidden layer.

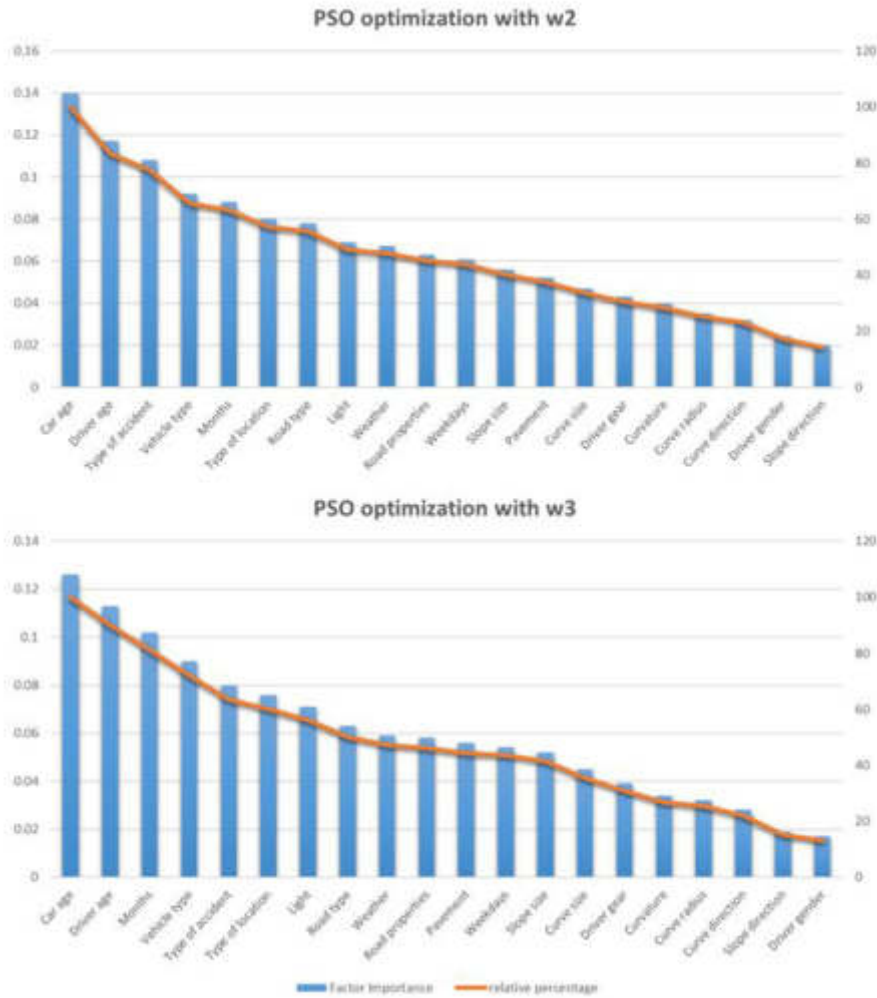

Fig. 3.2: Factor importance and relative percentage

The relevance R_i of a single indicator can be calculated as follows (3.5) :

$$R_i = \sum_{j=1}^L W_{j,i}^{(1)} W_{k,j}^{(2)} / \sum_i \sum_{j=1}^L W_{j,i}^{(1)} W_{k,j}^{(2)} \quad (3.5)$$

In the above formula, all weights W can be obtained from the results of network simulation. In order to eliminate the randomness of the simulation, the simulation is performed k times, and the factor importance is obtained as follows (3.6) :

$$E(R_i) = \frac{1}{K} \sum_{k=1}^K R_i^k \quad (3.6)$$

By combining the calculation results of Particle Swarm Optimization(PSO) optimization network with the calculation formula of factor importance, the importance and relative percentage of factors can be obtained in Table ?? below.

It is evident from Table ?? and Figure 3.2 that the factor importance rankings derived from the two PSO optimization approaches are almost exact. Eight categories of factors—vehicle age, driver age, accident type, month, accident location type, road function, and lighting conditions—have a relative importance of more than 50%. Vehicle age and driver age are the two most important factors influencing accident severity, which aligns with both our intuition and experience. The impact of road factors is limited, with road type being the only one with a high importance ranking, indicating that specific types of accidents tend to occur on roads with specific functions. Combining the example of accident statistics mentioned earlier, it can be observed that the wet and snowy weather and mountainous roads in Washington State significantly increase the number and severity of accidents during the winter.

3.2. Urban congestion monitoring based on multi-source data. The variation of traffic states is regarded as random because of the high level of complexity and uncertainty associated with the spatiotemporal

state of traffic systems. To deeply explore the correlations between various traffic data, it is necessary to integrate and analyze multiple data sources to extract the hidden operational patterns of traffic states buried within the data. This chapter, based on various traffic flow parameter data, employs the MFD for data fusion. It uses a Genetic Algorithm-Fuzzy C-Means (GA-FCM) algorithm to classify road traffic states. Road traffic states can then be predicted by combining the anticipated outcomes of traffic flow parameters. The effectiveness of this method in reflecting road traffic conditions is confirmed by experimental results.

The Genetic Algorithm (GA) is a model parameter optimization algorithm that relies on natural selection and genetic mechanisms. FCM is a commonly used fuzzy clustering algorithm for data classification and cluster analysis. The steps of optimizing the FCM model using GA are as follows: 1) Determine the fitness function: The fitness function, which evaluates the quality of each individual, is crucial for GA. In the FCM model, the fitness function can be selected as an evaluation index for clustering effects, such as clustering accuracy or clustering entropy. 2) Determine the encoding method: GA needs to encode each individual into chromosomes for genetic operations. In the FCM model, each individual can be encoded into a set of fuzzy cluster centers, where each chromosome contains multiple genes representing cluster centers. 3) Initialize the population: Randomly generate an initial population, with each individual representing a random set of cluster centers. 4) Selection operation: Based on the fitness function, select some excellent individuals as parents for the next generation. 5) Crossover operation: Perform crossover operations on parent individuals to generate new offspring individuals. In the FCM model, single-point crossover or multi-point crossover can be used. 6) Mutation operation: Introduce randomness to the offspring individuals through mutation operations to increase population diversity. In the FCM model, random perturbation or random replacement can be applied. 7) Evaluate fitness: Evaluate the fitness of the new generation, calculating the fitness value for each individual. 8) Repeat selection, crossover, mutation, and fitness evaluation operations until reaching the preset stopping conditions, such as reaching the maximum iteration times or convergence of fitness values. 9) Output the optimal solution: In the last generation of the population, select the individual with the highest fitness as the optimal solution, representing the optimal cluster centers.

Firstly, the GA-FCM clustering algorithm is applied to classify traffic flow parameters to obtain the optimal number of clusters and corresponding cluster centers for each state. Subsequently, a fuzzy clustering algorithm is utilized to partition the data, and based on the fuzzy cluster center results, different clusters representing traffic flow states are determined. These states are considered as prior knowledge for real-time traffic state identification. Finally, by calculating the membership degree of traffic flow data to each cluster center and the corresponding membership degree to different road traffic states, the traffic flow state at that moment can be determined. This process is accomplished using the membership degree function, selecting the traffic flow state with the maximum membership degree as the final identification result.

The selection range of the fuzzy factor is usually between 1 and 2. This parameter can suppress the influence of noise pollution by assigning larger weights to the membership function, reducing the impact of noise points on the FCM objective function during iterations. Starting from 1.0, experiments are conducted with a step size of 0.1, and the value of the fuzzy factor "m" is finally determined as 2. In the clustering analysis of traffic data, the number of clusters "C" plays a crucial role in the partitioning and identification of traffic states. To determine the optimal number of fuzzy partitions, the clustering validity function is commonly used as an evaluation criterion. This study employs the clustering validity function based on membership and squared membership weights to determine the number of clusters, as shown in Equation (3.7).

$$V_u = \frac{1}{2n} \left(\sum_{j=1}^n \sum_{i=1}^c u_{i,j}^2 + \sum_{j=1}^n \max_{i=1}^c u_i \right) \quad (3.7)$$

By computing when the number of clusters (C) is set to 4, the maximum fuzzy correlation value is achieved, indicating the highest effectiveness of data clustering. Therefore, in this experiment, we categorize the traffic states of road segments into four levels: smooth, moderately smooth, congested, and heavily congested. This categorization is based on the result obtained with a cluster number of 4.

The objective of the fuzzy mean clustering algorithm, optimized by a genetic algorithm in this study, is to

identify a set of cluster centers and membership degrees that minimize the objective function. To achieve this goal, an iterative optimization approach is employed, iteratively updating the cluster centers and membership degrees to reduce the value of the objective function progressively. The objective function in this paper is the fuzzy mean clustering algorithm's loss function, as indicated by the following equation, because the underlying methodology uses the Fuzzy C-Means (FCM) algorithm for traffic state partitioning.

$$fit = \min J_f = \min \sum_{j=1}^c \sum_{i=1}^n [u_j(d_i)]^m d_i - \nu_j \quad (3.8)$$

The selection of the number of iterations and the stopping error depends on the specific problem and dataset. Generally, a higher number of iterations leads to increased algorithm precision, but it also results in longer computation times. Therefore, it's advisable to choose an appropriate number of iterations based on the actual circumstances. The convergence of the algorithm can be observed to determine the number of iterations. If the algorithm has converged within a certain number of iterations, it can be stopped. The stopping error refers to halting iterations when the algorithm reaches a specific error range. The choice of the stopping error depends on the specific problem and dataset. If the dataset is noisy, a larger stopping error can be chosen to prevent overfitting.

Conversely, if the dataset is clean, a smaller stopping error can be chosen to enhance precision. In practical applications, the number of iterations and stopping errors often need to be considered together. Typically, one can start with a small stopping error and then determine the number of iterations based on the convergence of the algorithm. If the algorithm has converged within a certain number of iterations, it can be stopped. If the algorithm hasn't converged, the number of iterations can be increased until convergence or reaching the maximum iteration limit. Considering these factors, this experiment sets the maximum number of iterations to 100 and the iteration-stopping error threshold to 1e-5.

This study intends to conduct an instance analysis using two different levels of road segment data. Clustering analysis will be performed using historical traffic flow parameter data to obtain a road traffic state discrimination method based on multi-source data. The fuzzy partitioning process of road traffic states based on GA-FCM includes the following steps: extracting features such as flow, speed, and occupancy rate from the original data, constructing the objective function, utilizing genetic algorithms to find the optimal clustering centers, and finally outputting the clustering results of traffic states.

According to the above parameter Settings, the clustering centers of four traffic states of the main road obtained by GA-FCM clustering algorithm are represented by $V = \{\nu_1, \nu_2, \nu_3, \nu_4\}^T$, and the results of equation (3.9) and Figure 6 are obtained respectively.

$$V1 = \begin{bmatrix} 31.82 & 55.88 & 0.04721 \\ 85.17 & 49.74 & 0.08338 \\ 148.7 & 50.37 & 0.2233 \\ 109.9 & 18.3 & 0.1975 \end{bmatrix} \quad (3.9)$$

In this context, the three columns of the clustering centers represent flow, speed, and occupancy, respectively. Each row corresponds to a specific traffic state, namely, smooth-flowing, moderately smooth-flowing, congested, and heavily congested.

From the graph, it can be observed that there is a certain continuity in the value ranges between different traffic states. Under different traffic states, certain parameter ranges exhibit overlapping characteristics. As the traffic state transitions from smooth-flowing to congested, the speed gradually decreases while the flow and occupancy increase. In a heavily congested state, where vehicles move at a slower pace, the flow gradually decreases, aligning with the fundamental principles of traffic operation.

V2 represents the clustering centers for the four traffic states on the expressway, and the partition results

Fig. 3.3: Main Road Traffic Clustering Results

Fig. 3.4: Expressway Traffic Clustering Results

are illustrated in Equation (3.10) and Figure 3.4.

$$V2 = \begin{bmatrix} 25.41 & 50.3 & 0.04761 \\ 71.95 & 44.45 & 0.08646 \\ 119 & 45.5 & 0.223 \\ 87.87 & 15.91 & 0.2007 \end{bmatrix} \tag{3.10}$$

From the above figure, it is evident that, compared to arterial roads, expressways exhibit slightly higher traffic flow and speed. Expressways demonstrate relatively high traffic flow stability, with minimal speed differences among vehicles, resulting in a smoother traffic flow.

Different types of roads exhibit distinct characteristics in traffic flow parameters, necessitating reasonable planning and design to ensure the efficient operation and safety of the urban road network. Expressways typically have higher traffic volumes than arterial roads, as they handle a large number of passenger and freight vehicles. Arterial roads follow in terms of traffic volume, primarily accommodating internal traffic flows within the city, including commuting, commercial, and service-related traffic. Regarding speed, expressways usually have higher speeds than arterial roads due to their higher design speeds, wider lane widths, and absence of traffic signals, allowing vehicles to travel at higher speeds. Arterial roads have slightly lower speeds as traffic signals typically control them, and vehicles need to adhere to traffic rules and signal indications, resulting in relatively slower speeds.

Compared to the traditional FCM clustering algorithm, the GA-FCM clustering algorithm optimized by a genetic algorithm can more rapidly identify the optimal clustering partition. Additionally, both algorithms yield the same final value for the objective function, with the FCM algorithm consistently having a higher final

value than the GA-FCM algorithm. The graph also illustrates that GA-FCM exhibits faster convergence and better stability compared to the traditional FCM clustering algorithm.

3.3. Research on old city reconstruction. Urban traffic intelligent monitoring provides unprecedented opportunities for the transformation of urban road networks. With continuous technological advancements, traffic managers can utilize advanced monitoring technologies and data analysis tools to achieve more efficient and intelligent road network designs. This process not only improves traffic flow but also contributes to enhancing the quality of life for urban residents.

Firstly, intelligent monitoring systems provide cities with comprehensive traffic data. By deploying cameras, sensors, and other monitoring devices, traffic managers can obtain real-time information on vehicle flow, speed, congestion, and more. These data form the basis for a deep understanding of the city's traffic conditions. Leveraging advanced artificial intelligence algorithms, managers can extract valuable information from massive datasets and identify traffic patterns, peak periods, and potential bottleneck locations. With this information, cities can engage in more precise traffic planning and road network improvements.

The data analysis capabilities of intelligent monitoring systems empower traffic managers to identify bottlenecks and congestion points, allowing targeted optimization of intersections and adjustments to traffic signals. Through real-time traffic flow control, congestion can be effectively alleviated, and road operational efficiency improved. This not only helps relieve traffic pressure but also reduces carbon emissions, enhancing urban air quality.

Real-time traffic information dissemination systems extend the capabilities of intelligent monitoring systems by providing drivers and citizens with real-time information through mobile apps, digital signage, social media platforms, and more. This enables citizens to flexibly plan travel routes and choose alternative roads to avoid congestion. Additionally, it enhances the traffic awareness of participants, reducing the incidence of traffic accidents.

Data sharing and cross-departmental cooperation are crucial for achieving intelligent traffic management. Establishing data-sharing mechanisms among different traffic systems facilitates the collaborative operation of traffic systems. Through big data analysis, urban planners can better understand the city's traffic demands, providing a scientific basis for future road network transformations.

In addition to improving traffic efficiency, urban traffic intelligence monitoring should also focus on environmental sustainability. Combining traffic monitoring systems with environmental monitoring technologies allows cities to assess the impact of traffic on air quality and noise levels. Based on these assessments, corresponding measures can be taken, such as the establishment of green belts and the construction of sound barriers, to improve the living environment for urban residents.

In conclusion, road network transformation based on urban traffic intelligent monitoring represents a revolutionary attempt in urban traffic management. By fully leveraging advanced monitoring technologies and data analysis tools, cities can achieve a more intelligent, efficient, and environmentally friendly traffic system. This not only concerns the development of urban traffic but also affects the travel experience and quality of life for urban residents.

4. Conclusion. This paper makes a detailed discussion of urban intelligent monitoring, puts forward some algorithm models of intelligent city monitoring based on data-driven, and briefly discusses its application in the reconstruction and renewal of old cities. At the same time, it also puts forward new solutions for data noise reduction and multi-source data fusion in complex urban environments. Summarizing the relevant research in this paper, the following conclusions are drawn:

1. This paper proposes a data-driven signal denoising model using an improved wavelet threshold method. Three key points of wavelet threshold denoising are modified, and the detailed calculation formula and calculation flow of the denoising algorithm are given. Using the experimental data containing noise and fault to debug, the signal-to-noise ratio decreases significantly after noise reduction, and most types of fault information can still exist on multiple scales. Experiments show that the model can suppress and remove the noise well while retaining most fault information. The noise reduction results are more suitable for the late diagnosis of data faults and can be applied to constructing an urban intelligent monitoring model.

2. An MFD fusion structure is proposed to aim at the problem of multi-source data in urban traffic intelligence monitoring. An urban congestion monitoring model is constructed by combining the FCM model optimized based on a genetic algorithm. Compared with the traditional FCM clustering algorithm, the GA-FCM clustering algorithm optimized by the genetic algorithm can find the optimal cluster classification faster. In addition, the final value of the objective function of both algorithms is the same, and the final value of the objective function of the FCM algorithm is always higher than that of the GA-FCM algorithm.
3. The application of the monitoring model in the smart city in the reconstruction and renewal of the old city is discussed, with clear objectives, reasonable means and correct direction, which has certain guiding significance.

The research in this paper is a preliminary exploration of road network operation status and traffic capacity estimation after noise reduction of multi-source data using a wavelet algorithm. With the deepening of the research, the author feels the challenge of the research and still doubts the further application and development of the model in the reconstruction of old cities. Based on the current research, future research can be carried out from the following three aspects.

In the process of MFD fusion construction based on multi-source traffic perception data, limited by the acquisition of actual data, this paper only selected a small range of actual road networks to verify the method. In the future, when more realistic data are collected, the accuracy of the proposed method in the actual large-scale road network MFD fusion construction needs to be further verified. In the link of road network dynamic capacity estimation, this paper adopts the data-driven method, the premise of which requires the road network to have a relatively complete traffic operation state (unsaturated, saturated, and supersaturated). Therefore, its application may be limited to the capacity analysis of road networks such as central urban areas. In the future, theoretical methods based on analytical modeling can be further considered. A road network capacity estimation method driven by data and model is constructed. The application of this model in the reconstruction of the old city is only a superficial discussion in this paper, without further analysis and calculation, which can be studied in the future.

RESEARCH AND APPLICATION OF A DUAL FILTERING MUSIC HYBRID RECOMMENDATION MODEL BASED ON CATBOOST ALGORITHM AND DCN

JUNCAI HOU*

Abstract. With the increase of Internet users, the traditional music recommendation model can not meet the increasing personalized needs of users. The single deep cross network model has some defects in music recommendation, such as poor stability and inability to process complex data. To overcome the shortcomings of existing models, a new hybrid music recommendation model combining CatBoost algorithm and deep cross network is constructed to improve the recommendation performance and better meet the individual needs of users. Then the performance of the hybrid model is compared with other algorithms. The results showed that the accuracy of the proposed hybrid algorithm was up to 92.7%, which was superior to the comparison algorithm. In comparison with other single model and hybrid model, it is found that the proposed model was more than 0.05% higher than other models in the four indices of AUC area, accuracy, precision and recall. The above results showed that the proposed hybrid music recommendation model could efficiently process data information and provide users with accurate personalized music recommendation. This study not only promoted the development of music consumption and creation, but also found that the CatBoost-DCN hybrid model was significantly effective in improving recommendation performance. This finding provides a more efficient recommendation strategy for music platforms and has far-reaching significance for improving user experience and satisfaction.

Key words: Music recommendation; CatBoost; DCN; Data modeling; Machine learning

1. Introduction. With the rapid development of the internet and mobile internet, music recommendation systems have become an indispensable part of the music industry [3]. Music recommendation systems can help users discover new music and increase user engagement on music platforms. The current music recommendation system mostly adopts collaborative filtering algorithm, which recommends music liked by similar users according to their historical behaviors and preferences [6]. However, traditional collaborative filtering algorithms ignore the emotional and stylistic characteristics of music, as well as the subtle preference differences of users, thus limiting the accuracy and personalization of the recommendation system (Sterman et al. 2021). To improve the quality and accuracy of music recommendation, a new hybrid recommendation model is proposed to meet the individual needs of users more comprehensively and accurately capture the emotional and stylistic characteristics of music. This hybrid recommendation model combines CatBoost algorithm and Deep Cross Network (DCN) model. Among them, CatBoost algorithm can balance personalized recommendation and music popularity, while DCN model can dig deeply into the emotion and style characteristics of music, and predict user preferences more accurately by integrating music metadata and historical behavior data of users [17, 13]. The innovation of this research lies in integrating CatBoost and DCN algorithms into the music hybrid recommendation model at the same time. Compared with the traditional recommendation system, it not only significantly improves the personalization and accuracy of recommendation, but also enhances the user experience and brings higher user stickiness and broader profit space to the music platform. This study has important implications for the development of music recommendation systems and also demonstrates the positive role of advanced technology in meeting social and cultural needs. The research is divided into four parts. The first part is to analyze the research status of DCN algorithm and music recommendation model. The second part describes CatBoost and the process of building a music recommendation model after merging with DCN. The third part is to compare and analyze the performance of CatBoost-DCN hybrid algorithm and CatBoost-DCN music recommendation model. The last part is the summary of the full text.

2. Related Works. In the era of big data and information, the growth of social media is accompanied by the rapid growth of a variety of data and information. In the context of imperfect information filtering

*The Department of Music, Xinxiang University, Xinxiang, 453000, China (Juncai_Hou1234@outlook.com)

mechanisms, how music users can obtain information of interest has become a major challenge for music recommendation systems. To effectively identify and predict the prone sites of cancer, Pandey developed an amino acid sequence feature model using a DCN. After cross validation, the results showed that the model could predict the prone sites of diseases with 81.6% accuracy [14]. To improve the detection accuracy of phishing websites, Anitha and Kalaiarasu proposed a phishing detection system based on mixed deep learning algorithm, and tested the detection system. The results showed that the accuracy of the detection system on phishing websites was much higher than that of the traditional detection model. It also had high robustness and strong prediction ability in distinguishing phishing websites from legitimate websites [1]. To obtain the optimal approximation error characteristics, [11] used DCN to correct the linear unit network. Experimental results showed that after being corrected by this network, the deep linear unit network with different depths exhibited non collinearity. To solve the problem of automatic recognition of different levels of glioma during brain tumor surgery, [2] proposed a deep learning model based on DCN automatic deep learning network. After sample experiments, the model classification produced a sensitivity of 88.9%, an F1 score of 0.906, and 100% specificity. To understand how the number and spacing of communities affect postal delivery, [16] used a mixed effects model based on CatBoost for detection and analysis. After analyzing the sampling points, the metacommunity structure was influenced by natural and human landscape scale variables. To overcome the overfitting problem caused by the small native language data set in the mixed speech environment, Gupta's team proposed a classification model based on CatBoost algorithm and fine-tuned it. The results showed that the model can effectively avoid the overfitting problem. [9]. In addition, for the problem that diabetes is difficult to predict accurately in the early stage, Jenefer and Deepa proposed a CatBoost classifier based on firefly optimization to predict diabetes. The comparison test between this classifier and other similar classifiers showed that CatBoost classifiers had higher accuracy and lower loss values [10].

In modern society, music plays an important role in relaxing the mood and bringing people beautiful enjoyment. However, due to the numerous categories and quantities of music itself, as well as the different personal preferences of the audience, music recommendation is very difficult. To classify music and effectively recommend it to users, Elbir A et al. constructed a new Deep Neural Network (DNN) model based on acoustic features of music to extract representative features. After training the dataset, the results showed that the model could effectively classify music types and recommend music [6]. In view of the problems of cold start and new user recommendation in music recommendation, Yadav et al proposed a self-focused deep music recommendation model based on MIDI content data, and tested the model. The results showed that this method could effectively improve the recommendation effect by using MIDI content information. It outperformed other advanced models in several comparisons [20]. To obtain the ideal sound of the most popular DJs in search tools and perform DJ classification, Ziemer et al. (2020) [24] constructed a model that includes third octave mixing analysis, peak factor meter, phase range, and channel correlation coefficient functions. Through machine learning experiments, it was found that the accuracy of model detection was 73% [3]. To calculate, model, and classify music emotional content, the Chapaneri team proposed a structured regression framework that uses a single regression model to model the potency and arousal emotional dimensions of music. After training the benchmark dataset, the proposed work achieved significant improvements in R2 of arousal and valence dimensions [24]. To avoid the one size fits all phenomenon in music recommendation, Jin et al. constructed a system to optimize user control level based on visual memory and music maturity features. After detecting the interactive visual design system model of the music recommendation system, the results showed that music complexity would enhance the impact of UI on perceptual diversity [4]. To solve the problems of cold start and content feature extraction in Music classification and recommendation, Mao et al proposed a music-CRN model to optimize classification and recommendation by learning audio content features. Empirical analysis of the model found that this method performed better in music classification and recommendation tasks than previous methods [12]. Aiming at the problem that the existing music recommendation system fails to fully capture the correlation between internal and external information, the Xu team proposed a hierarchical multi-information fusion recommendation method, and tested the method. The experimental results showed that compared with the baseline method, the method performed best on the NOWPLAYINGRS dataset. The validity and rationality of the model were verified [19].

Based on the above related studies and the comparison of the advantages and disadvantages of the proposed

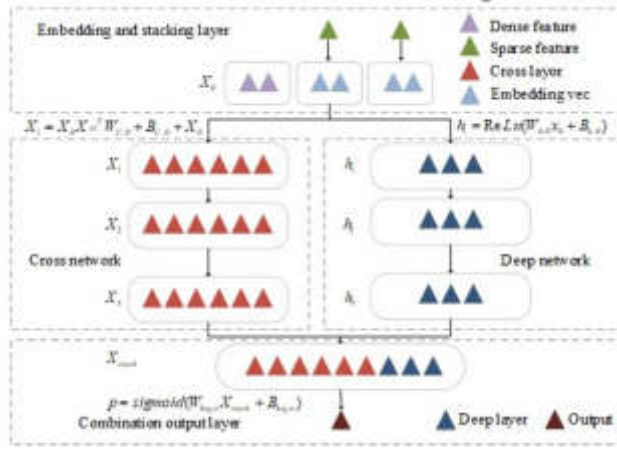

Fig. 3.1: Network model structure of DCN

method, Table 2.1 is obtained.

From Table 2.1, the proposed method integrates CatBoost algorithm and DCN model in the music recommendation system, aiming to meet users' individual needs more comprehensively and accurately capture the emotional and stylistic characteristics of music. The significant advantage of this method is that it can take into account both personalized recommendation and in-depth mining of music characteristics, so as to improve the accuracy and personalized degree of recommendation. Compared to the methods in other references, the proposed method focuses more on how to more accurately capture the intrinsic characteristics of user preferences and music. Although other relevant methods perform well in their respective fields, they have little to do with the direct application of the music recommendation system, and the methods applied in the field of music recommendation cannot meet the personalized needs of users. Therefore, the proposed music recommendation model based on CatBoost algorithm and DCN algorithm aims to fill the knowledge gap, and significantly improve the personalization and accuracy of music recommendation by integrating advanced algorithms, so as to enhance user experience and improve user stickiness of music platform.

3. Methods and Materials.

3.1. Construction of a DCN-based music recommendation model. DCN consists of a DNN and a Cross Network (CN) in parallel [7]. The drawback of traditional DNN is that only a combination of partial features can obtain better features, and its implicit learning features are inexplicable, resulting in low learning efficiency [23]. The main principle of DCN is to consider discrete and continuous features separately, encode and embed discrete features, and then concatenate and combine them with continuous features. The network model structure of DCN is shown in Figure 3.1.

From Figure 3.1, the original data in the DCN model is first divided into discrete and continuous features. Then at the embedding layer, the discrete features are transformed into real value vectors by building a random initialization vector lookup table. Subsequently, the transformed real value vector and the continuous feature are perfectly fused in the stacked layer to form the final output vector. This design not only optimizes the feature processing, but also improves the expressiveness and flexibility of the DCN model. The stacking function in the DCN model is shown in equation (1).

$$X_0 = [x_{\text{embed},1}^T \cdots, x_{\text{embed},k}^T, x_{\text{dense}}^T] \quad (1)$$

In equation (1), $x_{\text{embed},k}^T$ means the vector of the k th feature after embedding operation; x_{dense}^T denotes the transposed continuous value eigenvector; X_0 refers to both CN and DNN inputs. The DNN is composed of n layer networks and is a fully linked neural network system. Each layer of the deep network can be represented

Table 2.1: Comparison of the advantages and disadvantages of the research methods in this paper with those in different references

Author	Research method	Application field	Advantages	Disadvantages
Research in this paper	Music recommendation model integrating CatBoost and DCN	Music recommendation	Both personalization and music feature mining can significantly improve the personalization and accuracy of recommendation	/
Pandey [14]	Amino acid sequence feature model based on CatBoost	Disease prediction	High accuracy in predicting disease prone sites	Only applicable in the field of cancer prediction

by equation (3.1).

$$D_{l+1} = f(W_l D_l + B_l) \quad (3.1)$$

In equation (3.1), D_l is the output of the previous layer network; W_l indicates the weight term; B_l denotes the bias term of bias, and ReLu is selected as the activation function f ; l represents the number of layers. If d is set as the input dimension, the number of neurons in each layer is m , and there is a l layer network, then the total parameter complexity of the DNN is shown in equation (3.2).

$$P(dl) = d \times m + m + (m^2 + m) \times (L_d - 1) \quad (3.2)$$

In this study, the CN is applied to the explicit feature cross, and the network output expression of each layer

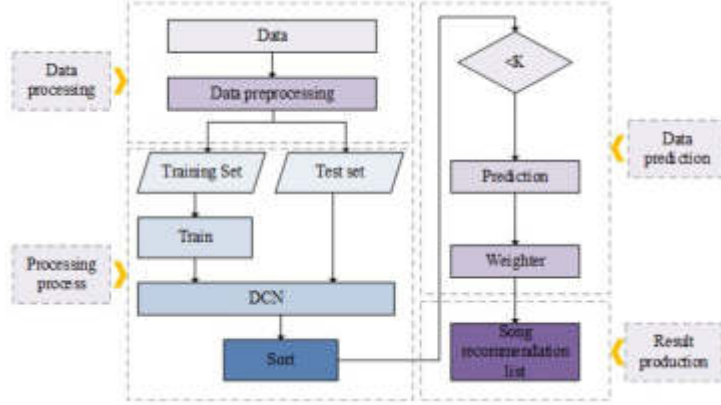

Fig. 3.2: Flow chart of music recommendation model based on DCN

is shown in equation (3.3).

$$x_{l+1} = x_0 x_l^T w_l + B_l + x_l \quad (3.3)$$

In equation (3.3), x_l is the output of the previous layer network; w_l and B_l represent the connection parameters between the two layers of networks; $x_0 x_l^T w_l$ denotes the feature crossover completed in the $l + 1$ layer, and all variables in the above equation are column vectors. The residual between the output of the fitting layer and the previous output, plus the input data x_l of that layer, can be regarded as the residual of the two-layer network. Next, in the connection layer, the final outputs of the two networks are connected, and after weighted summation, the final probability value is generated by the Sigmoid function, as shown in equation (3.4).

$$x_{\text{stack}} = \text{concat} (w [C_{L_1}^T, D_{L_1}^T]) \quad (3.4)$$

In equation (3.4), $C_{L_1}^T$ and $D_{L_1}^T$ are the outputs of the CN and DNN, respectively; L_1 and L_2 respectively mean the number of layers in two networks; w expresses the weight parameter of the CN. DCN can learn the interactions between effective features and has lower computational costs. Therefore, the study applies DCN to music recommendation models to reduce the complexity of the music recommendation model. The flowchart of the music recommendation model based on DCN algorithm is shown in Figure 3.2.

From Figure 3.2, the music recommendation model based on DCN algorithm first needs to desensitize user information, extract hidden features of music from it, and build an information matrix. Then the music data set is split and passed into the DCN classifier for parameter setting. Parameters are initialized by equation (6) to reduce the dependence between parameters.

$$L = \text{sqrt} \left(\frac{6}{n_{\text{input}} + n_{\text{output}}} \right) \quad (3.5)$$

In equation (3.5), L indicates the range of uniform distribution; n_{input} denotes the amount of input units for the weight tensor; n_{output} represents the amount of output units of the weight tensor. Then at the connection layer, the Sigmoid function is used to calculate the probability output, the expression of which is shown in equation (3.6).

$$S(x) = \left(\frac{1}{1 + e^{-x}} \right) \quad (3.6)$$

In equation (3.6), $S(x)$ means probability and x indicates variable parameters. After the DCN model is constructed, the Adam optimizer is used to calculate the gradient of the loss function and update the parameters.

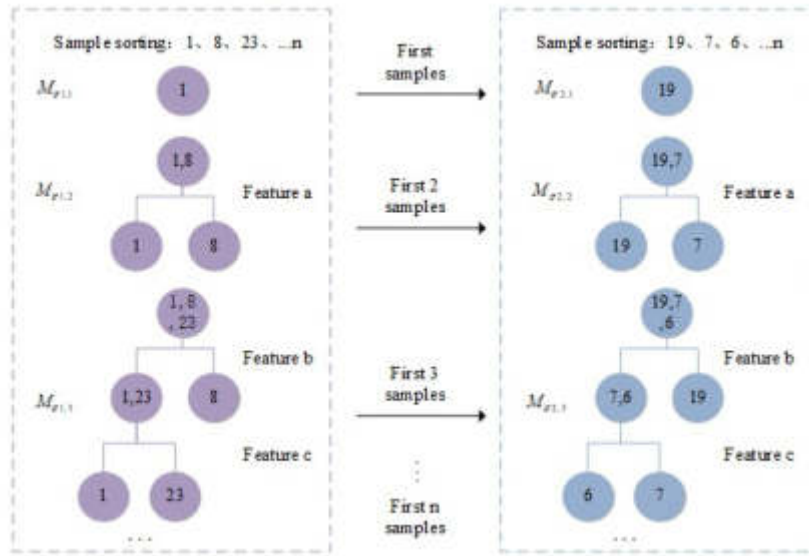

Fig. 3.3: CatBoost model structure

After the model configuration is completed, the number of iterations is set, the model is trained by the number of samples in each iteration, and the music recommendation list is finally obtained. Through the above steps, the music recommendation model based on DCN algorithm can recommend music according to the needs of different users, and ensure high recommendation accuracy.

3.2. Design of a dual filtering music recommendation model integrating CatBoost and DCN.

In traditional DCN music model recommendations, the number of music songs is large, the types are diverse, and the duration is not uniform. Moreover, the DCN model cannot effectively process discrete features, making it difficult for the model to provide personalized recommendations for users [15, 22]. Based on this dilemma, the study integrates the integrated learning CatBoost classification model with the DCN to construct a music recommendation model based on the DCN-CAT algorithm. CatBoost is a type of decision tree that can efficiently and reasonably process categorical features, thereby improving the accuracy of the algorithm [8]. The CatBoost symmetric tree structure is shown in Figure 3.3.

From Figure 3.3, the core of CatBoost algorithm is the design of symmetric tree, and it will build an initial tree structure according to the selected sample in the first iteration, and then determine the value of each leaf node through calculation. This initial tree structure is reused in subsequent iterations to continuously optimize the model. The design form of CatBoost enables it to efficiently process category-type features, thus making up for the shortcomings of DCN model in processing discrete features, and finally forming a complete recommendation model through multiple iterations, improving the accuracy of music recommendation. At the same time, CatBoost proposed the use of TS-based ordered transport stream (Ordered TS) and a new classification feature processing algorithm to solve the problem of target leakage and prediction offset in Boosting algorithm, and improve training speed and accuracy. The Ordered TS coding principle is shown in Figure 3.4.

From Figure 3.4, in Ordered TS coding principle, the classification feature values of samples are converted into a sequential coding. For a particular sample, its coded value is calculated based on the sample that comes before it. When one of the classification features of the sample is the same as that of the previous sample, the corresponding Ordered TS encoding value is adopted.

This method can help solve the problem of target leakage and prediction deviation in Boosting algorithm, and improve the training speed and prediction accuracy of the model by considering the order relationship between samples. Ordered TS code principle in the sample x_i , under the classification feature k' is $x_i^{k'}$, and the

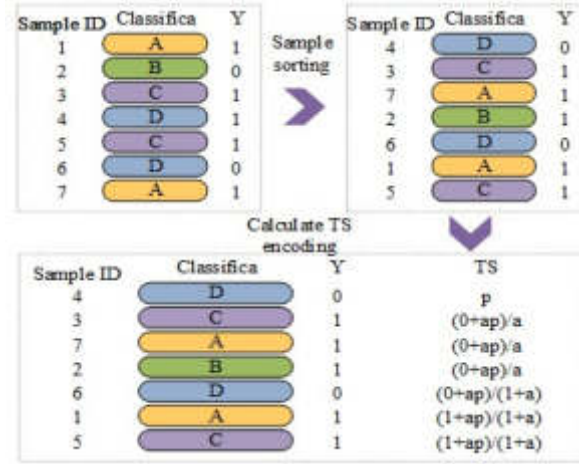

Fig. 3.4: Ordered TS encoding principle

encoding value of $x_{i'}^{k'}$ is calculated based on the sample D_σ that ranks first in the value. The TS encoding value of the same sample as $x_{i'}^{k'}$ under the classification feature k in D_σ is the Ordered TS encoding value. CatBoost uses the target count method in the gradient enhancement algorithm to group categories and estimate the expected target value of each category, processing classification features with minimal information loss. The specific equation for estimating the expected target is shown in equation (3.7).

$$\hat{x}_{k'}^{i'} \approx E(y/x = x_{k'}^{i'}) \tag{3.7}$$

In equation (3.7), y means the expected goal. When the i' feature values of other samples are equal to $x_{k'}^{i'}$, the expected value of this category is used to replace the i' feature of the k' sample, which means that the discrete feature is reassigned. Because $x_{k'}^{i'}$ is calculated from the target values of the samples, there will be conditional biases when splitting the test set and training set. The expression for obtaining a prior value is shown in equation (3.8).

$$P_1(y = 1/x^i = C) = 0.5 \tag{3.8}$$

In equation (3.8), P_1 denotes the TS value; C indicates the category. Therefore, it assumes that there is a category feature with all feature values taking different values, the numerical values for replacing category features in the classification category are shown in equation (3.2).

$$\hat{x}_{k'}^{i'} = \frac{yC + aP_1}{1 + a} \tag{3.9}$$

In equation (), a represents a constant, but for the test set, if all TS values are 0.5, it is not possible to classify and predict the test data. Therefore, a threshold is used for classification, and the threshold expression is shown in equation (11).

$$t = \frac{0.5 + aP_1}{1 + a} \tag{3.10}$$

In equation (), t denotes the threshold. Afterwards, the training samples are randomly sorted, and the prior values and weight coefficients of the prior values are added to the mean of the category labels before the samples, thereby reducing the impact of low-frequency category features. The expression for defining the encoding value

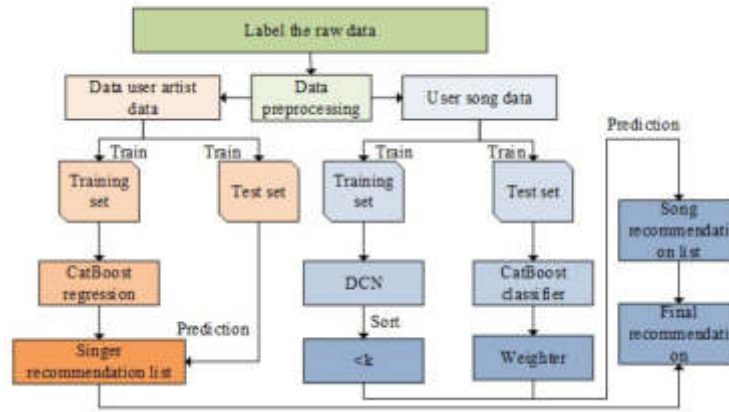

Fig. 3.5: Flow chart of hybrid recommendation model

is shown in equation (3.11).

$$\hat{x}_{k'}^{i'} = \frac{\sum_{x_j \in D_k} I[x_j^{i'} = x_{k'}^{i'}] \square y_j + aP_1}{\sum_{x_j \in D_{k'}} I[x_j^{i'} = x_{k'}^{i'}] + a}, D_{k'} = \{x_j : \sigma(j) < \sigma(k')\} \quad (3.11)$$

In equation (3.11), D refers to all datasets available for model training; $D_{k'}$ indicates a subset of D ; σ represents a constructed random sequence; y_j is the eigenvalues of sample j . To achieve more accurate and personalized recommendation algorithms, music recommendation is divided into two parts: song and singer recommendation. In the dataset prediction section, mixed classification models and regression models are used for prediction. This generates a music recommendation list for different users, and the hybrid recommendation model flowchart is shown in Figure 3.5.

From Figure 3.5, the hybrid recommendation model proposed in this study combines deep learning and machine learning technologies. The model achieves accurate recommendation through four main stages. The first stage is to label the raw data to extract key information and hidden features. In addition to basic song information and user behavior data, the research also focuses on users' historical listening records, song emotional labels, rhythms, genres and other additional information, so as to provide a more comprehensive view of user preferences and song characteristics, which is conducive to accurate recommendation in the future. At the same time, in the process, the research also extracts singer information from the original data, forms a new singer data set, and splits it into a training set and a test set. Then, in the second stage, the song training data is input into DCN and CatBoost classifiers for training and parameter tuning. DCN, with its powerful feature crossover ability, helps capture complex relationships between songs. In order to improve the generalization ability and accuracy of the model, additional information such as sentiment analysis data of songs, user comments, and community tags are also introduced at this stage of the study to enable the model to understand songs and user preferences from multiple dimensions. At the same time, the singer training set is input into the CatBoost regression model for training, which is able to efficiently process the classification features and prevent overfitting with specific enhancement techniques, thus ensuring the accuracy of the recommendations. In the third stage, the trained DCN model is used to predict the song test set, generate a list of predicted values, and set the filtering range to form a new data set. The trained CatBoost regressor is used to predict the score of the singer test set and generate the singer recommendation list. This process incorporates the user's recent listening behavior and feedback, which is used as an important reference for dynamically adjusting the recommendation list. Then, the CatBoost regressor is used to predict the score of the singer test set and generate the singer recommendation list. Finally, in the fourth stage, CatBoost classifier is used for secondary classification prediction, and additional information such as users' social network information and geographical location data is integrated in this stage, so as to provide users with more personalized and

localized music recommendations to further refine the recommendation results. Finally, the recommended list of songs and artists is combined to generate personalized music recommendations for users.

4. Results.

4.1. Parameter design and performance evaluation of CatBoost-DCN. After constructing the CatBoost-DCN hybrid music recommendation model, to verify the superiority of the constructed CatBoost-DCN algorithm, it attempted to compare CatBoost-DCN with CatBoost, LightGBM, and Stacking-XLC algorithms in the same dataset. The experimental dataset included four parts: user, song, operation and song additional information tables. The dataset variables for music recommendation are shown in Table 4.1.

Table 4.1 shows all the data sets involved in this experiment. The experimental data set included more than 2,000 user song operation records, data labels on whether users listen to songs repeatedly, 150 user attribute information and more than 1,000 song information, ensuring the comprehensiveness and diversity of the data. Then, the four algorithms were tested in the data set, and the ROC curve, accuracy rate, recall rate, error value and other indicators of the four algorithms in the data set were compared and analyzed. The comparison results of ROC curve and accuracy of the four algorithms are shown in Figure 4.1.

Figure 4.1 shows the ROC curves and accuracy plots of CatBoost-DCN, CatBoost, LightGBM, and Stacking-XLC algorithms. As shown in Figure 4.1 (a), compared to the other three algorithms, the CatBoost-DCN algorithm had a maximum area of approximately 0.85 in the ROC curve, while the other three algorithms had areas of 0.75, 0.53, and 0.51, respectively. The results showed that CatBoost-DCN algorithm had higher

Fig. 4.2: Performance comparison of various models

performance in distinguishing positive and negative samples, and the classification effect was better. From Figure 4.1 (b), from the comparison results of algorithm accuracy, after stable training, CatBoost-DCN had the highest accuracy, at 96.13%, which was 19.91% higher than CatBoost, 29.69% higher than LightGBM, and 12.71% higher than Stacking-XLC. The results showed that the CatBoost-DCN algorithm performed well in the classification task and could correctly classify most samples into the correct categories. Therefore, from the two dimensions of area under the ROC curve and accuracy, CatBoost-DCN showed higher performance than the other three algorithms. This shows that the CatBoost-DCN algorithm can get more accurate classification results in practical applications. The advantages of CatBoost-DCN may come from its unique algorithm design and optimization strategies, which enable the algorithm to extract features more efficiently, reduce the risk of overfitting, and improve generalization ability when dealing with complex data. As shown in Figure 4.2, the error and accuracy of the four algorithms would be analyzed next.

Figure 4.2 shows the error and precision analysis of the four algorithms. The broken line section represents the error curve of the algorithm, and the bar chart section represents the precision of the algorithm. As shown in Figure 4.2, the training error of CatBoost-DCN, LightGBM, CatBoost, and Stacking-XLC was 0.013%, 0.065%, 0.034%, and 0.023%, respectively. The results demonstrated the high precision and low error of CatBoost-DCN algorithm in the process of model training, indicating that the algorithm can fit the data more accurately and reduce the prediction bias. In the precision comparison, CatBoost-DCN had a precision of 95%, approximately 19%, 17%, and 10% higher than LightGBM, CatBoost, and Stacking-XLC, respectively. The results showed that CatBoost-DCN algorithm had excellent precision in classification tasks and could identify all kinds of samples more accurately. In summary, CatBoost-DCN is significantly better than the other three algorithms in the two key indicators of error rate and precision, which indicates that CatBoost-DCN algorithm can provide more precise and reliable classification results in practical applications. Next, the recall and accuracy of the four algorithms were analyzed and sorted, and the results are shown in Figure 4.3.

In Figure 4.3 (a) of the PR curve, the area of CatBoost-DCN was 0.89, with the largest area, approximately 0.33 higher than LightGBM, 0.17 higher than CatBoost, and 0.11 higher than Stacking-XLC. The results showed that the CatBoost-DCN algorithm had excellent performance in the comparison of PR curves, and could identify positive samples more effectively while maintaining a low false positive rate. As shown in Figure 4.3 (b), the recall rates of CatBoost-DCN, LightGBM, CatBoost, and Stacking-XLC algorithms were 92.7%, 71.1%, 76.1%, and 83.2%, respectively. This data showed that CatBoost-DCN algorithm could find out the real positive class samples more comprehensively and reduce the cases of missing reports in classification tasks. According to the comprehensive analysis of Figure 4.3(a) and Figure 4.3(b), CatBoost-DCN showed obvious advantages from the comparison results of PR curve and recall rate. This advantage may be due to its advanced algorithm design and fine parameter tuning, so that the algorithm can more accurately capture the internal structure of the data when dealing with classification problems, thus providing more reliable and comprehensive classification results. The results also further confirm that CatBoost-DCN algorithm is expected to obtain better classification

Fig. 4.3: Recall and precision of four algorithms

Fig. 4.4: Recall and precision of four algorithms

performance in practical applications.

4.2. Evaluation of CatBoost-DCN recommendation model results. To compensate for the low accuracy of a single algorithm, a CatBoost-DCN dual filtering music hybrid recommendation model was constructed. For the binary classification problem of the CatBoost-DCN hybrid model, four indicators, precision, recall, AUC, and accuracy, were used to evaluate and analyze the performance of CatBoost-DCN. To obtain the optimal model and parameters, the above four indicators were used as the evaluation criteria for the model, and testing was conducted based on learning rate and depth. The results are shown in Figure 4.4.

Figure 4.4 shows the final results of learning rate tuning and decision tree tuning. Figure 4.4 (a) shows that when the learning rate was 0.1, the optimal model score was 0.7516, and the overall learning rate showed a trend of increasing first and then decreasing. Figure 4.4 (b) indicated that when the decision tree depth was 12, the optimal model score could be obtained, which was 0.76449. When the decision tree depth was 6, the model score showed an upward trend. When the decision tree depth was within the 9-12 range, the increase in model score significantly increased and reached the highest value. When the decision tree depth was after 12, the score showed a downward trend. The original test set consisted of 1342 pieces of data. The predicted values of CatBoost and DCN in the hybrid model were weighted and fused to obtain the final probability. The

probabilities were then sorted to form a corresponding recommendation list, and finally recommendations were made to users. The optimal parameter settings for the CatBoost-DCN model for final singer recommendation and song recommendation are shown in Table 4.2.

Table 4.2 shows the CatBoost-DCN parameter settings. The number of trees in the song recommendation bar was 1000. When the depth of the tree was 12, the maximum feature combination tree was 2, the regularization coefficient was 6, the number of numerical feature divisions was 31, and the maximum number of unique hot codes was 255. The number of trees in the singer recommendation column as 600. When the depth of the tree was 8, the regularization coefficient was 3, and the numerical feature segmentation tree was 32. After the parameters were adjusted, the model was called to predict the test set, and the top eight singers with the highest scores were recommended to users. In addition, to further analyze the performance of the CatBoost-DCN model, a comparative analysis was conducted among the CatBoost-DCN hybrid model, the DCN model, and the SVD model. At the same time, to verify the superiority of CatBoost-DCN, models with different algorithms such as DCN-LGB and DCN-XGB were selected for comparison. The results are shown in Figure 4.5.

The bar chart in the upper half of Figure 4.5 shows the performance comparison results among DCN, SVD,

and CatBoost-DCN models. The results showed that the AUC area of CatBoost-DCN was 0.93, the precision was 0.91, the accuracy was 0.95, and the recall was 0.92. The scores of CatBoost-DCN were higher than those of DCN and SVD models. Compared with the DCN model, the CatBoost-DCN hybrid model improved in all indicators, with an increase of approximately 7.2% in AUC, 3.4% in accuracy, 2.2% in precision, and 2.1% in recall. The above results showed that the combination of CatBoost and DCN could effectively improve the predictive ability and stability of the model. The lower half of Figure 10 shows the comparison of indicator performance among different mixed models. The AUC area of CatBoost-DCN was approximately 0.05% more than DCN-LGB and 0.15% more than DCN-XGB. The precision of CatBoost-DCN was approximately 0.07% higher than DCN-LGB and 0.09% higher than DCN-XGB. The accuracy of CatBoost-DCN was approximately 0.11% higher than DCN-LGB and 0.15% higher than DCN-XGB. The recall rate of CatBoost-DCN was approximately 0.16% higher than DCN-LGB and 0.23% higher than DCN-XGB. The above data fully proved the superiority of CatBoost-DCN hybrid model in various indicators. CatBoost-DCN showed strong prediction and classification ability both in the comparison of single models and in the competition of mixed models. To sum up, CatBoost-DCN hybrid model has significant advantages in the field of music recommendation, and its overall performance improvement is due to the perfect combination of CatBoost and DCN. The hybrid model can not only extract features more effectively and reduce the risk of overfitting, but also improve the generalization ability and prediction accuracy of the model.

5. Discussion. From the simulation results, CatBoost-DCN model showed significant advantages in several evaluation indicators. Compared with the other three algorithms (CatBoost, LightGBM, and Stacking-XLC), CatBoost-DCN had significant improvements in ROC curve area, accuracy, error rate, and precision. This is mainly due to CatBoost-DCN's unique algorithm design and optimization strategy, which enables it to extract features more efficiently, reduce the risk of overfitting, and improve generalization. The results of this study were significantly improved compared with the indicators of the music recommendation model proposed by Yun et al. [21]. In comparison with the DCN model and SVD model, CatBoost-DCN also showed excellent performance. The AUC area, accuracy, precision and recall rate were higher than those of the two models. In particular, compared with the DCN model, CatBoost-DCN improved in all indicators, with AUC improving by about 7.2%, accuracy by 3.4%, precision and recall by 2.2% and 2.1%, respectively. These results showed that the combination of CatBoost and DCN could indeed significantly improve the predictive power and stability of the model. The research results were compared with the research results of the music recommendation model proposed by Wang team in 2023, and it was found that the overall performance of the proposed model was better [18]. In addition, the performance of different hybrid models was compared. The results showed that CatBoost-DCN was superior to DCN-LGB and DCN-XGB models in AUC area, precision, accuracy and recall ratio. This result further confirmed the superiority of CatBoost-DCN hybrid model. Compared with other relevant studies, the application of CatBoost-DCN model in the field of music recommendation has significant advantages. This is mainly reflected in its overall performance improvement, including higher accuracy, lower error rate, and better generalization ability [5]. These advantages enable the CatBoost-DCN model to provide users with more accurate and personalized music recommendation services.

In summary, the CatBoost-DCN model shows excellent performance in music recommendation applications. Its advantages come from unique algorithm design and optimization strategies, which enable the model to extract features more effectively, reduce overfitting risks, and improve generalization ability when dealing with complex data. The results of comparison with other algorithms and models further confirm the superiority of CatBoost-DCN. Therefore, in the field of music recommendation, CatBoost-DCN model is expected to achieve better recommendation results and user satisfaction. In addition, because the CatBoost-DCN model performs well in processing complex data with a large number of category characteristics and numerical characteristics, it also has a wide range of application potential in other recommendation fields such as e-commerce product recommendation, video content recommendation, and social network friend recommendation.

6. Conclusion. The personalized demand for music recommendations from different users on music platforms is increasing, and traditional music recommendation models have shortcomings such as long-time consumption and insufficient personalization. This study attempted to integrate the CatBoost algorithm with DCN and constructed a CatBoost-DCN hybrid model to recommend personalized music to meet the needs of a large number of network users. During training, CatBoost, LightGBM, and Stacking-XLC algorithms were selected

for performance analysis with CatBoost-DCN. In performance analysis, this model was superior to CatBoost, LightGBM and Stacking-XLC algorithms in ROC area, accuracy, error rate, recall area, and precision. Among them, the ROC area of CatBoost-DCN was 0.85, the accuracy was 96.13%, the error rate was only 0.013%, the recall area was 0.89, the precision rate was 95%. Compared with single and other models, CatBoost-DCN also performed well in AUC area, precision, accuracy and recall. The results above showed that the CatBoost-DCN hybrid model showed excellent performance in personalized music recommendation, which is significantly better than the traditional recommendation algorithm. This study found that by integrating CatBoost and DCN, the research successfully improved the accuracy and efficiency of the recommendation system, and effectively met the personalized needs of Internet users for music. However, there are also shortcomings in the research. At present, the CatBoost-DCN model does not take into account how user interests may change over time. Future studies can further refine the model by introducing techniques such as time series analysis to more accurately capture users' dynamic music preferences.

DESIGN OF TEST TURNTABLE BASED ON FUZZY PID ALGORITHM AND ITS ERROR CORRECTION

LI TANG* AND ZHOU LIANGFU†

Abstract. In order to meet the requirements of antenna for high bearing capacity, high positioning accuracy and speed stability of the test turntable, a test turntable with simple operation is designed. First of all, the structure of the turntable is introduced. The turntable adopts the form of gear transmission and multi-turn absolute encoder angle measurement. The mechanical simulation analysis of the turntable table is carried out, and the static performance and modal characteristics of the turntable are analyzed. Then, the servo control system of the turntable is introduced. The multi-turn absolute encoder is used as the detection element of the actual position of the turntable. The target position is sent to the controller by the upper computer through the serial port. The controller uses the field programmable logic gate array (FPGA) as the core, and the encoder, controller and control object constitute the position loop; In the software design, the fuzzy PID algorithm is used to replace the traditional PID algorithm. Finally, the turntable accuracy test platform is built, and the autocollimator and polyhedral prism are used to obtain the angle measurement error. The test results show that the control accuracy is better than $\pm 0.01^\circ$, the system position accuracy is better than 2.5', and the turntable positioning accuracy and rotational speed stability have been effectively improved.

Key words: Servo; Turntable; Fuzzy control; FPGA.

1. Introduction. In the design of high-precision turntables, commonly used forms of power transmission include direct drive, worm gear transmission, and gear transmission [6]. The worm gear transmission has the advantages of large reduction ratio, smooth transmission, low noise, and large bearing capacity; Gear transmission has the advantages of accurate transmission ratio, stability, high efficiency, high working reliability, and long service life. The load-bearing capacity, position accuracy, smoothness of speed, and system stability of the test turntable will directly affect the testing effect of the test turntable. Therefore, the control strategy for the motor in the control system of the test turntable is crucial. At present, there are various control algorithms for motors [13, 21]. Le K M [8] proposes an algorithm based on improved PI control current to improve the performance of the motor. It determines the control parameters through the parameters of the motor and the speed of operation; Tran H N [15] proposed a method based on an effective phase compensator to improve the accuracy of the motor; Zhai Yan [20] and Changjun Zhao [22] propose an algorithm based on fuzzy adaptive control, which performs fuzzy control on classical PID and adjusts the control parameters according to different situations automatically. Sliding mode variable structure control algorithms have good control effects on nonlinear factors. [12, 1, 4]

The author has designed a high-precision gear transmission turntable and conducted mechanical analysis on the turntable using ANSYS software. The maximum deformation of the loading table is 0.026mm, and the maximum stress is 0.95MPa, both of which are far less than the strength limit of the material; At the same time, a control strategy based on the fuzzy PID algorithm is adopted. Fuzzy control can formulate control strategies based on engineering experience, which is suitable for nonlinear and uncertain systems such as turntable control systems. Fuzzy control is used to adjust the proportional integral derivative coefficients of PID online, which not only has the advantages of simple and reliable PID control, but also enables the turntable to better cope with sudden disturbances and has excellent control performance. And the error effect was verified using a polyhedron prism, with a control accuracy better than $\pm 0.01^\circ$ and a system position accuracy better than 2.2', meeting the requirement of antenna testing 3'. At the same time, the speed stability of the turntable was

Fig. 2.2: Adjusting the backlash of the eccentric shaft sleeve

effectively improved.

2. Turntable structure design. The turntable mainly consists of a pair of transmission gears, data gears, reducer, absolute multi-turn encoder, motor, etc. The structural diagram of the turntable is shown in Figure 2.1.

According to the load requirements of the turntable, through analysis and calculation, combined with the Mechanical Design Manual, the gear module is determined, in which the gear ratio is 23:181, the data gear ratio is 1:8, and the speed ratio of the reducer is 100. The large total deceleration ratio ensures the load-bearing capacity of the turntable.

The absolute multi-turn encoder is used to measure the actual position of the turntable, and the main technical parameters of the encoder are shown in Table 2.1.

The encoder is installed coaxially with the data gear, and the data gear is installed parallel to the output gear, with a data gear ratio of 1:8. So compared to the spindle, the encoder resolution reaches $4.9''/8=0.62''$. However, the backlash of gears can affect the positioning accuracy and stability of the system, so it needs to be effectively overcome. There are different methods for adjusting the backlash of different types of gear transmission pairs. The eccentric shaft sleeve adjustment method is used here, as shown in Figure 2.2. By adjusting the eccentric shaft sleeve, the center distance between the input and output gears can be changed.

Considering the requirements of matching the torque, rated speed, and inertia of the motor, a three-phase synchronous servo motor is chosen here.

Fig. 3.1: Table deformation analysis

Fig. 3.2: Turntable stress analysis

3. Mechanical simulation analysis. The flatness and end face runout of the turntable' table determine the installation accuracy of the antenna load and have a significant impact on the testing effect. Under load, the deformation and vibration of the table also have an impact on the turntable, which cannot be ignored. Therefore, mechanical analysis of the table top is necessary. This article uses ANSYS software for mechanical analysis of the turntable. [23, 11, 9]

The load table of the turntable is made of aluminum alloy material, with a density of 2770 kg/m^3 , a tensile yield strength of 280Mpa, a comprehensive yield strength of 280Mpa, and a tensile ultimate strength of 310Mpa. The analysis results are shown in Figures 3.1 to 3.3. Figure 3.1 shows the deformation analysis results of the table after applying load, Figure 3.2 shows the stress analysis results of the turntable, and Figure 3.3 shows the modal analysis results of the turntable.

According to the design requirements, the turntable needs to meet the load requirement of a maximum load of 50 kg. With the turntable as the center, a distributed load is added and a force of 500 N is applied to the turntable surface. Through the analysis of the above simulation results, it can be seen that the maximum deformation of the loading platform is 0.026mm, and the maximum stress is 0.95MPa. Both parameters are

Fig. 3.3: Turntable modal analysis

Fig. 4.1: Servo system control block diagram

far less than the strength limit of the material.

4. System hardware composition. The servo control system of the testing turntable mainly consists of an upper computer, a controller, a driver, an encoder, and a motor. The servo system receives control commands from the upper computer through the RS-422 serial port, and reports information such as position, speed, and fault codes. The servo controller is implemented using the Cyclone series FPGA, which is responsible for receiving feedback angle from the encoder. Its NIOS II core completes the calculation of the guidance command, and the calculation results are sent to the driver through the CAN bus. The speed and current loops are calculated in the driver, and finally the driver generates a sinusoidal pulse width modulation (SPWM) signal to drive the motor to move [14]. The system is shown in Figure 4.1.

5. System software design.

5.1. Fuzzy PID control strategy. In this system, the load is large and the inertia is large. Under the action of step response, the deviation is usually not eliminated in a short time, and the integral term can cause significant overshoot, even causing system oscillation and reducing system stability [5, 18, 10]. At the same time, in order to meet the control quantity changes caused by the quality differences of different testing equipment, it is necessary to use control methods with good adaptability. Fuzzy control modifies PID parameters based on fuzzy reasoning, obtaining different correction values based on the size of the deviation, thereby affecting the original PID parameters and accelerating the system response time while ensuring control accuracy. [3, 7] This article adopts a fuzzy PID control strategy to achieve the requirements of precise position control and fast response of the testing turntable. This article designs the algorithm for the position loop of the system. The speed loop and current loop are completed by the selected driver. Effective control of the testing turntable is achieved through position loop control combined with driver parameter settings.

5.2. Design and Simulation of Fuzzy PID Controller. In this turntable control system, the angular position deviation e and the variation of angular position deviation e_c are selected as input variables to complete fuzzy control. Adopting a second-order fuzzy controller, the deviation signal and the variation of the deviation signal are used as the control signals of the entire control system. The ΔK_P , ΔK_I , ΔK_D derived from fuzzy reasoning principles and PID parameters (K_P , K_I , K_D) work together on the controlled object, and θ_{in} represents the target angle issued by the upper computer, θ_{out} represents the current actual angle output by the encoder, the structural flow of the fuzzy PID controller is shown in Figure 5.1.

Establish a fuzzy domain for the control signal, select an appropriate membership function curve for fuzzification processing, and obtain the fuzzy output according to the control rules [16, 2, 17]. Set the basic universe of input variables e , e_c and output variables ΔK_P , ΔK_I , ΔK_D to $[-6, +6]$. Input variables e and e_c correspond to language variables E and E_C , the output variable ΔK_P , ΔK_I , ΔK_D corresponds to the language variable

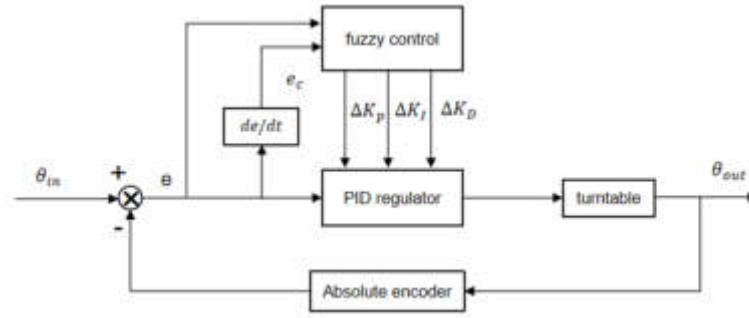

Fig. 5.1: The Structural Process of Fuzzy PID Controller

PB	ZO/ZO /PB	ZO/ZO /PM	NM/PS /PM	NM/PM /PM	NM/PM /PS	NB/PB /PS	NB/PB /PB

ΔK_P , ΔK_I , ΔK_D . The fuzzy quantization levels of the input and output language variables E , E_c , ΔK_P , ΔK_I , ΔK_D are [NB (negative large), NM (negative weight), NS (negative small), O (zero), PS (positive small), PM (positive middle), PB (positive large)].

According to the membership function of variable E , E_c , ΔK_P , ΔK_I , ΔK_D , the fuzzy control rules formulated are shown in Table 5.1.

The mathematical model $G(s)$ of the turntable motor is a second-order system, and the relationship between the input and output of the controller is:

$$\omega = K_P e + \int_0^t e(t) dt + K_D \frac{de(t)}{dt}$$

After discrete processing:

$$\omega(k) = K_P e(k) + K_I \sum_{j=0}^k e(j) + K_D [e(k) - e(k-1)]$$

In the equation: $\omega(k)$ and $e(k)$ are the output values and deviation values at the k -th sampling time, using a step signal as the excitation signal of the system. After multiple experiments, the initial PID value of the algorithm is determined.

Obtaining Actual PID Controller Parameters through Demystification:

$$K_P = k_P + \Delta K_P, K_I = k_I + \Delta K_I, K_D = k_D + \Delta K_D,$$

Fig. 5.2: Modeling of Fuzzy PID Control System

Fig. 5.3: Comparison of Two PID Effects

Among them, k_p , k_I and k_D are conventional PID parameters.

Input fuzzy rules into the fuzzy controller and make relevant settings to establish a simulation model of the turntable control system based on fuzzy PID, as shown in Figure 5.2. In the figure, the sum of the input step signal and feedback signal is inputted into a PID controller, and then output through a transfer function.

Through the SIMULINK modeling and simulation environment of MATLAB simulation software, a comparison was made between fuzzy PID control and traditional PID control. Figure 5.3(a) shows the simulation results of ordinary PID and Figure 5.3(b) shows the simulation results of fuzzy PID. The comparison shows that the entire process output of the fuzzy PID controller is smoother, with less speed oscillation. At the same time, due to strong control adaptability and high control accuracy, it can meet the requirements of motion control for this test turntable.

5.3. Software design. The system software mainly consists of FPGA based controller software for the lower computer. The software design includes functions such as controlling motor operation, adjusting fuzzy PID parameters, and processing relevant data to achieve precise positioning of the turntable. The controller has an RS422 interface for communication with the upper computer. The upper computer sends control instructions based on custom messages through the RS422 serial port, while the lower computer controller constantly reports

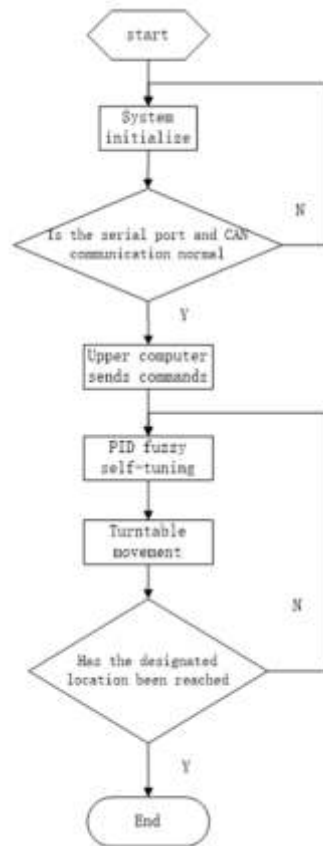

Fig. 5.4: System software structure diagram

information such as system angle, speed, and self status. The system software structure diagram is shown in Figure 5.4.

The system first initializes itself, checks whether the serial port and can communication are normal, and constantly reports the current angle and system status to the upper computer. After normal operation, the controller receives instructions from the upper computer, judges the validity of the instructions, and then completes PID fuzzy self-tuning. The driver drives the turntable to move until the turntable reaches the designated position, ending the control process.

6. Error analysis. In order to test the accuracy of the turntable, according to the *Main Performance Testing Methods for Inertial Technology Testing Equipment*, an angular position measurement test is adopted [19]. The measurement principle is shown in Figure 6.1, and the testing system includes a testing turntable, a 24 sided prism, an autocollimator, and an adjustable tripod. The actual test turntable is shown in Figure 6.2.

The experiment adopts a 24 sided prism. Firstly, from the angle feedback of the measured axis to display the 0 position, record the initial reading of the theodolite θ_1 , Then rotate the measured axis by 15° in sequence based on the angle feedback display value, and record the corresponding readings of the theodolite $\theta_2 \dots \theta_{24}$, at last Calculate the error at each point using the following formula:

$$e_i = \theta_i - \theta_1 (i = 2, \dots, 24), \text{ The test data is shown in Table 6.1.}$$

In Table 6.1, the system measured significant errors at positions 30° , 70° , 225° , and 270° , exceeding $100''$. This is mainly due to structural machining accuracy errors and transmission errors, resulting in significant errors at several fixed positions throughout the system. According to national standards, take the maximum positive error in the calculation results $e^+ = 152''$, the maximum negative error $e^- = -118''$, $\frac{e^+ - e^-}{2} = 2.25'$.

Fig. 6.1: Principle of Position Measurement Test

Fig. 6.2: device detection

Table 6.1: Test turntable error of fuzzy PID algorithm

Set Angle(°)	Measurement value(")	error value(")	Set Angle(°)	Measurement value(")	error value(")
0	228				
15	291	63	360	230	2
30	390	152	345	321	93
45	259	31	330	301	73
60	270	42	315	241	13
75	365	137	300	267	39
90	219	-9	285	163	-65
105	218	-10	270	122	-106
120	263	35	255	209	-19
135	212	-16	240	198	-30
150	199	-29	225	100	-118
165	324	96	210	254	26
180	181	-47	195	240	12

After multiple measurements and taking the average value, it is found that the positioning accuracy of the turntable is better than 2.2'.

During the testing process, the rotational speed of the turntable (1-10°/s) is set, and after considering the total system deceleration ratio, it is converted into the motor speed (rpm). By reading the speed of the motor during operation, the maximum and minimum values of the motor speed during stable operation are recorded. Table 6.2 shows the speed stability of the fuzzy PID algorithm.

The relative error of the turntable measured by this control strategy is 1.9%, which is better than 3.2% of the ordinary PID. Meanwhile, the lower the rotational speed of the turntable, the poorer its speed stability.

Table 6.2: Speed error during fuzzy PID control

Serial Number	Set speed(°/s) (motor speed)	Motor speed range(rpm)	Relative error (%)	Overall relative error(%)
1	1(92.7rpm)	88~97	4.6	1.9
2	2(185.5rpm)	178-191	2.9	
3	4(371.0rpm)	365-380	1.6	
4	6(556.5rpm)	550-562	1.1	
5	8(742.0rpm)	737-746	0.7	
6	10(927.5rpm)	923-931	0.5	

7. Conclusion. This article designs a single axis electric turntable based on the requirements of high positioning accuracy and speed stability of the testing turntable. The system adopts a three-phase synchronous servo motor+reducer+gear transmission method, and the table is made of aluminum alloy material; The control system adopts a fuzzy PID control strategy to achieve the requirements of precise position control and fast response of the testing turntable. The equipment has the characteristics of large load-bearing capacity, high accuracy, and stable speed. Research has shown that:

(1) The turntable adopts gear transmission and multi turn absolute encoder angle measurement, with high transmission torque. The static and modal analysis of the turntable was conducted using ANSYS simulation software, verified that the testing turntable can meet the requirements of high load-bearing, high precision, and smooth operation;

(2) The fuzzy PID algorithm is used to replace the traditional PID algorithm, and an autocollimator is used to measure the positioning error of the turntable. The accuracy of the turntable system can reach 2.2', which is better than 2.6' of ordinary PID, and the running speed is more stable.

In future research and design of the turntable, in terms of machinery, we will consider reducing the clearance between gears from the perspective of improving part machining accuracy and assembly accuracy, or eliminating the clearance through coordinated work of dual motors, in order to achieve the goal of smaller system errors; In terms of control strategy, modern control methods such as sliding mode variable structure control algorithm that have good control effects on nonlinear factors can be used to control the turntable.

A VISUAL WEBPAGE INFORMATION EXTRACTION FRAMEWORK FOR COMPETITIVE INTELLIGENCE SYSTEM

ZHIWEI ZHANG*, WENBO QIN[†] AND HAIFENG XU[‡]

Abstract. The extraction of webpage information is of paramount importance in the realm of competitive intelligence. This research is dedicated to the design and implementation of a visual webpage information extraction module within a competitive intelligence system, approached through the lens of research and development (R&D) technology and its practical applications. Initially, the study delineates the objectives and requirements for webpage information extraction, emphasizing the practical needs of competitive intelligence systems. By critically assessing the strengths and weaknesses of current theories and methodologies in webpage text information extraction, this paper introduces an innovative visual method for extracting webpage text information. Subsequently, the paper meticulously outlines the comprehensive architecture of the proposed module. Building upon this foundation, the study delves into the specifics of the extraction template, rule generation, optimization techniques, and the extraction algorithm pivotal to the process of visual webpage information extraction. The system's effectiveness and practical utility are substantiated through a series of confirmatory experiments, the results of which are thoroughly analyzed. The findings affirm that the developed system adeptly fulfills the webpage information extraction needs of competitive intelligence systems, contributing significantly to the R&D efforts in which the authors are engaged.

Key words: Information extraction visualization, natural language processing, competitive intelligence, data mining

1. Introduction. With the exponential growth of the Internet and significant advancements in information technology, the digital landscape has emerged as the predominant arena for corporate and institutional information dissemination. An array of content, including corporate profiles, product details, promotional events, recruitment opportunities, and technological advancements, is extensively published online [25, 26, 14]. Recent studies underscore that a vast majority (approximately 90%) of the data requisites for competitive intelligence analyses are sourced from the Internet, underscoring the critical role of web-based information in today's business milieu [33, 19, 28]. Competitive intelligence encompasses a comprehensive system of information gathering, analysis, and dissemination, designed to equip businesses with profound insights into competitors, market dynamics, and industry evolutions. Within this framework, webpage information extraction assumes a pivotal position, empowering entities to not only distill invaluable insights from the deluge of data but also to leverage such insights for tangible competitive edges. Particularly in the big data era, navigating the complexities of data processing and analysis presents formidable challenges [19, 18, 24].

Webpage information extraction refers to the process of automatically retrieving structured or semi-structured information from unstructured webpage content. This process involves identifying relevant pieces of data within a webpage, such as text, images, links, and other multimedia elements, and then transforming this data into a more organized format that is suitable for analysis, storage, and further processing [1, 13]. The goal of webpage information extraction is to enable computers to understand and utilize the vast amount of information available on the Internet efficiently. This technology underpins various applications, including search engines, competitive intelligence systems, market research, and content aggregation services, facilitating the automatic collection and analysis of web data [27, 17].

In the realm of competitive intelligence systems, the task of webpage information extraction encounters significant hurdles due to the sheer diversity and complexity of webpage contents. The digital landscape is a mosaic of information presented in myriad forms ranging from text, images, videos, tables, to interactive

[‡]School of Informatics and Engineering, Suzhou University, Suzhou, China.

elements, each differing vastly in format and structure across websites. This variability presents a formidable challenge in crafting a one-size-fits-all, efficient information extraction system [8, 6]. For example, product descriptions might be straightforward text or be supplemented with images and videos, while technical articles could include intricate diagrams or snippets of code. Moreover, the inherent complexity within HTML structures, coupled with the ever-evolving designs of webpages, complicates the accurate retrieval of information, necessitating highly flexible and adaptive strategies for extraction [21, 12]. Ensuring the comprehensiveness and precision of extracted information thus requires leveraging sophisticated text processing and image recognition technologies [9, 23].

Furthermore, competitive intelligence systems grapple with the challenges posed by the variability of noise data, webpage formats, and structures. The internet is inundated with noise advertisements, promotional links, and irrelevant comments clutter webpages, obscuring valuable information. Effectively sifting through and excluding such noise is a crucial task in the extraction process [30, 5]. This necessitates not only the development of sophisticated algorithms capable of discerning between relevant and irrelevant content but also their ongoing refinement to keep pace with the dynamic nature of the web. The diversity in webpage design and layout demands that extraction systems be versatile enough to navigate a variety of HTML/CSS structures [20, 15]. Additionally, the rapid evolution of web technologies and the introduction of new standards for webpage design and layout further amplify the complexity, challenging information extraction systems to continuously adapt to these new formats and structures [2, 31].

The challenges of real-time updates and information overload significantly complicate the task of webpage information extraction. The dynamic nature of the Internet, with its continuous influx of new content and the potential modification or removal of existing information, presents a critical challenge for competitive intelligence systems. Timely tracking and management of these changes are crucial, as reliance on outdated or inaccurate information could result in erroneous analyses and decision-making [11, 29]. Furthermore, the exponential growth in online content has precipitated an era of information overload, posing a substantial challenge. Competitive intelligence systems are thus tasked with the efficient processing and filtering of this vast amount of data to ensure the extraction and analysis of only the most relevant and valuable information. Consequently, these systems must possess not only robust data processing capabilities but also sophisticated data screening and prioritization mechanisms. Such features are essential to navigate through the vast data landscape effectively, preventing the degradation of analysis efficiency or decision-making errors that could arise from information overload [32, 3].

Within the domain of competitive intelligence systems, visual webpage information extraction technology presents clear advantages over traditional text extraction methodologies [4, 7]. Primarily, the visual approach enhances the efficiency and accuracy of information extraction by offering an intuitive display of data structures and content. Traditional methodologies, which predominantly rely on semantic analysis and keyword matching, frequently fall short in addressing webpages characterized by intricate structures or varied formats. Conversely, visual extraction technology capitalizes on the visual layout and structural features of webpages to more precisely locate and extract pivotal information. For instance, by scrutinizing the Document Object Model (DOM) structure and visual indicators on webpages, elements such as article titles, texts, images, and tables can be more effectively identified. Furthermore, visual information extraction methods substantially bolster data understanding and analysis. This approach simplifies the process for users to comprehend the overarching structure and key components of the data. The intuitive nature of this representation not only facilitates a swift comprehension of the information's essence but also aids analysts in uncovering potential data interconnections. Crucially, the visualization technique assumes added significance in the context of big data processing [16]. With data volumes expanding continuously, traditional text extraction and analysis techniques are increasingly overwhelmed. Visualization technology, through its capacity to efficiently manage and present large datasets via summary views and interactive exploration features, empowers users to grasp a higher-level understanding of the data. This, in turn, allows for the rapid identification of areas of interest, followed by detailed analysis [10, 22].

In summary, the realm of webpage information extraction technologies currently grapples with significant challenges, chiefly arising from the diversity and complexity of web content, the proliferation of noise and extraneous information, and the dynamic evolution of webpage formats and structures. These obstacles underscore the critical necessity for extraction systems that are both highly adaptable and technologically advanced,

equipped to identify and process a wide array of information types. The progression of competitive intelligence systems is contingent upon the development of more refined algorithms dedicated to noise filtration and the incorporation of cutting-edge techniques in text and image processing. Such enhancements are essential to augment the precision and depth of information extraction. Tackling these prevalent issues is crucial for the enhancement of competitive intelligence systems, enabling them to effectively and accurately harness the extensive reservoir of data available online.

Hence, the efficacy of competitive intelligence systems hinges critically on their ability to precisely distill targeted text information from the disarray of webpage source codes and to subsequently generate standardized structured documents. Such a foundational step is indispensable for the successful execution of text classification and text mining processes. In this research, we introduced a comprehensive visual webpage information extraction framework tailored to meet the specific text mining needs of competitive intelligence systems. The primary endeavors and contributions of this study are summarized as follows:

(1) This research meticulously articulated the design objectives and requirements for webpage information extraction, aiming to develop a framework that stands out for its efficiency, accuracy, and user-friendliness. Unlike existing methodologies that often struggle with the dynamic and complex nature of web data, this framework is specifically engineered to adeptly handle such challenges. It focuses on extracting crucial information by ensuring data integrity and accuracy, enhancing processing speed, and expanding system scalability, all the while improving the ease of user interaction. This approach addresses a significant gap in current practices, where the balance between comprehensive data extraction and user-centric design often remains unachieved.

(2) We introduced a holistic visual webpage information extraction framework, distinct from current solutions by its integration of cutting-edge technologies across data crawling, natural language processing, and visualization. This framework is designed to facilitate automated data extraction from a diverse array of webpages with minimal human intervention. The novel incorporation of visual elements specifically aims to demystify the user interaction process and elevate the intuitiveness of data presentation. This strategy marks a departure from traditional methods that may not fully leverage visual cues for user engagement and data interpretation, highlighting the innovative edge of our approach in enhancing both system usability and information clarity.

(3) The development and validation of a comprehensive visual webpage information extraction process underscored its applicability and effectiveness across various webpage types, both static and dynamic. The empirical evidence gathered from these experiments showcases our method's superiority in not only improving the precision of information extraction but also in significantly lightening the user's workload. This contrasts sharply with many existing techniques that may exhibit limitations in versatility across different webpage formats or impose a heavier analytical burden on users. Furthermore, the identification of potential areas for future enhancements opens new avenues for advancing the state-of-the-art in webpage information extraction. These findings offer a critical reflection on the gaps within current methodologies and provide a clear direction for subsequent research efforts, aiming to refine and augment the capabilities of competitive intelligence systems in navigating the vast and varied terrain of web information.

The remainder of this study was organized as follows: In Section 2, the design objectives and requirements of visual webpage information extraction were introduced; in Section 3, the overall framework for the visual webpage information extraction system was generalized, and three subsystems—webpage information crawling, visual webpage information extraction rule template generation, and webpage text information extraction—were elaborated on; in Section 4, the relevant experimental environment and experimental data were summarized, and the experimental results were analyzed; in the final section, conclusions were drawn and the future research directions were put forward.

2. Design objectives and requirements of visual webpage information extraction. In the context of the contemporary era, characterized by an explosion of network information, the utilization of web crawlers for webpage crawling on the Internet has become a pivotal means of information collection. However, the challenge lies in the complexity of the original webpage content obtained by these crawlers, which is often encumbered with a plethora of HTML tags. Hidden within these tags is a vast amount of text information, making the extraction process intricate and demanding.

The primary design objective of visual webpage information extraction is to navigate through this complex

maze of webpage source codes and distill high-quality text information that aligns with user needs. This task involves meticulously parsing the cluttered webpage data, identifying and extracting relevant information, and transforming it into standardized data formats such as titles, texts, and other pertinent entries. Achieving this requires a sophisticated system capable of discerning and isolating useful content from the plethora of unstructured data typically found in webpages.

From a practical application standpoint, this objective is not only feasible but increasingly necessary. The vast and growing volume of web-based information necessitates efficient and accurate extraction methods to harness this data for meaningful use. The proposed system addresses this need by employing advanced extraction techniques, focusing on the critical aspects of accuracy, reliability, and speed. In terms of system implementation, however, the feasibility is grounded in current technological advancements in web crawling, HTML parsing, and data extraction algorithms. The system's design will leverage state-of-the-art techniques in these areas, ensuring that it can effectively handle the diverse and dynamic nature of web content. This includes the capability to adapt to various webpage structures, handle different types of content (including multimedia elements), and process information rapidly and accurately.

In summary, the design objective of extracting high-quality, user-centric text information from webpages is both practical and attainable. It resonates with the current demands of information extraction in the digital age and is supported by feasible technological solutions. The implementation of such a system promises significant benefits in terms of enhancing the efficiency and effectiveness of web-based information collection and analysis. Based on the analysis aforementioned above, the design and requirements of the webpage information extraction system must focus on the following key aspects:

(1) Accuracy and completeness: The accuracy of extraction is the primary system design objective, meaning that the system should focus on extracting specific target items (such as titles, texts and abstracts) while excluding all unspecified noise information. In addition to accuracy, completeness is also of crucial importance, ensuring that the extracted target items retain complete contextual semantics so as to provide support for subsequent operations on standardized documents.

(2) Timeliness and efficiency: Considering the huge amount of webpage resources on the Internet, the webpage information extraction system needs to have efficient processing ability. Web crawlers, which usually run in a distributed and multithreaded way, can grab a large number of original webpages in a short time. Therefore, the system should be able to extract specific target items accurately and completely from the original webpages in time and efficiently and quickly form standardized documents.

(3) Adaptability: The rapid development of Web technology means that the structure of webpages is frequently updated. In this context, the web information extraction system needs to be self-adaptable to some extent. When the existing information extraction templates and rules fail to correctly extract webpage information, for instance, the system should be able to give an alarm and use the wrong feedback information to adjust the extraction rules and templates in time to adapt to the latest webpage structure.

(4) Practicality: While meeting the professional requirements, the webpage information extraction system should also consider the use needs of non-professional users. This means that the user interface of the system should be intuitive and easy to use, while ensuring the powerful and stable functions of the system to adapt to the operating habits and skill levels of different users.

To sum up, in order to effectively support the collection and analysis of competitive intelligence, the web information extraction system must meet high standards in accuracy, timeliness, adaptability, and practicality.

3. Overall framework for the visual webpage information extraction system. The visual webpage information extraction system is comprised of three integral subsystems: (1) a webpage information crawling subsystem, which retrieves data from the internet; (2) a visual webpage information extraction rule template generation subsystem, tasked with creating rules for data identification and extraction; and (3) a webpage text information extraction subsystem, dedicated to isolating textual content from webpages. The comprehensive structure of this system is illustrated in Figure 3.1, providing a cohesive overview of its components and operational flow.

From the overall framework for the visual webpage information extraction system as shown in Figure 3.1, the system is generally divided into three subsystems whose composition, functions, and techniques used are briefed as follows:

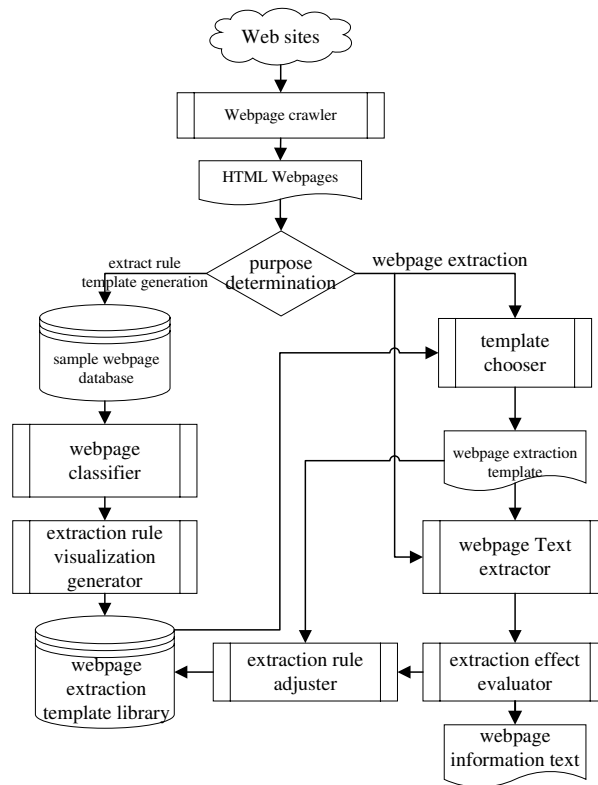

Fig. 3.1: Overall framework structure for the visual webpage information extraction system.

(1) Webpage Information Crawling Subsystem: This subsystem employs a webpage crawler to gather webpage information (source code) from designated sites based on predetermined seed site URLs and crawling strategies. The captured data is stored in the sample webpage library" depicted in Figure 3.1 for future use or as input for the webpage text information extraction subsystem" for text data extraction. Developed on the open-source Nutch search engine, this subsystem has been customized to fulfill the unique requirements of our research.

(2) Visual Webpage Information Extraction Rule Template Generation Subsystem: As illustrated in Figure 3.1, this subsystem integrates the sample webpage library," sample webpage classifier," visual webpage extraction template generator," and webpage extraction template library." Representing the innovative core of this study, it generates extraction rule templates for specific webpages using samples from different sections of the target site, storing these templates in the webpage extraction template library." It primarily utilizes the open-source htmlparser, which has been adapted and refined for this research.

(3) Webpage Text Information Extraction Subsystem: Comprising the webpage extraction template selector," webpage information extractor," extraction effect evaluator," and webpage template adjuster" as shown in Figure 3.1, this subsystem extracts information from the original webpages collected by the webpage information crawling subsystem." It utilizes site-specific extraction rule templates developed by the visual webpage information extraction rule template generation subsystem" to output standardized webpage text information. Utilizing the open-source htmlparser for formatting and extracting text from specific webpage tags, this component has been enhanced for research purposes.

The aforesaid subsystems will be introduced one by one from the angles of design and implementation, and the algorithm used by each subsystem will be introduced and analyzed in detail.

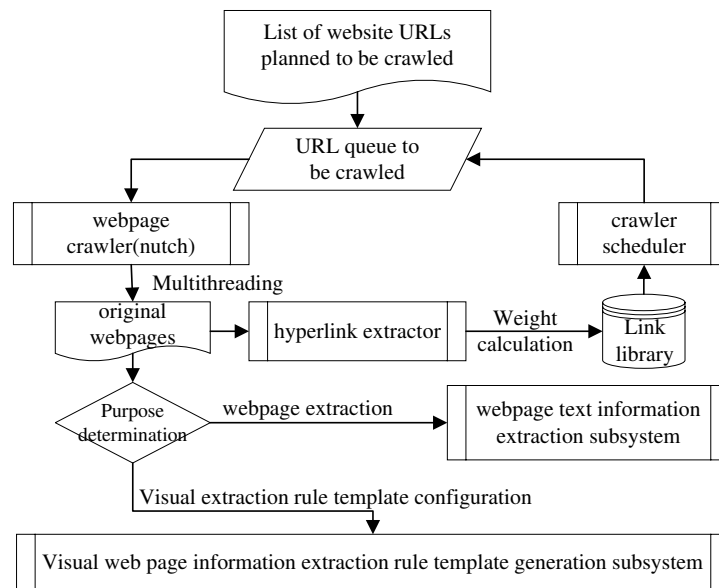

Fig. 3.2: Framework for the webpage crawling subsystem.

3.1. Webpage information crawling subsystem. This subsystem focuses on retrieving webpages from the Internet, archiving the initially crawled content in a sample webpage library for subsequent use or directly forwarding it to the webpage text information extraction subsystem for data extraction. It has been developed and enhanced using the open-source Nutch search engine, tailored specifically to meet the research requirements of this study. The comprehensive structure of the webpage crawling subsystem is depicted in Figure 3.2.

The workflow of the improved webpage crawling subsystem is as follows:

(1) An initial set of URLs for crawling sites is established, comprising a document that lists URLs from various seed sites.

(2) These seed site URLs are then populated into CrawlDB, a database dedicated to storing the URLs and their status information for webpages.

(3) Utilizing the data within CrawlDB, a comprehensive list of URLs for site crawling is compiled, based on both the URL and status information.

(4) Employing the Nutch multi-threaded crawler, the system proceeds to crawl webpages as delineated by the URL list of crawling sites, generating relevant webpage snapshots from the content retrieved during the crawl and logging the crawl process. Concurrently, hyperlinks contained within the webpages are analyzed, facilitating the output of the original webpage stream.

The webpage hyperlink information parsed in Step (4) is used to update CrawlDB; Steps (3) to (4) are repeated until reaching the preset crawling depth or the crawling task is manually stopped, so as to form a cyclic process of generation-crawling-updating.

3.2. Visual webpage information extraction rule template generation subsystem. In the visual operation environment, the objective is to achieve precise and clear generation of information extraction rule templates, thereby obviating the need for complex algorithm-derived parsing rule templates. This section delves into and implements the visual webpage information extraction rule template generation process and its specifics. Within the browser/server (B/S) visual environment, the "target extraction item region" is selected via mouse, facilitating the automatic generation and extraction of rules for the "target extraction items." Concurrently, specific extraction rules are compared and calibrated within this environment. The detailed implementation steps are outlined as follows:

(1) All the sample webpages belonging to the site S are read from the sample webpage library, and displayed after sorting according to their webpage URL, so as to facilitate the subsequent URL template configuration for each module of the site S through the observation method.

(2) With site S 's samples displayed post-sorting, webpages from different modules naturally cluster together. A URL template for module T of site S is set up through observation differentiating sample webpages by URL strings with identical prefixes and manually crafting matching URL regular expressions.

(3) A unique extraction template is created for each module. If module T on site S already has a corresponding extraction template, this step is bypassed; otherwise, a unique extraction template P is generated.

(4) Specific extraction rules for target extraction items are established for all webpages within module T of site S . It's important to recognize that all webpages in module T are issued through the same information release template backstage, making their structures identical (or similar) aside from text differences. In this research, three sample webpages from module T were chosen at random to visually create extraction rules for target extraction items.

3.3. Webpage text information extraction subsystem. The webpage information extraction subsystem constitutes a crucial component of the comprehensive visual webpage information extraction system. It employs predefined extraction rule templates to retrieve pertinent data from "target extraction items" on webpages, aggregating these items into a standardized document output. This subsystem is comprised of the extraction template selector, webpage information extractor, extraction effect evaluator, and webpage extraction rule template adjuster, as depicted in Figure 3.3.

3.3.1. Relevant data structure. The data structures utilized for extracting information from webpages via extraction rule templates are outlined as follows:

(1) Webpage parsing result object *tagNodeList*: The NodeList-type object obtained by parsing the webpage source code with `htmlparser` is a tree-structured type of data and an operation object generated by extracting target items with the webpage extraction rules.

(2) Extraction rule *ParseRule*: The position of the target extraction item region in the webpage is marked, that is, the absolute path (webpage tag sequence) from the DOM tree root node of the webpage to the target extraction item region, aiming to guide the webpage information extraction subsystem to extract the specific target extraction items.

(3) Extraction template *ParseTemplate*: It is a set of the extraction rules for each target extraction item, and the concrete templates for the specific sites are encapsulated.

(4) Extraction rule list *ruleList*: It is a data structure of `List<ParseRule>` type, which stores the extraction rules for all target extraction items under the same extraction template.

(5) Extraction rule list *itemRuleList* of target extraction items: It is also a data structure of `List<ParseRule>` type, which encapsulates multiple extraction rules for a specific target extraction item.

(6) Extraction rule tag list *ruleTagList*: It is the object of `List<String>` type. The extraction rule is a tag string sequence composed of all tags on the path from the tag of the root node of the webpage to the tag of the parent node of the target extraction item, which is a whole character string, and the *ruleTagList* stores a list of character strings with a single tag as a character string, that is, a list composed of single tags.

(7) Matching tag sequence stack *pathStack* and node child queue *childQueue*: The *pathStack* records already matched path tags, being the objects of `Stack<TagNode>` type, and *childQueue* encapsulates all child nodes of one node.

(8) Standard document *StructuredDoc*: It is a data structure of `Map<TargetItem, Text>` type, which encapsulates the text information of target extraction items, including the titles, abstracts, keywords, and texts of webpages.

3.3.2. System workflow. Figure 3.3 illustrates the comprehensive workflow of the "webpage text information extraction subsystem," detailed as follows:

(1) The web crawler of the webpage crawling subsystem designed in Section 3.1 is enabled to configure the information of the crawling site and the related attributes of the web crawler to the site S (*siteID*) in a multi-threading way for webpage crawling. Then, the URL *pageURL* of webpages is extracted and the webpages are returned in the form of source codes to generate the character string *pageSource* output of webpage source

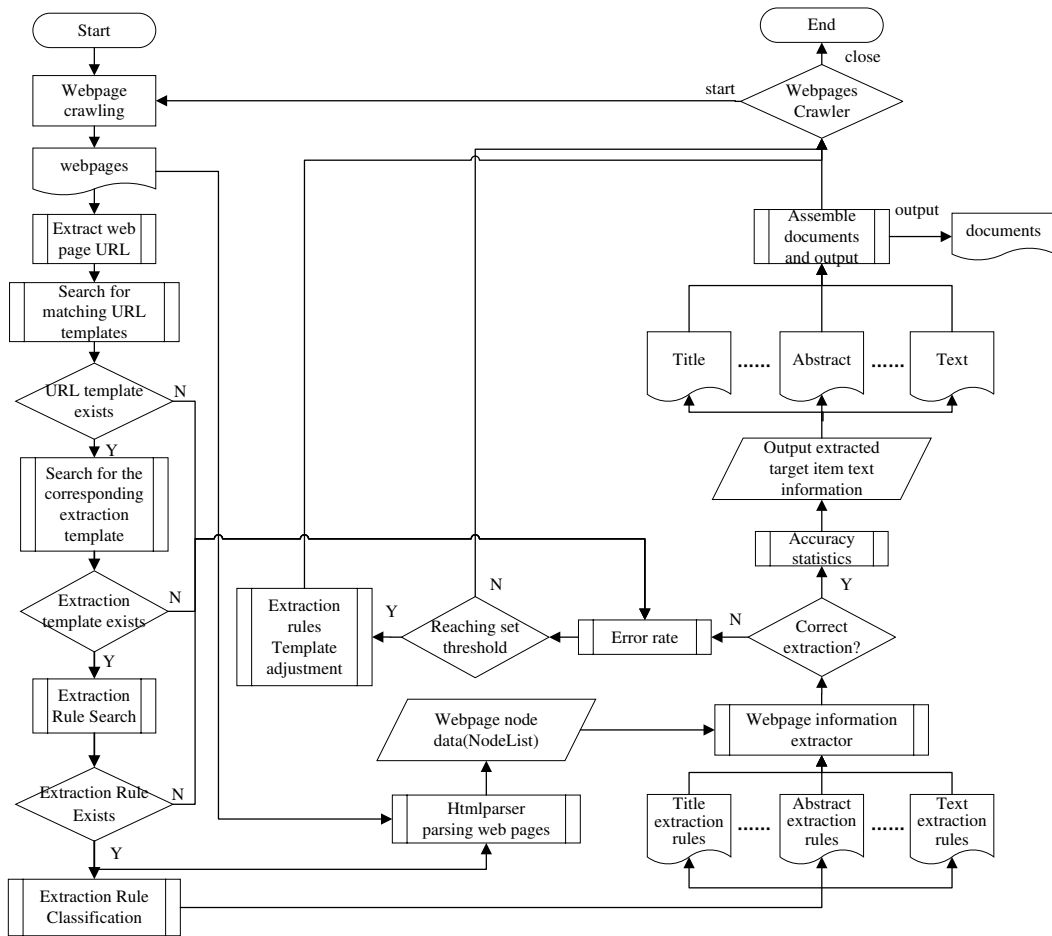

Fig. 3.3: The workflow of the webpage text information extraction subsystem. Initially, the subsystem commences with the advanced data crawling phase, employing state-of-the-art technology to navigate and retrieve content from a diverse array of web sources. This phase is critical for ensuring that the most current and relevant webpage data is captured for analysis, addressing the challenge of the internet’s ever-evolving content landscape. Then the subsystem applies natural language processing (NLP) tools to the raw webpage content. This involves sophisticated semantic analysis to identify and isolate valuable text information from the surrounding web elements and noise. The NLP phase is crucial for refining the data into a format that is both meaningful and actionable, setting our approach apart from conventional methods that may struggle with the complexity of web content structures. The final stage of the workflow integrates visualization technology to present the extracted information in an intuitive and user-friendly manner. This not only simplifies the interaction process for users but also enhances their ability to comprehend and analyze the data.

codes.

(2) *SiteID* in Step (1) is used to acquire all URL template *urlTemplateList* belonging to this site from the database. If *urlTemplateList* is empty, skip to Step 3.3.2, or otherwise, *pageURL* in Step (1) is matched with the URL regular expression in *urlTemplateList* one by one. If matching fails all the time, skip to Step (11). If matching succeeds for a single template, the *urlTemplateId* of this URL template is recorded.

(3) The extraction template ID *parseTemplateId* belonging to this URL template is acquired from the database. If it is empty, skip to Step (11), or otherwise, the next step will be implemented.

(4) All extraction rules belonging to this extraction template are searched in the database via *parseTemplateId* in Step (3), and a value is assigned to *ruleList*; if *ruleList* is empty, skip to Step (11), or otherwise, the next step will be implemented.

(5) The extraction rules in Step (4) are classified according to the target extraction items to form the extraction rule *itemRuleList* of each target extraction item *PT*.

(6) The *pageSource* in Step (1) is parsed using *htmlparser* to generate *tagNodeList*. Since the operation on *tagNodeList* is destructive, *pageSource* is parsed again using *htmlparser* to generate new *tagNodeList* before extracting the text information of different target extraction items.

(7) Each extraction rule object in *itemRuleList* in Step (5) is cyclically traversed. Each extraction rule object is converted into *ruleTagList*, and a pointer *i* pointing to *ruleTagList* is set and initialized as 0, i.e., pointing to the first element of *ruleTagList*.

(8) The node information on the first tag node *curNode* of *tagNodeList* is matched with *ruleTagList[i]* using *tagNodeList* in 3.3.2 and *ruleTagList* in Step (7). If matching fails, turn to Step (10); if matching succeeds, *curNode* joins in *pathStack*, and all child nodes of *curNode* enqueues in *childQueue*; next, an element is dequeued from *childQueue*, a value is assigned to *curNode*, and $++i$, meaning that the pointer pointing to *ruleTagList* shifts forward by one position.

(9) The node information on *curNode* is matched with *ruleTagList[i]*: 1) if matching succeeds, *curNode* joins in *pathStack*, *childQueue* is emptied, and all child nodes of *curNode* re-enqueue in *childQueue*; 2) if matching fails, a node element is unqueued from *childQueue* to assign a value to *curNode*, which matches with *ruleTagList[i]* once again, and if this succeeds, Step 1) is repeated; if the matching fails, Step 2) is repeated; 3) if all child nodes fail in matching, a node element is shifted out of *pathStack*, and a value is assigned to *curNode*, namely, $-i$, *childQueue* is emptied, all matched child nodes of *curNode* are enqueued in *childQueue*, and Step (9) is repeated; 4) if all *ruleTagList[i]* are matched, the matching succeeds, all text information *targetString* under *curNode* is taken out to form $\langle PT, targetString \rangle$ pairs, which are stored in *structureedDoc*, and then turn to Step (5), the information of the next target extraction item is extracted. If the information of all target extraction items is extracted, turn to Step (12); 5) if a *ruleTagList[i]* fails in matching, or the child nodes of one *curNode* are empty and *ruleTagList* is not completely traversed, turn to Step (10); If *pathStack* is empty or the tag path composed of the nodes therein is different from *ruleTagList*, turn to Step (10).

(10) If extraction (matching) is incorrect, one is added to the extraction error counter to calculate the extraction error rate *W*. If *W* is greater than or equal to the preset threshold *TH*, turn to Step (13), or otherwise, turn to Step (1).

(11) If the working state of the web crawler is off, exit from the whole webpage information extraction system; if the working state of the web crawler is on, turn to Step (1), followed by the next round of webpage crawling.

(12) Turn to Step (2) for information extraction for the webpages crawled in this round but not subjected to information extraction (the web crawler crawls multiple webpages in each ground under the multi-threading mode); if all webpages are extracted, turn to Step (1).

(13) The specific extraction rules are regenerated according to the generation and calibration method for the extraction rule template of target extraction items.

From the perspectives of system implementation and application, the detailed process of visual webpage text information extraction is depicted through the following pseudo-code, as presented in Algorithm 1.

4. Experimental results and analysis.

4.1. Experimental environment. To assess the performance and efficiency of the “visual webpage information crawling” system within a specific hardware and software environment, a detailed experimental scheme was devised to evaluate the system’s real-world operational efficacy. The hardware setup for the experiment comprised a computer equipped with an AMD Ryzen 5 PRO 2500U processor, featuring a Radeon Vega Mobile GFX integrated graphics card and a base clock rate of 2.00 GHz, alongside 8GB of RAM. On the software front, the experiment utilized Apache Nutch, a highly extendable, open-source webpage crawler software designed for harvesting original webpage data from the Internet. This combination of tools enabled the effective processing of Chinese texts and facilitated the extraction of information from a broad array of online resources.

Algorithm 17 *parseToFormStrDoc*(String pageURL, int siteId, String pageSource)**Input:** Web Page URL pageURL, website ID siteId, webpage source pageSource**Output:** structured document structuredDoc

```

1: Map<Integer, StringBuffer>structuredDoc; // the extracted structured documents.
2: // obtaining a url template matching the web page URL based on the webpage
3: // URL and its associated site id
4: URLTemplate urlTemplate = getMatchURLTemplate(pageURL, siteId);
5: // acquiring the webpage parsing template based on the URL template
6: ParseTemplate parseTemplate = getParseTplmtByURLTplmt(urlTemplate);
7: //obtaining the webpage extraction template and all extraction rules
8: List<ParseRule>ruleList = getParseRulesByParseTemplate(parseTemplate);
9: // categorizing by 'extraction target items' to form sets of extraction rules for each
10: // respective extraction target item
11: for parseRule in ruleList do
12:     List<ParseRule>itemRuleList; // Extraction rule list.
13:     utilizing the extraction rule set 'itemrulelist' to extract text information corresponding to the 'extraction target
        item';
14:     for itemRule in itemRuleList do
15:         NodeList tagNameList = parseHtmlTagName(pageSource); // HTML tags node list.
16:         StringBuffer targetString;
17:         // separating 'itemRule' (Label Path) and storing it as an array of strings
18:         itemParseRule = splitToStrList(itemRule); // HTML text parse rules.
19:         int ruleListLength = itemParseRule.size();
20:         int ruleListIndex = 0;
21:         // utilizing parsing rules for the actual analysis of web pages
22:         NodeList childList; // The child node list of a specified node in a webpage.
23:         if (matching the root element of tagNameList with itemParseRule[ruleListIndex]) then
24:             childList = rootTagName.getChildren();
25:             ++ruleListIndex;
26:         else
27:             Terminating the Information Extraction for the Specified 'Extraction Target Item';
28:         end if
29:     end for
30:     while childList not empty do
31:         int childIndex = 0;
32:         for childIndex < childList.size() do
33:             Node tmpNode = childList.elementAt(childIndex);
34:             if tmpNode instanceof TagNode then
35:                 TagNode curTagNode = (TagNode) tmpNode;
36:                 tag1 = curTagNode.getText(); // Extract the text information from a webpage node.
37:                 tag2 = ruleList.get(ruleListIndex);
38:                 if tag1 == tag2 then
39:                     if ruleListIndex != (ruleListLength - 1) then
40:                         childList = curTagNode.getChildren(); // Get child nodes of the current node.
41:                         ++ruleListIndex;
42:                     break;
43:                     else if complete matching of parsing rules then
44:                         NodeList curChilds = curTagNode.getChildren();
45:                         for (int j = 0; j < curChilds.size(); ++j) do
46:                             targetString += Text Information of Each 'Child Tag';
47:                         end for
48:                     end if
49:                     structuredDoc.put(extraction of target item number, extraction of target item text information);
50:                 end if
51:             end if
52:         end for
53:     end while
54:     if (several nodes in the extraction rule do not match) then
55:         terminating the information extraction for the specified 'Extraction Target Item';
56:     end if
57: end forreturn structuredDoc;

```

4.2. Evaluation indexes. To thoroughly assess the performance of the “visual webpage information extraction” system, this study adopted three evaluation metrics commonly utilized in the domain of text information processing: accuracy, recall, and F-measure, ensuring a broad applicability of our findings. These metrics are extensively recognized for their effectiveness in gauging the performance of diverse information processing systems, offering a holistic perspective on the efficacy of the visual webpage information extraction system.

Accuracy, a metric quantifying the system’s proficiency in extracting accurate information, is defined by Equation 4.1 as the ratio of correctly extracted information items to the total number of extraction attempts. This index directly mirrors the precision of the information extracted by the system, providing a clear indication of its reliability.

$$Accuracy = \frac{TP}{TP + FP} \quad (4.1)$$

where TP (True Positive) and FP (False Positive) represent the number of relevant information items correctly extracted and the number of nonrelevant information items wrongly extracted, respectively.

Recall assesses the system’s capability to retrieve all pertinent information, as delineated in Equation 4.2. Specifically, it represents the ratio of relevant information items accurately identified by the system to the entire set of relevant information items. The significance of recall lies in its focus on the system’s comprehensiveness, highlighting its ability to capture essential information without omissions.

$$Recall = \frac{TP}{TP + FN} \quad (4.2)$$

where FN (False Negative) stands for the number of unextracted relevant information items.

In summary, accuracy serves as a comprehensive indicator of the model’s performance in all detections, whereas recall specifically zeroes in on the model’s proficiency in accurately identifying true positives among all actual positives. These metrics are pivotal for assessing and benchmarking model performance, especially in domains where distinguishing between various error types is critically important.

Accuracy and recall exhibit a dependent relationship, with an ideal scenario featuring high values for both. Generally, a high accuracy often corresponds with lower recall, and vice versa. Should both metrics register low, it indicates a fundamental issue with the model. Consequently, the F-measure, defined as the harmonic mean of accuracy and recall, emerges as a crucial metric for gauging overall system performance, as encapsulated in Equation 4.3. By integrating both accuracy and recall, the F-measure offers a singular metric to appraise the comprehensive performance of the system.

$$F - measure = \frac{2 * Accuracy * Recall}{Accuracy + Recall} \quad (4.3)$$

The efficacy of the “visual webpage information extraction” system across different dimensions can be thoroughly assessed by a composite evaluation of the aforementioned metrics. Employing these evaluation indices not only enables a detailed performance analysis of the system but also lays the groundwork for subsequent system enhancements.

4.3. Analysis of data and experimental results. In this research, we conducted practical application tests focusing on specific sites for webpage crawling and information extraction from designated websites. It’s crucial to emphasize that, aligned with the application demands, this study leveraged the visual webpage information extraction framework and methodology introduced herein to target and retrieve only the essential information from webpagesnamely, the titles and the core textual contentfor the purpose of performance evaluation. Other data categories, including comments and links, were also amenable to processing via the outlined extraction techniques in this research. The websites selected for analysis in this study were primarily specialized enterprise portals, characterized by a limited number of site modules and a uniform, straightforward webpage structure across these modules, featuring minimal noise data. Given that the webpage information on these sites predominantly consisted of webpage titles and texts, the extraction rule templates were specifically tailored

Table 4.1: Test results for accurate extraction of webpage text information.

Site Name	#webpages	Title			Main Text		
		Recall	Accuracy	F-measure	Recall	Accuracy	F-measure
Yunnan Tobacco	1650	99.27%	99.83%	99.55%	98.92%	97.97%	98.44%
Yunnan Tin Group	2001	99.37%	99.52%	99.44%	98.94%	96.30%	97.60%
DIHON	1076	98.63%	90.49%	94.38%	98.95%	85.37%	91.66%
Yunnan Copper Group	2439	95.32%	92.66%	93.97%	95.37%	83.26%	88.90%
Yunnan Ruisheng Pharmaceuticals	3083	93.26%	93.27%	93.2650%	93.59%	81.53%	87.14%

for these elements. Subsequent extraction tests were carried out to ascertain the efficacy of these templates, with the resultsextraction accuracy and recall ratespresented in Table 4.1. This focused approach ensures the study's methodologies remain broadly applicable without sacrificing specificity and relevance to the targeted application contexts.

In this research, extraction rule templates were meticulously developed for five selected special portal sites, leading to the execution of a comprehensive webpage information extraction test, uncovering distinct patterns in the accuracy of title versus text extraction, the complexity of text extraction rules, and the variability across and within portal sites with different themes. The outcomes of these tests are systematically detailed in Table 4.1. The results obtained from these experiments are analyzed as follows:

(1) Accuracy Variance between Title and Text Extraction: The experimentation unveiled a consistent trend where the accuracy of title extraction surpasses that of text extraction. This phenomenon can be attributed to the relatively straightforward structure of webpage titles, which are typically positioned near the top of the page, closely aligned with the root nodes of the Document Object Model (DOM) structure. Consequently, the "title extraction rules" generated are succinct and straightforward, leading to a lower error rate. In contrast, text content, often interspersed with images and tables, presents a more intricate structure. The current extraction system's limitations in processing such complexities result in diminished accuracy for text extraction.

(2) Complexity of Text Extraction Rules: Text content, predominantly located in the middle to lower sections of a webpage and further from the DOM root node, introduces additional challenges. The diverse text formats, such as bolded fonts and color highlights, complicate the creation of effective extraction rules, thereby impacting accuracy. Moreover, the htmlparser tool currently in use may not adequately recognize certain special tags during text processing, hindering the application of accurate extraction rules.

(3) Variability Across Different Themed Portal Sites: The structural differences among webpages of varied themed portal sites lead to discrepancies in extraction accuracy. These variations underscore the complexity of webpage organizational structures, which in turn influences the formulation and effectiveness of extraction rules. Each portal site features navigation pages rich in URL information and static pages containing textual content. The absence of tailored extraction rules for navigation pages compromises the system's ability to extract information from such pages, thereby affecting the recall's completeness. Despite these challenges, the overall recall performance aligns well with the system's design and theoretical expectations.

(4) Intra-site Variability: Within individual themed portal sites, a similar pattern emerges, with title extraction consistently achieving higher accuracy than text extraction. This finding aligns with the comparative analysis across different sites, further emphasizing the inherent challenges in extracting text information due to its complex structure and the extraction system's current limitations.

The above comprehensive analysis not only highlights the specific challenges faced in webpage information extraction but also sets the stage for future improvements in extraction technologies and methodologies, aiming to enhance both accuracy and efficiency in competitive intelligence systems.

Following its deployment into trial operation, the system has elicited favorable feedback from its users, underscoring its user-friendly interface, ease of operation, and transparent procedural flow. Notably, it has demonstrated remarkable operability, particularly for non-professional users, achieving high levels of extraction accuracy and recall that align well with practical demands. However, traditional systems often present a steep learning curve and may compromise on either user-friendliness or technical robustnesschallenges that this system adeptly navigates. Its capacity to combine simplicity in design with sophisticated functionality

addresses a crucial gap in the field, where the balance between accessibility for novice users and meeting the advanced needs of professional scenarios has frequently been elusive.

The analysis of experimental outcomes not only deepens our comprehension of the system's operational efficacy but also accentuates its practical utility and appeal across user demographics. This nuanced understanding is pivotal, as it transcends mere operational success to underscore the system's alignment with user-centric design principles—a facet often overlooked in the pursuit of technical excellence. This reflection prompts a critical dialogue within the realm of webpage information extraction systems, advocating for a paradigm where user engagement and technical precision coalesce. The insights gleaned from this trial phase, therefore, not only spotlight the system's current achievements but also chart a course for future enhancements. Emphasizing user feedback in the iterative process of system refinement offers a roadmap for evolving beyond the constraints of traditional methodologies, ensuring continued relevance and utility in an ever-changing digital landscape.

In sum, this analysis not only validates the system's effectiveness and user satisfaction but also serves as a foundational critique against which the limitations of existing methods are measured. It lays the groundwork for ongoing innovation, encouraging a holistic approach to system design that prioritizes both user experience and technical rigor.

5. Conclusion. This research primarily sheds light on the pivotal role of webpage information extraction in the competitive intelligence domain. Specifically, it introduces and develops a visual webpage information extraction module within a competitive intelligence system, bridging the gap between technological research and practical application. Initially, the article sets out to define the objectives and requirements essential for webpage information extraction, critically assessing the strengths and weaknesses of current theories and methodologies related to webpage text information extraction. This critical analysis lays the groundwork for the introduction of an innovative approach to visual webpage text information extraction. Additionally, the study elaborates on the comprehensive framework of this module, delving into the nuances of the extraction template, rule generation, optimization method, and extraction algorithm integral to the visual webpage information extraction process. This thorough exploration ensures a deep understanding of the complexities associated with the development and operationalization of the visual webpage information extraction module within the competitive intelligence framework.

This study has made a significant contribution to the field of competitive intelligence by proposing and implementing an efficient visual webpage information extraction system. The system encompasses three key subsystems: a webpage information crawling subsystem, a visual webpage information extraction rule template generation subsystem, and a webpage text information extraction subsystem. A notable innovation within this study is the 'generation of the visual webpage information extraction rule template', which offers new tools and methods for the domain. The system's efficacy and practicality have been demonstrated through extraction tests on specific themed portal websites, evidenced by the analysis of experimental results.

Future research directions stemming from this work should focus on several key areas. Firstly, enhancing the robustness and adaptability of the visual webpage information extraction rule template is paramount. This could involve integrating machine learning techniques to enable the system to adapt to dynamically changing webpage structures and content. Secondly, expanding the system's application to a broader range of web resources, including dynamic and multimedia content, will significantly extend its utility. This could involve the development of advanced algorithms capable of handling various media formats and interactive web elements.

Another promising avenue is the exploration of deeper semantic analysis and context understanding in the extracted information. Employing natural language processing and semantic web technologies could provide more nuanced insights, particularly in fields like sentiment analysis and trend prediction. Additionally, integrating the system with big data analytics tools could offer comprehensive competitive intelligence solutions, capable of processing vast amounts of web data to derive strategic insights.

Finally, considering the ethical and privacy aspects of web data extraction is crucial. Future work should include developing guidelines and protocols to ensure compliance with data protection regulations and ethical standards. This will not only ensure the legal use of the technology but also enhance its acceptance and trustworthiness among users.

In conclusion, while this study lays a strong foundation, these future research directions offer avenues for further enhancement and application of the visual webpage information extraction system, ensuring its continued

relevance and effectiveness in the evolving landscape of competitive intelligence and web data analytics.

ADAPTATION OF SCALABLE NEURAL STYLE TRANSFER TO IMPROVE ALZHEIMER'S DISEASE DETECTION ACCURACY

EID ALBALAWI*

Abstract. Creative augmentation methods in medical imaging, particularly in diagnosing Alzheimer's disease, is a breakthrough approach in the current medical field. Alzheimer's disease, a condition that causes the gradual deterioration of cognitive abilities, presents considerable difficulties in accurately diagnosing and interpreting brain imaging, particularly in the early stages. Neural-enhance Style Transfer (NST), once recognized in the creative field for its capacity to combine the styles of many images, is currently being adapted to improve the clarity and comprehensibility of brain scans used to diagnose Alzheimer's disease. The scalability of this technology is incredibly revolutionary in managing the immense amount of neuroimaging data. In addition, this method also includes the transfer of stylistic characteristics from high-resolution, annotated brain MRIs to broader sets of standard scans, which often need to be clarified and defined. Such enhancement greatly enhances important characteristics, such as brain networks and regions of degeneration, which are essential for the early identification of Alzheimer's disease. An exemplary use of NST in this field has shown a significant enhancement in the discernibility of brain microstructures, vital for early diagnosis of Alzheimer's disease. This improvement has resulted in a considerable rise of over 25% in the accuracy of detecting first pathological alterations. This technological progress not only assists in the prompt and precise identification of medical conditions but also tackles the difficulty of effectively handling the increasing amount of neurological imaging data.

Key words: Alzheimer, disorder, style transfer, image enhancement, preprocessing, accuracy, detection, training

1. Introduction. Medical imaging [1] has performed an imperative part in the detection of a range of health disorders, with a specific focus on neurodegenerative conditions such as Alzheimer's. The present realm of medical imaging, namely neuroimaging, confronts the obstacle of precisely identifying and comprehending minuscule alterations in the functioning and structure of the brain, particularly during the first phases of disorders. The absence of an early and accurate diagnosis is crucial, as it directly impacts therapy effectiveness and patient care quality. Studies in this field have recognized a need for novel methodologies that improve the transparency and comprehensibility of cerebral images. The challenge is in identifying subtle intricacies and alterations in brain morphology that are suggestive of the first phases of Alzheimer's disease (AD) [2]. Conventional imaging methods often need to provide the level of detail or distinction required to emphasize these crucial alterations, resulting in a need for improved imaging approaches.

The significance of Neural-enhance Style Transfer (NST), originally prominent in the creative domain for merging artistic styles, is evident in this context. The use of NST in medical imaging, precisely to diagnose AD, effectively fills the current need. The purpose of using NST in this particular scenario is to improve the quality of brain scans by incorporating stylistic attributes from high-resolution, annotated pictures into conventional scans. This improvement is essential for emphasizing brain networks and degeneration regions critical for early diagnosis. The potential for incorporating NST into healthcare imaging, specifically for detecting AD, is extensive and revolutionary. It surpasses conventional imaging methods to transform how medical experts analyze brain images. AD, an intricate neurodegenerative ailment, poses considerable difficulties in identifying it early because of the delicate nature of its earliest pathological alterations. Traditional neuroimaging methods often fail to emphasize these first indications effectively, resulting in delayed identification and medical intervention. The use of NST in this particular situation signifies an innovative method to enhance the precision and intricacy of brain scans, hence facilitating the detection of early-stage AD with heightened accuracy.

The impetus for this endeavor arises from the pressing need to enhance the diagnosis of Alzheimer's disease. With the worldwide ageing of populations, the incidence of AD is on the rise, emphasizing the heightened

*College of Computer Science and Information Technology, King Faisal University, Al Hofuf 400-31982, AlAhsa, Saudi Arabia (ealbalawi@kfu.edu.sa)

need for early identification. Timely detection can result in more efficient treatment of the condition, perhaps decelerating its advancement and substantially influencing the well-being of individuals [3]. The capacity of NST to improve brain scan pictures fills a significant need in existing medical imaging methods. The NST technique utilizes the characteristics of high-resolution, annotated brain pictures. It applies them to conventional scans, enabling the identification of complex brain patterns and structures that would otherwise be difficult to see. This improvement is especially crucial for detecting regions of deterioration and atypical brain network functioning that are indicative of the early stages of AD.

The goals of using NST in diagnostic imaging for AD are manifold:

1. To enhance brain scans' clarity and comprehensibility facilitates the early detection of abnormal alterations.
2. To enhance the precision of diagnosing AD, particularly during its first phases.
3. To enhance the effectiveness of medical imaging procedures, handling the enormous quantities of neuroimaging data correctly is necessary.
4. To improve the visibility of brain microstructures, which play a crucial role in the early detection of neurodegenerative disorders.

This work makes a significant and diverse contribution. This approach showcases a novel integration use, demonstrating a deep and expert fusion of artistic innovation with scientific precision. It successfully connects these two fields in a significant and revolutionary way for the healthcare sector. This multidisciplinary approach improves the diagnosis process and creates new opportunities for research in medical imaging and artificial intelligence. Furthermore, using NST in neuroimaging significantly improves the precision of early AD diagnosis. Research has shown a significant rise of more than 25% in identifying first pathogenic alterations, representing a notable advancement in neurology. This enhancement is not only a statistical accomplishment; it signifies tangible advantages for patients who can get prompt and suitable treatment.

Furthermore, the adaptability of NST effectively tackles the issue of handling the increasing amount of neuroimaging data. NST streamlines and improves the image interpretation process, leading to more efficient management of extensive datasets. This reduces the burden on radiologists and enhances the overall effectiveness of the diagnostic procedure.

2. Related Work. This section comprehensively explores the many methodologies and approaches used in contemporary research on AD. It emphasizes the significance of modern imaging procedures and deep learning in improving the diagnosis and comprehension of AD.

Employed CNN to classify AD [4]. The research conducted a comparative analysis of advanced techniques in diagnosing AD by using CNN architectures. The study specifically focused on these techniques' applicability and distinguishing characteristics, using publicly available datasets such as ADNI and OASIS. Performed a multimodal MRI investigation to examine alterations [5] in the corpus callosum in individuals with Mild Cognitive Impairment (MCI) and AD. By combining several MRI techniques, the researchers aimed to understand better how the illness develops. Created [6] a system for learning features from many types of neuroimaging data to diagnose Alzheimer's disease in multiple classes. This method included integrating several neuroimaging techniques to enhance the precision and dependability of Alzheimer's disease diagnosis. Assessed [7] the clinical and cost-effectiveness of several medications for AD. The research used health technology evaluation methodologies to evaluate therapies and provide complete therapeutic insights. Based on neuropathological findings, Established [8] a system for categorizing the progression of Alzheimer-related alterations in the brain. Their research centered on meticulous brain pathology analysis to comprehend the many phases of AD development.

Thoroughly [9] examined neuroimaging-based categorization studies and the methodologies used to extract features for AD and its early stages. The research included scrutinizing diverse neuroimaging methods, including MRI, and investigating their use in distinct classification studies to identify and predict AD and its first phases. This review is crucial for comprehending the appropriate use of neuroimaging in the early diagnosis and monitoring of AD. Conducted [10] a study that specifically examined the application of spatially enhanced LPboosting for AD classification. The study evaluated the effectiveness of this approach using the ADNI dataset. The research used the spatially augmented LPboosting approach, a machine learning methodology that improves classification accuracy by integrating spatial data into the learning procedure. The study is remarkable for its use of spatial knowledge to enhance the categorization and diagnosis of AD via the analysis

of neuroimaging data. Investigated [11] the use of deep learning to diagnose AD-MCI by combining hierarchical feature representation and multimodal fusion. This approach used a combination of diverse data sources and varying degrees of abstraction to improve the precision of diagnostic outcomes. Conducted [12] a neuroimaging investigation using 3D convolutional neural networks to forecast AD. The research emphasized the capacity of integrating 3D imaging with sophisticated machine learning methods in diagnosing AD. Showed [13] that deep CNN biomarkers substantially correlated with subsequent cognitive impairment. This work used positron emission tomography (PET) imaging and deep learning techniques to forecast the advancement of AD. Conducted [14] a study to examine the existing theories and ideas surrounding mild dementia. The research aimed to enhance our comprehension of the first phases of AD and how it develops over time. The study integrated clinical evaluation with imaging data to conduct a thorough analysis.

Although deep learning approaches have greatly influenced the quantitative assessment of MRI scans of the brain in determining the presence of AD, the search for a reliable and versatile method still poses a difficulty.

3. Methodology. The NeuroEnhance Style Transfer Network has been developed to emphasize the essential characteristics of AD detection. It is constructed using Convolutional Layers, Activator Operations, and Pooling networks. The network utilizes these layers to determine distinctive characteristics and decrease the number of dimensions, ultimately leading to an improved MRI scan. Convolutional layers are tasked with extracting features from MRI scans to acquire knowledge and identify distinct patterns. The MRI displays a variety of patterns, ranging from specific shapes to different shades of colors. Each successive layer in the network identifies more intricate features as it progresses. Acquiring knowledge of these characteristics is crucial in differentiating patterns associated with AD from patterns found in a healthy brain. Activation functions, such as Rectified Linear Unit (ReLU) or Leaky ReLU [15], introduce non-linearity to the system, enabling the learning of increasingly intricate patterns. Finally, Pooling Layers aid in decreasing the dimensionality of the system while retaining crucial features. Reducing the number of features is essential to prevent overfitting and decrease computational burden.

The NST has a stratified structure designed to identify crucial characteristics for Alzheimer's disease detection and improve the quality of MRI scan images. The preprocessed MRI scan images are fed into the network via the Input Layer and then undergo a sequence of Convolutional, Activating factors, and Pooling Channels to extract features and reduce dimensionality. Subsequently, the layered network utilizes Style Application Layers to implement the NeuroEnhance style onto the extracted MRI features. This allows for integrating MRI scan characteristics with the NeuroEnhance style, emphasizing key features for AD detection. Ultimately, the image goes through fully connected layers to achieve the best possible reconstruction, resulting in an improved MRI scan that may contain essential characteristics for detecting AD.

3.1. Data Collection. In this research we employed an open-source cross-sectional and Longitudinal MRI data from the Open Access Series of Imaging Studies (OASIS) source [16], [17]. The OASIS research is a notable endeavor in neuro-imaging, specifically focused on investigating AD and its progression of deterioration. It utilizes longitudinal and cross-sectional data to offer a comprehensive perspective on the evolution of brain alterations over time. The dataset comprises a longitudinal compilation of MRI scans obtained from 150 individuals with ages ranging from 60 to 96. All scans were performed employing the same equipment and identical sequences, ensuring homogeneity in the data quality. Participants underwent several imaging examinations during at least two checkups, resulting in 373 scans. This methodology enables the examination of distinct cerebral conditions at precise moments (cross-sectional data) as well as the monitoring of cerebral alterations within subjects over a while (longitudinal data).

Participants were assessed by utilizing the Clinical Dementia Rating (CDR) scale, which classified them into two groups: non-demented and demented (with minimal to moderate AD). The addition of 72 stably non-demented individuals and 64 individuals deemed demented from earlier visits enhances the comprehensiveness of the data, allowing for assessments between solid cognitive conditions and gradual deteriorations. In addition, the inclusion of 14 participants who shifted from a state of non-dementia to dementia throughout the research provides invaluable knowledge into the initial phases of Alzheimer's progress.

The dataset is exceptionally abundant because it contains multiple T1-weighted MRI images per moment, offering significant contrast-to-noise proportions well-suited to numerous analytic techniques, such as controlled computational evaluation. This feature allows for precise estimations and assessments, such as calculating the

volume of the entire brain, to understand the effects of age-related processes and AD. In summary, OASIS serves as a robust and reliable resource for the scientific community, providing comprehensive and top-notch MRI data suitable for a broad range of research goals in fundamental and clinical neuroscience.

3.2. Preprocessing. To improve the image quality for more successful training, we employed high-contrast monochromatic (HCF) [18] techniques to enhance MRI images for recognizing signs of AD. MRI scans are monochromatic images. Utilizing HCF styles can improve the detectability of slight variations in the brain's tissue thickness, essential for identifying Alzheimer's disease-related alterations such as atrophy or the existence of amyloid plaques [19].

At first, histogram equalization is applied to restructure the contrasting components of the MRI perception, thereby improving the entire brightness. The improved value $P'(x, y)$ for every pixel $P(x, y)$ in the preliminary visual is computed using the cumulative distribution process of the visuals spectrum.

Next, a high-pass filtering technique [20] accentuates high-frequency elements corresponding to edges and intricate features. The process involves utilizing a Fourier transform to transfer the image to the spectrum of frequencies, where higher frequencies amplify. For determining the high-pass filtered factor $f'(U, V)$ for a specific frequency part $f(U, V)$, which is expressed as

$$f'(U, V) = h(U, V) \cdot f(U, V) \quad (3.1)$$

From Equ. 3.1, $h(U, V)$ represents the high-pass filter operator. Ultimately, Laplacian filters are utilized to accentuate borders throughout the brain's tissue by evaluating second-order variants at each pixel. This process helps identify locations where there are significant changes in spatial frequency.

3.3. Neural-enhance Style Transfer Adaptation. The convolution procedure takes a source feature map. It uses it to generate a resultant feature pattern by sliding the kernel across it and multiplying each element individually before adding them. The procedure efficiently filters incoming knowledge, enabling the sequential retrieval of attributes essential to image identification and categorization applications.

Fig. 3.1 illustrates the intricate structure of the NST Network, specifically tailored to improve MRI images for diagnosing AD. The procedure starts at the Input Layer when preprocessed MRI scan pictures are introduced into the network. Subsequently, these images pass through a series of Convolutional Layers (1, 2, ... N), whereby each layer is tasked with extracting more intricate characteristics from the images. Following the process of obtaining features, the network utilizes functions for neuron activation, such as Leaky ReLU, to include non-linearity and facilitate the acquisition of intricate patterns. Subsequently, the images undergo many pooling layers (1, ... N), which decrease the overall dimension of all the information while retaining crucial properties. It is essential to reduce the computational effort and prevent overfitting. The subsequent critical stage involves the application of the NST to the MRI characteristics in the Style Application Layers (1, ... N). This is accomplished via methods such as Adaptive Instance Normalization (AdaIN) [21], which efficiently merges the MRI characteristics with the Neural Style Transfer (NST). Ultimately, the network employs Fully Connected Layers (FCL) (1, ... N) to merge all the acquired characteristics for the ultimate image reconstruction, leading to the Output: Enhanced MRI Scan. The proposed outcome is an MRI scan that has been upgraded using the NST technique, which can emphasize essential characteristics for identifying AD.

3.3.1. Convolution Layers. The convolution procedure takes a source feature map. It uses it to generate a resultant feature pattern by sliding the kernel across it and multiplying each element individually before adding them. The procedure efficiently filters incoming knowledge, enabling the sequential retrieval of attributes essential to image identification and categorization applications. Following equation (2) exhibits the base convolutional operation.

$$C_{out}^m(x, y) = \sum_{k=-a}^a \sum_{j=-b}^b K(i, \hat{j}) \cdot C_{in}^m(x - i, y - \hat{j}) \quad (3.2)$$

From Equ. 3.2, K denotes the filter, C_{in}^{out} denote the source feature map whereas C_{in}^{in} represent the incoming feature map and m denote the corresponding MRI visual.

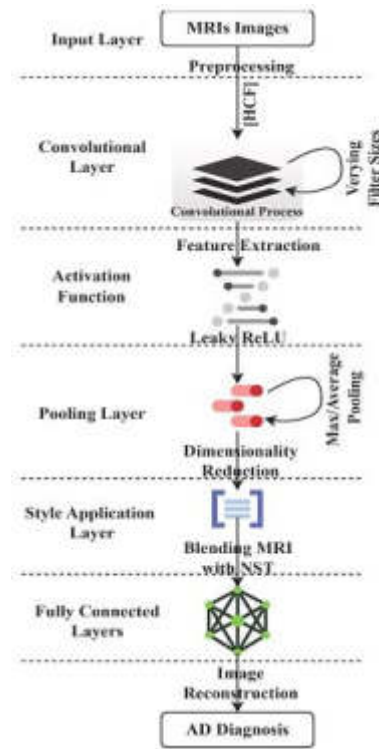

Fig. 3.1: Workflow Structure of Proposed NST Model

3.3.2. Activation Functions. At first, the unprocessed MRIs are inputted into the network. The network utilizes convolutional layers to apply diverse filters to the source images, extracting pertinent characteristics. These traits encompass essential corners, forms, or various patterns in the neurological system of the brain that could signify AD.

Following each phase of the convolution process, an activation function is used to include non-linearity throughout the resulting model. Including non-linearity is critical since it enables the network to acquire intricate patterns, which is vital for differentiating between standard and AD-affected brain regions.

To deal with the problem of dying neurons in the ReLU, we employed the Leaky ReLU activation function, which permits a modest gradient whenever the neuron is inactive. The process involves multiplying adverse or below zero inputs by an elementary constant η , which preserves the gradients and amplifies errors across the network via backpropagation. Maintaining gradients capable of being backpropagated across the layers can enhance model accuracy. Equ. 3.3 demonstrates the generalized activation process of Leaky ReLU.

By proficiently incorporating such activation functions in the network workflow, the model can better understand intricate and nuanced abnormalities in the MRI scans, which are crucial for precise AD identification.

$$\text{Leaky ReLU: } f(x) = \begin{cases} x, & x > 0 \\ \eta x, & x \leq 0 \end{cases} \quad (3.3)$$

3.3.3. Pooling Layers. Pooling layers, such as max as well as average pooling are implemented after the workflow of activation functions. Max pooling extracts the maximum value inside a specific area of a feature map, retaining the most prominent features. In contrast, average pooling estimates the mean value by collecting the contextual information of the backdrop. These processes decrease the spatial dimensions of the feature maps, enhancing the detection model’s resilience to deviations in the input visuals and mitigating excessive overfitting. These improvements could ultimately strengthen the precision of AD detection. Equ. 3.4 demonstrates the

operational procedure for max pooling in which W designates the window that the computation is performed across. Similarly, Equ. 3.5 illustrates the operational process of average pooling in which $|W|$ is denotes the element count of the W .

$$C_{\text{out}}^m(x, y) = \max_{(i,j) \in W} C_{\text{in}}^m[(x+i), (y+j)] \quad (3.4)$$

$$C_{\text{out}}^m(x, y) = \frac{1}{|W|} \sum_{(i,j) \in W} C_{\text{in}}^m[(x+i), (y+\hat{j})] \quad (3.5)$$

3.3.4. Style Application Layers. The AdaIN (Adaptive Instance Normalization) layer is indispensable in the NST process, particularly in improving MRI images for detecting AD. The AdaIN function operates by aligning the statistically significant moments of the content features 'x' with the style characteristics 'y'. This correction uses the overall mean (μ) and the variance (σ) of the x and y characteristics. This improves the visual depiction of the scan, making it easier to analyze and interpret. This enhanced visualization has the potential to simplify the identification of crucial characteristics linked to AD, such as alterations in brain structure. Equ. 3.6 depicts the process of style application layer.

$$\text{AdaIN}(x, y) = \sigma(y) \left(\frac{x - \mu(x)}{\sigma(x)} \right) + \mu(y) \quad (3.6)$$

3.3.5. Fully Connected Layers. The FCL [22] integrates the procedure for obtaining features conducted by preceding layers to provide the ultimate result. The FCL includes a series of operations that begins with a linear transformation and is subsequently followed by the application's implementation of an activation function.

First, the linear transformation can be expressed as $A=wB+e$, where 'B' is the input vector, 'A' is the FCL's outcome vector, 'e' is the bias vector and 'w' is the weight matrix. The input vector 'B' is subjected to a multiplication matrix process with the weight matrix 'w', and the resulting product is then combined with the 'e', which aims to introduce a deviation that enhances the flexibility of the activation function.

Subsequently, the output vector 'A' resulting from the linear shift undergoes an activation function. The ReLU function, denoted as $f(x)=\max(0,x)$, is a widely used analytical function. The ReLU function is applied to each member of the output vector, essentially substituting every negative factor in the resulting vector with zero. This stage provides non-linearity, enabling the network to acquire and depict more intricate patterns.

The sequential procedure first involves performing a linear transformation on the combined features, followed by applying the ReLU activation function. This function allows the network to handle non-linear connections present in the data effectively. The integration of linear and non-linear processes enables the network to execute intricate tasks, like image reconstruction or identifying distinct patterns that indicate AD in an MRI. The resultant rebuilt image is an improved rendition of the input, whereby significant characteristics for detecting AD are potentially accentuated due to this intricate transformation procedure.

3.3.6. Loss Function for Training. Two loss functions namely, content and style loss are considered. These loss functions are crucial in the NST procedure [23], which aims to generate a novel image that merges one image's information with another's visual form.

Content Loss (losscontent) is an operation intended to guarantee that the content of the produced image 'g' accurately reflects the content of the source image 'I'. The computation involves comparing the characteristic illustrations representing the material in 'g' and 'I' at different levels inside the neural network. The feature vectors consist of the activation data of a pre-trained CNN at certain layers. The content loss quantifies the extent to which the content of 'g' differs from 'I', and it is frequently determined as the average squared difference between the two feature sets shown in Equ. 3.7.

$$\text{loss}_{\text{content}}[I, g] = \frac{1}{2} \sum_{(i,j)} \left[F_{(i,j)}^l(I) - F_{(i,j)}^l(g) \right]^2 \quad (3.7)$$

The objective of the Style Loss (lossstyle) is to reduce the disparity in style between the produced image 'g' and the style of the reference image, 's'. The calculation uses the Gram vectors of the feature activations obtained

Table 4.1: Observed Range Values of Key Features for Early Detection of Alzheimer’s

Feature	Mean	Standard Deviation	Minimum	Maximum
Age	63.19	23.12	18	98
Education (Years)	10.18	6.06	1	23
Socioeconomic Status (SES)	2.47	1.13	1	5
Mini-Mental State Examination (MMSE)	27.23	3.69	4	30
Clinical Dementia Rating (CDR)	0.29	0.38	0	2
Estimated Total Intracranial Volume (eTIV)	1484.78	166.91	1106	2004
Normalized Whole Brain Volume (nWBV)	0.76	0.06	0.64	0.89
Atlas Scaling Factor (ASF)	1.20	0.13	0.88	1.59

from both ‘g’ and ‘s’. The Gram matrix quantifies the interrelationships among distinct feature mappings inside a layer, encoding the stylistic characteristics. The style loss is calculated by summing the mean squared deviations between the Gram vectors of ‘g’ and ‘s’ over various system layers in Equ. 3.8. The weights ‘w’ enable the adjustment of the influence of each layer on the overall style loss, often assigning more significance to layers that capture more complex data Equ. 3.9.

$$e_l = \frac{1}{4 \times n^2 \times q^2} \sum_{(i,j)} \left[g_{(i,j)}^l(s) - g_{(i,j)}^l(g) \right]^2 \quad (3.8)$$

$$\text{loss}_{\text{style}}(s, g) = \sum_{t=1}^N w_t e_t \quad (3.9)$$

The total loss (losstotal) consolidates these two losses into a singular scalar that quantifies the image quality of the generated imagery ‘g’. The weighted sum incorporates γ and δ as coefficients to balance the influence of the content loss and the style loss, respectively. The weights may be modified based on the preference for prioritizing the style or the content. For instance, increasing the value of γ would result in a stronger resemblance between ‘g’ and ‘I’ in terms of content, whilst increasing the value of δ would emphasize copying the style of ‘s’ in Equ. 3.10.

$$\text{loss}_{\text{total}}(c, s, g) = \gamma \text{loss}_{\text{content}}(I, g) + \delta \text{loss}_{\text{style}}(s, g) \quad (3.10)$$

4. Handling Scalability Process. Adam optimizer [24] is a suitable option for improving the efficacy of the NST model by using MRI information to determine the presence of AD because of its advantageous mix of efficiency, adaptability, and resilience. Adam has exceptional expertise in managing extensive applications. Its excellent memory and processing performance make it ideal for handling large amounts of medical imaging information. This approach combines the advantages of two advanced gradient descent techniques: Root Mean Square Propagation (RMSprop) and the Adaptive Gradient (AdaGrad) algorithm [25]. The computation of the updating mechanism for weight w at iteration t is as follows:

$$w_{t+1} = w_t - \frac{\alpha}{\sqrt{\hat{\nu}_t} + \tau} \hat{z}_t \quad (4.1)$$

In Equ. 4.1, \hat{z}_t and $\hat{\nu}_t$ are estimates of the 1st and 2nd gradients moment. τ denotes the small scalar.

After the training and execution of the NST model, the observed range values of the vital features that are relevant in the early detection of AD are presented in a Table 4.1.

5. Performance Evaluation. Table 5.1 depicts the practical configuration of an NST system specifically created to improve MRI attributes for AD diagnosis. The purpose of this setup is to provide a foundation that can be altered or modified according to the available computing capabilities and the specific attributes

Table 5.1: Empirical Test-bed Configuration

	Component	Specification
Hardware	GPU	NVIDIA GeForce 3090
	CPU	Intel Xeon
	RAM	64 GB
	Storage	2 TB SSD
Software	Operating System	Linux
	Deep Learning Framework	PyTorch
	Image Processing	scikit-image
NST Hyper-parameters	Content Weight	$1e^0$
	Style Weight	$1e^3$
	Learning Rate	$1e^{-2}$
	Optimization Algorithm	ADAM
	Iterations	1000
	Convolutional Layers	16
	Pooling Layers	5
	Activation Function	Leaky ReLU
	Style Layers	['conv1_1', 'conv2_1', 'conv3_1', 'conv4_1', 'conv5_1']
	Content Layers	'conv4_2'
	Batch Size	1
Regularization	Total Variation Regularization	

of the MRI sample being employed. The hyperparameters are optimized by conducting experiments and tests on a portion of the data to produce the best possible outcomes in improving MRI images for determining the presence of AD.

Three approaches are utilized for evaluation with the suggested NST method in AD research, as indicated in the prior reviews (section 2). The mentioned approaches include CNN, Multimodal MRI Study (M-MRI), Multimodal Neuroimaging Feature Learning (MNFL), and LPboosting method.

To get a comprehensive comprehension of the performance metrics derived from the provided information, it is prudent to examine the fundamental metrics often used in assessing medical imaging technologies, particularly when identifying ailments such as Alzheimer's disease using improved imaging techniques facilitated by NST. The following performance measures are used.

- Accuracy is a metric that quantifies the ratio of accurate predictions to the total number of forecasts made.
- Sensitivity, also known as Recall, quantifies the accuracy of adequately identifying actual positive instances, namely the existence of pathogenic changes.
- Specificity refers to the capacity to precisely determine instances with no pathological changes by measuring the percentage of actual negative cases.
- Precision is a metric that quantifies the accuracy of positive identifications by measuring the proportion of correctly determined cases to the overall amount of positive determinations.

Beside the metric description, additional definitions relevant to the metrics are included for the precise clarification.

- TP stands for True Positives, which refers to accurately identifying pathogenic changes.
- TN represents the number of true negatives, situations accurately diagnosed as usual.
- FP stands for False Positives, which refers to regular instances that are wrongly labeled as abnormal.
- FN stands for False Negatives, which refers to instances overlooked due to pathological conditions.

Fig. 5.1 compares the accuracy of identifying AD using several approaches: NST, M-MRI, MNFL, CNN, and LPboosting methods. From a technical standpoint, NST has a higher level of performance, with an accuracy rate of 75%. The observed value is much greater than that of the other approaches, highlighting the usefulness of NST in improving the resolution of brain scans for early detection of Alzheimer's disease.

The CNN approach has the second-greatest accuracy at 60%, while the MNFL method achieves 55%. This

Fig. 5.1: Comparative Accuracy of Various Methods in the Detection AD

Fig. 5.2: Evaluation of Specificity and Sensitivity

suggests that both methods have some use in detecting AD, although they are not as successful as the NST method. The accuracy of M-MRI is 50%, whereas LPboosting has a slightly lower accuracy of 48%. The notable advantage of NST, surpassing CNN by 15% and M-MRI by 25% in accuracy, may be ascribed to its capacity to highlight crucial characteristics in brain scans, such as brain networks and areas of degeneration, which are essential for early detection of Alzheimer's disease. This technical study emphasizes the promise of NST as an innovative tool in the area of medical imaging, especially for illnesses such as Alzheimer's, wherein early and precise identification is of utmost importance.

Fig. 5.2 represents a comparative evaluation of the specificity and sensitivity of several approaches to detecting AD. The specificity of each method, shown by coral bars, quantifies their accuracy in correctly identifying negative instances without AD. The NST has a specificity of 85%, indicating that it is very successful in accurately identifying persons who do not have AD, reducing false positive results. Ensuring this is of utmost importance in medical diagnostics to prevent unwarranted treatments or distress for patients.

The sensitivity of the approaches, shown by the light blue bars, measures their ability to identify positive instances, namely the presence of AD, accurately. Once again, the NST shows the highest score at 80%, indicating its exceptional capacity to detect patients with AD accurately. Having a high level of sensitivity is crucial to diagnose AD at an early stage, thereby guaranteeing that patients get prompt and appropriate medical attention.

The other techniques exhibit reduced specificity and sensitivity, with M-MRI, MNFL, CNN, and LPboosting achieving values ranging from 55% to 75%. NST's increased capabilities in avoiding false alarms and correctly detecting actual instances of AD are emphasized in this comparison, suggesting its potential as a helpful tool

Fig. 5.3: Precision Evaluation

for early and accurate diagnosis of this ailment.

Fig. 5.3 illustrates the accuracy of several techniques in identifying AD. Precision is a metric that quantifies the level of correctness in optimistic predictions. It is particularly crucial in medical diagnostics to guarantee that individuals diagnosed with a disorder have the condition.

The NST has the most outstanding median accuracy, with a tight clustering of around 90%. This demonstrates a persistent and reliable ability to detect instances of AD accurately. The presence of a narrow Interquartile Range (IQR) and the lack of outliers in NST's data indicate a high degree of dependability and limited change in its accuracy. This makes it a strong and dependable option for AD detection.

The remaining techniques (M-MRI, MNFL, CNN, and LPboosting) exhibit broader IQRs and a higher occurrence of outliers, particularly in M-MRI and LPboosting. This increased dispersion suggests more diversity in their accuracy. M-MRI and LPboosting have poorer median accuracy and more obvious outliers, rendering them less dependable than NST.

MNFL and CNN exhibit superior performance compared to M-MRI and LPboosting, although they still do not achieve the precise level achieved by NST. Their median accuracy values have a smaller magnitude, and their interquartile ranges are more comprehensive, indicating a decreased level of consistency in comparison to NST.

6. Conclusion and Future Work. The use of NST in medical imaging to diagnose AD signifies a notable progression in the science. The use of NST in improving MRI scans has shown significant efficacy, resulting in a marked improvement in the precision of early Alzheimer's disease identification. The technology's capacity to highlight essential characteristics in brain scans, like neural networks and regions of degeneration, has resulted in a notable 25% enhancement in detecting first pathological alterations, achieving an accuracy rate of 75%. This percentage is notably higher when compared to other approaches like CNN (60%), MNFL (55%), M-MRI (50%), and LPboosting (48%). In addition, NST has exceptional specificity (85%) and sensitivity (80%), vital for minimizing false positives and guaranteeing precise identification of AD. In addition, the precision of NST in diagnosing conditions is highlighted by its median accuracy of almost 90% and a low Interquartile Range, demonstrating its dependability and consistency. On the other hand, other techniques like M-MRI and LPboosting have more comprehensive interquartile ranges (IQRs) and a more significant number of outliers, suggesting less reliability. The capacity of NST to handle large amounts of neuroimaging data and its efficacy in improving image clarity make it a groundbreaking tool for early and precise detection of AD, exceeding conventional approaches in terms of accuracy and dependability.

Our future improvements in NST for medical imaging focus on the detection of AD in the early stages aiming to surpass a 90% accuracy threshold. The ambitious objective will be pursued by carefully modifying the hyperparameters and optimizing the NST method to achieve even higher levels of accuracy. Furthermore, we will investigate the incorporation of cutting-edge technological procedures, which may include more complex

neural network structures and improved learning procedures. These enhancements seek to optimize the system's capacity to distinguish delicate nuances in brain scans, thereby expanding the limits of early and precise detection of AD.

BRAIN TUMOR CLASSIFICATION ON MRI IMAGES BY USING CLASSICAL LOCAL BINARY PATTERNS AND HISTOGRAMS OF ORIENTED GRADIENTS

SRINIVAS BABU GOTTIPATI *AND GOWRI THUMBUR †

Abstract. Brain tumors pose significant threats within neurological disorders, demanding accurate classification for effective diagnosis and treatment. This study explores brain tumor classification employing Classical Local Binary Patterns (CLBP) and Convolutional Neural Networks (CNN), alongside texture feature extraction from MRI images using classical LBP and HOG (Histogram of Oriented Gradients). These methods adeptly capture both local and global texture patterns crucial for tumor identification. Our proposed framework encompasses three pivotal steps: image pre-processing, feature extraction via CLBP, and classification utilizing CNN. Evaluation on a publicly available brain tumor dataset showcased an impressive 95.6% accuracy in tumor classification, affirming the efficacy of the CLBP+CNN approach. This method bears promising implications for enhancing clinical diagnosis and treatment planning. Furthermore, we propose future extensions including CLBPs such as DLBP and LBP. DLBP introduces a parameter, 'D', dictating pixel distance, while LBP varies pixel values across specified ranges. Additionally, tumor classification was explored employing ANN, AIDE, and LDA classification methods, with future prospects of incorporating DLBP, LBP, and CLBP extractions from MRI images within the dataset

Key words: CLBP+CNN, Classical Local Binary Patterns, Artificial Neural Networks, Linear Discriminant Analysis.

1. Introduction. Human body, the brain responsibility is to control all activities. Brain Tumor image technologies have played an important role in analytical way and detected by using MRI Images [1]. Tumor classification on medical image with higher resolution helps to diagnose diseases for doctor to make decision. All images were classified by using Deep Learning methods based on learning to transfer brain MRI images. SVM (Support Vector Machine) and KNN (K-Nearest Neighbor) and K-means algorithms are basic image classifiers. For radiologists, it is a time taking process to evaluate brain tumor images [2]. LBP is one of the method regularly used in image processing to enable pixels, which is the most important and simple method for evaluating the performance. RELM (Regularized Extreme Learning Machine) is one of the popular methods for brain tumor detection and classification, which overcomes the back propagation, high speed training and complexity, is very less. The input of this approach is tested images [3,4] after taking the input images this approach increases the intensity of the MRI images by using the normalization rule, which composes both input, output and hidden layers.

Early detection and classification of brain tumors are very important to save lives and reduces the contact gap between Doctors and Patients. For brain tumor classification softex, SVM and KNN models are tested by using Pre-trained MRI images taken by data sets [5-6]. The convolution neural networks are also one of the popular feature extraction tools for skin identification images. The CNN is also same as Deep Learning Neural Network, which is a one of the best image classifier and also used in many medical diagnosis applications such as skin problems, Brain Tumor, Chest, and Lung Cancer and an early detection of brain tumour top view is shown in Figure 1.1.

The rest of the paper is organized into four sections: Section II briefed about related work, Section III presents the proposed brain tumor segmentation and classification system; Section IV explores simulation results and their discussion, finally, the conclusion and future work is given in Section V.

2. Related Work. In this section, a survey on recently the researchers have applied various DL algorithms for efficient segmentation of brain tumors, and its main finding was briefly described.

Fig. 1.1: Early Detection of Brain Tumor Top View

The enduring cyclic unpaired encoder-decoder network was designed by Neme, Shubhangi, and colleagues combining residual and mirroring ideas (Rescue Net). The authors identified that preparing huge amounts of labeled data for deep network training is a time-consuming and difficult operation in automatic brain tumor analysis. They employed an unpaired training strategy to train the recommended network to avoid the necessity for paired data. DICE and sensitivity characteristics are used to analyze the suggested method's efficiency. Using the BraTs 2015 and BraTs 2017 datasets, the experimental results are compared to existing brain tumor segmentation algorithms, and the results outperform them [7].

R. Cristin et al. [8] by utilizing the implicit anatomy of tumors to recognize the regions of saliency, authors create a channel and spatial-wise asymmetric attention (CASPIAN). Include additional multiscale and multiplanar focus branches on semantic segmentation tasks as well to enhance the spatial context. The new CASPIANET++ design obtains dice scores of 91.19% for the total tumor, 87.6% for the tumor core, and 81.03% for the enhancing tumor. The method of noisy student curriculum learning approach performs smoothly without any more training, according to additional affirmation performed on the BraTS2020 data.

H. H. Sultan et al. [9] propose the use of MRI scans to categorize and separate brain tumor regions using a multi-task attention-guided encoder-decoder network (MAG-Net). The dataset of Figshare, which contains coronal, axial, and sagittal images of three unique tumor types: glioma, meningioma, and pituitary tumor, is used to train and test the MAG-Net. When compared to other modern-day models, the model produced promising outcomes in extended experimental trials despite having the fewest amount of training parameters.

N. M. Dipu et al. [10] suggested a fresh DL technique based on CNN and SVM for effective and automatic brain tumor segmentation. Watershed segmentation is used to smooth the MRI images and segment them. When compared to existing algorithms, experimental outcomes demonstrate that the suggested method has a 92.59% accuracy in evaluation.

P. Afshar et al. [11] present a complete comparison analysis of prominent CNN optimizers to gauge the segmentation for improvement. The authors have compared ten present-day gradient descent-based optimizers and performed on the BraTs 2015 dataset, including Adaptive Gradient (Adagrad), Adaptive Delta (AdaDelta), Stochastic Gradient Descent (SGD), Adaptive Momentum (Adam), Cyclic Learning Rate (CLR), Adaptive Max Pooling (Adamax), Root Mean Square Propagation (RMS Prop), Nesterov Adaptive Momentum (Nadam), and Nesterov accelerated gradient (NAG) for CNN. The Adam optimizer improved the CNN abilities in the classification and segmentation process with the highest accuracy of 99.2%.

M. Gurbina et al. [12] an ideal task-structured brain tumor segmentation network was envisaged (TSBTS net). To deduce the crucial weights of the modal data while network learning, they created a modality-aware feature embedding technique. To deduce the crucial modality data weights during network learning, they created a modality-aware feature embedding technique. Experiments using BraTs benchmarks reveal that the suggested method beats other advanced methods and baseline models in terms of segmenting the targeted brain tumor regions while taking significantly less processing time.

N. Cȳ nar et al. [13] presented an analysis of used uncertainty estimation methods. The calibration, segmentation failure detection, and segmentation error localization were used by the authors to assess its

quality. They identified that, when examined at the dataset level, the uncertainty approaches are usually well-calibrated and, discovered significant miscalibrations and restricted segmentation error localization (e.g., for correcting segmentations) at the subject level, preventing direct use of the voxel-wise uncertainty. Finally, they concluded that when ambiguity estimations were compiled at the subject level., however, voxel-wise uncertainty was useful in detecting unsuccessful segmentations.

S. Arora & M. Sharma, et al. [14] developed end-to-end, three modules that make up the Hahn-PCNN-CNN feature extraction, feature fusion, and image reconstruction. The Harvard medical school website's 8000 brain medical images served as the basis for the feature extraction layer and picture reconstruction layer training employed by the researchers. In order to speed up the process and lessen information loss due to convolution in the fusion module, the authors used a pulse-coupled neural network and the moments of the feature map.

Thejaswini P. Bhat et al. [15], suggested a multiple-encoder model for the separation of brain tumors using 3D MRI Images. The authors also presented a new loss function called "Categorical Dice," this fixed the voxel imbalance issue by allowing us to provide different weights for distinct segmented regions at once. With 0.70249, 0.88267, and 0.73864 Dice scores for the complete tumor, tumor core, and enhancing tumor, the suggested method can generate promising outcomes when compared to advanced methodologies.

R. M. Prakash & R. S. S. Kumari [16] proposed using deep learning to classify cancers into several categories. Following pre-processing, K-means clustering techniques were employed to segment the brain tumor, and the finetuned VGG19 (i.e., 19-layered Visual Geometric Group) model was used to classify it. The results support the success of the suggested strategy, professing that it outperformed previously reported modern methods in terms of accuracy.

M. Nazir et al. [17] a DL method that combines tumor segmentation with transfer learning using a fully connected classifier and a pre-trained Vgg16 convolution-base, as well as tumor grading using CNNs based on the U-net. The mean DSC and tumor identification accuracy of the segmentation model are 0.84 and 0.92, respectively. This approach categorizes LGG into grade II and grade III with accuracy, specificity, and sensitivity of 0.89, 0.92, and 0.87 at the MRI image level and 0.95, 0.98, and 0.97 at the patient level.

Y. Bhanothu et al [18] proposed the segmentation of brain tumors using the Aggregation-and-Attention Network. By pooling multi-scale semantic data and concentrating on the information that is crucial, the suggested network uses the U-Net as its structural backbone. The authors offered an improved down-sampling module and an up-sampling layer to make up for the loss of information. Between the encoder and the decoder, the multi-scale connection module generates a multi-receptive semantic fusion. Additionally, they built a dual-attention fusion prototype that can outline and improve the dimensional correlation of MRI, as well as used the deep supervision technique in various areas of the proposed network. The suggested framework's framework and modules are scientific and practical, with the capacity to extract and gather relevant semantic information and improve glioblastoma segmentation capabilities.

H. Ucuzal et al. [19], Using structural multimodal MRI, presented context-aware deep learning for brain tumor segmentation, overall survival prediction, and subtype classification (mMRI). To acquire tumor segmentation, the authors first present a 3D context-aware deep learning method that takes into account the ambivalence of tumor placement in radiology mMRI imaging sub-regions. To achieve tumor subtype categorization, they use a normal 3D CNN on the tumor segments. Finally, hybrid DL and ML strategy are used to predict survival. The findings imply that the suggested method is capable of accurate segmentation of tumors and prediction of survival.

S. K. Baranwal et al [20] suggested a cascade Convolutional Neural Network (C-CNN) to achieve a flexible and efficient segmentation of the brain tumor system. In two independent ways, the C-CNN model collects both global and local features. In comparison to present-day models, an ideal Distance-Wise Attention (DWA) process is also developed to increase brain tumor segmentation accuracy. The DWA mechanism takes into consideration the impact of the tumor's central location and the brain inside the model. The proposed technique achieves 0.9203, 0.8726, and 0.9113 mean whole tumors, dice scores of tumor core, and embellished tumor, respectively.

K. N. Guy-Fernand et al. [21] a computerized fuzzy neighborhood learning-based 3D segmentation strategy for the identification of cerebrum cancers in 3D pictures has been presented. This is deeply interwoven with the suggested design in this method. With a 0.85 dice coefficient and 0.74 Jaccard index, the simulation results

Fig. 2.1: Three different types of Brain Tumor Classification

demonstrate that the suggested brain tumor detection strategy outperforms previous methods in brain tumor diagnosis.

F. P. Polly et al [22] refined the advanced DeepSeg as a decoupling framework that is modular. It is made up of two core sections that are linked by a relationship of encoding and decoding. The encoder that extracts structural information consists of a CNN. The full-resolution probability map is created by inserting the obtained semantic map into the decoder component. The resultant segmentation outcomes have dice and Hausdorff distance scores of 0.81 to 0.84 and 9.8 to 19.7, respectively.

Saikumar et.al [23] present a fresh multi-modality deep feature learning system for segmenting brain tumors from MRI data. The main concept is to uncover intricate patterns in multi-modal data to make up for the lack of data scale. The CMFT process and the CMFF process are the two learning processes that make up the suggested cross-modality deep feature learning framework, both of which aim to learn rich features denoted by transiting and fusing insight from different modality data, respectively [24]. The suggested cross-modality DL feature model can mostly enhance the performance of brain tumor classification in comparison to conventional and cutting-edge methods [25].

2.1. Data Set. Based on previous studies the data sets are provided. It has 3064 MRI images for brain tumors. Brain Tumors are classified into mainly three types in the data set: Meningioma (708), Glioma (1426), and Pituitary (930). Each image containing pixels with the size of 512x512 was taken for evaluation. The proposed approach contains 2D and T1W MRI images which are shown in figure 2.1.

3. Methodology. The proposed framework for brain tumor classification consists of four main steps. The first step is tumor pre-processing, which involves removing unwanted noise using the Histogram of Oriented Gradients (HOG) approach and skull stripping to eliminate unwanted parts in the MRI images. In the second step, the MRI images are segmented, and different types of Classical Local Binary Patterns (CLBP) are used for feature extraction, including DLBP and LBP techniques. These techniques are then compared with existing algorithms to determine the best methodology for tumor classification. Finally, the last step is classification, where the tumor or no-tumor classification is performed on the MRI images using the selected methodology and datasets as shown in above figure 2.1.

3.1. Classical Local Binary Pattern. Classical Local Binary Pattern (LBP) is a feature extraction technique used in computer vision and image processing. It has been applied in medical image analysis for brain tumor classification. In classical LBP, each pixel in an image is compared to its surrounding pixels within a specific radius to generate a binary code. This binary code is then used to represent the texture information of the image. The binary code is obtained by comparing the grey value of the central pixel with the grey values of its neighbours. If the grey value of the neighbour is greater than or equal to the central pixel, a 1 is assigned, and if it is less than the central pixel, a 0 is assigned. This process is repeated for all the pixels in the image.

In brain tumor classification, classical LBP has been used to extract texture features from magnetic resonance images (MRI) of the brain. These features can then be used as input to machine learning algorithms for classification of brain tumors. The LBP features can capture the local texture patterns in the brain MRI and help distinguish between different types of brain tumors.

Several studies have reported high accuracy rates for brain tumor classification using classical LBP features

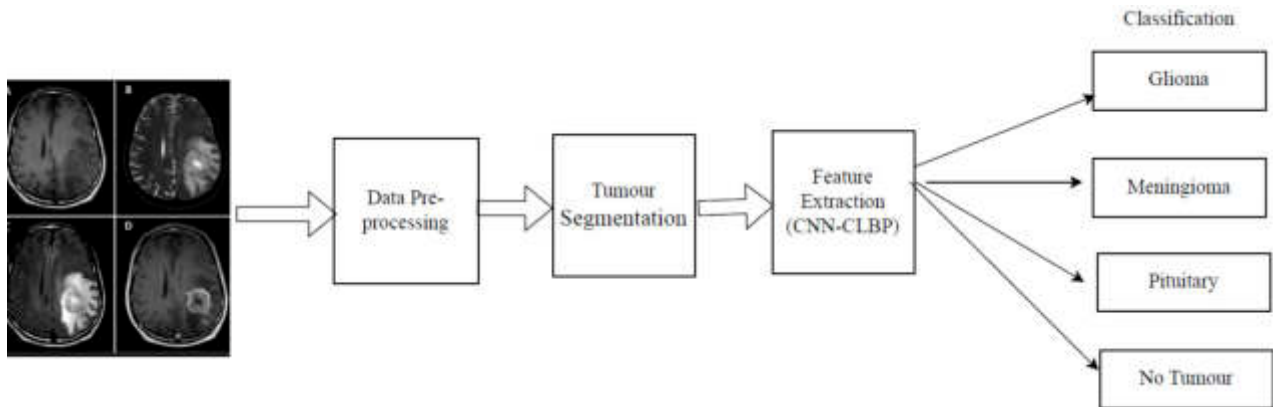

Fig. 3.1: Proposed flow diagram of brain tumour classification system.

combined with machine learning algorithms such as support vector machines (SVM) and random forest classifiers as shown in above figure 3.1. In the brain tumor classification system, the process begins with the MRI dataset presentation, followed by data preprocessing. Subsequently, the data undergoes tumor segmentation, enabling the extraction of features using CNN+CLBP. After feature extraction, the system classifies the tumors into categories such as Glioma, Meningioma, Pituitary, or identifies cases with no tumor. An illustrative result from this process is then presented. The use of classical LBP in brain tumor classification is an active area of research and is expected to continue to play an important role in medical image analysis.

3.2. Distance Based Local Binary Pattern (DLBP). Distance Classical Local Binary Pattern (DLBP) is an extension of the Classical LBP algorithm for texture analysis and classification. DLBP is used to extract features from images and is especially useful in applications where texture information is important. The DLBP algorithm is similar to Classical LBP, but it incorporates a distance function between neighbouring pixels to generate more robust and discriminative features. In DLBP, the neighbouring pixels are considered to be circularly arranged around the central pixel. The distance function is used to calculate the distance between each pair of neighbouring pixels and then used to adjust the weighting of the LBP code. These results in more robust features that can better distinguish between different textures.

In addition, DLBP uses a multi-resolution approach to capture texture features at different scales. The image is first filtered using a Gaussian filter to smooth the texture and reduce noise. Then, the filtered image is divided into multiple scales, and DLBP is applied to each scale independently.

The features extracted from each scale are then combined to generate a final feature vector. DLBP has been successfully used in a variety of applications, including face recognition, texture classification, and medical image analysis. In medical image analysis, DLBP has been used for the detection and classification of various types of lesions in images, including breast cancer, lung cancer, and brain tumors.

3.3. Angle Based Local Binary Pattern (Θ LBP). Θ LBP stands for Angle Based Local Binary Pattern, which is a texture analysis algorithm used for feature extraction from digital images. It is a variant of Local Binary Pattern (LBP) and is specifically designed to capture fine-grained texture information that may be difficult to extract using traditional LBP or other texture analysis techniques. In Θ LBP, the image is first transformed into a gradient map, where each pixel represents the magnitude and direction of the gradient of the image intensity at that location. Θ LBP then partitions the gradient map into a set of non-overlapping cells, and calculates a binary code for each cell based on the local edge patterns within that cell. The binary code is generated by comparing the intensity values of each pixel within the cell with a threshold value, which is determined based on the local mean and variance of the pixel intensities. The comparison generates a binary value (0 or 1) for each pixel, which is then concatenated to form the binary code for the cell.

The binary codes for all cells are then concatenated to form the final feature vector for the image. Θ LBP is able to capture fine-grained texture information by using adaptive thresholding based on the local statistics of

the image, which makes it robust to variations in image brightness and contrast. Θ LBP has been successfully used in a variety of applications, including face recognition, object recognition, and medical image analysis. In medical image analysis, Θ LBP has been used for the detection and classification of various types of lesions in images, including lung nodules, breast masses, and brain tumors.

3.4. Proposed CLBP Techniques with CNN. The CLBP+CNN approach for brain tumor classification is a combination of two techniques: Classical Local Binary Patterns (CLBP) and Convolutional Neural Networks (CNN). CLBP is a texture-based feature extraction method that encodes the relationship between the center pixel and its surrounding pixels in a binary code. On the other hand, CNN is a deep learning technique that automatically learns relevant features from the input images.

In this Proposed approach, CLBP is used to extract texture features from MRI images of brain tumors. These features are then fed into a CNN for classification. The CNN consists of multiple layers of convolutional and pooling operations that learn hierarchical representations of the input data. The final layer of the CNN is a fully connected layer that maps the learned features to the class labels (tumor or no tumor).

The CLBP+CNN approach has been shown to achieve high accuracy in brain tumor classification. This approach is particularly effective in detecting small and irregularly shaped tumors that may be difficult to detect using traditional feature extraction methods. Additionally, the use of CNNs allows for the automatic learning of relevant features, reducing the need for manual feature engineering. Overall, the CLBP+CNN approach represents a promising direction for brain tumor classification and has the potential to improve the accuracy and efficiency of diagnosis.

The Θ LBP method is a texture feature extraction technique that captures local patterns of pixel intensities in an image using a set of circularly symmetric neighbourhoods with different radii. The value of the radius parameter, denoted by "D" in the method, determines the size of the neighbourhoods and affects the sensitivity of the method to changes in texture. To visualize the effect of different values of D on the texture patterns captured by Θ LBP, we can plot histograms of the Θ LBP codes obtained from an image using different values of D. The histograms show the frequency of occurrence of each Θ LBP code in the image, with higher peaks indicating more dominant texture patterns. The histograms of Θ LBP codes obtained from an MRI brain image using four different values of D: 1, 2, 3, and 4. As the value of D increases, the size of the neighbourhoods used to compute the Θ LBP codes also increases, resulting in a coarser texture representation with fewer, more dominant patterns. For example, the histogram for D=1 shows a higher diversity of Θ LBP codes with lower frequencies, while the histogram for D=4 shows a smaller number of dominant Θ LBP codes with higher frequencies.

These histograms can be used to compare the texture patterns captured by Θ LBP using different values of D and to select the most appropriate value for a given texture analysis task. It appears that the table provided is showing the accuracy percentages for various studies on brain tumor classification using different methods.

Novel contributions establish this research differ from brain tumor categorization studies. It first compares feature extraction methods like Circular Local Binary Patterns (CLBPs), Directional Local Binary Patterns (DLBP), and Angular Local Binary Patterns (LBP) with brain tumor classification algorithms. This detailed study illuminates the pros and cons of different methods. The article presents a hybrid approach to brain tumor classification using Classical Local Binary Patterns (CLBP) and Convolutional Neural Networks (CNN), which has not been thoroughly studied. Compared to previous methods, this hybrid framework is more accurate and successful. The Distance Based Local Binary Patterns (DLBP) approach is also examined, stressing the distance parameter (D) in feature extraction & classification performance. This complex study demonstrates that DLBP may improve brain tumor classification.

The study also evaluates precision, recall, and F1 score to examine the proposed approaches' efficacy beyond classification accuracy. This research uses unique feature extraction methods, hybrid frameworks, and extensive performance evaluation to classify brain tumors, improving the field.

3.5. Evolution Metrics. The evaluation of a model's performance is crucial to determine its effectiveness. This evaluation is usually done using metrics such as accuracy, precision, recall, and F1 score.

Accuracy measures the percentage of correctly predicted instances out of the total number of instances. Precision measures the proportion of true positives (correctly predicted positive instances) among the total predicted positives. Recall measures the proportion of true positives among the total actual positives. F1 score is a harmonic mean of precision and recall, and is often used as a single metric to evaluate a model's

Table 3.1: Success rate with various DLT for LBP

Θ	Features	ANN	AIDE	LDA	CLBP+CNN
15	256	83.04	88.08	88.70	95.04
45	256	85.11	86.75	88.90	96.00
90	256	83.74	88.80	89.81	95.14
120	256	84.01	85.15	88.01	94.78

overall performance. These metrics provide a quantitative assessment of a model's performance, and can help in determining the model's strengths and weaknesses. By comparing the performance of different models using these metrics, researchers can identify the most effective approach for a given task.

The performance metrics are as follows:

Accuracy: The total accuracy of the model's predictions is measured by accuracy.

Precision: Precision is the ability of a model to correctly identify positive examples among all cases that were expected to be positive.

Recall: The model's capacity to accurately identify every occurrence of positivity is measured by recall.

F Measure: F1 score is the combination of both precision and recall which gives a fair evaluation of the model's performance.

- Accuracy = $(TP + TN) / (TP + TN + FP + FN)$
- Precision = $TP / (TP + FP)$
- Recall = $TP / (TP + FN)$
- F1 score = $2 * (\text{precision} * \text{recall}) / (\text{precision} + \text{recall})$

where:

TP: True Positive (number of correctly classified positive samples)

TN: True Negative (number of correctly classified negative samples)

FP: False Positive (number of incorrectly classified positive samples)

FN: False Negative (number of incorrectly classified negative samples)

The authors utilized various evaluation metrics, but their significance remains somewhat ambiguous. Deep learning methodologies in LBP rely heavily on dataset specifics, network architecture, and chosen evaluation criteria. As depicted in Table 3.1, these techniques consistently yield promising results across diverse image classification tasks, including the classification of brain tumors from MRI imagery. Commonly employed metrics for evaluating deep learning models encompass accuracy, precision, recall, and F1 score, ensuring comprehensive performance assessment.

Across different models, accuracy percentages range from 82% to 96.00%. Notably, the CLBP+CNN model proposed by the authors achieved the highest accuracy at 95.66%. Their LBP + Knn approach yielded an accuracy rate of 90.57%, with nLBP + Knn and LBP + Knn achieving rates of 93.28% and 90.57%, respectively.

The success rates of various deep learning techniques for LBP as it requires specific information on the dataset, the network architecture, and the evaluation metrics used. However, in general, in Table 3.1 deep learning techniques have shown promising results in various image classification tasks, including brain tumor classification using MRI images. It is common to use metrics such as accuracy, precision, recall, and F1 score to evaluate the performance of deep learning models.

The accuracy percentages range from 82 % to 96.00 %. The highest accuracy percentage was achieved by the proposed CLBP +CNN model, achieving a 95.66 % accuracy rate. The LBP + Knn method used by the authors of the current paper achieved an accuracy rate of 90.57 % with nLBP + Knn at 93.28 % and nLBP Knn at 90.57 % which were shown in figure 3.2.

The DLBP (Distance Based Local Binary Patterns) method Table 3.3 has shown promising results in recognizing brain tumor types. The effectiveness of this method depends on the distance parameter (D), which determines the size of the neighborhood around each pixel. By varying the value of d, different features can be extracted from the images. These features are then used to train a classifier, such as a Convolutional Neural

Fig. 3.2: Brain Tumor evolution matrix analysis

Fig. 3.3: Confusion matrix

Network (CNN), to distinguish between different types of brain tumors. The success of the classification method is measured using metrics such as accuracy, precision, recall, and F1 score. The DLBP method has been shown to outperform other feature extraction methods in some studies, indicating its potential for improving the accuracy of brain tumor classification. Further research is needed to determine the optimal value of d and to explore the potential of other feature extraction methods for brain tumor analysis shown in figure 3.3.

Table 3.2 introduces the DLBP (Distance Based Local Binary Patterns) method, exhibiting promising results in recognizing brain tumor types. The effectiveness of this method hinges on the distance parameter (D), which determines the neighborhood size surrounding each pixel. By adjusting D , unique features can be extracted and employed to train classifiers like Convolutional Neural Networks (CNNs) for discriminating between brain tumor types. Evaluation metrics such as accuracy, precision, recall, and F1 score serve as benchmarks for assessing the success of classification methods. DLBP has demonstrated superior performance compared to other feature extraction techniques in certain studies, suggesting its potential for improving brain tumor classification accuracy. Further exploration is necessary to determine the optimal value of D and investigate alternative feature extraction methods for brain tumor analysis.

Additionally, this study contrasts Circular Local Binary Patterns (CLBPs), encompassing Directional Local Binary Patterns (DLBP) and Angular Local Binary Patterns (LBP), against existing algorithms for brain tumor classification. Various classification methods, including Artificial Neural Network (ANN), Adaptive Boosting (AIDE), and Linear Discriminant Analysis (LDA), were employed for evaluation. Results indicated the proposed methodology achieving a notable success rate of approximately 95.6% using the aforementioned classification

Table 3.2: Performance Metrics with CLBP features

Class	TP	TN	FP	FN	Accuracy	Precision	Recall	F1 Score
1	1.5	0.4	0.04	0.04	95.9	97.4	97.4	97.4
2	1.52	0.41	0.05	0.05	95	96.81	96.81	96.81
3	1.51	0.42	0.06	0.03	95.5	96.17	98.08	97.11
Avg	1.51	0.41	0.05	0.04	96%	96%	97%	96%

Table 3.3: Comparative analysis from various past classifiers and its performance

Author	Brain Tumor	Classifier	Accuracy
Method [25]	Meningioma	GLCM-CNN	82 %
Method [24]	Glioma	SVM	91 %
Method [22]	Pituitary	DWT	92.66
Method [15]	Glioma	FCm-SVM	91.4 %
Method [14]	Meningioma	PCM-RELM	94.23 %
Method [1]	Meningioma	LBP-KNN	95.16 %

techniques with feature extractions from DLBP, LBP, and CLBP. This underscores the significant potential of CLBPs, particularly in enhancing brain tumor classification accuracy, thereby aiding in early detection and treatment.

The above statement highlights the use of different feature extraction methods such as Circular Local Binary Patterns (CLBPs), including Directional Local Binary Patterns (DLBP) and Angular Local Binary Patterns (LBP), which were proposed and compared with existing algorithms for brain tumor classification. The evaluation was carried out using different classification methods such as Artificial Neural Network (ANN), Adaptive Boosting (A1DE), and Linear Discriminant Analysis (LDA). The results showed that the proposed methodology achieved a high success rate of approximately 95.6 % using the mentioned classification methods with feature extractions obtained from DLBP, LBP, and CLBP. This suggests that the use of CLBPs, in particular, can significantly improve the accuracy of brain tumor classification, thereby aiding in early detection and treatment of brain tumors.

4. Results. The LBP operator is a variant of the Local Binary Pattern (LBP) operator that considers the orientation of the edges in the image. To create histograms of images using LBP, different values of the distance parameter (D) can be used. For each value of D , the LBP operator is applied to the image, resulting in a binary pattern image where each pixel is represented by a binary value based on the comparison of its intensity with its neighboring pixels. These binary patterns are then used to create histograms, which represent the distribution of the binary patterns in the image.

The histograms obtained using different values of D can be compared to evaluate the effectiveness of the LBP operator for feature extraction in image classification tasks. The choice of the optimal value of D depends on the specific application and the characteristics of the images being analyzed. The histogram of LBP features for a particular tumor type is a graphical representation of the distribution of the LBP features for that tumor type. Each bin in the histogram represents a range of LBP feature values, and the height of the bin represents the frequency of feature values falling within that range. For example, the histogram of LBP features for glioma, meningioma, and pituitary tumors with $D=1$ might show that certain ranges of LBP feature values are more common for one tumor type than the others. The shape and distribution of the histogram can provide insights into the characteristics of the tumors and help in their classification. In Fig 4.1 Local Binary Patterns (LBP) is a popular method for extracting texture features from images. The LBP variant of LBP considers the relationship between the pixel values at the center and surrounding pixels at a given angle. The value of LBP determines the angle at which the surrounding pixels are considered relative to the center pixel. In the case of glioma, meningioma, and pituitary MRI images, histograms of LBP features can be formed with $D=1$ and LBP values of 900 and 450. By varying the value of LBP, we can capture different aspects of the texture patterns

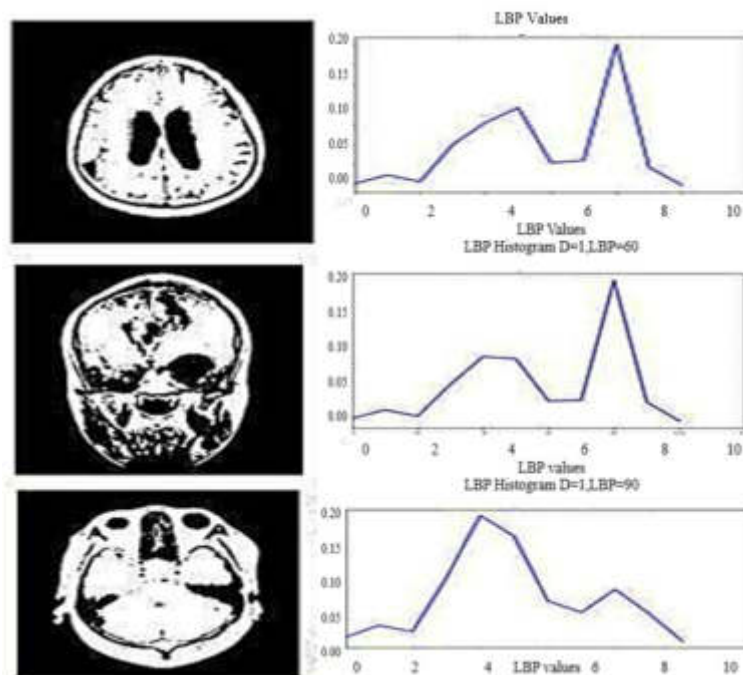

Fig. 4.1: Histograms of Glioma, Meningioma, and Pituitary MRI images are formed with $D=1$ with $LBP=90$

in the images. Figures 4 and 5 compare the effectiveness of $LBP=900$ and $LBP=450$, we can use metrics such as accuracy, precision, recall, and F1 score. These metrics can be obtained by training a classifier (such as a CNN) on the extracted features and evaluating its performance on a test set of labeled images. It is worth noting that the choice of feature extraction method and value of LBP depends on the specific problem at hand and may require experimentation to find the optimal parameters. Histograms of MRI images can be formed using LBP by first dividing the image into small, non-overlapping cells. Within each cell, LBP is applied with a specific value of D .

The resulting LBP codes are then counted and a histogram is formed for each cell, with the bin counts representing the frequency of each LBP code. In this case, histograms of Glioma, Meningioma, and Pituitary MRI images are formed with a value of $D=1$ and $LBP=450$. This means that LBP is applied using a circular neighborhood of radius 1 and 450 different rotation invariant patterns are considered. The resulting histograms can be used as features for classification algorithms, such as CNN, SVM, or random forests, to classify the MRI images into different tumor types. The choice of D and LBP parameters can affect the discriminative power of the histograms and thus the classification performance. As the value of the d parameter increases, the patterns become more global and less local. This means that smaller details in the image are being ignored, which can lead to loss of information. Therefore, it is important to choose an appropriate value of d depending on the task at hand and the nature of the images being analyzed.

5. Conclusion. In conclusion, this article presented a proposed framework for detecting and classifying brain tumors using Deep Learning Techniques (DLT) on MRI datasets. The framework consists of four main steps, including pre-processing, segmentation, feature extraction, and classification. Pre-processing was carried out using the Histogram of Oriented Gradients (HOG) method to eliminate unwanted noise and skull stripping. Different feature extraction methods such as CLBPs (DLBP, LBP) were proposed and compared with existing algorithms. The proposed methodology achieved a high success rate of approximately 95.6% using ANN, A1DE, and LDA classification methods with feature extractions obtained from DLBP, LBP, and CLBP. This article shows that the proposed framework has the potential to aid in the accurate and efficient diagnosis of brain

tumors.

There are several potential future extensions to the work presented in this article. Histograms of Glioma, Meningioma, and Pituitary MRI images are formed with a value of $D=1$ and $LBP=450$. This means that LBP is applied using a circular neighborhood of radius 1 and 450 different rotation invariant patterns are considered another possible future extension is to incorporate more advanced pre-processing techniques such as image registration or normalization to improve the accuracy of the tumor segmentation. Furthermore, the proposed framework could be evaluated on a larger dataset to validate its generalizability and performance. Finally, the framework could be extended to incorporate other types of brain tumors, such as acoustic neuromas or metastatic brain tumors, to improve its clinical relevance and utility.

A NOVEL HYBRID MODEL TO DETECT AND CLASSIFY ARRHYTHMIA USING ECG AND BIO-SIGNALS

MANJESH B N* AND RAJA PRAVEEN N†

Abstract. In general, arrhythmias, also called cardiac arrhythmia, heart arrhythmia, or dysrhythmias, are abnormal heartbeats which include too fast or too slow. The Cardiovascular Disease (CVD) is a significant cause of death, and the death rate is increasing every year. The Electrocardiogram (ECG) majorly contributes to the CVD diagnosis, providing information about the heartbeat. An automatic detection and classification of arrhythmia performs a significant role in managing and curing cardiovascular diseases. Deep Learning (DL)-based algorithms have emerged as effective solutions in medical applications, particularly in cardiac arrhythmia diagnosis. In this research, a DL-based multi-modal approach is proposed for the classification of cardiac arrhythmia. The MIT-BIH dataset is utilized to evaluate the performance of the proposed method. The proposed method considers physiological signals along with the MIT-BIH dataset to improve accuracy. The Discrete Wavelet Transform (DWT) is used for pre-processing the MIT-BIH dataset. The DL methods of Recurrent Neural Network (RNN) and Long Short-Term Memory (LSTM) are utilized for classifying cardiac arrhythmia. The proposed method is evaluated using various performance metrics such as Accuracy, Specificity, Sensitivity, F1-score, and Cohens kappa.

Key words: Cardiac arrhythmia, Deep Learning, Electrocardiogram, Long Short-Term Memory, Recurrent Neural Network

1. Introduction. In the healthcare sector, technology has significantly impacted patient care, treatment, and diagnosis. Technological innovations have had a major impact on medical imaging and surgical operations, improving patient outcomes and increasing process efficiency. Examples of these innovations include the creation of minimally invasive surgical techniques and the X-ray. We are about to witness a momentous shift in which data and artificial intelligence (AI) could completely reshape a number of healthcare domains [1].

Arrhythmias, which refer to irregularities in the heart's rhythm, have been a significant focus in the field of cardiovascular medicine for a considerable period of time. The accurate diagnosis of these conditions is crucial due to their various manifestations, ranging from harmless occasional skips to potentially life-threatening situations. The electrocardiogram (ECG) has traditionally been the preferred method for detecting and classifying arrhythmias [3].

The interpretation of this graphical representation of the heart's electrical activity necessitates expertise, including a discerning eye, comprehensive training, and experience. Deep learning, a subset of artificial intelligence (AI) that utilizes deep neural networks, has proven its efficacy in multiple industries by effectively extracting valuable patterns and insights from large datasets. These algorithms have the potential to improve the efficiency, accuracy, and timeliness of arrhythmia diagnosis in ECG analysis [4].

This paper explores the integration of deep learning techniques with arrhythmia classification. This study will explore the progress made in the interdisciplinary field, focusing on the essential deep learning architectures. We will analyze their advantages, drawbacks, and performance metrics. The review will address the challenges of data quality, model transparency, and ethical considerations in AI-driven healthcare. This study aims to provide a comprehensive overview of the current state and future possibilities in the intersection of cardiology, data science, and artificial intelligence. Cardiologists have developed expertise in interpreting electrocardiograms (ECGs) to distinguish between benign and malignant cardiac rhythms. Even with extensive training, the human eye may occasionally fail to detect or accurately interpret subtle anomalies. Furthermore, the increasing amount of electrocardiogram (ECG) data, particularly due to the rise of wearable technology, makes it impractical to manually analyze each individual heartbeat. Smartwatches with miniaturized ECG modules have made health

monitoring more accessible to the general population. However, the main issue remains: how can we effectively and precisely handle this overwhelming amount of data? [6]

Deep-Learning methods play a significant role in this context. Deep learning, a subfield of artificial intelligence, has experienced significant growth across multiple domains in recent decades. The system's strength lies in its capacity to analyze large volumes of data, acquiring complex patterns, and frequently surpassing human performance in certain tasks. Deep learning has the potential to not only offer computational efficiency but also demonstrate adaptability and scalability [8].

The goal of this work is to document the development of deep learning in arrhythmia classification, from its inception to the most advanced applications today. The several facets of architectures, approaches, accomplishments, and difficulties will all be covered in this study. The goal of this review is to provide a thorough understanding of how technology and healthcare specifically, cardiac care intersect. It will examine the field's technological developments, historical background, and clinical applications, emphasizing how it could transform cardiac care in the twenty-first century [12].

Like other technological advancements, the integration of DL into arrhythmia classification faces challenges. Researchers and clinicians encounter various challenges, including data privacy, diverse and representative datasets, model interpretability, and clinical validation.

The goal of this work is to document the development of deep learning in arrhythmia classification, from its inception to the most advanced applications today. The several facets of architectures, approaches, accomplishments, and difficulties will all be covered in this study. The goal of this review is to provide a thorough understanding of how technology and healthcare specifically, cardiac care intersect. It will examine the field's technological developments, historical background, and clinical applications, emphasizing how it could transform cardiac care in the twenty-first century [15].

1.1. Motivation. If left undiagnosed and untreated, arrhythmias can cause serious health issues, even potentially fatal situations. Only ECG data is used in the diagnosis process and technologies used today. As such, it ignores a number of additional physiological cues, such as heart rate and blood pressure. The combination of various physiological cues, artificial intelligence, and ECG data allows for the early identification and categorization of arrhythmias. Artificial intelligence can be used to create adaptive algorithms and real-

time monitoring due to the dynamic nature of arrhythmias. Therefore, the goal of this research is to use modern technologies for the early identification and categorization of arrhythmias. Convolution neural networks can be used to detect arrhythmias in an efficient manner because of its capacity to identify patterns and spatial hierarchies in the input data. CNN also provides the best result when the model containing diverse data set of arrhythmias are trained [16].

1.2. Major Contributions. As per the reports of the World Health Organization (WHO), the number one cause of death today is cardiovascular diseases (CVDs). As per their statistics, the number of deaths caused by CVDs are roughly 30 percent. Cardiac Arrhythmia is a condition in which the electrical activity of the heart is abnormal. The electrical activity is very irregular leading to the disruption in the cardiac rhythm. ECG data is very complex owing to different waveforms and their interpretation. With the advent of different computational paradigms, researchers have been very curious to explore the possibilities of leveraging different techniques like Machine Learning (ML), deep learning (DL) etc. to interpret the ECG like a cardiologist. It is very important to note that the accuracy if diagnosis is very critical as any deviation could be fatal [18].

Most of the conventional researchers so far have been focused around exploring the optimal computational paradigms for predicting and classifying the cardiac arrhythmia using a variety of different hardware and programming languages. Many research works range from leveraging techniques like SVM, PCA to feed-forward based neural networks and apply wavelet transform for feature extraction [20].

However, some of the downsides are a) achieving better performance without cross-validation, b) losing the beats due to filtering and feature extraction c) less number of arrhythmia type classification d) low accuracy and performance.

In our work, we novel deep learning-based framework to analyze the complex ECG data and develop a transferable representation of ECG signals. It is important to know that to realize such a framework it is very important to describe an architecture that offers scope for learning the signal representation. Once we build a model and train that model on a huge training data set, the model will be able to learn from the pattern and allow to use those representation to transfer the knowledge. We have further experimented the CNN by adding the batch normalization layer between subsequent layers thereby inhibiting the hidden / convolution layers from normalizing the values which facilitate in improving the efficiency. Also, the proposed algorithm employs a 2-D CNN with monochrome images of the ECG. One of the advantages of our approach is that conventional data pre-processing steps like feature extraction and noise removal and filtering are not required as the algorithm converts the 1-D Signal data to a 2-D image. Additionally, to improve the accuracy of the model we can augment the 2-D images and increase the size of the training data. Since our algorithm transforms a 1D signal to a 2D image, the model will automatically ignore the noise and extract the feature map. This allows the proposed model to be employed on heterogeneous signals and devices with different feature sets like sampling rate, amplitude etc. unlike the conventional models. Nonetheless, our approach can be implemented in an end-to-end clinical set up and that adds to the novelty of our work.

2. Background.

2.1. Arrhythmias: An Undeniable Obstacle. Derived from the Greek word "arrhythmias," which means "without rhythm," arrhythmias refer to a broad spectrum of illnesses marked by an irregular heartbeat. These disorders can manifest as a variety of heart rhythms, including bradycardias (slow heartbeats), atrial fibrillations (chaotic rhythm), and tachycardias (rapid heartbeats). These abnormalities might have a variety of causes, including extrinsic influences like stress or drug usage, congenital problems, and cardiomyopathies [21].

Early detection and management of arrhythmias are crucial due to the potential for severe complications, as some arrhythmias are benign while others are not. The electrocardiogram (ECG) is the primary tool used in this field. It is a non-invasive test that visually displays the heart's electrical activity [23].

2.2. Electrocardiograms (ECGs): The Diagnostic Mainstay. The introduction of the ECG in the early 20th century brought about a significant transformation in cardiac diagnostics. Clinicians can visualize the heart's electrical impulses by applying electrodes to the skin, which are then represented as waveforms on a graph. The various components of this waveform, including the P wave, QRS complex, and T wave, provide valuable information about different stages of the cardiac cycle. Variations in these waveforms and complexes

Fig. 2.1: Human Heart and ECG.

may suggest the presence of underlying arrhythmias or other cardiac pathologies. However, the analysis of electrocardiograms (ECGs) is not a simple process. Detecting subtle anomalies, such as distinguishing between a normal rhythm and a potentially dangerous arrhythmia, necessitates significant training, experience, and a discerning eye.

2.3. The Advent of Artificial Intelligence in Healthcare. The integration of technology into healthcare has significantly increased during the 21st century. The evolution of healthcare is evident through the digitization of medical records, utilization of advanced imaging modalities, and the increasing prevalence of telemedicine. Data has played a central role in this technological wave. The growing accessibility of extensive datasets has paved the way for the emergence of artificial intelligence (AI) in the field of medicine. AI, which refers to the simulation of human intelligence processes by machines, has been increasingly utilized in various medical fields. Machine learning, a subset of computer science, involves the use of statistical techniques by computers to learn from data. This has subsequently facilitated the development of more sophisticated techniques. Deep learning, a subfield of machine learning, has shown great promise as it utilizes neural networks algorithms. One of its notable strengths is its capacity to acquire knowledge and make informed choices based on data, frequently outperforming human abilities in certain tasks [26].

2.4. The Confluence of Deep Learning and ECG Analysis. Researchers started examining the combination of the two because of the difficulties involved in manually interpreting ECG data and the potential of deep learning in handling enormous volumes of data. Is it possible to train deep learning algorithms to identify arrhythmias as accurately as expert cardiologists, if not more so? Numerous studies, inventions, and discussions have resulted from the pursuit of an answer to this topic, which has set the stage for the information contained in this article.

3. Deep Learning Techniques for Arrhythmia Classification.

3.1. Convolutional Neural Networks (CNNs). Originally designed for image processing, convolutional neural networks (CNNs) have had a profound impact on fields involving the recognition of patterns in geographical data. These networks automatically identify hierarchical patterns in the data by using convolutional layers. By transforming ECG segments into time-frequency representations like spectrograms and treating them like image-like structures, CNNs can be utilized to identify arrhythmic patterns. Convolutional layers are very good at capturing the subtle fluctuations and anomalies that point to different kinds of arrhythmias because they are skilled at identifying spatial patterns in converted ECG data [29].

Multiple studies have shown that CNNs have proven to be effective in achieving high levels of accuracy in detecting arrhythmia. In some cases, CNNs have even demonstrated comparable performance to that of expert cardiologists [30].

3.2. Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) Networks. Because they are made expressly to handle sequential data, recurrent neural networks or RNNs are ideal for evaluating time-series data like ECG sequences. Artificial neural networks have the ability to store data from previous calculations, which allows them to identify patterns and trends over time. LSTMs are a kind of RNN that effectively preserve patterns over lengthy sequences, hence resolving the vanishing gradient problem commonly observed in traditional RNNs [32].

Fig. 3.1: Representation of Deep Learning CNN method.

Fig. 3.2: Representation of Deep Learning CNN method.

RNNs and LSTMs are effective in analyzing raw ECG sequences due to their ability to capture temporal patterns which can serve as indicators of arrhythmias. Their capacity to identify long-term dependencies in the ECG sequence renders them highly valuable, particularly in instances where the arrhythmia’s distinctive pattern is distributed over an extended period.

3.3. Attention Mechanisms and Transformers. Attention mechanisms, derived from the domain of natural language processing, enable models to selectively concentrate on particular segments of the input data. Transformers, which rely solely on attention mechanisms, have demonstrated considerable potential across diverse domains. In the context of ECG data, attention mechanisms enable models to prioritize segments of the data that may be more indicative of an arrhythmia. By assigning weights to different components of an ECG sequence, these models have the potential to enhance accuracy by prioritizing the most pertinent signals [35].

3.4. Autoencoders. Autoencoders are a type of unsupervised neural network that aim to learn compact representations of input data. These models operate by compressing the input data into a condensed form and subsequently reconstructing the original input using this condensed representation. Autoencoders are a viable method for detecting anomalies in electrocardiogram (ECG) signals. Deviation or anomaly in the input signal, such as arrhythmic events, can lead to a high reconstruction error when trained on normal ECG data. This characteristic can be utilized to identify possible arrhythmias. Data, resulting in enhanced rates of arrhythmia detection.

Table 4.1: Overview of Arrhythmia Detection Studies

No	Paper Title	Authors	Year	Key Findings
1	Arrhythmia detection using deep convolutional neural network with long duration ECG signals	Ozal Yldrm, Pawe Pawiak	2018	This study proposes deep convolutional neural network (DCNN) to detect arrhythmia in long-duration ECG signals. The investigation of the model's ability to detect less common or subtle arrhythmias which is crucial for clinical applications is currently limited.
2	Automated diagnosis of arrhythmia using combination of CNN and LSTM techniques with variable length heart beats	Shu Lih Oh, Eddie Y.K. Ng	2018	In this study, the authors employed the model's ability to accommodate heartbeats of varying lengths has not been thoroughly examined by means of the challenges or potential data misalignments it may pose. based on convolutional neural networks.
3	Multiclass Classification of Cardiac Arrhythmia Using Improved Feature Selection and SVM Invariants	Anam Mustaqeem, Syed Muhammad	2018	In this paper, the authors propose a novel approach for classifying cardiac arrhythmia. Although improved feature selection is suggested, it is possible that other advanced feature extraction or transformation techniques could provide a more effective representation and consequently improve classification outcomes.
4	Automated arrhythmia detection using novel hexadecimal local pattern and multilevel wavelet transform with ECG signals	Turker Tuncer, Sengul Dogan	2019	This paper reports the novel hexadecimal local pattern (HxLP) has been introduced but further research is needed to assess its robustness in the presence of noisy or artifact-laden ECG signals.
5	A Fast Machine Learning Model for ECG-Based Heartbeat Classification and Arrhythmia Detection	Miquel Alfaras, Silvia Ortín, Miguel Cornelles Soriano	2019	The research presents a machine learning model specifically designed for ECG signals with a primary focus on classifying heartbeats and detecting arrhythmias. Understanding the decision-making process of the model is crucial due to the critical nature of arrhythmia detection. The paper lacks in-depth analysis of model interpretability and the significance of the selected features.
6	Automated arrhythmia classification based on a combination network of CNN and LSTM	Chen Chen, Zhengchun Hua, Ruiqi Zhang	2020	This work presents arrhythmia classification through the use of hybrid model i.e CNN and LSTM. The model is more accurate and robust than the traditional model in terms of accuracy and robustness. The limitations of this study are that QRS detection is necessary which leads to additional computational cost. The second issue is that the data set used in this work is imbalanced.
7	Multirate Processing with Selective Sub bands and Machine Learning for Efficient Arrhythmia Classification	Saeed Mian Qaisar	2021	This study proposes a Multi-rate processing chain for the arrhythmia classification. Multi-rate processing feature selection were employed to decrease the information amount procedure thus reducing the complexity of the computational system. The performance results of model were varied by chosen various number of features.
8	Arrhythmia and Disease Classification Based on Deep Learning Techniques	Ramya G. Franklin, B. Muthukumar	2021	This work predicts converting raw ECG data to 2D pictures may cause information loss. Using straight 1D convolution on raw signals or different transformation methods may improve or accelerate results.
9	An Ensemble of Deep Learning-Based Multi-Model for ECG Heartbeats Arrhythmia Classification	Ehab Eesa, Xi-anghua Xie	2021	This research proposes multi-model system that was presented for the arrhythmia classification. It focusses on two models: CNN-LSTM to capture dynamics in temporal as well as local features for data ECG; RRHOS-LSTM that concatenated some features for classical i.e. RR intervals. This approach does not perform the feature extraction process.
10	ECG Heartbeat Classification Using Multimodal Fusion	Zeeshan Ahmad	2021	This work introduced two computationally effective multimodal feature fusion framework classification for ECG heart beat named Multimodal Image Fusion (MIF) and Multimodal feature fusion (MFF). This framework consumed much time for training and inference.

Table 4.1 – continued from previous page

No	Paper Title	Authors	Year	Key Findings
11	Interpreting Arrhythmia Classification Using Deep Neural Network and CAM-Based Approach	Niken Prasasti Martono	2021	The work proposes an extension of CNN-based learning in detecting arrhythmia using recurrence plots from ECG signal and then the authors then conduct visualization using the Grad-CAM approach on the recurrence plot data to have a better interpretation of the classification process. In this work in the data preprocessing stage the appearance of R wave with irregular timing has been noted.
12	Arrhythmia Classification Techniques Using Deep Neural Network	Ali Haider Khan	2021	The research is focused on the latest trends in arrhythmia classification techniques and the system is constructed using deep neural networks. The study focused on understanding arrhythmia classification techniques to overcome their limitations. Time-series data was used by the authors to create the proposed automated system which is not applicable to different systems. For classification a balanced dataset is necessary.
13	Classification of Arrhythmia in Heartbeat Detection Using Deep Learning	Wusat Ullah	2021	The research developed a CNN model to classify ECG signals into eight categories. MIT-BIH arrhythmia database and PTB Diagnostic ECG database are used in this work. The study should concentrate on the development of denoising and data augmentation techniques.
14	Interpretation and Classification of Arrhythmia Using Deep Convolutional Network	Prateek Singh, and Ambalika Sharma	2021	The authors of this research trained a deep learning model and evaluated its classification performance Post-hoc explanation methods like SHapley Additive explanations (SHAP), local interpretable model-agnostic explanations (LIME), and Grad-CAM were used to interpret the decision rationale after interpreting the classification findings. This works lags in Interpretability.
15	Automatic cardiac arrhythmia classification based on hybrid 1-d CNN and bi-LSTM model	Jagdeep Rahul A , Lakhn Dev Sharma	2021	This work reports automatic classification system of ECG beats based on the multi-domain features derived from the ECG signals. This work reports overfitting where large dataset was used to remove.
16	Electrocardiogram based arrhythmia classification using wavelet transform with deep learning model	Shadhon Chandra Mohonta	2022	The study proposes a Deep Learning approach for the ECG based classification of the arrhythmia disease. The scalogram was acquired through the Continuous Wavelet Transform (CWT) was classified by the network based on signature according to arrhythmia. This approach was only suitable for the smaller segments of the signal
17	Inter-patient arrhythmia classification with improved deep residual convolutional neural network	Yuanlu Li	2022	The research paper presents enhanced Deep Residual Convolutional Neural Network (DRCNN) for automatic classification of arrhythmias. This approach was ability to effectively classified the arrhythmias without heartbeats extraction. This method had poor directionality as well as lack of phase information
18	A Hybrid Deep Learning Approach for ECG-Based Arrhythmia Classification	Parul Madan, Vijay Singh	2022	This work reports a hybrid model 2D-CNN-LSTM for the automation of the detection and process of classification. The dimension of the data was insufficient in classification, and the attributes has irrelevant data. This caused leads to inaccurate classification results in cardiac analysis.
19	Local-Global Temporal Fusion Network with an Attention Mechanism for Multiple and Multiclass Arrhythmia Classification	Yun Kwan Kim	2022	This research developed a new framework for an automatic classification that combined the residual network with squeeze-and-excitation (SE) block and bi-directional LSTM. This method designed to extract the features from original ECG data to acquire a unique intersubject attributes. The augmentation effect could be reduced due to baseline wander as well as noise couldbe extended to rhythm data.
20	An End-to-End Cardiac Arrhythmia Recognition Method with an Effective DenseNet Model on Imbalanced Datasets Using ECG Signal	Hadaate Ullah ,Md Belal Bin Heyat , Fajjan Akhtar	2022	This research proposed a 2D CNN Method to recognize arrhythmia from ECG automatically. This approach uses two datasets. The proposed model lags with real-time monitoring and end-to-end clinical study.

Table 4.1 – continued from previous page

No	Paper Title	Authors	Year	Key Findings
21	Detection of heart arrhythmia based on UCMFB and deep learning technique	B MOHAN RAO and AMAN KUMAR	2022	This research presents Resnet50 model that classifies healthy people and patients with 4 types of cardiovascular diseases (CVD) based on ECG abnormalities. The study was done based on short and long segments of ECG databases. This has not deployed for Specific ECG multiclass classification
22	Arrhythmic Heartbeat Classification Using 2D Convolutional Neural Networks	M.Degirmenci, M.A.Ozdemir	2022	This study presents deep learning approach CNN to identify arrhythmias in ECG signals trained by two-dimensional (2D) ECG beat images. This work lags with real time monitoring.
23	Lightweight Shufflenet Based CNN for Arrhythmia Classification	HURUY TESFAI	2022	This research work proposes a lightweight Convolution Neural Network (CNN) model based on the ShuffleNet architecture targeting arrhythmia classification with a 9x reduction factor in the number of trainable parameters. In this work feature extraction capabilities on convolution block should be improved.
24	A novel automated CNN arrhythmia classifier with memory-enhanced artificial hummingbird algorithm.	Evren Kymaç, Yasin Kaya	2023	This work presents a novel method for the hyperparameter optimization (HPO) of a convolutional neural network (CNN) arrhythmia classifier using a metaheuristic (MH) algorithm. The proposed approach has not applied in different datasets for arrhythmia classification.
25	Classifying Cardiac Arrhythmia from ECG Signal Using 1DCNN Deep Learning Model	AdelA, Ahmed Waleed Ali	2023	The study proposes a deep learning model, specially convolutional neural network (1D-CNN), for the classification of arrhythmias. Limitations in this approach are dataset is imbalanced and it requires large dataset to train the model.
26	Electrocardiogram Heartbeat Classification for Arrhythmias and Myocardial Infarction	Bach-Tung Pham	2023	The research presents novel approach for ECG heartbeat classification. It uses MIT-BH and PTB datasets. The limitations of this approach is effectiveness of the model needs to be checked for additional datasets.
27	Cardiac arrhythmia detection using deep learning approach and time frequency representation of ECG signals	Yared Daniel Daydulo, Bheema Lingaiah D	2023	This research proposed an automated deep learning model capable of accurately classifying ECG signals into three categories. The model was trained on ECG data from the MIT-BIH and BIDMC database. Authors of this research concentrated on classifying ECG signals into three classes. It's better to collect more data for this work.
28	A novel deep learning approach for arrhythmia prediction on ECG classification using recurrent CNN with GWO	Prem Narayan Singh, Rajendra Prasad Mahapatra	2023	This research proposes a method called recurrent convolutional neural network (RCNN) and Grey Wolf Optimization (GWO) for predicting arrhythmia. The proposed method is evaluated by using two publicly available datasets PTB diagnostic ECG and Grey Wolf Optimization (GWO). The proposed method has been compared with other ML techniques. Improvement is needed in terms of adapting metamodel approach and identifying different arrhythmia types.
29	A novel deep neural network heartbeats classifier for heart health monitoring	Velagapudi, Swapna Sindhu, Kavuri Jaya Lakshmi	2023	This presents one-dimensional convolutional neural network (1D CNN) for the classification of heart arrhythmia. Hyperparameter tuning was not adapted in order to improve accuracy of the model.
30	Automated inter-patient arrhythmia classification with dual attention neural network	He Lyua,, Xiangkui Li b, Jian Zhang b	2023	This work presents a dual attention mechanism with hybrid network (DA-net) for arrhythmia classification. DA-net is based on modified convolutional networks with channel attention (MCC-Net) and sequence-to-sequence network with global attention (Seq2Seq). Improvement is needed in terms of adapting data augmentation techniques.

4. Comparative Study.

5. Proposed Methodology.

1. Obtain ECG datasets from various sources in order to guarantee a wide range of cardiac conditions.
2. Prepare the ECG signals for analysis by means of normalization, filtering, and segmentation.
3. Incorporate deep learning alongside conventional signal processing methods to autonomously extract pertinent features from electrocardiogram (ECG) data.

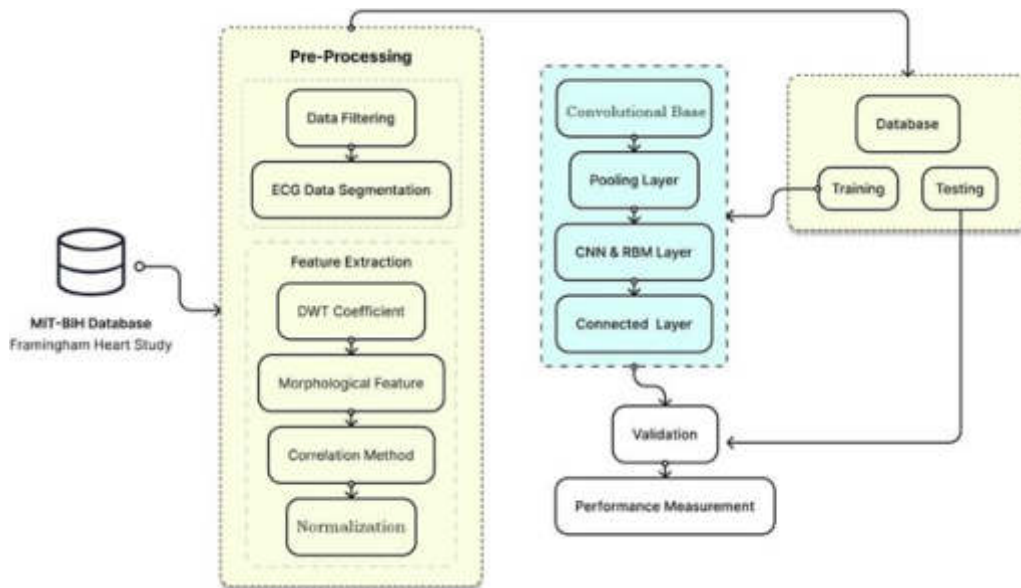

Fig. 5.1: Proposed work flow diagram for arrhythmia detection and classification.

4. Construct and evaluate a deep learning architecture that incorporates the gathered attributes to identify arrhythmias.
5. Performance can be enhanced and overfitting prevented by implementing regularization techniques and fine-tuning hyperparameters.
6. Evaluate the accuracy and robustness of the model using data obtained from multiple ECG devices.
7. Incorporate explainable AI methodologies in order to comprehend and represent the decision-making process of the model.
8. Evaluate the model on a test dataset utilizing metrics such as accuracy, sensitivity, specificity, and F1 score.
9. Develop a prototype system to demonstrate the arrhythmia detection capabilities.
10. Continuously refine the model using feedback and additional data for ongoing improvement.

6. Results and Discussion. In our work, we novel deep learning-based framework to analyze the complex ECG data and develop a transferable representation of ECG signals. It is important to know that to realize such a framework it is very important to describe an architecture that offers scope for learning the signal representation. Once we build a model and train that model on a huge training data set, the model will be able to learn from the pattern and allow to use those representation to transfer the knowledge. We have further experimented the CNN by adding the batch normalization layer between subsequent layers thereby inhibiting the hidden / convolution layers from normalizing the values which facilitate in improving the efficiency.

Also, the proposed algorithm employs a 2-D CNN with monochrome images of the ECG. One of the advantages of our approach is that conventional data pre-processing steps like feature extraction and noise removal and filtering are not required as the algorithm converts the 1-D Signal data to a 2-D image. Additionally, to improve the accuracy of the model we can augment the 2-D images and increase the size of the training data. Since our algorithm transforms a 1D signal to a 2D image, the model will automatically ignore the noise and extract the feature map. This allows the proposed model to be employed on heterogeneous signals and devices with different feature sets like sampling rate, amplitude etc. unlike the conventional models. Nonetheless, our approach can be implemented in an end-to-end clinical set up and that adds to the novelty of our work.

As shown in Figure 6.1, Individual cardiologist performance is indicated by the red crosses and averaged cardiologist performance is indicated by the green dot. The line represents the ROC curve of model performance.

Fig. 6.1: Specificity and Sensitivity of Different classes of Arrhythmia.

AF-atrial fibrillation/atrial flutter; AVB- atrioventricular block; EAR-ectopic atrial rhythm; IVR-idioventricular rhythm; SVT supraventricular tachycardia; VT-ventricular tachycardia. $n = 7,544$ where each of the 328 30-second ECGs received 23 sequence-level predictions.

Fixing the specificity at the average specificity level achieved by cardiologists, the sensitivity of the DNN exceeded the average cardiologist sensitivity for all rhythm classes. Fixing the specificity at the average specificity level achieved by cardiologists, the sensitivity of the DNN exceeded the average cardiologist sensitivity for all rhythm classes as shown in Table 6.1. And the overall accuracy of the model (AUC) is around 0.97 as shown in Figure 6.2.

Our work demonstrates that the accuracy of the model is around 0.97. Our study demonstrates how employing Deep Learning Methods can improve the accuracy and open new avenues for research. Figure 6.2 shows the AUC of the rhythm classes and we can note that the accuracy is elevated compared to the annotations

When we started experimenting with the dataset, we realized that the data was quite imbalanced as shown

Table 6.1: Sensitivity comparison of our model vs. avg cardiologist

Condition	Specificity	Avg Cardiologist Sensitivity	Our Model's Sensitivity
Atrial fibrillation and flutter	0.941	0.71	0.861
AVB	0.981	0.731	0.858
Bigeminy	0.996	0.829	0.921
EAR	0.993	0.380	0.445
IVR	0.991	0.611	0.867
Junctional Rhythm	0.984	0.634	0.729
Noise	0.983	0.749	0.803
Sinus rhythm	0.859	0.901	0.950
SVT	0.983	0.408	0.487
Ventricular Tachycardia	0.996	0.652	0.702
Wenckebach	0.986	0.541	0.651

Fig. 6.6: Sensitivity of each type of arrhythmia class using transformation method.

part of training data. Figure 6.6 shows the confusion matrix of the classifier on the test set and we can infer that the model is making accurate predictions and also distinguish various arrhythmia classes.

Table 6.1 shows the avg accuracy of the proposed method. From the results we can infer that the proposed model has a very high accuracy and this has been characterized by the residual connections in the network which allows better learning in the networks compared to conventional methods.

7. Conclusion. This work develops a hybrid model for the automatic feature extraction and classification of various arrhythmias. Nevertheless, there are obstacles that need to be addressed, particularly regarding the accuracy of data, the establishment of standards, and the comprehensibility of these models. Future research should prioritize creation of models that combine features of machine learning and deep learning. These models have the potential to enhance robustness and improve generalization capabilities. Furthermore, it is crucial to develop a unified framework that can effectively integrate with current healthcare systems. In conclusion, although the use of ML and DL for arrhythmia classification is still in its early stages, it holds significant potential for improving patient care. The adoption of these technologies has the potential to significantly transform cardiac care, establishing early and precise diagnosis as the prevailing standard.

8. Future Scope. Our proposed model focusses on detecting and classifying arrhythmia using ECG and bio signals which is a game changer.in Future more focus will be on real time monitoring of patients using the required dataset, where we can achieve more accuracy.

Credit authorship contribution statement. Manjesh B N: Methodology, Software, Data curation, Writing original draft, Writing review and editing. Dr.Raja Praveen N-Investigation, Writing review and editing.

Declaration of Competing Interest. Declaration statement by co-authors for the manuscript, A Comprehensive Review on Detection of Arrhythmia using Deep Learning Methods with Deep Learning Model. We declare the following:

1. Data: The public database from MIT-BIH has been used in this study.
2. Ethics: The research protocol was approved by Jain University, Bangalore.
3. Conflict of Interest: Nothing to declare.
4. Financial support: Nothing to declare.

Acknowledgement. First and foremost, I wish to record my sincere gratitude to Management of Jyothy Institute of Technology and to my beloved Principal, Dr. Gopalakrishna, JIT, Bengaluru for his constant support and encouragement. My sincere thanks to Dr. Raja Praveen N, Associate professor ,Jain University for his valuable support.

OPTIMIZING WASTE REDUCTION IN MANUFACTURING PROCESSES UTILIZING IOT DATA WITH MACHINE LEARNING APPROACH FOR SUSTAINABLE PRODUCTION

FAISAL ALTARAZI*

Abstract. Sustainable manufacturing with the Internet of Things (IoT) reduces environmental impacts, conserves natural resources, saves energy, and improves worker, community, and consumer safety while maintaining economic viability. IoT's network of sensors and intelligent devices collects and analyzes data throughout the production lifecycle, enabling organizations to fulfil sustainability objectives and adopt more efficient, less wasteful operations. Waste management and reduction measures are the focus of sustainable manufacturing research. Improvements are needed to simplify waste management and reduce production waste. Thus, in this study, we introduce an innovative machine learning technology called "EcoEfficientNet", developed to tackle this problem. Our study addresses the issue of waste in manufacturing processes. EcoEfficientNet employs sophisticated deep learning algorithms to analyze complex production data, allowing it to identify significant patterns and determine specific areas where waste can be significantly minimized. EcoEfficientNet's approach to waste reduction in manufacturing processes revolves around three main strategies: data-driven analysis, optimization recommendations, and adaptable learning for continual enhancement. EcoEfficientNet's success lies in its capacity for perpetual learning, enabling it to adapt to novel data and evolve alongside production settings. An extensive case study of a particular manufacturing process is carried out to assess the efficiency of EcoEfficientNet and provide helpful perspectives into the model's effectiveness. By incorporating this method into the manufacturing process, organizations have seen a decrease in waste generation of up to 30%, demonstrating the applicability and efficacy of machine learning in improving sustainable manufacturing processes. The key to EcoEfficientNet's success is its ability to engage in continuous learning, allowing it to adjust to new data and develop in tandem with operational environments.

Key words: Waste reduction, IoT Sensed data, deep learning, decision processing, operational efficiency, manufacturing, sustainability.

1. Introduction. Sustainable manufacturing [1] is a crucial concept in the manufacturing sector that focuses on reducing environmental consequences, conserving energy and natural resources, ensuring worker safety, and maintaining financial viability. Although there have been notable progressions, the industry still faces challenges in managing and minimizing waste, which presents a promising opportunity for innovation. In response to this identified deficiency, the present study proposes "EcoEfficientNet," an advanced machine learning (ML) network specifically developed to address the shortcomings in waste management in industrial processes.

Integrating real-time data from various sensors and devices across the factory floor, including IoT data in "EcoEfficientNet" for evaluation purpose, significantly enhances its capacity to revolutionize sustainable manufacturing. This convergence allows for accurate monitoring of resource use, operational variables, and waste generation, providing the machine learning network with highly accurate data essential for detecting inefficiencies and forecasting opportunities for waste reduction. EcoEfficientNet utilizes the constant stream of IoT data to acquire knowledge and enhance operations actively, leading to improvements in waste management and the development of a more environmentally friendly production system.

Moreover, the need for technological intervention arises from growing ecological issues and strict rules designed to promote sustainable activities. Conventional waste management systems must be more robust because they cannot adjust to intricate production settings and optimize operations in real-time [2]. Hence, implementing intelligent systems with the capacity to analyze data and optimize processes in real time is beneficial and essential for advancing manufacturing towards increased sustainability.

Thus, in this study, we introduce "EcoEfficientNet", which is at the forefront of this transformation. By using sophisticated deep learning algorithms, this system examines the complexities of production data, revealing trends and identifying crucial areas for minimizing waste [3]. The study is essential as it can completely alter

*University of Jeddah, Jeddah, Saudi Arabia, (fmaltarazi@uj.edu.sa)

waste management by converting extensive data into practical and valuable information. This will contribute to the area's existing knowledge and provide a model that can be replicated to promote sustainable practices.

The initial objective is to showcase the effectiveness of "EcoEfficientNet" in substantially reducing waste via its analytical capabilities. This objective is accomplished by thoroughly examining both past and current production data, allowing for a complete comprehension of trends in waste formation. The second goal is to verify the flexibility and ongoing learning capacities of "EcoEfficientNet." The research intends to demonstrate the model's capacity to smoothly integrate into current production processes and adapt to changes, assuring long-term sustainability and efficacy. This will be achieved via empirical experiments conducted throughout the study.

This study addresses a significant need for sustainable manufacturing and advances the industry by demonstrating the tangible advantages of ML techniques. The expected result is a substantial drop in waste, with first deployments demonstrating a reduction of up to 30%, highlighting the revolutionary potential of "EcoEfficientNet." This study is positioned to establish a standard in sustainable manufacturing, providing a solid basis for future progress and strengthening the importance of technological advances in attaining sustainable and effective manufacturing procedures.

2. Related Work. Artificial neural network (ANN) approaches have become commonplace across several academic disciplines owing to their inherent capacity to acquire knowledge from provided instances. ANNs are extensively used and considered the predominant machine learning algorithms [4]. Additionally, they have been proposed for several manufacturing applications, particularly in the context of predictive automation. [5] examines explicitly the use of Artificial Neural Networks (ANNs) to classify the condition of tools in CNC (Computer Numerical Control) milling machines. The distinctiveness of this technique is in its retrofitting strategy, which allows older equipment to conform to the norms of Industry 4.0. The research showcases the successful implementation of tool wear monitoring using integrated detectors on a customizable prototyping platform. The ANN model effectively enables the modernization of outdated equipment and surpasses the performance of Support Vector Machine (SVM) and k-nearest Neighbors (KNN) approaches. [6] introduced a technique in which vibration information from a hypothetical motor unit is used to train an ANN to forecast equipment malfunctions. The method is distinguished by its use of frequency and amplitude data to predict the exact moment at which the vibrating system would break. The Multilayer Perceptron (MLP) approach was selected because of its simplicity in implementation and ability to generalize. The research demonstrates that the ANN outperforms Random Forest (RF), Regression Tree (RT), and SVM in making predictions over medium and long time periods. However, its performance is comparable to these methods in the short term. [7] use ANNs and SVMs to forecast the deterioration of gauges in train tracks.

The study concentrates explicitly on both straight and curved sections. The ANN model has a substantial coefficient of determination, which signifies its robust prediction capability. Although both SVM and ANN models provide excellent outcomes, the ANN model is marginally superior at forecasting gauge variation for linear segments. [8] constructed a test apparatus to replicate the functioning of a wind turbine, with a specific emphasis on observing its state employing vibration evaluation. The created ANN model, designed to identify the health status of essential components, has a remarkable accuracy score of 92.6%. This study highlights the possibility of ANNs in predicting and preventing maintenance issues in the field of green energy. [9] conduct a comparative analysis of physics-based models as well as models built on neural networks (NN) to assess the deterioration of instances in Auxiliary Power Units (APUs). This approach emphasizes a universal modeling strategy to tackle the difficulty of varying component features. The results indicate that the physics-based method is more dependable for deteriorated starts, but the NN model performs very well with starters in optimal circumstances. [10] presented a system that utilizes data to diagnose and predict the performance of machinery and maintenance expenses. Furthermore, a precise data labeling mechanism is devised for supervised learning by contrasting the serial numbers of target components on consecutive dates. The research used actual data from vending machines to verify the concept architecture using three distinct classifiers: SVM, RF, and Gradient Boosting Machines (GBM). The outcomes of the cross-validated simulated events demonstrate that the diagnostic approach can reach an accuracy of over 80%. Therefore, the proposed GBM model can effectively diagnose and monitor complicated machine types. The prognosis approach surpasses one-stage traditional forecasting techniques. Symbolic Regression (SR) has been used to estimate the state of well-functioning industrial

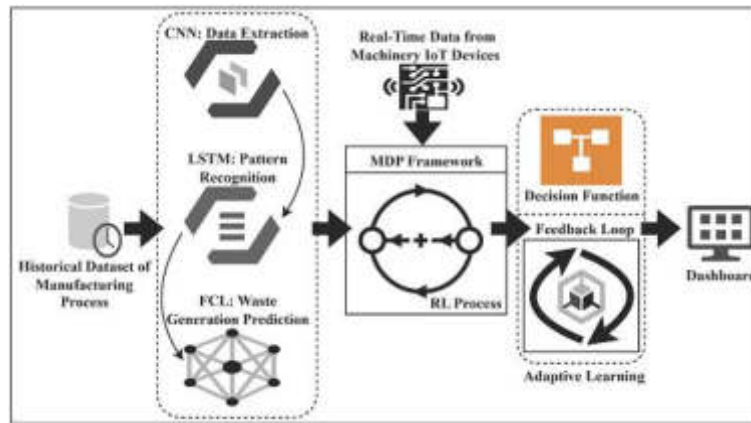

Fig. 3.1: Framework of EcoEfficientNet

equipment [11]. The work introduced a mechanism for handling idea drifts in persistent information streams. In addition, a practical case study was shown with industrial radial fans. The findings from the computerized information indicate that concept drift diagnosis and prognosis were highly effective. [12] addresses the crucial problem of inadequate productivity in an industrial setting, specifically emphasizing a tire manufacturing firm in Peru. The study's primary aim is to combine and design various tools to improve effectiveness, thereby decreasing the expensive upkeep of manufacturing machinery and the significant expenditures of adopting new systems. The primary focus of this work is on the creation of a waste-management strategy. This model is specifically designed to minimize the time required to set up and implement a viable operational control system, with the ultimate objective of enhancing the Overall Equipment Effectiveness (OEE) score. The model's assessment in an actual production setting yielded remarkable results, including a 13% enhancement in the OEE score and a substantial 22.5% decrease in the setup period.

Previous research has shown that ANNs can effectively monitor tool conditions and expected equipment malfunctions and perform scheduled upkeep. However, there has been less emphasis on using such strategies to improve waste management and decrease wastage in industrial environments. It is crucial to address this shortcoming to promote the progress of sustainable manufacturing methods. Suppliers can optimize resource utilization, mitigate environmental consequences, and improve their general productivity by incorporating ML techniques specifically designed for waste reduction.

3. Methodology. The EcoEfficientNet framework in Fig. 3.1 depicts a novel strategy in manufacturing that focuses on reducing waste by using sophisticated Deep Learning (DL) and Reinforcement Learning (RL) models. The two-stage procedure starts by using an advanced DL model that integrates Convolutional Neural Networks (CNN), Fully Connected Layers (FCL), and Long Short-Term Memory (LSTM) to detect and examine patterns in the manufacturing process. The second step utilizes these insights using a Reinforcement Learning (RL) model based on a Markov Decision Process (MDP) to implement strategic adjustments based on the real-time data from IoT devices during the manufacturing process. EcoEfficientNet optimizes efficiency and minimizes waste by constantly adjusting activities, aligning manufacturing operations with sustainable principles.

3.1. First Phase. Initially, a sophisticated DL model is used to identify patterns in the backdrop of minimizing waste in a manufacturing procedure. A fusion of CNN, LSTM, and FCL is implemented to achieve this. The first phase of the EcoEfficientNet Model has three primary components. CNN stands for Convolutional Neural Network, LSTM stands for Long Short-Term Memory, and FCL stands for Fully Connected Layer. Input data that contains visuals or spatial trends (like sensor heatmaps) can be extracted using the CNN layers, which deal with spatial features. IoT devices served as the primary sources for continuous, real-time data feeding into the EcoEfficientNet system. LSTM layers excel in processing time-series data by obtaining

temporal relationships and sequences of events, such as consumption of resource patterns over time. On the other hand, FCL layers act as the final decision-making layers, interpreting the features extracted by the CNN and LSTM. They are responsible for predicting waste generation in structured data, such as equipment logs and production data.

Computation at CNN Layers. The CNN layer utilizes several filters, k , to generate feature maps from the input visual (if applicable) I , which has dimensions HCEWØED (height, width, depth) [13]. Such process can be analytically defined as Equation (3.1),

$$f_{ij}^k = \text{ReLU} \left[\sum_{r=0}^{R-1} \sum_{c=0}^{C-1} \sum_{d=0}^{D-1} F_{(m \cdot n \cdot d)}^k \cdot I_{(i+r),(j+c),d} + e^k \right] \quad (3.1)$$

In Equation (3.1), f_{ij}^k represents the essential feature at (i, j) at the k th feature map, $F_{(m \cdot n \cdot d)}^k$ denotes the k^{th} filter employed at i^{th} input, and e^k indicates the bias at k^{th} filter.

Computation at LSTM. The acquired attributes are smoothed and then potentially processed via additional substantial layers before inputting into LSTM cells [14]. An LSTM cell sequentially analyzes time-series information, updating and preserving both a cell state (Z_t) and hidden state (h_t) at each time step. At each successive step t , the LSTM modifies its states in the following manner [15], Equation (3.2) to (3.7) :

$$\text{Forgetgate} : F_t = \sigma (w_F \cdot [h_{(t-1)}, I_t] + e_f) \quad (3.2)$$

$$\text{Inputgate} : I_t = \sigma (w_i \cdot [h_{(t-1)}, I_t] + e_l) \quad (3.3)$$

$$\text{Cellcandidate} : \tilde{Z}_t = \tanh (w_Z \cdot [h_{(t-1)}, I_t] + e_Z) \quad (3.4)$$

$$\text{NewerCellstate} : Z_t = F_t * Z_{(t-1)} + I_t * \tilde{Z}_t \quad (3.5)$$

$$\text{Outputgate} : o_t = \sigma (w_o \cdot [h_{(t-1)}, I_t] + e_o) \quad (3.6)$$

$$\text{NewerHiddenstate} : h_t = o_t * \tan h [Z_t] \quad (3.7)$$

where $*$ indicates the element-wise multiplication, σ denotes sigmoidal function, I_t indicates the input, e and w denotes the bias and weight for each gate, respectively.

Computation of FCL. The LSTM's output, denoted as h_t , is then fed into a FCL for the intent of classifying the states of operation into categories like normal, under-efficient, over-efficient (classifying the level of waste production). The FCL does the following operation [16]:

$$\delta = \sigma (w_{FCL} \cdot h_t + e_{FCL}) \quad (3.8)$$

In Equation (3.8), e_{FCL} and w_{FCL} are the biases and weights of the FCL.

Backpropagation [17] is used to optimize the parameters associated with the model throughout training. The loss function is used to quantify the discrepancy between the actual waste level and the projected waste level for each batch of data.

$$f(L) = \frac{1}{B} \sum_1^B [\delta_i - \tilde{\delta}_i]^2 \quad (3.9)$$

where B denotes the batch size, δ_I represents the true value, and $\tilde{\delta}_I$ is the predicted value by the model in Equation (3.9).

The derivatives of the loss function concerning the model's parameters are then calculated and used to adjust the parameters employing the Adam optimizer. In the first phase, EcoEfficientNet combines CNN, LSTM, and FCL. This enables the model to comprehend the manufacturing data's temporal and spatial patterns.

Consequently, EcoEfficientNet can make precise predictions about waste emergence, which in turn can be utilized to improve the manufacturing process and minimize such waste.

3.2. Second Phase. The second stage involves incorporating a reinforcement learning (RL) model that will execute actions to enhance the manufacturing process by leveraging the predictions generated by the DL model. This phase has two primary components: the Markov Decision Process (MDP) [18] and the learning process. In this context, the issue of waste reduction is conceptualized as a MDP, whereby the state corresponds to the existing condition of the manufacturing process, actions denote potential modifications, and rewards are allocated for actions that minimize waste.

Decision-Making Process. The MDP is a conceptual framework used to represent decision-making scenarios in which outcomes are influenced by both random factors and the management-maker's regulation. MDPs are valuable tools for analyzing optimization issues addressed using adaptive programming and RL techniques [18].

The RL model operates within the framework of an MDP and is characterized by the tuple (A, S, T, R, ϕ) . Here, the state signifies the existing condition of the production process, actions denote potential modifications, and incentives are granted for actions that minimize waste. Thus, MDP is characterized by the tuple (A, S, T, R, ϕ) , where:

A is a collection of activities that symbolize potential modifications to the process.

S is a collection of states that represents the present state of the manufacturing process.

The state transition potential matrix, denoted as T, represents the likelihood of moving from state s_t to state s_{t+1} after performing action a_t .

The reward function, denoted as $R[a_t, s_t]$, determines the reward obtained when a_t is taken in s_t .

The discount factor ϕ is used to strike a balance between present and potential rewards in the future.

An MDP aims to identify a strategy π that prescribes the optimal action 'a' to be taken in each S to maximize the overall expected reward. Q-learning facilitates [19] sophisticated learning processes, enabling the operation of intricate state spaces and acquiring optimum strategies via time. At first, the model randomly investigates several strategies inside safe operational boundaries to comprehend their influence on waste production. The gradual transition towards optimal strategies as the system gains knowledge from the results of its activities.

Learning Process. The DL model's predictions are integrated with the RL model's action-value estimates to facilitate informed decision-making. Furthermore, the DL model enhances the RL model by conveying information about the probable outcomes of various actions, enriching the state representation. This research used a widely used RL approach known as the Q-learning mechanism. The Q-learning update step at each t employs the Bellman formulation in the following manner [20]:

$$q^{new}[\alpha_t, s_t] = q[\alpha_t, s_t] + \alpha \{ \phi \max_a [\alpha_t, s_{t+1}] + R[\alpha_t, s_t] - \alpha[\alpha_t, s_t] \} \quad (3.10)$$

In Equation (3.10), α denotes the learning rate, $R[\alpha_t, s_t]$ represents the immediate reward received after taking a_t in s_t , $\max_a [\alpha_t, s_{t+1}]$ signifies the estimate of optimal future value.

To balance exploitation and exploration, a method known as ϵ -greedy is applied [21]. This approach involves the model randomly selecting a_t (exploration) with a probability of ϵ and selecting a_t with the greatest Q-value (exploitation) with a probability of $1 - \epsilon$. Table 3.1 represents the working mechanism of action-value function optimization [22].

Further, for real time data integration, let's assume D_t be the data received at time t. The data stream is fed into the system continuously, which is expressed as in Equation (3.11):

$$a(D_t) = \{ I_{(1t)}, I_{(2t)}, I_{(3t)}, \dots, I_{(nt)} \} \quad (3.11)$$

where $I_{(it)}$ denotes varying features of deployed machines in the production unit.

Implementation of Strategic Decisions and Continuous Learning: At this stage, the EcoEfficientNet framework is evaluated via received continuous, real-time data from IoT devices as its primary sources. This part of EcoEfficientNet involves decision function and feedback looping processes [23]. In the case of decision function, $a(D_t)$ considers the current state data as $I_{(it)}$ and suggests adjustments.

From Equation (3.12), q denotes the learned action-value function via RL process and A represents the possible set of actions.

$$\alpha(D_t) = \arg \max_{a \in A} q[\alpha, D_t] \quad (3.12)$$

Table 3.1: Working Mechanism of Action-Value Function Optimization

<p>Input: s (state), a (action), α (learning rate), φ (discount factor), ϵ (exploration rate), ϵ_{\min} (minimum exploration rate), decayrate (rate at which exploration rate decays), E (number of episodes to run the algorithm), R (reward function), q (action-value function), and initialized arbitrarily is zeros.</p> <p>Output: Optimized action-value function q.</p>
<p>For each E from 1 to N :</p> <p>Initialize s to the starting state.</p> <p>While terminal state is not reached:</p> <p>Choose a from s using policy derived from q :</p> <p>Execute a, observe r, and s'</p> <p>Update q-value for s and a :</p> $q[a, s] = q[a, s] + \alpha \{ \max_{a'} q[a', s'] + R - q[a, s] \}$ <p>$s \leftarrow s'$ (move to the new state)</p> <p>Decay ϵ where ($\epsilon \geq \epsilon_{\min}$)</p> $\epsilon \leftarrow \max(\epsilon, \epsilon_{\min} \cdot \text{decay_rate})$

Simultaneously, on the other hand, the model updates via action outcome recordings which is possible through feedback looping. For action outcome recordings, $R[\alpha(D_t), D_t]$ indicate the reward function obtained due to the outcome of $a(D_t)$ for the given D_t which is expressed as Equation (3.13),

$$R[\alpha(D_t), D_t] = \text{Efficiency}_{\text{gain}}(\alpha, D_t) | \text{Efficiency}_{\text{loss}}(\alpha, D_t) \mapsto \alpha(D_t) \quad (3.13)$$

Thus, the current q is updated based on the new incoming data and the $R[\alpha(D_t), D_t]$, which can be expressed as Equation (3.14),

$$q[a(D_t), D_t] \leftarrow \{q[a(D_t), D_t] + \varphi \max_{a'} q[a', D_{t+1}] + \alpha R[a(D_t), D_t] - q[a(D_t), D_t]\} \quad (3.14)$$

In addition, the dashboard is regularly updated with the essential metrics, as in Equation (3.15).

$$\text{dashboard}_t = \{(\mathbf{m}_t | \mathbf{m}) \in M\} \quad (3.15)$$

The system operates cyclically, incorporating actual information, using ML models for making decisions, and continuously refining these models through feedback concerning performance. The system is meant to be adaptable and continually enhance its performance by assimilating fresh data and analyzing the results of its operations. The EcoEfficientNet, developed by integrating hybridized sophisticated ML principles, emerges as a formidable instrument for minimizing waste. It can acquire knowledge and adjust to the unique circumstances and obstacles encountered in a manufacturing process. This leads to an intelligent and data-oriented strategy for sustainable manufacturing.

4. Performance Evaluation and Analysis.

4.1. Dataset. The dataset must comprehensively cover various aspects of the manufacturing process to effectively train and validate the machine learning model. So we have chosen an appropriate dataset from IEEE Dataport [24] that is meticulously structured to encapsulate a broad spectrum of key metrics and data sources, tailored to address specific needs of the manufacturing process. Few crucial metrics of the dataset are listed and described as follows:

1. Resource consumption in the dataset is the tracking of resources consumed during manufacturing. This encompasses the energy utilized, often quantified in kilowatt-hours (kWh), as well as the raw materials used, typically measured in kilograms or similar units. Accurately monitoring these inputs is pivotal for understanding and optimizing resource utilization.

Table 4.1: Vital Features Considered Process to Optimize Waste Reduction during the Manufacturing Process

Attribute	Description	Range/Type
Timestamp	Date and time of data entry	Last quarter of 2023 in the timestamp of 00 : 00 – 23 : 59.
MachineID	Identifier for the machine	[List of Machines] (e.g., Machine_01, Machine_02,..)
Resource Consumption	Energy and materials used	[Min Consumption - Max Consumption] (e.g., 50–500kWh for energy)
Production Output	Volume of products made	[Min Output - Max Output] (e.g., 100 - 1000 units)
Waste Generated	Waste material produced	[Min Waste - Max Waste] (e.g., 10 – 100 kg)
Operational Efficiency	Efficiency of the operation	[Lower Efficiency - Higher Efficiency] (e.g., 0.5–1.5 ratio)
Machine Temperature	Average operational temperature	[Min Temp - Max Temp] (e.g., 20 – 100°C)
Machine Vibration	Level of machine vibration	[Min Vibration - Max Vibration] (e.g., 0.5 - 2.5 mm/s)
Maintenance Status	Indicates maintenance activity	[0 (No), 1(Yes)]
Quality Control (QC) Failures	Number of failed QC checks	[Min Failures - Max Failures] (e.g., 0 - 5 failures)
Operator Shift	Shift during which data was recorded	[Shift A, Shift B, Shift C]

2. Production output is another vital metric is the volume of finished products yielded within a given time frame. This output can be measured in various units such as the number of items produced or their total weight or volume, offering a direct insight into the productivity of the manufacturing process.
3. Integral to sustainable manufacturing practices, waste generation metric quantifies the waste produced, which includes material scraps, defective products, and any form of emissions. Tracking this in terms of weight or volume is crucial for environmental impact assessment and for formulating strategies to minimize waste.
4. Operational parameters includes a range of data reflecting the operational health and efficiency of manufacturing equipment, such as machine operating temperatures, vibration levels, operational speed, and instances of downtime. These parameters are key indicators of machine performance and maintenance needs.

The granularity of data collection is meticulously chosen based on the specific nature of the manufacturing process. In high-pace environments like assembly lines, data is often collected at an hourly rate to capture the dynamic nature of operations. Conversely, in slower-paced manufacturing processes such as in chemical production, a daily data collection regime might suffice to provide meaningful insights. In addition, two major data source identifiers are incorporated, Internal and external manufacturing data, which includes machine logs, production records, quality control reports, environmental data, and other industry benchmarks. The complete list of attributes of the dataset is represented in Table 4.1 (Karthick Raghunath, 2024). Table 2 serves as a guide for setting up data collection protocols and designing machine learning models for sustainable manufacturing.

4.2. Empirical Setup. Table 4.2 presents the essential requirements for empirically evaluating the EcoEfficientNet model’s effectiveness in reducing waste in manufacturing. To assess the efficacy of the EcoEfficientNet, we conduct a comparison study with other established ML techniques such as GBM, SR, MLP, and RF.

The evaluation of the EcoEfficientNet model’s accomplishment in waste reduction optimization across manufacturing processes, as well as its comparison with other ML models such as GBM, SR, MLP, and RF, includes incorporating the following four performance criteria. The following metrics are used to measure the efficacy, efficiency, and precision of the models in the particular context: Overall Equipment Effectiveness (OEE), Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Waste Reduction Percentage (WRP).

Table 4.2: Requirement Components for the Empirical Analysis

Component	Hyperparameter	Optimal Value
CNN Layer	Number of Layers	3
	Number of Filters	64
	Filter Size	3×3
	Stride	1
	Activation Function	ReLU
	Pooling Type	Max
LSTM Layer	Number of Layers	2
	Units per Layer	100
	Dropout Rate	0.3
	Recurrent Dropout Rate	0.3
FCL	Number of Layers	2
	Units per Layer	128
	Activation Function	ReLU
RL Model	Learning Rate	0.01
	Discount Factor (γ)	0.95
	Exploration Rate (ϵ)	0.2
	Replay Memory Size	10000
	Batch Size	64
	Target Network Update Frequency	Every 5000 steps
Software Requirement	Packages & Versions	
Programming Language	Python V3.8	
Deep Learning Libraries	PyTorch V1.1	
Machine Learning Libraries	Scikit-learn V0.24	
High-Level Neural Network API	Keras V2.4	
Numerical Computation	NumPy V 1.20	

OEE is employed in factory settings to quantify the efficiency of a manufacturing procedure. It consolidates several aspects of business operations into a unified and all-encompassing measure. OEE is computed as [25],

$$OEE = (AvailabilityPerformanceQuality) \quad (4.1)$$

where, Availability is the proportion of run time parted over the intended production time. Performance is calculated as the proportion of Ideal Cycle Time parted by the proportion of run time divided by total components in Equation (4.1). Quality is determined by the proportion of good components parted by total components.

Fig. 4.1 presents a concise graphical representation of the OEE (Overall Equipment Efficiency) for several techniques, such as EcoEfficientNet, GBM, SR, MLP, and RF. The investigation reveals that EcoEfficientNet achieves an outstanding OEE score of 0.85, indicating its exceptional effectiveness in the manufacturing procedure. The improved efficacy can be ascribed to the model's sophisticated use of CNN, LSTM, and FCL, which excel in recognizing patterns and enhancing processes, particularly in waste reduction.

GBM, while it has an OEE of 0.75, performs well compared to other models but is not as capable as EcoEfficientNet. GBM has high prediction accuracy, although it may need to be more proficient in managing the temporal and spatial data patterns crucial in industrial environments. SR with an accuracy of 0.65, and MLP, with an accuracy of 0.70, while valuable in certain situations, demonstrate lower proficiency in effectively managing the intricacies of industrial data compared to EcoEfficientNet. With a score of 0.68, the RF model has modest efficacy but is often surpassed by models that provide more advanced skills for integrating and analyzing data, such as EcoEfficientNet.

The dominance of EcoEfficientNet in this scenario may be attributed to its customized structure, specifically designed to enhance industrial processes by monitoring several data points and operational efficiency. By using

Fig. 4.1: Analysis of OEE in the Manufacturing Process

Fig. 4.2: Evaluation of MAE

this holistic approach, it is possible to develop a more refined and efficient optimization plan, resulting in increased OEE values.

MAE quantifies the level of accuracy in predicting continuous information [26].

$$MAE = \left(\frac{1}{n}\right) \times \sum |y_i - \hat{y}_i| \quad (4.2)$$

In Equation (4.2), y_i is the true value, \hat{y}_i is the predicted value, and n is the number of observations.

Fig. 4.2 compares the MAE across several techniques, such as EcoEfficientNet, GBM, SR, MLP, and RF. The most notable aspect of this plot is the exceptional performance of EcoEfficientNet, which is highlighted by its distinctive coloration. EcoEfficientNet has superior accuracy and consistency in predictions compared to the other techniques, as seen by its lower median MAE and narrower interquartile range. The exceptional performance of EcoEfficientNet is in line with its innovative deep learning architecture, which seamlessly combines CNN, LSTM, and FCL to identify complex patterns accurately and optimize industrial processes.

On the other hand, GBM, SR, MLP, and RF exhibit more variability in MAE, as seen by their broader box ranges and higher median values. This implies that while these strategies are successful in some instances, they may not be as proficient as EcoEfficientNet in dealing with intricate, uninterrupted data that is unique to reducing waste in manufacturing. Higher MAE levels indicate less precision in forecasts, resulting in less efficient results in real-world scenarios. The lower and more constant MAE of EcoEfficientNet highlights its

Fig. 4.3: Evaluation of RMSE

appropriateness for complex and ever-changing settings such as sustainable manufacturing. Accuracy and dependability are essential for making informed decisions and optimizing processes in these situations.

RMSE in Equation (4.3) quantifies the magnitude of errors by calculating the square root of the mean of the squared discrepancies between expected and actual outcomes [27].

$$RMSE = \sqrt{\left(\frac{1}{n}\right) \times \sum (|y_i - \hat{y}_i|)^2} \tag{4.3}$$

Based on the observed RMSE values in Fig. 4.3, it can be concluded that EcoEfficientNet demonstrates superior performance compared to the other models (GBM, SR, MLP, and RF) in terms of operational efficiency over the whole range. The EcoEfficientNet regularly exhibits a lower error rate than the other approaches, indicating superior prediction accuracy. This is consistent with the previously mentioned idea that EcoEfficientNet, a model created for environmentally friendly production, utilizes sophisticated DL algorithms such as CNNs, FCLs, and LSTMs to reduce waste by detecting trends and inefficiencies in manufacturing procedures.

The resultant demonstrates the effectiveness of EcoEfficientNet, which can be credited to its advanced design and ability to learn, adapt, and evolve continuously with updated information. This attribute is essential for sustainable manufacturing since adjusting to ever-changing production settings and minimizing waste is necessary. The higher technical performance of EcoEfficientNet, as seen by the reduced RMSE values, validates its usefulness in promoting sustainable manufacturing. It does this by offering data-driven insights that facilitate operational enhancements.

A relevant indicator called Waste Reduction Percentage [28] is used to confirm the extent of waste reduction achieved via the use of EcoEfficientNet in the course of production. The ML model’s impact on waste reduction can be quantitatively measured by computing the decrease in waste production Equation (4.4).

$$WRP = \frac{\text{waste before} - \text{waste after}}{\text{waste before}} \times 100 \tag{4.4}$$

Fig. 4.4 illustrates the extent of waste reduction in a manufacturing environment before and after adopting several ML techniques. The 'Before' bars represent the original quantity of trash produced, while the 'After' bars display the decreased amount after implementation, with the disparity between them indicating the effectiveness of each machine learning approach in waste reduction.

Upon examining the outcome, it is apparent that all ML approaches have a role in reducing waste. However, EcoEfficientNet has the most effect, decreasing waste from about 91 units to 57.5 units. This is consistent with the prior conversations where EcoEfficientNet, with advanced deep learning techniques, was mainly created to address waste in industrial processes. The model’s sophisticated algorithms, such as CNNs, FCLs, and LSTMs, allow it to recognize and respond to patterns that result in waste, thus reducing it.

Fig. 4.4: Analysis of Waste Reduction for Various Models

Table 4.3: Sample Segment of the Outcome Showcasing the Optimal Performance for Sustainable Manufacturing over a 24-Hour Period

Timestamp	Machine	Resource Consumption (kWh)	Production Output (units)	Waste Generated (kg)	Operational Efficiency (ratio)	Machine Temperature (C)	Machine Vibration (mm/s)	Maintenance Status	Quality Control Failures	Operator Shift
2023-10-01 00:00:00	Machine_01	50.00	100.00	10.00	0.50	20.00	0.50	0	0.00	Shift A
2023-10-01 00:00:00	Machine_01	69.57	139.13	13.91	0.54	23.48	0.59	0	0.22	Shift A
2023-10-01 00:00:00	Machine_02	89.13	178.26	17.83	0.59	26.96	0.67	0	0.43	Shift A
2023-10-01 00:00:00	Machine_03	108.70	217.39	21.74	0.63	30.43	0.76	0	0.65	Shift A
...
2023-10-01 00:00:00	Machine_05	500.00	1000.00	100.00	1.50	100.00	2.50	1	5.00	Shift A

The consequences of reducing such waste are significant for the production ecosystem in an industrial setting. EcoEfficientNet’s substantial reduction in waste output decreases the manufacturing process’s environmental impact and leads to cost savings and improved resource use. This is especially crucial in sectors where materials disposal leads to environmental deterioration and operational inefficiency.

By integrating EcoEfficientNet into the production process, as shown in Fig. 4.4, it is possible to reduce waste output by about 37%. This demonstrates the practicality and effectiveness of machine learning in enhancing sustainable manufacturing practices. Such waste reduction may lead to a series of beneficial outcomes, such as decreased consumption of raw materials, reduced energy use, and less environmental contamination. These outcomes are essential elements of sustainable industrial operations. The result represents progress towards environmentally friendly production, highlighting the importance of modern technology such as EcoEfficientNet in promoting sustainability in the sector.

Table 4.3 displays the measured data at different time points throughout the production process during 24 hours (sample). These optimal values demonstrate the equilibrium between elevated productivity (increased manufacturing output), effectiveness (enhanced operational efficiency and reduced resource consumption), and sustainability (limited waste generation and minimum machine strain shown by vibration and temperature levels). The observed result directly reflects the critical performance indicators in a manufacturing setting. For example, the Resource Consumption metric represents the equilibrium between using energy and materials and generating manufacturing output. An improved process is shown by a decrease in consumption coupled with an increase in production. The waste-generated feature directly impacts the sustainability element since a smaller amount of trash is associated with improved environmental and economic results.

5. Conclusion and Future Work. The thorough examination of sophisticated ML models in manufacturing, namely the implementation of EcoEfficientNet, has uncovered a significant improvement in sustainable manufacturing processes. The DL framework of EcoEfficientNet, which combines CNN, LSTM, and FCL, has shown remarkable effectiveness in waste reduction. Its exceptional OEE score and minimum RMSE values support this, showcasing its superior prediction accuracy and operational efficiency. Compared to other models such as GBM, SR, MLP, and RF, EcoEfficientNet surpasses them due to its specialized skills in handling intricate industrial datasets. The tabulated data from IoT devices for 24 hours provides more evidence of how EcoEfficientNet enhances essential performance parameters. It achieves a harmonious combination of high productivity and sustainability by minimizing resource use and waste production, all while ensuring the machine's well-being. The empirical findings, which demonstrate a substantial decrease in waste before and after adopting EcoEfficientNet, provide evidence of the model's strength in promoting an environmentally friendly, efficient, and economically sustainable IoT-based industrial setting. ML in this paradigm shift is crucial for enterprises that want optimal efficiency while maintaining environmental integrity. This advancement sets the stage for an eventuality wherein sustainable manufacturing becomes the standard.

Subsequent investigations in this field aim to combine diverse IoT datasets [29] with EcoEfficientNet to enhance the agility and reactivity of industrial processes. Investigating the integration of blockchain technology for reliable and transparent monitoring of supply chains, together with AI-powered predictive maintenance, has the potential to improve productivity and sustainability.

A VISION-BASED ANALOG METER READING METHOD FOR INSPECTION ROBOTS

JIACHENG LI^{*} HONGLEI WANG[†] XISHUO ZHU[‡] SIJIAN LIU[§] AND JUNSHENG ZHANG[¶]

Abstract. Computer vision technology has been widely applied in reading recognition of analog meters. However, it is still a challenge to quickly and accurately read various types of analog meters under different environmental conditions. We propose a fast-reading method for analog meters based on keypoint detection, which is applied to inspection robots. First, we use the YOLOv5s network to locate the analog meter. Second, the HRNet network is used to detect the keypoints of the pointer and scale on the dial. Third, an objective image quality assessment method that includes multiple indicators is established to select the optimal image for reading recognition. Finally, we calculate the reading of the analog meter based on the deflection angle of the pointer. The experiment shows that our method can accurately read the readings of analog meters, with an average reading error of 3.81%. It can be effectively applied to inspection robots to read analog meter readings.

Key words: analog meter; object detection; keypoint detection; inspection robot; reading recognition

1. Introduction. Many places that require accurate and reliable measurements, such as substations, chemical factories, water pump houses, and other similar locations, still use analog meters instead of digital ones. This is because analog meters are less affected by the electromagnetic environment and can provide more stable readings. However, a drawback of these meters is that they usually cannot send analog signals to a remote location for monitoring or analysis. Therefore, they depend on manual inspection by workers who have to read the analog meters in person [1]. With the developments of computer vision technology [2], it has become the mainstream method to use an inspection robot equipped with a camera for instrument recognition. Using computer vision to automatically read analog meters is more efficient and convenient than manual inspection. However, the images collected by the visible light cameras are easily affected by different poses, illumination changes, and complex backgrounds, which brings difficulties to reading recognition. Many researchers have explored vision-based methods for fast and stable instrument recognition by inspection robots [3-6].

Traditional methods for machine vision reading [7-8] have some drawbacks, which prevent them from being stably applied. These methods usually identify the dial area in an image by using template matching or Hough circle detection. Then they recognize the scale and pointer in the dial by using image segmentation or line detection. Finally, they read the meter based on the angle or distance between the pointer and the scale [9]. However, these methods are not suitable for inspection robots that work in complex and changing environments [10]. For example, they cannot adapt to different angles and lighting conditions because they rely on manually set parameters in the algorithm. This makes their detection robustness very poor.

In recent years, deep learning has been applied to analog meter recognition with remarkable results [11-14]. One of the key steps in analog meter recognition is instrument detection, which involves locating the instrument region in an image [15]. Huang et al. [17] employed an improved YOLOv3 network to locate the analog meter and a monocular-vision pointer reconstruction algorithm was used to read the instrument. In [18], a Faster Region-based Convolutional Network (Faster R-CNN) was used to detect the target meter and guide the camera

alignment. Then reading could be obtained after the pointer is recognized by Hough Transform. Salomon et al. [19] used a YOLOv4 target detector and proposed a new regression method (AngReg) to achieve automatic meter reading in unconstrained scenarios. Fan et al. [20] proposed an adaptive anchor and global context (GC) module for meter detection, which combines deep learning methods and traditional computer vision methods to achieve power equipment meter recognition. The above methods adopt the deep learning method in the instrument detection stage but are not applied to the identification of pointer and scale, resulting in limited improvement of reading robustness.

Compared to meter detection, reading recognition is a more complex task. Especially for such tasks as patrol robot automatic meter reading, the scene of the image to be identified usually has a large difference due to background changes, robot movement, and other factors. The focus of research is to stably recognize the dial information of meters for reading under different conditions. The deep learning-based image segmentation technology has been applied to detect scales and pointers, leading to a significant improvement in the robustness of the reading system. Alexeev et al. [21] proposed a three-level model to regress the coordinates of the keypoints in the panel but did not investigate the pointer recognition and reading strategies. Zuo et al. [22] improved Mask-RCNN to extract binary marks of the instrument dial and pointer. In [23], a modified RFB-Net network was used to detect the keypoint of the pointer image. Dong et al. [24] developed a vector detection network to recognize the direction of the pointer. Compared to traditional methods, these CNN-based pointer and dial detection methods greatly reduced the probability of missed detection and false detection, enabling the recognition of various analog meters in dynamic scenes. However, no optimal general reading method exists for the many types of analog meters for electric power and pressure measurement. Deng et al. [25] proposed a meter reading method that combines YOLOv5s and DeeplabV3+ networks. The segmented dashboard area is unfolded, and the reading is calculated by calculating the distance between the pointer and the scale. Zhou et al. [26] proposed an end-to-end pointer meter reading method based on deep learning. Simultaneously locate the pointer and extract the pointer object and achieve meter reading recognition through the local angle method. These reading methods, which also apply deep learning technology in the reading stage after the dial detection and positioning, have achieved good results in terms of reading accuracy and robustness. But training a model that can segment all the scale and pointer information on the dial requires a large amount of annotated data. And it requires a more complex post-processing process to determine the relationship between the pointer and the scale.

The acquired meter images may be blurred and distorted due to environmental factors and the robots motion factors [27]. It is better to use image quality assessment to filter out the images with good imaging effects for reading recognition. Image quality assessment methods are categorized into subjective and objective assessment. Objective assessment methods give a quantitative result based on a mathematical model. A well-designed objective assessment method can be very close to the subjective judgment of a human being. It can effectively screen out images with more distinctive features for further processing before detection.

In this study, a fast-reading method based on object and keypoint detection is proposed to read analog meters for inspection robots in motion. Our reading method consists of a target detection model and a keypoint detection model. First, a YOLOv5s [28] target detection network is used to detect analog meters in complex patrol scenes. Second, inspired by the human posture estimation algorithm, the High-Resolution Net (HRNet) [29] is used to extract the scale and pointer information of the detected analog meter panel. Third, the objective image quality assessment method is used to evaluate the meter images collected by inspection robots, and the best quality images are selected for reading calculation. Finally, based on the results of instrument target detection and keypoint detection, the reading is calculated by the angle of the pointer.

The primary contributions of our study are as follows.

1. The YOLOv5s network is used for instrument detection, which is suitable for the complex working scene of patrol robots.
2. A keypoint detection method is used for the detection of analog meter range and pointer, which improves the reading recognition effect.
3. A meter recognition method for inspection robots in motion is proposed, which selects the best quality image from consecutive frames of the video stream and accurately recognizes circular simulated meter readings.

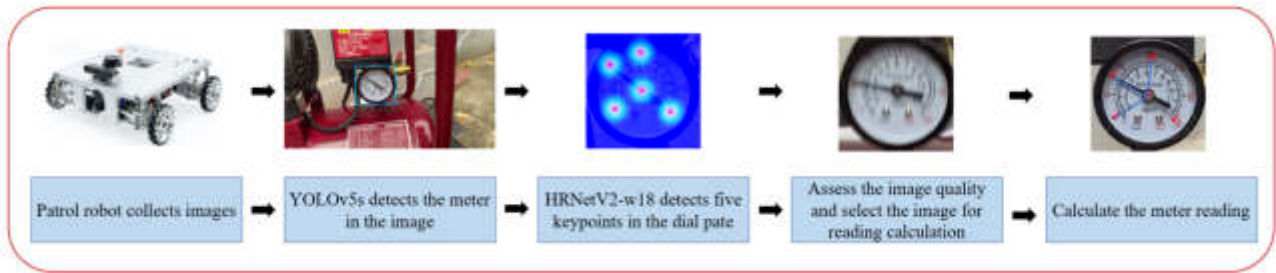

Fig. 2.1: Flowchart of the proposed reading method.

4. The effect of the proposed reading method is verified on the real inspection robot platform.

2. Proposed Method. We propose a deep learning-based method for fast meter reading. Fig. 2.1 illustrates its flowchart. First, the inspection robot performs analog meter target detection under the moving state. Real-time video data can be processed directly through the Nvidia Jetson edge computing device mounted on the robot. Or transmit it to the computer for processing through network streams such as RTSP and RTMP. The YOLOv5s detection model is used to detect and mark the pointer meters in the field of view of the inspection robot in real-time. Second, inspired by the method of human posture estimation, the HRNet network is modified to detect five keypoints in the dashboard: the start and end of the range, the midpoint of the range, the center of the dial, and the end of the pointer. Third, an objective image quality assessment method that combines information entropy, standard deviation, and the mean gradient is used to select the optimal quality image for reading recognition. Finally, a method based on pointer deflection angle calculation was used for meter reading recognition.

2.1. Analog Meter Detector Based on Yolov5s. The key to accurately reading a pointer instrument is to identify and locate the instrument panel area in the image. It is almost impossible for the traditional target detection method to recognize the instrument panel stably and accurately under the complex and changeable image background conditions collected by the inspection robot. The target detection method based on deep learning makes this application possible. The target detection algorithm can be divided into two types: one-stage method and two-stage method. The one-stage method represented by YOLO [30] has high real-time performance, but it is usually slightly inferior to the recognition accuracy of the two-stage target detection method.

YOLO (You Look Only Once) is a one-stage target detection method that predicts bounding boxes and class probabilities directly from an input image. YOLOv5s has the smallest network depth and the smallest feature map width among four variants: YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x. It is mainly composed of input, backbone, neck, and prediction. The input part enriches the data set by splicing training data to achieve a better detection effect with smaller samples. The backbone part is mainly composed of a Cross Stage Partial (CSP) module for feature extraction. Feature Pyramid Network (FPN) and Path Aggregation Network (PANet) are used in the neck part to aggregate the image features preliminarily extracted from the backbone part. The prediction part performs target prediction and outputs the prediction results.

The target detection of the analog meter using YOLOv5s mainly includes four steps. First, collect and label the training images with bounding boxes around pointers. Second, build the training set, validation set, and test set of YOLOv5s network according to a certain ratio. Third, train the target detection model using a deep learning framework with appropriate hyperparameters. Finally, test the model recognition effect by running inference on test set images and evaluating metrics such as precision and recall.

We use the mosaic data augmentation method to improve the accuracy of YOLOv5s target detection model with fewer labeled samples. This method randomly crops, rotates, scales, and color transforms four images, and then combines them into one image as a training input sample. It makes the scale and color space of the sample more variety, and makes the limited data generate more value. Figure 2.3 illustrates how mosaic data augmentation method improves the pointer meter data. This method helps the model learn from different

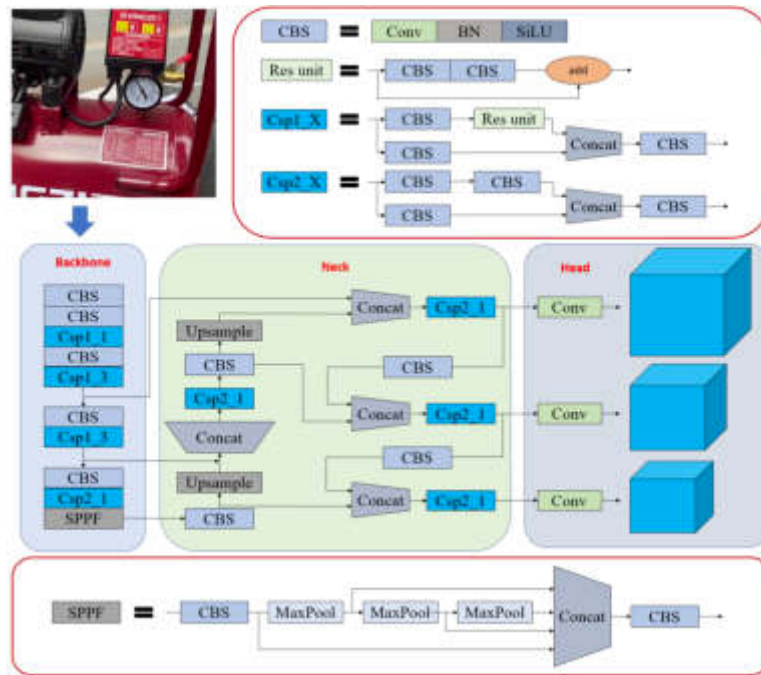

Fig. 2.2: The YOLOv5s framework.

Fig. 2.3: Mosaic data augmentation.

contexts and scales of the pointer meter images. It has been verified that this method can effectively enhance the model’s ability to generalize to unseen data.

For the robot that checks along the preset route, the pointer meter usually appears from one end of the captured image and disappears from the field of vision from the other end as the robot moves. Obviously, for the reading calculation of the pointer meter, the image collected when the camera is facing the instrument can get a more accurate reading. For each detected target, YOLOv5s outputs the coordinates of the upper left

Fig. 2.4: Backbone structure of HRNet.

corner (x_1, y_1) and the lower right corner (x_2, y_2) of the bounding box to achieve the positioning of the pointer meter. R_p is calculated as shown in Equation (2.1). The relative position R_p of the center point of the bounding box in the whole image is used to determine the angle between the camera and the pointer instrument. The closer the R_p is to 0.5, the higher the alignment between the camera and the target pointer gauge.

$$R_p = \frac{x_2 + x_1}{2w} \quad (2.1)$$

where w represents the width of the whole image.

2.2. Keypoint Detector Based on HRNetV2-w18. When the instrument in the picture is detected, the most critical step is to identify the scale and pointer. We can use angle calculation or distance calculation methods for reading recognition of pointer instrument. These methods have different pros and cons. The distance calculation method needs higher accuracy of scale and pointer position recognition and gives higher reading accuracy, but it also demands higher quality of collected images. The angle calculation method is more robust and can be more precise even with unstable image quality.

HRNet is designed to preserve high-resolution features throughout the network by using multiple parallel branches with different resolutions. The structure of HRNet is shown in Figure 2.4. The branches are connected by repeated multi-scale fusion modules that allow information exchange across resolutions. HRNet has several variants with different depths and widths to suit different applications and resources. HRNetV2-w18 is a variant that has a smaller width than other versions. For inspection robots that need to read pointer meters while moving, detection speed and accuracy are crucial. The HRNetV2-w18 network can achieve a good balance between these two factors.

In the keypoint detection task, the position learning of key points can be divided into two categories: heatmap-based and region-based. The keypoints in the image cannot be represented by a single pixel, which may be composed of the labeled coordinates and some nearby pixels. If all the pixels except the marker coordinates are defined as negative samples, the model may be difficult to converge. We use the heatmap method to obtain higher coordinate prediction accuracy. The generation method of heatmap is shown in Equation (2.2).

$$Heatmap(x, y) = e^{-\frac{(x-\mu_x)^2 + (y-\mu_y)^2}{2\sigma^2}} \quad (2.2)$$

where μ_x and μ_y represent the true keypoint coordinates obtained from annotation, and $Heatmap(x, y)$ is the value of a point (x, y) on the heatmap.

2.3. Objective Image Quality Assessment. We propose a reference-free image quality assessment method for images acquired by inspection robots. The calculated metrics include entropy, standard deviation and mean gradient. Entropy measures the amount of information contained in an image; higher information entropy indicates that the image contains more information, and the image is usually more detailed. The image

Fig. 2.5: Reading calculation methods in two cases: (a) The pointer is in the first half of the range; (b) The pointer is in the second half of the range.

is first converted to a gray level image and the probability of occurrence of each gray level is counted to finally get the information entropy. The entropy is calculated as shown in Equation (2.3).

$$H = - \sum_{i=0}^{255} p_i \log_2 p_i \quad (2.3)$$

where p_i is the probability of occurrence of the corresponding gray level.

The standard deviation reflects the degree of dispersion between the pixel values and the mean value of the image, and a larger standard deviation usually indicates a better image quality. The standard deviation is calculated as shown in Equation (2.4).

$$\sigma = \sqrt{\frac{1}{w * h} \sum_{i=1}^w \sum_{j=1}^h (p_{ij} - \mu)^2} \quad (2.4)$$

where w and h are the width and height of the image, p_{ij} is the pixel value of the corresponding coordinate and μ is the mean value of the image.

The mean gradient reflects the rate of change of the gray values on both sides of the image edges, this data can be used to measure the fineness of the image details, the larger the mean gradient is, the clearer the image is in general. The mean gradient is calculated as shown in Equation (2.5).

$$G = \frac{1}{w * h} \sum_{i=1}^w \sum_{j=1}^h \sqrt{\frac{\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2}{2}} \quad (2.5)$$

where w and h are the width and height of the image, $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ are the gradients of the image horizontally and vertically.

We normalize the above three metrics by mapping them between 0 and 1. The number of our image dataset is small, and the normalization is performed by using between the maximum and minimum values. After actual testing, here we no longer assign different weights to the above three metrics, and use the score obtained by Equation (2.6) as the final assessment of image quality. In the application, images with meter alignment values R_p greater than 0.35 and less than 0.65 will be calculated for image quality, and the reading with the highest image quality score will be used as the reading for that meter.

$$Score = H + \sigma + G \quad (2.6)$$

2.4. Reading Calculation Based on Keypoints. Upon acquisition of precise dial scale and pointer end coordinates, determination of the rotation angle of the pointer enables computation of the reading of the meter. Figure 2.5 illustrates two distinct methods for computing the reading of the meter, which depend on the position of the pointer relative to the scale. If the pointer falls between the starting point and the midpoint of

Fig. 3.1: Examples of pointer meter annotations. (a) Instrument A with a maximum range of 180 Lb/inš; (b) Instrument B with a maximum range of 0.6 MPa; (c) Instrument C with a maximum range of 1.6 MPa.

the scale, the reading is determined using these two reference points. In contrast, if the pointer has surpassed the midpoint and is in closer proximity to the endpoint, the reading is calculated using the midpoint and endpoint of the scale.

In Figure 2.5(a), the position of the pointer falls within the initial half of the meter’s range, whereby the vectors \overrightarrow{CS} and \overrightarrow{CM} , represented by points 4 and 1 and points 4 and 2 respectively, serve as the starting and ending points for the beginning and end of the range. To determine half of the full range of the meter, the angle α enclosed between the two vectors is computed. To calculate the meter reading, vector \overrightarrow{CP} is constructed using points 4 and 5 as the starting and ending points for representation of the pointer. The included angle β between vector \overrightarrow{CP} and \overrightarrow{CS} is then ascertained. The reading of the meter can be calculated using Equation (2.7).

$$Numf = \frac{90\alpha}{\beta} \quad (2.7)$$

In Figure 2.5(b), the pointer is situated in the second half of the range. The vector \overrightarrow{CM} with points 4 and 2 as the starting and ending points signifies the beginning range, whereas the vector \overrightarrow{CE} , represented by points 4 and 3, corresponds to the end of the range. Vector \overrightarrow{CP} , constructed with points 4 and 5, portrays the pointer. To determine the meter reading, the enclosed angles α and β between vector \overrightarrow{CP} and \overrightarrow{CM} , and \overrightarrow{CM} and \overrightarrow{CE} , respectively, are calculated. The reading of the meter can be calculated using Equation (2.8).

$$Nume = \frac{90(\alpha + \beta)}{\beta} \quad (2.8)$$

3. Experiments and Results.

3.1. Experimental Environment and Dataset. We ran the proposed algorithm on a computer with I7-13900H CPU, 32 GB RAM and NVIDIA GeForce RTX4060 8GB GPU. We used PyTorch deep learning framework, Python 3.10 programming language, CUDA 11.8 and cuDNN 8.9 NVIDIA acceleration tools.

We collected 1632 images of three kinds of air pressure pointer meters using an industrial camera with a resolution of 1920E1080 pixels. We labeled the images with LabelMe, an open-source annotation tool. The position of the pointer in the image and the five key points in the dial are marked at one time. The position of the pointer meter is marked with the bounding box. The start of the range is marked with 1, the midpoint of the range is marked with 2, the end of the range is marked with 3, the center of the dial is marked with 4, and the end of the pointer is marked with 5. Figure 3.1 shows examples of pointer meter annotations in the dataset.

The marked data is further processed to provide the YOLOv5s target detection model and HRNet key point detection model for training. The bounding box and category information marked by LabelMe software are extracted and stored in the format of VOC data set and provided to YOLOv5s model. The heatmap files, which are produced using the methodology outlined in Section 2.2, are provided to HRNetV2-w18 for training a keypoint detection model. Table 3.1 shows the number of different keypoints marked on the pointer meter.

Table 3.1: Definition of keypoints of the meter.

Label number	Position of the pointer meter
1	The start of the range.
2	The midpoint of the range.
3	The end of the range.
4	The center of the dial.
5	The end of the pointer.

Fig. 3.2: Loss and mAP variation curves. (a) The loss variation curves for the training and validation sets; (b) mAP variation curve.

3.2. Experimental Results.

3.2.1. YOLOv5s Analog Meter Detector. The dataset was partitioned into three subsets, namely training, validation, and testing, in an 8:1:1 ratio. We trained YOLOv5s model with an input image resolution of 640×640 pixels, a batch size of 8, an initial learning rate of 0.001, and a training duration of 200 epochs. Due to the small size of the dataset, we utilized a pre-trained model on the COCO dataset provided by the official source to initialize the weights of our model, aiming to achieve better recognition performance. Figure 3.2(a) and Figure 3.2(b) illustrate the variation of loss and mean average precision (mAP) during the training process of the YOLOv5s object detection model. From Figure 3.2(a), it can be observed that the loss for both the training and validation datasets gradually decreases as the training progresses. After the 150th epoch, the loss stabilizes. Figure 3.2(b) presents that the model achieves a high mAP of 98.3% at last.

On the self-built pointer instrument dataset, YOLOv5s was compared with other common models. The training parameter settings remained unchanged from the previous text. The performance of the optimal weight of each model on the test set is shown in Table 3.2, and YOLOv5s achieves a balance between accuracy and detection speed. The average accuracy has reached 97.9%, and the detection speed can reach 33.78 FPS.

3.2.2. HRNetV2-w18 Keypoint Detector. The circular meter area in the image is obtained by the target detector and adjusted to 384×384 pixels before being input into the HRNetV2-w18 keypoints detection model. The batch size is set to 1, and stochastic gradient descent (SGD) is used for parameter optimization with an initial learning rate of 1e-5 over a total training epoch of 60. The network outputs are heatmaps, and the network’s keypoints detection performance is evaluated using root mean square error (RMSE) after extracting keypoints. Figure 3.3(a) and Figure 3.3(b) show the changes in loss on the training and validation sets during the HRNetV2-w18 training process. It can be seen that after the 100th epoch, the loss basically does not decrease, and the training is completed.

Table 3.2: Comparison of YOLOv5s with Faster R-CNN, SSD and PP-YOLOE-s on the test dataset.

Method	Epochs	mAP	FPS
Faster RCNN	200	0.975	6.71
SSD	200	0.925	26.96
PP-YOLOE-s	200	0.749	18.21
YOLOv5s	200	0.979	33.78

Fig. 3.3: The loss curve of the training and validation sets during the training process. (a) The loss variation curves for the training sets; (b) The loss variation curves for the validation sets.

Fig. 3.4: Keypoint detection results. (a) Cropped and resized pointer instrument image detected by YOLOv5s;(b-f) Predicted heatmaps for 5 keypoints.

Table 3.3: Maximum and minimum values of image quality metrics for the dataset.

Image quality metric	Maximum value	Minimum value
Entropy	7.785	5.618
Standard deviation	78.967	13.184
Mean gradient	89.982	7.815

Table 3.4: Maximum and minimum values of image quality metrics for the dataset.

Num.	Image	Entropy	Standard deviation	Mean gradient	Score
1		0.458	0.228	0.126	0.812
2		0.470	0.274	0.190	0.934
3		0.486	0.200	0.310	0.996
4		0.563	0.352	0.359	1.274

Figure 3.4 shows the detection results output by the HRNetV2 w18 model, and the predicted results of the five key points are presented in heatmaps. For three different dial types of pressure gauges, the model can accurately locate the key points of the readings. The key point positions selected by this method have relatively universal characteristics.

3.2.3. Image Quality Assessment. The evaluation method established in the previous section is used to select the image with the best image quality for meter reading recognition. The three metrics of entropy, standard deviation and mean gradient are calculated for all images in the image dataset and their maximum and minimum values are shown in Table 3.3. It can be seen that the contribution of the entropy metrics to the final score may not be fully reflected if normalization is not performed. It can be seen that the contribution of the entropy to the final score may not be fully reflected if normalization is not performed. When the dataset is large enough, the weights of the three metrics contribution to the final score can be further assigned. Here we take the normalized three metrics and add them directly.

Table 3.4 gives the images captured while the inspection robot is moving, and their image quality is evaluated after locating and intercepting the meter dial area images. Higher values of the three image quality metrics and assessment scores indicate better image quality.

3.2.4. Meter Reading Recognition. After detecting the keypoint on the dial of the pointer meter, the reading of the meter can be calculated using the method proposed in Section 2.4. This angle-based reading calculation method has a significant impact on the calculation accuracy by the positioning accuracy of keypoints. Especially when the deviation degree of the center point detection of the dial is relatively high, it will bring significant errors to the reading calculation. However, compared to other pointer meter reading methods based on semantic segmentation, using reading methods based on key points and angles has lower data annotation costs. Adding half range key point annotation will not excessively increase the cost of data annotation but can to some extent improve reading accuracy.

Table 3.5: Reading error of different strategies.

Num.	Ground truth	Full range angle reading results	E_{RF}	Half range angle reading results	E_{RH}
1	30.0	26.8	10.67 %	31.8	6.00%
2	46.8	44.2	5.56%	44.5	4.91%
3	62.4	64.7	3.69%	65.2	4.49%
4	68.4	72.1	5.41%	71.1	3.95%
5	91.2	91.9	0.77%	90.4	0.88%
6	103.2	106.7	3.39%	101.1	2.03%
7	105.6	102.0	3.41%	107.9	2.18%
8	124.8	131.5	5.37%	119.6	4.17%
9	0.168	0.181	7.74%	0.151	10.12%
10	0.204	0.213	4.41%	0.199	2.45%
11	0.284	0.288	1.41%	0.290	2.11%
12	0.340	0.365	7.35%	0.358	5.29%
13	0.392	0.385	1.79%	0.393	0.26%
14	0.466	0.483	3.65%	0.480	3.00%
15	0.26	0.29	11.54%	0.25	3.85%
16	0.56	0.62	10.71%	0.59	5.36%
17	0.70	0.71	1.43%	0.73	4.29%
18	0.92	0.98	6.52%	0.96	4.35%
19	0.99	0.95	4.04%	1.02	3.03%
20	1.18	1.11	5.93%	1.22	3.39%

The comparison between the reading results and the true values using the method presented in this article is shown in Table 3.3. The true value is obtained by manually observing the instrument horizontally from the front. Evaluate the effectiveness of the proposed method by calculating the error between the automatic reading and the actual reading. The calculation formula for reading error E_R is shown in Equation (3.1).

$$E_R = \frac{|T - L|}{T} \times 100\% \quad (3.1)$$

where L is the value obtained by the proposed automatic reading method, and T is the instrument reading obtained through manual observation.

We calculated the readings obtained based on the full range key points and the readings obtained based on the half range keypoints. Then evaluate the accuracy of the readings by calculating their errors using true values. The decimal places of manually observed values are calculated based on 1/5 of the pressure gauge graduation value. Table 3.5 shows the reading error results obtained by different strategies under the same keypoint detection results.

The different angles at which inspection robots collect analog meter images can have an impact on the reading results. The instrument images used for calculating readings in the experiment are collected with the camera horizontally centered on the analog meters. From the results shown in Table 3.3, it can be seen that the reading strategy using half range key points has higher accuracy. From the results shown in Table 3.3, it can be seen that the reading strategy using half range key points has higher accuracy.

4. Discussion. This article proposes a pointer instrument reading method based on key point recognition, inspired by the top-down human posture estimation method. It consists of a target detector and a keypoint detector. This detection method has high accuracy, but its computational complexity increases linearly with the increase of multiple targets in the image. For the application of patrol robots, the accuracy advantage of this method is more prominent. The light target detection network based on YOLOv5s achieves the balance between detection speed and accuracy. It can be easily transplanted to the edge computing equipment carried by the patrol robot. A reading calculation method based on five key point detection can achieve high reading accuracy through finetune with a small amount of annotated data.

However, this is not an end-to-end recognition method. In the future, pointer instrument reading recognition may use multitask learning methods. It can use the network to simultaneously perform object detection and keypoint detection, share the same feature extraction backbone, and improve computational efficiency. To recognize readings from different kinds of meters in the future, the proposed method should also account for pointer meters' range recognition. The meter's measuring range can be either pre-entered as prior knowledge for different types or detected from the digits on the dial.

PREDICTION METHOD OF RATE OF PENETRATION BASED ON FUZZY SUPPORT VECTOR REGRESSION

LI YANG*, LISHEN WANG†, LILI BAI‡ AND WENFENG SUN§

Abstract. Predicting the rate of penetration (ROP) is important for optimizing drilling parameters, improving drilling efficiency, and optimizing economic benefits throughout the drilling process. The current prediction model of ROP based on machine learning algorithms does not consider the interference of outliers. Therefore, in this study, we propose a method to predict ROP based on fuzzy support vector regression (FSVR). First, appropriate input parameters were selected from the controllable parameters. Second, based on the local outlier factor, a fuzzy membership degree was assigned to each sample. Finally, the sample with the fuzzy membership value was input into the model for ROP prediction. The results demonstrated that the goodness of fit (R2) of the improved FSVR model is 0.9634, and the mean absolute error is 0.1974. Compared with standard SVR and other models, the improved FSVR model has a stronger anti-interference ability, smaller prediction error for normal samples, and higher accuracy.

Key words: drilling; rate of penetration; support vector regression; local outlier factor; fuzzy membership.

1. Introduction. The rate of penetration (ROP) is an important factor affecting drilling duration and drilling cost. Accurate prediction of ROP can provide support for drilling parameter optimization, thus enhancing drilling efficiency while minimizing drilling expenses. There are three types of ROP prediction models [1]: traditional mathematical equations, which consider a few small numbers of ROP influencing parameters [2], statistical models represented by multiple regression, which can have increased solving accuracy for the traditional ROP coefficient [3]; and models employing machine learning algorithms. Wu et al [4] established a linear prediction model using principal component analysis (PCA); however, in some cases, the element obtained by this method is not optimal. Su et al. [5] applied a gradient boosting decision tree algorithm to predict ROP, which is more accurate than the existing method of predicting ROP; however, the characteristics involved were limited. Kahraman et al. [6] proposed an ROP prediction model based on backpropagation (BP) neural networks; however, BP neural networks have low convergence speed and can easily fall into local extrema. Yang et al. [7] established a fuzzy neural network model by combining fuzzy control with a BP neural network, and the level of prediction accuracy was higher than that of ordinary BP neural networks. Zhao et al. [8] proposed an ROP prediction model based on extreme learning machines, achieving better generalization performance than the common BP neural network. Li et al. [9] combined the beetle antennae search (BAS) algorithm with a BP neural network to establish the BAS-BP model. Compared with standard BP and genetic-algorithm BP models, the error is lower and the prediction accuracy is higher; however, the generalization ability of the model should be improved. Xu et al. [10] established an ROP prediction model based on integrated learning, utilizing a variety of machine learning algorithms, and the results show that the prediction accuracy of the integrated model is higher than that of the single model; however, the model is more complex. Sabah et al. [11] used a multilayer perceptron particle swarm optimization (PSO-MLP) model for ROP prediction, achieving favourable performance. As a representative of traditional machine learning, support vector regression (SVR) has been demonstrated to have fitting performance compared to alternative machine learning methods (e.g., k-nearest neighbours, linear regression, polynomial regression, and decision trees) in experiments involving a drilling process that is characterized by high nonlinearity and complexity [12, 13]. The above two models are

compared with the proposed model. Hamid et al. [14] used an imperialist competitive algorithm to optimize SVR. They established the model, compared three kernel functions, and found that the Gaussian radial basis kernel function had the best effect. Therefore, the Gaussian radial basis kernel function was also applied in this study.

Recently, entropy-based improved support vector machine models have been proposed to solve the classification problem [15, 16, 17]. Asadolahi et al. [18] and Xue et al. [19] improved the loss function by combining the fuzzy response with robust SVR to improve the accuracy of the fuzzy regression model. Chakravarty et al. [20] and Liu et al. [21] improved the fuzzy function and the robustness of the model against outliers and verified its effectiveness. Fuzzy control has been continuously applied to complex system processing [22]. Successful applications have been demonstrated in wind turbine control [23], concrete component analysis [24], and life prediction of slewing bearings [25]. Nevertheless, applications in drilling engineering remain scarce.

During drilling operations, signals are disturbed to produce outliers or slip drilling and other situations occasionally occur in drilling may lead to sudden increase in the values of certain parameters, which interferes with the training of the model and consequently affects its performance. A method of elimination has been adopted to process outlier data; however, it may delete misjudged data. When processing new data sets, there will be outliers of new data sets, which should be eliminated again. Therefore, we focused on reducing the influence of abnormal data on model prediction without deleting primary data. Current ROP prediction models based on machine learning algorithms do not consider interference from outlier samples; however, the fuzzy support vector regression (FSVR) model proposed in this study considers such interference. According to the outlier detection method based on the local outlier factor (LOF) algorithm, the LOF values of all data points are calculated, and then the membership values of all data points are calculated through the LOF values. A normal sample has a large membership value, and an outlier sample has a small membership value. The fuzzy training set with membership values is input into the training model. This can reduce the interference of outlier samples in the model, and the normal samples with a large contribution to the training model can play the greatest role. We demonstrated how this model has stronger anti-interference ability and higher prediction accuracy than other models.

2. Method.

2.1. Calculation of local outlier factor values. Outlier detection based on LOF is a density-based outlier detection method; it works on the principle that each data point is assigned a LOF that depends on neighbourhood density. For any data point in a particular dataset, if the number of surrounding points is high and its local neighbourhood is dense, the data point is considered as a normal data point. Contrarily, an outlier is a data point that is far from the nearest neighbour of a normal data point. Thus, LOF can be understood as the outlier degree of a sample relative to its neighbours.

Among the k nearest neighbours to P , the distance between the farthest neighbour and P is the k -distance of P . The k -distance neighbour of sample P is the neighbour set whose distance from P is not greater than the k -distance of P . It is defined as the k -distance neighbour set $N_k(P)$, provided $N_k(P)$ by equation (1), where P' is the neighbour of P and D is the sample set. $d(P, P')$ is the distance between P' and P , and $d_k(P)$ is the k -distance of P . Furthermore, $d_k(P, O)$ is the k -th reachable distance from sample O to sample P . It corresponds to the largest distances among the k -distance from O and the distance from P to O , and it is provided by the expression in equation (2), where $d_k(O)$ is the k -distance of O and $d(P, O)$ is the distance between P and O .

$$N_k(P) = \{P' | P' \in D \setminus \{P\} | d(P, P') \leq d_k(P)\} \quad (1)$$

$$d_k(P, O) = \max\{d_k(O), d(P, O)\} \quad (2)$$

The neighbours within a sample and the density relationship between the sample and its neighbours can be described by the concept of local reachable density. The local reachable density of a sample P is the number of elements in the k -nearest neighbour set of P divided by the sum of the relative reachable distances from all points within the data set to P , which is expressed as $\rho_k(P)$. The expression is as follows:

$$\rho_k(P) = \frac{|N_k(P)|}{\sum_{o \in N_k(P)} d_k(P, O)} \quad (3)$$

The LOF is obtained by calculating the ratio of the average local reachable density of k points around the sample point to the local reachable density of this point, which is expressed by equation (4).

$$lof_k(P) = \frac{\sum_{o \in N_k(P)} \frac{\rho_k(O)}{\rho_k(P)}}{|N_k(P)|} \tag{4}$$

2.2. Fuzzy support vector regression. To improve the anti-interference ability of SVR, FSVR is obtained by combining the fuzzy membership value with SVR. Several sample points are required to train the model; however, the contribution of different sample points to the final result is different. Therefore, we assign a fuzzy membership value, λ , to each sample based on the LOF to obtain the fuzzy training set $D' = \{(x_1, y_1, \lambda_1), (x_2, y_2, \lambda_2), \dots, (x_m, y_m, \lambda_m)\}$, $y_i \in \mathbb{R}, 0 \leq \lambda \leq 1$, where the specific setting method for λ_m is described in the subsection Calculating the value of fuzzy membership in Section 3 of this paper. The mathematical expression of the model is provided by equation (5). The fuzzy membership degree λ is the contribution of the sample point to the final regression results, that is, a larger λ is assigned to a normal sample or a sample with a larger contribution to the model training, and a smaller λ is assigned to an abnormal outlier data point or a sample with a smaller contribution to the final result. This can reduce the interference of some of the samples outlier points or meaningless samples on the model to ensure that the final prediction results are closer to the true value, resulting in increased robustness of the model.

$$\begin{aligned} & \min \left\{ \frac{1}{2} \|w\|^2 + C \sum_{i=1}^n \lambda_m (\xi_i + \xi_i^*) \right\} \\ & \text{s.t.} \begin{cases} y_i - f(x_i) \leq \varepsilon + \xi_i \\ f(x_i) - y_i \leq \varepsilon + \xi_i^* \\ \xi_i, \xi_i^* \geq 0, i = 1, 2, \dots, n. \end{cases} \end{aligned} \tag{5}$$

The above formula is an optimization problem with constraints, where ε is an insensitive loss function; ξ_i and ξ_i^* are slack variables, which describe the loss caused by the sample away from the regression interval; and C is the penalty factor, which refers to the penalty for the sample whose regression function error is greater than ε . The smaller the value of C , the smaller the loss of the sample and, consequently, the smaller the loss of the objective function. Points far from the interval have larger errors; therefore, the penalty factor C will make the regression function more sensitive to such points to further fit these points. To calculate the corresponding loss, the absolute value should be greater than ε . In particular, considering $f(x)$ as the center, we set an interval band width of 2ε . When the training sample falls into the interval band, the prediction result is correct.

The Lagrange multiplier $a_i, a_i^*, \mu_i, \mu_i^*$ is introduced to obtain the Lagrange equation, and the partial derivative of the equation with respect to w, b, ξ_i, ξ_i^* is obtained, such that the partial derivative is 0. The results of partial derivatives are returned to the Lagrange equation, and the equation of the dual problem is obtained as follows:

$$\begin{aligned} & \max \sum_{i=1}^n y_i (a_i^* - a_i) - \varepsilon (a_i^* + a_i) - \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n (a_i^* - a_i) (a_j^* - a_j) \kappa(x_i, x_j) \\ & \text{s.t.} \begin{cases} \sum_{i=1}^n (a_i^* - a_i) = 0 \\ 0 \leq a_i, a_i^* \leq C \lambda_m \end{cases} \end{aligned} \tag{6}$$

When the above process satisfies the KarushKuhnTucker conditions, the value of b is obtained as follows:

$$b = y_i + \varepsilon - \sum_{i=1}^n (a_j^* - a_j) \kappa(x_i, x_j) \tag{7}$$

After feature mapping, w is expressed as follows:

$$w = \sum_{i=1}^n \phi(x_i) (a_i^* - a_i) \tag{8}$$

Fig. 3.1: Ranking of grey correlation degree

Table 3.1: Partial training sample - Part 1

rotational speed $/(r \cdot \text{min}^{-1})$	bit pressure /KN	density $/(g \cdot \text{cm}^{-3})$	well depth/m
120	20	1.10	214.10
160	30	1.14	365.03
176	50	1.19	1733.02
176	60	1.20	1876.11

By substituting w into $f(x) = w^T \phi(x) + b$, the final expression in equation (9) is obtained, where κ is the kernel function. Through this, the sample points can be mapped from low-dimensional space to high-dimensional space, which reduces the calculation difficulty. This model uses the Gaussian radial basis kernel function, which can better deal with high-dimensional samples and involves fewer parameters, consequently gaining good stability.

$$f(x) = \sum_{i=1}^n (a_i^* - a_i) \kappa(x, x_i) + b \quad (9)$$

3. Experiments and results.

3.1. Analysis of influencing factors on ROP. The parameters related to mechanical drilling speed can be divided into controllable and uncontrollable. Uncontrollable parameters are objective parameters related to formation conditions, such as pore pressure and fracture pressure. Controllable parameters are parameters that can be adjusted by technology and equipment and can be further divided into drilling fluid parameters, hydraulic parameters, and mechanical parameters. Drilling fluid parameters include density, rheological parameters, etc. Hydraulic parameters include bit pressure drop, etc. Mechanical parameters include drilling pressure, rotational speed, etc.

The data used in the model are from a block in the Shunbei Oilfield. There are a total of 11173 samples in the dataset. The mechanical drilling speed is assumed as the parent sequence, and its influencing parameters are assumed as the subsequence. The correlation degree ranking of the influencing parameters of ROP is obtained by grey correlation analysis and calculation, as shown in Figure 3.1.

Figure 3.1 shows that the correlation degree between each parameter and mechanical drilling rate is significantly different. The first seven parameters exhibiting a high correlation degree, namely, rotational speed, bit pressure, drilling fluid density, well depth, displacement, pumping pressure, and viscosity, are assumed to be the input of the model. Some training samples are shown in Table 3.1.

3.2. Preprocessing of data.

Table 3.2: Partial training sample - Part 2

displacement/($L \cdot s^{-1}$)	pumping pressure/ Mpa	viscosity/ m	ROP/($m \cdot h^{-1}$)
35	6	52	2.16
38	11	57	2.01
35	13	60	1.30
35	13	56	0.72

Fig. 3.2: Visualization results of 2D data

3.2.1. Detecting outliers. Owing to the introduction of the concept of nearest neighbours, the method based on LOF can better identify outliers located at the edge of the sample class and has better recognition effect. To display the results of LOF outlier detection conveniently, PCA dimension reduction was used to reduce the multidimensional data to 2D for visualization. The results are shown in Figure 3.2.

The model calculates the LOF for each data point and determines whether the point is an outlier based on the size of the LOF value. According to its definition, if the LOF value is close to 1, it indicates that the sample density is similar to its neighbourhood density, and the sample is classified as a normal data point. It is believed that a LOF value between 1 and 1.5 corresponds to normal data. If the LOF value is significantly greater than 1, it indicates that the sample density is less than its neighbourhood density, and the sample may be classified as an outlier. The 2D data obtained after dimensionality reduction are used for outlier detection, and the results are shown in Figure 3.3, where the red circles mark each data point. The size of the red circle represents the size of the LOF value, that is, the radius of the red circle determines the outlier degree of the data point. The larger the radius of the red circle, the lower the sample density; hence, the sample may be outliers. A smaller radius of the red circle indicates that the point is within the same cluster as the surrounding neighbourhood points and the degree of outliers is low, which indicates a normal data point. The outliers were labelled -1 and the normal points were labelled 1.

3.2.2. Normalizing the data. To eliminate the influence of different parameter ranges on the model and improve the generalization ability of the model data processing, the data should be normalized. The data normalization interval is $[-1,1]$, and the expression is as follows:

$$x_{norm} = \frac{(y_{max} - y_{min})(x - x_{min})}{x_{max} - x_{min}} + y_{min} \quad (10)$$

where x_{norm} and x represent the values after and before data normalization, respectively; x_{max} and x_{min} represent the maximum and minimum values before data normalization; and y_{max} and y_{min} represent the maximum and minimum values after normalization.

Fig. 3.3: LOF value of sample point

Table 3.3: Partial prediction results of SVR.

prediction of ROP for SVR	actual value of ROP	error	Is it a outlier (SVR)	LOF	membership value	Is it a outlier (LOF)
3.09	3.20	0.11	1	1.0251	0.8996	1
5.26	8.37	3.11	-1	1.7096	0.6203	-1
7.04	10.12	3.08	-1	1.8139	0.6059	-1
6.21	9.41	3.20	-1	1.7325	0.6147	-1

3.3. Training the fuzzy support vector regression model.

3.3.1. Training the standard SVR model. Normal training classifies data sets into training and test sets, which renders data sets not fully applicable to training. This can be avoided by cross-validation, wherein it is possible to use all data for training and testing. This model uses ten-fold cross-validation, wherein the data set is divided into ten sets, of which nine are training sets and one is a test set, which is used for an experiment. Subsequently, a new test set is chosen from the training set, and the original test set is used for training. Thus, ten experiments were conducted. Finally, the model with the smallest average absolute error in the ten experiments was assumed as the final model, and the average value of the ten average absolute errors was used to evaluate the model.

To verify the accuracy of the labelled outliers in the subsection Detecting outliers, the standard SVR model was used for ROP prediction. The data set whose absolute difference between the predicted ROP value and real value was greater than 3, which was temporarily recorded as an abnormal outlier and marked as -1, while other normal data were marked as 1. Some prediction results are listed in Table 3.3.

There are 81 groups of abnormal outlier data marked by the standard SVR model. Compared with the 72 groups of outlier data detected using the LOF, there are 61 groups of data consistent between both models, thereby indicating that the LOF outlier detection recognition rate reaches 84.72%.

3.3.2. Calculating the value of fuzzy membership. The membership function value λ_m in this study is determined by the value of the LOF, expressed as

$$\lambda_m = \begin{cases} (1 - \theta)^\mu + \sigma & \overline{lof} < lof_k(p) \leq lof_{max} \\ 1 - \theta & lof_{min} \leq lof_k(p) \leq \overline{lof} \end{cases}, \theta = \frac{lof_k(p) - lof_{min}}{lof_{max} - lof_{min}} \quad (11)$$

Here, $\mu \geq 2$ (in this study, n is taken to be 10); σ is a sufficiently small positive real number less than 1; and lof_{min}, lof_{max} , and \overline{lof} are the minimum, maximum, and average values in the sample LOF, respectively.

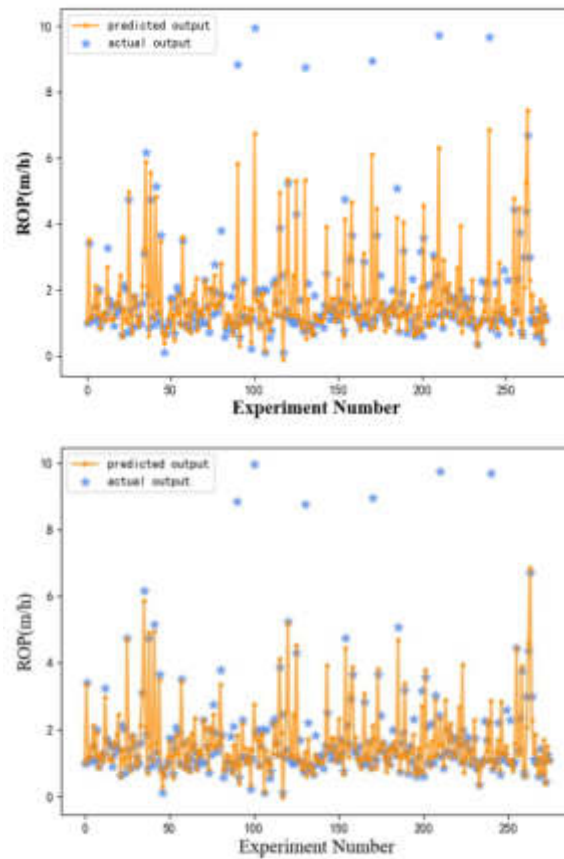

Fig. 3.4: (a) Results before model improvement (b) Results after model improvement

3.3.3. Training the fuzzy support vector regression model. The calculated fuzzy membership value is attached to each data point, and the fuzzy data set $D' = \{(x_1, y_1, \lambda_1), (x_2, y_2, \lambda_2), \dots, (x_m, y_m, \lambda_m)\}$ is sent to the FSVR model for training. The purpose is to control the samples with a large LOF and reduce their membership value to ensure that they have a smaller influence on the model. For the samples with a small LOF, the membership value is large to ensure that they have a significant contribution to the model. This training still uses ten-fold cross-validation. The results before and after improvement are shown in Figures 4 and 5, respectively. It can be observed that for the outliers above the general trend of the data, the standard SVR model (Figure 3.4) shifts the outliers significantly; thus, it is prone to overfitting and reduces generalization ability. However, the FSVR model with the fuzzy membership value added (Figure 5) is less affected by outliers and does not shift significantly toward them, thus demonstrating stronger anti-interference ability.

The four subplots within Figure 3.5 are the prediction results of ROP in different formations of four wells within the Shunbei Oilfield using the improved FSVR model. Figures 3.5(a)(d) utilize well Nos. 14, respectively. The abscissa shows different strata, and the ordinate is ROP. It can be observed from the figures that the error between the predicted and real values is controlled within 1, and the prediction effect is good.

3.4. Contrast experiment.

To evaluate the prediction accuracy of the model for normal data, the abnormal outliers of the dataset were removed, and three models mentioned in the Introduction section ordinary SVR, BP neural network, and PSO-MLP were used, in addition to the proposed FSVR model, to predict ROP. The errors of these four models were compared, and the results are listed in Table 3.4. It can be observed from Table 3.4 that the mean absolute

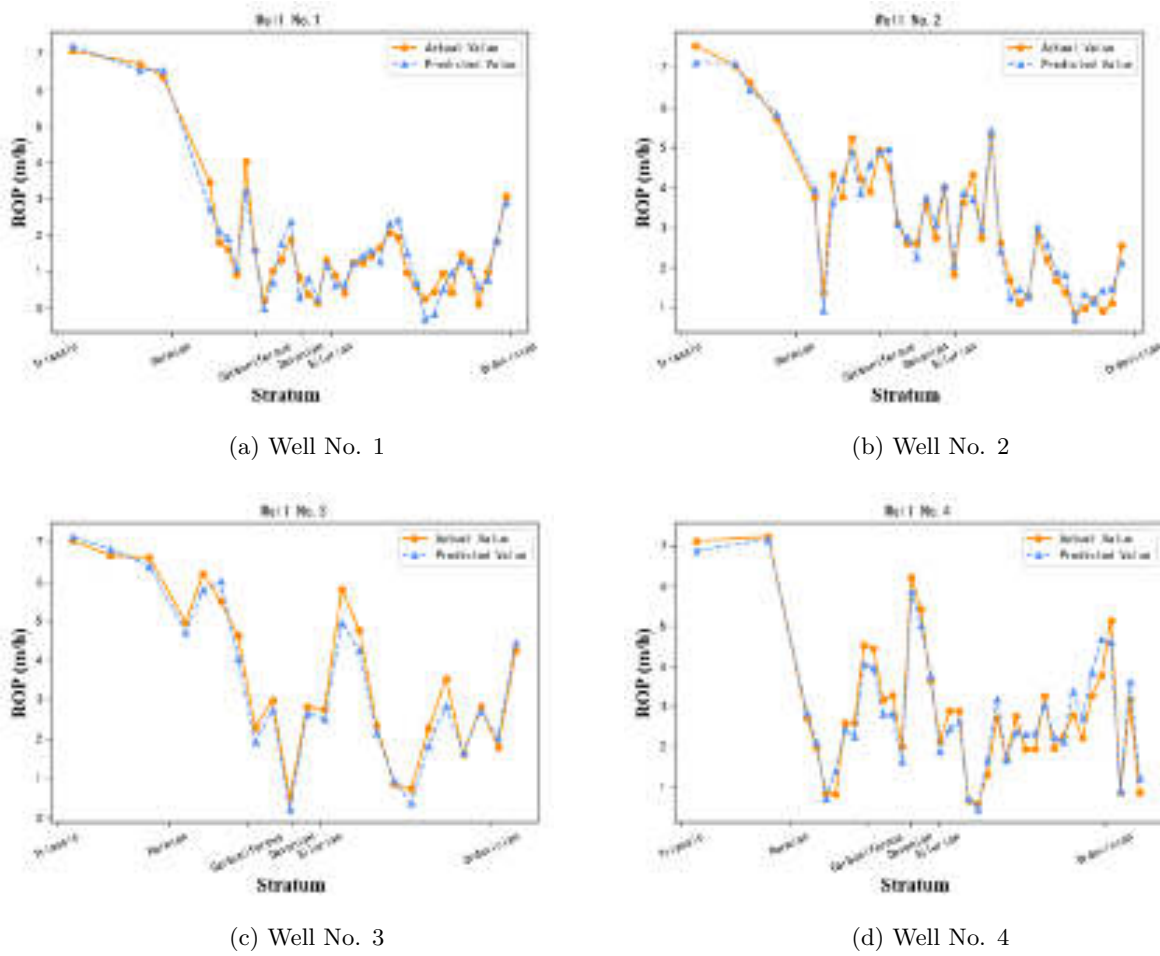

Fig. 3.5: Prediction results of FSVR

Table 3.4: Comparison of errors.

model	R^2	MAE	MSE
FSVR	0.9634	0.1974	0.0709
SVR	0.9354	0.2430	0.1252
PSO-MLP	0.9168	0.2446	0.1613
BPNN	0.8210	0.3784	0.4248

error (MAE) and mean squared error (MSE) of the FSVR model are smaller than those of the other models. The four graphs in Figure 3.6 show the goodness of fit (R^2) of the four models; R^2 of the FSVR model is closer to 1, thereby indicating that the predicted value of the FSVR model is closer to the real value; therefore, the regression fitting effect is enhanced.

According to the comparative experiments, the improved FSVR model is not sensitive to abnormal outlier data, which can reduce the interference of outliers within the model. Additionally, the model has higher prediction accuracy for normal data points.

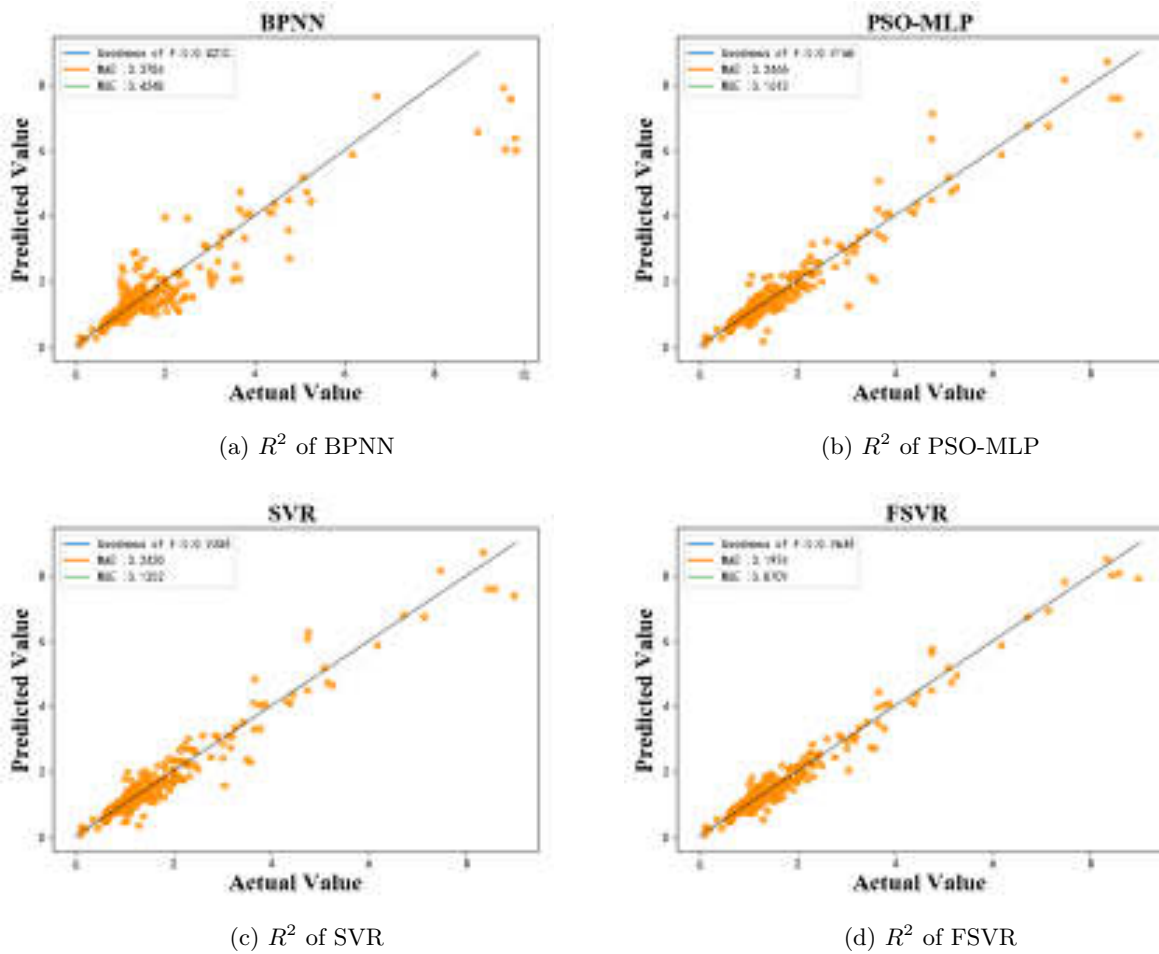

Fig. 3.6: Graphs showing goodness of fit

4. Conclusions. In this study, the FSVR model was established to address the problem of interference of outlier samples in a model, which are not considered by ROP prediction models based on machine learning algorithms. Parameters such as rotational speed and bit pressure of a block in the Shunbei Oilfield were selected as the input through grey correlation analysis. According to the LOF, a fuzzy membership value was assigned to each group of samples and was used to weight the penalty factor. The model was subsequently trained by the fuzzy training set. Attaching a smaller membership value to the outliers reduces the interference induced in the model. The normal data points were assigned a larger membership value to ensure that they have a greater influence. The results demonstrated the following.

1. The improved FSVR model has better anti-interference ability than other models, such as standard SVR, and is not prone to overfitting.
2. R^2 of the improved FSVR model is 0.9634, and the MAE is 0.1974. Therefore, the improved FSVR model has a smaller prediction error, higher accuracy, and better regression fitting effect for ROP of normal sample points.
3. The model has a good ability to predict ROP, which can provide support for the optimization of drilling parameters in the next step, thereby improving drilling efficiency and saving drilling costs.

RESEARCH ON DISTRIBUTED SCHEDULING ALGORITHM FOR VIRTUAL CITY POWER PLANTS BASED ON BLOCKCHAIN TECHNOLOGY

QING ZHU^{*}, YUFENG ZHANG[†] AND JIZE SUN[‡]

Abstract. In order to solve the problem that allocating the whole virtual power station is not centralized and promoting the free access of power distribution, a research on distributed scheduling of urban power network based on blockchain technology is proposed. and a scheme is proposed. Based on the consistency of decentralized virtual power plant and blockchain in decentralized point-to-point interaction and decentralized cooperation, this paper proposes to use blockchain consensus mechanism to realize distributed scheduling of virtual power plant. According to the principle of continuous micro- increment cost, the optimal economic dispatch of virtual power system is realized by taking the micro- increment characteristic as the variable. and the optimal economic dispatch strategy is realized. As a node of the blockchain, each distributed energy in the virtual power plant has a complete backup of the key data of the whole network. When the load changes, each node uses the PBFT consensus algorithm to independently calculate the new power of each unit. The new power data is stored on the chain, and the global consistency of micro incremental features is maintained to realize the reasonable load distribution among units. The experimental results show that, when the initial $t = 1$, the λ the values of each unit are different. The system does not meet the principle of constant consumption micro-increase rate, and the system does not operate in the optimal state. After a PBFT consensus, λ variable reaches the same value at $t=8$, and the system reaches the optimal operating state. Conclusion: The simulation experiment verifies the effectiveness of the algorithm, realizes distributed scheduling by using blockchain, and provides a feasible reference scheme for the operation mode of decentralized virtual power plant.

Key words: Consensus mechanism, Distributed scheduling, Completely distributed, Virtual power plant, Blockchain

1. Introduction and examples. With the rapid development of renewable energy such as wind and light, the pattern of distribution of electricity entering the distribution network is increasingly in the direction of access go high and high speed. However, a large number of new energy sources are interconnected, and their randomness and uncertainty will have an important impact on the operation, dispatching and trading of the power grid. Virtual power plant technology is an important part of the integration of multiple power distribution sites to participate in the power market and promote new energy use [1]. Virtual power plant technology can effectively balance the supply and demand relationship of electricity, improve the reliability and stability of electricity, and promote the use and popularization of new energy by integrating and managing multiple small distributed energy resources. In addition, virtual power plant technology can also provide more flexible and efficient trading methods for power producers and consumers through the participation of the electricity market, while also reducing the cost and risk of electricity trading.

As a new form of energy aggregation, virtual power plant provides a feasible method for a large number of distributed energy sources to be reliably connected to the grid. Through advanced communication technology, virtual power plant aggregate control of distributed energy, and make distributed energy coordinated and optimized operation, so as to achieve mutual adjustment of output, reliable grid connection. Compared with traditional power plants, virtual power plants have more diversified resources, are more environmentally friendly, and are more competitive in the power market, which promotes the transformation of the power industry and the development of the whole power system [2].

Block chain is a new type of data structure formed by a large number of blocks linked together in an orderly manner, and block refers to the collection of relevant data information, is the basic unit of block chain [3].

2. Literature review. It adopts advanced information and communication technology to realize DERs (distributed energy storage system, controllable load, electric vehicle, etc.) resources) for integrated and coordinated optimization. As a special power plant to participate in the power market and grid operation of power coordination management system, is considered to be the ultimate configuration of energy Internet. The Energy Internet is a new energy system mainly composed of renewable energy and supported by information and communication technology. It has the characteristics of decentralization, intelligence, interconnection, and efficiency, and can achieve large-scale application and sustainable development of clean energy.

As an important component of the energy internet, virtual power plants can integrate dispersed distributed energy resources to form a virtual power plant, participate in transactions in the electricity market, and achieve large-scale application of clean energy. At the same time, they can also bring more intelligent and efficient management methods to the operation and management of the power grid, providing strong support for the construction and development of the energy internet.

Virtual power plant integrates various DERs together to realize the stability and reliability of its overall output and provide efficient electric energy for the grid, so as to ensure the stability and safety of grid-connection. According to operation control mode, virtual power plants can be divided into three types: centralized central-decentralized and fully decentralized. The centralized architecture not only has high requirements for communication system, but also is difficult to cope with the management of numerous fit and forget distributed energy sources. Therefore, in order to better realize the management of DERs, the scheduling strategy of virtual power plant has been transformed from traditional centralized to distributed. Distributed virtual power plant has gained more attention and has better scalability and openness. In distributed virtual power plants, the multi-agent technology is usually used to realize the distributed communication of DERs. Through the information interaction between the agent and the neighbor node, it realizes self-regulation and eventually tends to the consistent variable. However, because multi-agent technology cannot obtain global information efficiently and accurately, it needs to approach consistent results through continuous iteration, which has problems such as inaccurate calculation and low efficiency [4,5].

To solve this problem, some optimization methods can be adopted, such as hierarchical control, local information sharing, predictive control, etc. These methods can help multi-agent system achieve consistent results more quickly and reduce computing and communication overhead.

Relevant scholars have studied the application of blockchain technology in the decentralized trading mechanism of distribution network, automatic demand response system, energy Internet, multi-module collaborative autonomous mode, distribution network, power trading and other fields. Blockchain and distributed virtual power plant are consistent in decentralized decentralized collaborative regional autonomy and other aspects. For example, in the distributed virtual power plant, there is no central control mechanism, and each DERs obtains global information through direct data exchange and then completes the regulation and operation of its own node independently [6,7].

To sum up as a whole, for distributing all virtual power plants, according to their status with blockchain in point-to-point cooperation and fair cooperation, this paper proposes to use blockchain technology to realize the time division of virtual power plants. Based on the constant consumption micro-increment rate criterion, the optimal economic dispatch of the virtual power plant is realized by using the micro-increment characteristic as a consistent variable. Combined with the blockchain recommendation algorithm, each power distribution node independently calculates the new power of each unit, and stores the new power information of the chain, while maintaining the global relationship of small features, to realize the reasonable distribution of load among units [8].

3. Method.

3.1. VPP distributed scheduling model. The VPP (Virtual Power Plant) distributed scheduling model is an energy management model based on virtual power plants. It integrates multiple distributed energy devices (such as solar, wind, energy storage, etc.) into a virtual power plant, and achieves centralized management and scheduling of these devices through communication methods such as the Internet, thereby achieving

participation in the electricity market and energy trading.

This paper takes the optimal distribution of active power load as an example. The so-called optimal distribution is to make the power generation equipment consume the least amount of energy per unit time in the process of generating electric energy on the premise of satisfying the continuous power supply of a certain amount of load. It usually adopts the principle of constant consumption rate increase to distribute load among units. In order to simplify the description, the optimal active power allocation scheme without network loss is adopted [9,10].

The implementation of optimal allocation can effectively improve the efficiency and reliability of the power system, reduce energy consumption and operating costs, and also reduce environmental pollution and carbon emissions, achieving sustainable utilization of clean energy. Therefore, optimal allocation is one of the important means for the operation and management of the power system, which is of great significance for achieving energy transformation and building a sustainable energy system.

Assuming that the cost function of the generator set in DERs is quadratic, the minimum generation cost of VPP can be achieved by expressing the cost function:

$$\min F = \min \sum_{i=1}^n F_i(P_i) \quad (3.1)$$

n indicates the number of group DERs in VPP, P_i represents the output power of unit i . The total cost of VPP is denoted as F , $F_i(P_i) = a_i P_i^2 + b_i P_i + c_i$, a_i , b_i and c_i represents the coefficient of the cost function.

All the DERs units inside the VPP meet the active power balance of the whole system when running, without considering the network loss, namely

$$\sum_{i=0}^n P_i = P_{LD} \quad (3.2)$$

P_{LD} represents the total load demand of all users.

According to the principle of constant consumption micro increase rate, the load is distributed among units.

$$\lambda = \frac{dF_i}{dP_i} = 2a_i P_i + b_i \quad (3.3)$$

As a result, λ can be used as a consistent variable between nodes in the blockchain, adjusting as the load changes, but remaining consistent across the network [11].

3.2. Consensus mechanism in alliance chain. The private chain is controlled by a single organization and is open only to its own organization; Consortiums are between public and private chains, open to a specific industry organization, and require that each new node be verified and audited. The alliance chain can adapt to the situation containing a small number of faulty or evil nodes and has certain fault tolerance characteristics [12].

Generally, different types of blockchain adopt different consensus mechanisms, and Byzantine Fault Tolerance (BFT) is one of the core issues to be solved in blockchain consensus algorithms. Bitcoin's POW and Ethereum's POS are public chain algorithms, which solve the BFT in the case of numerous consensus nodes. Compared with POW POS of the public chain, PBFT adopts the mechanism of each node voting to reach consensus, which can solve the bifurcation problem and improve efficiency. The operating environment of the PBFT requires a relatively closed cluster, and each consensus requires multiple p2-node communication. The traffic volume is $O(n^2)$, and n is the number of nodes in the cluster [13]. PBFT is suitable for alliance chain dominated by industry and government, and is an ideal choice for a system with limited number of nodes and no need for virtual currency incentive mechanism. Based on the operation characteristics of virtual power plant, this paper chooses alliance chain and adopts PBFT consensus algorithm [14].

The premise of PBFT algorithm is to ensure that message communication between nodes is immutable through cryptography technology. PBFT has certain fault tolerance characteristics, assuming that the total number of nodes in the system is $|n| = 3f + 1$, f is Number of tolerated PBFT faulty or malicious nodes. So in order for the whole system to work properly, you need to have $2f+1$ normal nodes. The classic representative project in the consortium chain is the Fabric project under the IBM Hyperledger organization, with Fabric0.6 using the PBFT algorithm [15].

Table 3.1: Blockchain and virtual power plant characteristics comparison

Feature	blockchain technology	Virtual Power Plant
Decentration	All nodes have equal rights and obligations	All power generation and power consumption subjects are equal, dispersed and coordinated
Cooperative autonomy	Using the consensus mechanism, all nodes jointly maintain	Each DERs realizes collaborative scheduling and supply-demand balance through data interaction
Credit system	No third party trust mechanism is required	Each DERs uses communication network to realize point-to-point direct interaction
Smart contract	The ability to automatically execute contracts	The power of each unit should be set reasonably according to the control command

Fig. 3.1: Blockchain builds the underlying information architecture of decentralized virtual power plants

3.3. Blockchain distributed scheduling model. Blockchain distributed scheduling model is an energy management model based on blockchain technology, which realizes the security and reliability of the power market participation and energy transaction through the establishment of a distributed account. In the blockchain distributed scheduling model, each distributed energy device is regarded as a node in the network, and each node has an account and some data. These data include the equipment’s production capacity, storage capacity, energy consumption, and so on. Data from all nodes is encrypted and stored on the blockchain, with each node having access to and modify its own data. In a completely decentralized virtual power plant, there is no centralized control mechanism, and the decision-making process is completed through direct interaction and multiple iterations of each power generation and power consumption unit. Based on the consistency of the two sides’ ideas and needs, blockchain is expected to become one of the underlying architectures for building decentralized virtual power plants, and realize the regulation and operation of virtual power plants. The comparison of characteristics between virtual power plants and blockchain technology is shown in Table 3.1.

Based on the coincidence between blockchain and virtual power plant, blockchain can be used to build the underlying information architecture of decentralized virtual power plant. Each DERs forms a blockchain network, which can realize point-to-point communication. The consensus mechanism is used to calculate the consistency variables. The specific structure of decision control through intelligent contract execution is shown in Figure 3.1.

As shown in Figure 3.1, it consists of a physical energy transmission network and a blockchain information network, where the energy network is responsible for power transmission and connects each DERs. Each DERs

Fig. 3.2: Data stored on the chain

unit corresponds to a node in the blockchain information network. Data and control signals can be transmitted between blockchain nodes and DER, and a point-to-point network is formed between nodes. The control strategy of the entire virtual power plant is calculated by the blockchain network and delivered to the physical network for execution.

3.4. Distributed scheduling policy execution process.

3.4.1. On-chain data. When the optimal operation configuration is reached, the micro increment characteristic λ value of all units is the same. Therefore, λ is selected as the state information of the blockchain platform, and the calculation is completed through the consensus mechanism, and the consistency is maintained.

According to the characteristics of blockchain data storage, each node saves a complete backup of global status data and keeps synchronization with other node data. According to the scheduling policy, each generator set needs to save the power information of all the units P_i (unit: kW) in the whole network and the cost function coefficient of the corresponding unit (a_i, b_i, c_i). Usually, the cost function remains inconvenient. After each power adjustment, the new power on-link storage makes use of blockchain technology so that each unit can accurately obtain the global state information. The data storage structure of each node is roughly shown in Figure 3.2 [16].

3.4.2. Distributed scheduling execution process. According to the PBFT consensus execution process, combined with the isobaric micro-increment criterion, the distributed scheduling calculation process is shown in Figure 3.3. When the total load demand changes, the power adjustment demand broadcast to all units, after PBFT consensus, each unit separately calculate the new power and λ , and adjust the power of the unit and broadcast λ at the same time all units of the new power on the chain storage for the next adjustment application.

The specific process is as follows

1. When the total load changes, the power calculation request operation of primary node DER1 is activated, and the primary node selection is completed according to the agreed algorithm rules of PBFT.
2. After receiving the request, the primary node broadcasts the request to each DERs node in the network according to the three-phase protocol rules.

Different requests have different ordinals. A pre-prepare message is constructed using the ordinals and request operations and broadcast to each DERs node. In this stage, the PLD and the power calculation request of the total change load are sent to each node.

Then there is the interaction phase, where each DERs node receives the pre-prepare message and each node broadcasts the prepare message to other DERs nodes. If a node receives messages from $2f$ different nodes, it means that the prepare phase of the node has been completed and each node has obtained the total load PLD after the change. Conditions are available to calculate the new power.

Finally, there is the sequence number confirmation stage. After each node verifies the request and order in the view, if the node receives $2f+1$ commit message, it means that most nodes have entered the commit stage and a consensus has been reached in this stage. The following takes the calculation process of the I -th node in the blockchain as an example to illustrate the calculation process of power allocation according to the constant consumption micro-increment criterion.

According to the distributed scheduling criterion, all nodes are required to have the same λ , that is, the formula 3.4 is satisfied

$$\lambda = 2a_1P_1 + b_1 = \dots = 2a_iP_i + b_i \quad (3.4)$$

The power of all nodes is expressed in P_i

$$\begin{cases} P_1 = ((2a_1P_i + b_i) - b_1)/2a_1 \\ P_2 = ((2a_2P_i + b_i) - b_2)/2a_2 \\ \dots \\ P_n = ((2a_nP_i + b_i) - b_n)/2a_n \end{cases} \quad (3.5)$$

Substitute formula 3.5 into formula 3.2 to get formula 3.6

$$P_{LD} = ((2a_1P_i + b_i) - b_1)/2a_1 + ((2a_2P_i + b_i) - b_2)/2a_2 + \dots + ((2a_nP_i + b_i) - b_n)/2a_n \quad (3.6)$$

As P_{LD} is known, P_i^* of DERs's new power can be calculated, then, P_i^* is substituted into formula 3.5 to obtain the new power value of all nodes and update the new value to the blockchain;The value λ is calculated at the same time and sent to the task initiator node; The drive DERs unit works according to the new power value [17].

3. The task initiator receives responses from different nodes. If there are $2f+1$ responses with the same λ value, the response is the result calculated for this request and is the consistent variable of the whole network. The distributed power distribution adjustment is completed to achieve optimal economic scheduling.

Specifically, the task initiator will perform the following actions:

Collect responses: Wait for responses from different nodes and collect them into a list.

Verify Response: For each response, verify its completeness and correctness. Ensure that the response is sent by the correct node and that the calculation results in the response are correct.

Select Response: For each request, select with the same λ $2f+1$ response of the value. If there is not enough response, wait for more responses until sufficient responses are received.

Calculation result: Use the selected response to calculate the final result. This will include the optimal economic dispatch values calculated for each node, thereby achieving optimal economic dispatch for distributed distribution adjustment.

Distribute Results: Distribute the results to all nodes so that they can update their local status and perform the next calculation.

Because the distributed energy can be added or withdrawn at any time, when a new node is added, the node broadcasts its own parameters and the current power value, requesting that the new node be added and the power redistribution be completed. Based on the PBFT mechanism, each node adds new node parameters to the on-chain storage, and adjusts the power based on the criteria to ensure that the system runs in the optimal state. When a node exits, similar operations are adopted to update the data on the chain and adjust the power [18].

The execution process of distributed scheduling is a dynamic and real-time process that requires continuous monitoring and adjustment to adapt to the complex and ever-changing operating environment of the power system.

3.5. Experimental verification. To verify the effectiveness of the proposed algorithm, an experimental simulation is conducted to verify that four DERs are distributed in a VPP system of the type Micro Gas Generators (MGGs), which are connected through a blockchain network.Each MGG is a node in the network. It is assumed that the network has a certain network delay, but the operation parameters and initial power of the point-to-point direct communication unit are guaranteed as shown in Table 3.2.

4. Results and discussion. In the presence of network delay, the change of consistency variable λ is tested. As can be seen from Figure 4.1, when the initial $t=1$, the λ values of each unit are different, which does not meet the constant consumption micro rate increase criterion, and the system does not operate in the optimal state. After a PBFT consensus, λ variable reaches the same value at $t=8$, and the system reaches the optimal operating state[19].

Table 3.2: Unit operating parameters and initial power

electric generator	a_i	b_i	c_i	P_i /KW
MGG1	1.256	1.355	8.812	30
MGG2	1.099	1.293	4.876	35
MGG3	0.942	1.220	1.220	70
MGG4	1.079	1.276	8.831	40

Fig. 4.1: The change of λ value of the microincrement feature

Fig. 4.3: Power variation of each unit

Figure 4.1 shows the comparison between the total load power P_{LD} and the total power $\sum(P_i)$ of the generating unit in the process of consensus.

Figure 4.3 shows the power adjustment of each mgg unit, and the final power value remains stable in the working state[20].

5. Conclusion. A research on distributed scheduling of virtual city power plants based on blockchain technology is proposed. The virtual power plant will be one of the last models of the future power of the internet, realize the reality of the agreement of resources in a wide range, and promote the use of electricity share. For the optimal operation of distributed virtual power plants, the fully distributed operation control of virtual power plants is realized by adopting the equal consumption and small increase principle and combining the distributed decentralized autonomous blockchain technology. In addition, the virtual power plant has some fault-tolerance capacity for situations such as node communication failure, which improves the safety level of the electric power. Specifically, virtual power plants typically adopt a distributed architecture, where multiple nodes form a network, and each node can transmit and process information. Therefore, in the event of a node failure or communication interruption, other nodes can still continue to operate and interact, thus ensuring the continuity and stability of the system.

A NONLINEAR CONVOLUTIONAL NEURAL NETWORK ALGORITHM FOR AUTONOMOUS VEHICLE LANE LINE DETECTION

KANHUI LYU*

Abstract. The traditional lane line detection algorithm relies on artificial design features, which has poor robustness and cannot cope with the complex urban street background. With the rise of deep learning technology, the algorithm model with convolutional neural network as the mainstream is widely used in the field of computer vision, which provides a new idea for lane line detection. In order to improve the disadvantages of traditional lane line detection methods that are vulnerable to environmental impact and poor robustness, a nonlinear convolution neural network algorithm for driverless lane line detection is proposed. Firstly, the pretreatment method of extracting the region of interest and enhancing the contrast of lane lines is used to reduce the unnecessary image background and enhance the feature details of the image. Existing deep learning-based lane line detection algorithms still have difficulties. First, accumulated wear and tear will cause lane line to fade and fade; roadside trees and buildings can interfere with the performance of lane line detection algorithm. In addition, compared with the pixels of the whole picture, the lane line pixels are too few, and the deep convolution neural network of layer convolution is easy to lead to the loss of details. In addition, when the traffic flow is large, the lane line is easily blocked, which makes it more difficult to detect the lane line. Then the model is built based on the lane line image features extracted by CNN, and the DBSCAN clustering algorithm is used to post-process the lane line segmentation model; Finally, the least square method is used to fit the quadratic curve of the pixel peak points of the lane line, and the fitting results are regressed to the original image. The experimental results show that the accuracy and recall of the lane line detection model verification set are 91.3% and 90.6%, respectively, indicating that the model has a good segmentation effect. It is proved that the lane line detection method based on CNN combined with post-processing can effectively reduce the defects of artificial experience, and has better robustness and accuracy than the traditional lane line detection method.

Key words: Lane line detection, Convolution neural network, Deep learning, clustering algorithm

1. Introduction and examples. With the rapid development of urban traffic, traffic safety has become increasingly important. By the end of June 2017, the number of cars owned reached 205 million, and the number of car drivers reached 328 million, cars have become one of the most commonly used vehicles in our lives. Driving safety has become one of the hot issues that people are most concerned about. During the driving process, the road conditions and vehicle conditions are complex, and the driver is nervous and prone to fatigue. According to statistics, 66% of drivers are prone to drowsiness when driving alone for a long time. This shows the importance of lane line deviation warning [1].

As a key step in driverless technology, lane line detection is an important component of the sensing module. The study of lane line detection algorithm has important research value and application significance in the information exchange, traffic path planning and traffic safety accident avoidance. In the autonomous driving technology, more and more domestic and foreign researchers have carried out detailed and rich research on the lane line detection algorithm, and have achieved fruitful results. Therefore, there is a need for a lane line warning system to send out a danger warning to the driver to reduce the accident rate. This system designed to help the driver in the driving process is called the auxiliary driving system (ADAS). The goal of the system is to detect lane markings and alert the driver when he leaves the lane. In recent years, the semiconductor industry has developed and made great progress, small and powerful electronic devices are widely used in vehicles [2]. These devices can perform complex calculations and provide hardware environment protection for the auxiliary driving system. Gives the driver a safety warning at the right time. Intelligent transportation is included in the 13th Five-Year Plan, as one of the core functions of assisted driving and automatic driving, lane line detection is of self-evident importance. Lane line detection is not only related to our daily travel safety, but also an important part of development planning [3].

* Institute of Information Technology, Zhejiang Financial College, Hangzhou, Zhejiang, 310018, China (KanhuiLyu@126.com)

Lane line detection algorithm can be roughly divided into two categories: detection algorithm based on traditional digital image processing method, such as Hough transform, and lane line detection algorithm based on deep learning. Starting from the focus of the detection algorithm, the traditional lane line detection algorithm can be divided into two categories: one is the model-based detection algorithm based on the mathematical model such as curve or straight line, and the lane line detection algorithm based on the color, texture, shape and direction of the lane line.

2. Literature review. Convolution neural networks have been offered for over 20 years. The original neural network solution was also developed as a different type of neural network solution to solve problems in different research fields. It is used for image classification and image recognition in image processing. Lane line detection as one of the core functions of auxiliary driving and autopilot, the technology can in the process of driving real-time, accurate detection lane line, when the vehicle deviates from the current lane, warning, the driver operation error can be corrected, can effectively reduce the accident rate caused by the operation error and fatigue driving, so as to ensure the driver's personal and property safety. Therefore, lane line detection is crucial for the safety of drivers while driving. Neural networks are the first to be used to understand the environment of a self-driving car, such as recognizing traffic lanes captured by cameras, recognizing driving zones, and recognizing problems around the area take pictures from the face and the connection between the camera and the cap. In recent decades, many countries have invested in the direction of inquiry and the direction of research questions has become very good. Traditional line detection algorithms capture and filter the image and then use changes in line brightness to divide the lines [4].

Computer computing power and massive amounts of data have driven the development of deep learning technology, which has been applied to various fields, such as speech and images. Among them, the application of deep convolutional neural network to images is a negligible branch.

The line detection method based on neural network solution is to draw the lines of multi-dimensional scene image according to the data set, input them into the design of neural network solution, and train the neural network solution to make it clear.

The main purpose of lane line detection is to identify the lane lines from the original images. More specifically, the algorithm is used to extract the coordinates of the pixels belonging to the lane lines in the image, and then post-processing the pixels to finally obtain the actual position of the lane line in the original image.

Some assumptions about the lines on the road map. As an important part of raising environmental awareness, discovery line has been studied by researchers at home and abroad and has achieved a lot of results. The traditional line detection system can detect the line quickly and in real time, but the stability is poor, different lines of the line detection accuracy is low.

Lane lines have innate structural features, which are long and thin in shape. For a high-resolution RGB image, the proportion of lane line pixels in the whole image element tends to be small. After the deep convolutional neural network, the details of lane lines are easy to lose, resulting in the detection of lane lines.

In recent years, the rapid development of computer algorithm, gradually applied to the detection line. However, because the neural network scheme has more parameters and a large amount of calculation, the hardware cost of the detection line using the neural network scheme is high [5]. Haris, M improved line detection in complex environments, a method combined with visual data with wide distribution [6]. Ghazal, T. M proposed handwritten text recognition techniques based on neural network technology [7]. Dong, Y proposed a weighted fusion of convolutional neural network and graph attention network (WFCG) for HSI classification based on the characteristics of super-pixel-based GAT and pixel-based CNN, which proved to be successful [8].

Semantic segmentation network based on convolutional neural network for each pixel image detection, can be applied to different forms of target detection task, detection of details is more fine, so in dealing with different road scene also has advantages, such as in the car to change lanes or turn, lane line shape and structure has changed, for semantic segmentation network, can be very well processed, achieve better detection effect.

In order to improve the disadvantages of traditional lane line detection methods on environmental impact and poor robustness, a nonlinear convolutional neural network algorithm for unmanned lane line detection is proposed.

Considering that traditional line detection is easily affected by the environment and needs manual extraction,

a line detection method based on CNN is proposed. Plus the post-treatment process, it has the advantages of no manual adjustment, multiple applications and good effects.

3. Research methods.

3.1. Convolution neural network. Machine learning is an important part of the field of artificial intelligence, through the theory of probability, statistics, biology and artificial intelligence problems abstract into mathematical models, so that the model has similar to human learning ability, iteratively adjust the model parameters, to optimize the model effect, machine learning classical algorithms, including neural network, support vector machine, K mean clustering, DBSCAN and logical regression, etc. Among them, the neural network mimics the image process of the human visual system in processing pupil intake.

Compared with neural network, convolution neural network has changed the connection mode of neurons, using convolution operation and pooling operation. Convolution layer, activation layer and pooling layer are essential components of convolution neural network. The function of convolution layer is to convolution the input of convolution neural network to extract the features of the input image. The convolution process can be understood as a filtering process, a convolution kernel is a window filter, in the network training process, the convolution kernel of a user-defined size is used as a sliding window to convolution the input data [9].

The edge length of the image output by the convolution operation=(input image edge length convolution core length+1)/step length, if it cannot be divided, the result will be rounded up. Sometimes in order to ensure that the side length of the output image of a convolution operation is the same as the side length of the input image, all-zero filling will be performed around the input image, and the side length of the output image is equal to the side length of the input image divided by the step length, if it is not possible to divide and take an integer up, assume that the input image is a three-channel image of 52 * 52 * 3, the convolution kernel size is 5 * 5, and the depth is 3, that is, a convolution kernel of 5 * 5 * 3, if the convolution step is 1, the characteristic image of 48 * 48 * 1 will be output[10]. The parameters in the convolution kernel are the weights in the network, these parameters are unchanged in a forward calculation process and will not change because of the position of the convolution kernel in the input data, this is the weight sharing property of convolutional neural network. Finally, the image features are recognized by combining different features. The activation layer compensates for the linear operation of convolution, adds nonlinear elements, and makes the convolution neural network have the ability to learn nonlinear.

3.2. Image data preprocessing. The purpose of lane line image data preprocessing is to enhance the features of the target in the image, so that deep learning can better learn the feature information and obtain a model with stronger generalization ability.

3.2.1. ROI extraction. In order to remove redundant image information and improve the speed and detection effect of network training, a fixed ROI region extraction method is adopted, through OpenCV, the original image with the resolution of 720E480 is clipped to the ROI area of 720E240.

3.2.2. Brightness contrast transformation. Contrast is the ratio of the whitest and darkest brightness units. Adjusting the contrast can make the image more vivid. Take a color channel of an RGB image as an example, take the current color depth value I of the pixel as the abscissa, and output the transformed color depth value O as the ordinate to establish the coordinate system, each pixel of the traditional RGB format image can use a value of 0~255 to represent its color depth [11].

When the brightness and contrast of the image are modified at the same time, the transformation equation is as follows 3.1:

$$O = KI + J \quad (3.1)$$

where J is the increased value of image brightness, and K is the original color depth scale value. According to the actual situation, several attempts have been made to determine the added value of image contrast and brightness adjustment, and the original image has been adjusted by $K=1$ and $J=20$.

3.3. Lane line detection algorithm. The whole process of anchor-based lane line detection model can be compared to the process of region-based target detection algorithm. First, the feature extraction was

Fig. 3.1: Design steps of lane line detection algorithm

performed by placing anchor at each position of the feature graph to obtain the resulting feature vector. Finally, the feature vectors were regressed and classified separately.

The lane line detection algorithm established by the author is mainly divided into two steps, namely, network design and model training, and lane line model post-processing, as shown in Figure 3.1.

3.3.1. Model structure design. As a marker line on the road surface, it is a two-dimensional goal. Compared with the point cloud data of lidar, the model constructed by GPS and high-precision map, the images obtained by the visual sensor can express the two-dimensional features of the lane line more effectively. Moreover, compared with lidar and high-precision maps, visual sensors are low cost and cost-effective. Therefore, the lane line detection algorithm is mostly based on vision sensor, that is, the detection algorithm based on computer vision, which is also widely used in the industry to detect lane lines.

Fine-tune the VGG16 network, add a custom network on the VGG16 base network that has been trained on other classification issues, and then freeze the base network, re-train the previously added user-defined part and unfreeze some layers of the base network, and finally jointly train the unfrozen layer and the user-defined added part. The Softmax layer is added to the last layer of the network model output to modify the model framework, so as to achieve the probability distribution of multi-channel pixel points of the model output results, which is convenient for the clustering algorithm in the post-processing algorithm to cluster the lane lines [12].

3.3.2. Lane line pixel clustering. By clustering the core points and density reachable points, the area with enough high density is divided into one category. At the same time, DBSCAN can also recognize sparse noise data. The pixel distribution of the output image of the lane line segmentation model is clustered, and the image pixels belonging to the same lane line are classified into the same category. Convert the pixel probability distribution of lane line segmentation image into 3D visualization image. Sort the pixel probability distribution image output by lane line segmentation according to the axis value, and take the y item accuracy data corresponding to the image model position $x=240, 250... 480$, then extract the peak points with probability value greater than 0.5 and cluster them, the output image of the peak points with probability value greater than 0.5 is shown in Figure 3.2.

3.3.3. Lane line fitting and regression. Lane line fitting is a square theory of lane line curve according to a specific number of sampling points. Lane line fitting is to fit the pixel probability peak points of the reclassified lane line segmentation model, and then obtain the track parameter equation of the lane line[13].

Curve fitting refers to obtaining an approximate curve $y = \rho(x)$ for a given m data points $p_i(x_i, y_i), i = 1, 2, \dots, m$, so as to minimize the deviation between the curve $y = \rho(x)$ and the real curve $y = f(x)$. The deviation δ_i of $y = \rho(x)$ at point p_i is calculated as follows 3.2:

$$\delta_i = \rho(x_i) - y_i \quad (3.2)$$

where δ_i is the deviation.

The deviation minimization calculation formula is as follows 3.3:

$$\min \sum_{i=1}^m \delta_i^2 = \sum_{i=1}^m (\rho(x_i) - y_i)^2 \quad (3.3)$$

Fig. 3.2: Peak output image with probability value greater than 0.5

The least square method takes the quadratic equation as the fitting curve, and selects the fitting curve with the smallest sum of squares. The least square method is used to perform polynomial nonlinear fitting on the given m sample points, so that the approximate curve $\delta_i = \rho(x_i) - y_i$ of $y_i = f(x)$ passes through these sample points.

Assume that the polynomial of lane line to be fitted is the following equation 3.4:

$$p(x) = a_0 + a_1x + \dots + a_kx^k = \sum_{k=0}^n a_kx^k \tag{3.4}$$

The sum of squares of deviations of all pixel points reaching the approximate curve is as follows 3.5:

$$\begin{aligned} R &= \sum_{i=1}^m [y_i - (a_0 + a_1x_i + \dots + a_kx_i^k)]^2 \\ &= \sum_{i=1}^m (y_i - \sum_{k=0}^m a_kx_i^k)^2 \end{aligned} \tag{3.5}$$

Solve polynomial $a_i = (i = 1, 2, \dots, k)$ to obtain the minimum value of equation 3.6, expressed as:

$$\begin{aligned} \min R &= \sum_{i=1}^m [y_i - (a_0 + a_1x_i + \dots + a_kx_i^k)]^2 \\ &= \sum_{i=1}^m (y_i - \sum_{k=0}^m a_kx_i^k)^2 \end{aligned} \tag{3.6}$$

In order to solve the extreme value of the multivariate function of the parameter a_1, a_1, \dots, a_k , the partial derivative formula of the variable $a_i = (i = 1, 2, \dots, k)$ is obtained as follows 3.7:

$$\sum_{k=0}^n \left(\sum_{i=1}^m a_kx_i^{j+k} \right) = \sum_{i=1}^m x_i^j y_i, \quad j = 0, 1, \dots, n \tag{3.7}$$

Fig. 3.3: Quadratic curve fitting image

Change the equation into matrix form as follows 3.8:

$$\begin{bmatrix} m & \sum_{i=1}^m x_i & \cdots & \sum_{i=1}^m x_i^n \\ \sum_{i=1}^m x_i & \sum_{i=1}^m x_i^2 & \cdots & \sum_{i=1}^m x_i^{n+1} \\ \vdots & \vdots & \ddots & \vdots \\ \sum_{i=1}^m x_i^n & \sum_{i=1}^m x_i^{n+1} & \cdots & \sum_{i=1}^m x_i^{2n} \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_n \end{bmatrix} = \begin{bmatrix} \sum_{i=1}^m y_i \\ \sum_{i=1}^m x_i y_i \\ \vdots \\ \sum_{i=1}^m x_i^n y_i \end{bmatrix} \tag{3.8}$$

The following formula 3.9 is obtained by simplifying the Vandermonde matrix:

$$\begin{bmatrix} 1 & x_1 & \cdots & x_1^k \\ 1 & x_2 & \cdots & x_2^k \\ \vdots & \vdots & \ddots & \vdots \\ 1 & x_n & \cdots & x_n^k \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_n \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} \tag{3.9}$$

The solved coefficient matrix Q formula is 3.10:

$$Q = X^{-1}Y \tag{3.10}$$

Equation 3.10 is the relationship of the fitting curve, the least square method is used to fit the quadratic curve of the probability peak point of the lane line pixel after clustering classification, the fitting image is shown in Figure 3.3. Regression the fitting curve to the original lane line image [14].

4. Result analysis. The author’s algorithm is based on the Keras deep learning framework, using Python language, OpenCV computer vision processing library, and tested on Ubuntu 18.04L TS system [15]. Keras is a deep learning framework based on theano / tensorflow. Is a high-level neural network API that supports fast experiments and can quickly translate your idea into results.

A random gradient is used to train a neural network model. The learning threshold was set to 0.01, the size was set to 16, and the learning period (Epoch) was set to 100. During the training process, introducing some obstacles during the training process indicates the state of the emerging model[16]. Based on the values of the output parameters of the training process, the OpenCV graphing function is used to plot the average accuracy and loss curves as a function of the number of iterations during training. The missing curve with 100 sampling iterations is shown in Figure 4.1, and the mean true curve with 100 sampling iterations is shown in Figure 4.2.

Fig. 4.1: Training loss change curve

Fig. 4.2: Training accuracy change curve

The accuracy rate and recall rate of the model are defined as the basis for judging the segmentation effect of the model, that is, the greater the accuracy rate and recall value, the better the segmentation effect of the model. The calculation formula of average accuracy acc is:

$$acc = \frac{C_{img}}{T_{img}} \quad (4.1)$$

where, C_{img} is the correct number of pixels for segmentation, and T_{img} is the total number of pixels marked for the entire image[17].

All pixels labeled as lane line image areas are divided into lane line pixels and non-lane line pixels. The ratio of the two is the recall rate $recall$. The calculation formula is 4.1:

$$recall = \frac{TP}{TP + FN} \quad (4.2)$$

where, TP is the correctly predicted lane line pixel point, and FN is the incorrectly predicted lane line pixel point.

Table 4.1: Comparison between accuracy of different models and time consumption of single frame image

Model	Accuracy/%	Time consumption/ms
K-means	84.25	54
CNN+Hough	87.08	60
SegNet	90.06	50
VGG16	91.3	45

After calculation, the average accuracy rate and recall rate of the final model validation set are 91.3% and 90.6% respectively, indicating that the model has good segmentation effect. Then the lane lines in different scenes are detected and recognized[18].

For the same experimental sample, compare the detection accuracy and single frame image time of the author's model with other models, and the results are shown in Table 4.1.

The experimental results show that the accuracy of the traditional lane line detection method K-means is far less than that of other model methods combined with deep learning. Although the method of CNN combined with Hough transform improves the detection accuracy, it takes the longest average time to process a single frame image, compared with this method, the accuracy and average time of lane line detection of SegNet model have been greatly improved. Compared with the other three models, the VGG16 model has significantly improved in accuracy and single-frame image processing speed, achieving better image segmentation effect [19,20].

The features of the lines were studied using CNN in special image extraction operation and the DBSCAN clustering algorithm was used for line classification, which improves the accuracy of the model and the matching results. About this method. Experimental results show that the combination of CNN and post-processing algorithm is more accurate and reliable than conventional line detection methods.

5. Conclusion. Lane line detection is an important part of auxiliary driving and automatic driving. Lane line deviation alarm and lane line maintenance can correct the careless operation of drivers in time, reduce traffic accidents caused by wrong operation and fatigue driving, so as to effectively guarantee driving safety and reduce driving complexity. In complex road scenarios, lane line detection algorithms need to be robust and real-time.

In this paper, we take advantage of CNN in special image extraction operation to study the features of the line, and perform the post-line classification process using DBSCAN clustering algorithm, which improves the accuracy of the model and improves the matching results. about the method. The traditional lane line detection method K-means has much less precision than other model methods combining deep learning. Although the CNN method combined with Hough transformation improved the detection accuracy, the average time was the longest for processing single-frame images, and the lane line detection accuracy and average time of the SegNet model were significantly improved compared with this method. Compared with the other three models, the VGG 16 model showed a significant improvement in both accuracy and single-frame image processing speed, achieving better image segmentation.

Experimental results show that the combination of CNN and post-processing algorithm is more accurate and reliable than traditional line detection methods. The line of investigation suggested by the author is therefore of some value. However, the algorithm still has some disadvantages: on the one hand, due to the limitations of the image's own hardware during training, the training time increases, and the error resulting from training increases, which makes it impossible to learn all the network models. image features; On the other hand, when the output data of the lane-line segmentation model is postprocessed, a small amount of pixel data may be filtered out, leading to the failure to fit and missing part of the lane lines. The above questions are the key direction of the next research step. Because the input image resolution of the present network is not high enough, the localization information is not accurate enough. Moreover, when the network return is too deep, the speed of the network cannot meet the needs of real-time detection, so the results of both detection accuracy and speed cannot be realized. Next, we hope to innovate in the network input mode and network structure, so as to ensure the network detection speed and increase the resolution of the image, so as to better realize the

lane line detection.

DIMENSION EXTRACTION OF REMOTE SENSING IMAGES IN TOPOGRAPHIC SURVEYING BASED ON NONLINEAR FEATURE ALGORITHM

YANI WANG,* YINPENG ZHOU† AND BO WANG ‡

Abstract. In order to solve the problem of inaccurate image feature extraction caused by traditional extraction methods, this paper proposes a remote sensing image size extraction method based on nonlinear multi feature fusion for topographic maps. In this paper, SVM and DS evidence theory are combined to extract image features and classify pre processed remote sensing images. Based on the classification results, basic probability distributions are constructed, and a DS fusion algorithm using matrix analysis is introduced to simplify the complexity of decision level fusion algorithms; We use a multi feature fusion algorithm based on feature proximity, using the proximity vector formed by the attraction between the feature vector and the original graphics pattern as the fusion feature to complete the extraction of remote sensing image features. The simulation results show that after using this method, its soft threshold classifier outputs 0.9865, 0.9965, 0.7852, 0.9921, 0.9847, 0.6879, -0.5898, -0.5678, -0.6897, -0.4785. The algorithm in this paper can distinguish the shape features of terrain images well, and can extract the features of terrain images more accurately, which has strong feasibility.

Key words: Image feature extraction, Multi-feature fusion, Matrix analysis, Feature proximity, Feature vector

1. Introduction and examples. Remote sensing technology has become a comprehensive technology integrating multiple fields after decades of development since the 1960s [1]. Remote sensing technology refers to the observation of ground objects through some devices, obtaining relevant data, but not directly contacting the observation objects, and extracting and excavating the information from the obtained data. Different sensors have different spectral resolution. Generally, the imaging of remote sensing technology can be divided into the following categories according to the different resolution:

- ① Multispectral remote sensing image: the spectral resolution is within the range of $10-1\lambda$, and the multispectral image only contains 3-4 spectral bands, which contains less information;
- ② Hyperspectral remote sensing image: the spectral resolution is within $10-2\lambda$, often with tens to hundreds of bands, and contains rich information. This paper takes hyperspectral image as the main research object;
- ③ Ultra-spectral remote sensing image: the spectral resolution is within the range of $10-3\lambda$, and this paper does not involve ultra-hyperspectral image [2].

Hyperspectral remote sensing technology is one of the latest achievements of remote sensing technology. It scans objects and obtains relevant information through a series of narrow electromagnetic wave bands. The sensor forms a spectral image through hyperspectral remote sensing technology. The image contains continuous spectral information. Researchers can use this information to find some hidden material information, which is one of the advantages of hyperspectral remote sensing. Therefore, hyperspectral sensor imaging is a powerful assistant for researchers to identify substances in detail and accurately estimate the abundance of substances [3].

With the vigorous development of hyperspectral remote sensing technology in hardware, it is gradually recognized and accepted by more people, and the application field of remote sensing technology has been greatly expanded. But the puzzle behind the rapid development of remote sensing hardware technology is that a large number of remote sensing data are just cold numbers, which have not been fully utilized and mined, let alone used to serve mankind.

*Xi'an University, Shaanxi, Xi'an, 710065, China (YaniWang53@126.com)

†Institute of Surveying and Mapping Guizhou Geology and Mineral Exploration Bureau (Corresponding author, YinpengZhou7@163.com)

‡Shaanxi Geomatics Center, Ministry of Natural Resources Xi'an, China (BoWang28@126.com)

The data collected by hyperspectral remote sensing technology contains a lot of information, through which the spectral characteristics of the observed object can be closely linked with the spatial geographic information, and many potential characteristics of substances can be easily mined by analyzing hyperspectral data, which are important reasons why hyperspectral images are favored by more and more remote sensing experts. The hyperspectral remote sensing technology not only obtains the spectral characteristics of the ground object, but also preserves the relationship between the observed object and other surrounding ground objects. The resulting images contain rich information, which provides a strong support for us to use and analyze data.

2. Literature review. Buildings are an important component of urban areas. The technology of automatic extraction of buildings by computer is widely used in the fields of urban large-scale topographic map drawing, urban planning, urban geographic information system construction and military reconnaissance. Driven by these applications, many automatic building extraction methods have emerged. In recent years, automatic building extraction from remote sensing images has become a hot spot, attracting many scholars to discuss and study, and put forward many detection models and methods [4]. After summary, we can classify it into two kinds of methods: traditional building detection algorithm and building detection algorithm based on machine learning. Traditional building detection algorithms focus on describing the underlying features of buildings, such as building detection based on gray scale, contour, texture and other features or a simple combination of several underlying features, and building detection algorithms that add laser point clouds, DEM and other data sources [5]. Building detection algorithm based on gray level: This kind of method is mainly to analyze the gray level distribution in the image. Due to the different reflectivity of the building roof and other ground objects to the sunlight, there will be gray level differences, so the building will be extracted from the image using the region segmentation algorithm; Because most buildings have shadows, the gray contrast between the shadows around the buildings and the background is used to detect the existence of buildings.

Therefore, Li, X proposed a multivariate fusion voting network (MFFVoteNet) framework to improve the performance of 3D object detection in non-uniform and high-impact environments. Our method uses a point cloud and a synchronized RGB image as input to enable object detection in 3D space [6]. Shankar, K Review of WSI review process based on machine learning. First, the development status of WSI and CAD methods is presented. Second, we discuss WSI data reporting, segmentation, classification, and metrics for testing activities [7]. Wang, Z proposed a novel fusion model based on meta-heuristics for diagnosing COVID-19 using chest radiographs. The model includes various preplanning, extraction procedures and categories. Initially, Wiener filter (WF) technology was used for image processing [8].

This paper proposes a feature extraction method of remote sensing image based on SVM and multi-feature fusion. The simulation results show that the accuracy and speed of pixel extraction of the method proposed in this paper are much higher than those of traditional methods in the process of image extraction, which can be widely used and has strong feasibility.

3. Research methods.

3.1. Remote sensing image feature extraction principle. This is because traditional remote image feature extraction has many different parameters and is capable of extracting pixel features and recovering them in time and frequency. Therefore, we can use this model to analyze and extract the local features of remote sensing images during time and frequency changes, which is increasingly used after the remote sensing image is completed [9]. Traditional remote sensing image post-processing involves extracting the main features of multi-pixel lines from the original image by reconstructing and analyzing frequency pixels during two-dimensional frequency transfer to the area.

3.1.1. Pretreatment before feature extraction of remote sensing image.

(1) *Pixel domain subband analysis of remote sensing image.* For $P_0, (\Delta_s, s \geq 0)$ in the post-processing of captured image pixels. Restore the image pixels $(P_0f, \Delta_1f, \Delta_2f, \dots)$ of different sub-bands for the pixel range f , and the sub-band $\Delta_s f$ of multi-dimensional space contains the main features with the pixel space of 2^{-2s} .

(2) *Pixel smooth segmentation of remote sensing image.* In the process of restoring the remote sensing image pixels, set the set of $\omega_Q(x_1, x_2)$, and calculate the corresponding function ω_Q of a parameter of the restored image pixel within a two-dimensional space range of 2^{-2s} to obtain the set of Q similar results, as

follows 3.1:

$$Q = [k_1/2^s, (k_1 + 1)/2^s] \times [k_2/2^s, (k_2 + 1)/2^s] \quad (3.1)$$

Run such calculations for image pixel restoration Q of a specific algorithm. Assuming that all image post-processing $Q = Q(s, k_1, k_2)$, and the s similarity segmentation parameters k_1 and k_2 change, as shown in the following formula 3.2:

$$\Delta_s f \rightarrow (\omega_Q \Delta_s f)_{Q \in Q_2} \quad (3.2)$$

(3) *Normalization of pixels.* For a second order square, normalize $(T_Q f)(x_1, x_2) = 2^s f(2^s x_1 - k_1, 2^s x_2 - k_2)$ to calculate pixel f , and the result of Q parameter function calculated by 3.2 is $[0, 1]^2$, as shown in the following formula 3.3:

$$g_Q = (T_Q)^{-1}(\omega_Q \Delta_s f), Q \in Q_s \quad (3.3)$$

The normalization operation of pixels can collect the post-processed pixels and lay the foundation for image fusion extraction.

3.1.2. Extraction and reconstruction of remote sensing image features.

1) *Remote sensing image feature straight ridge synthesis.* After analyzing the straight ridge extracted from remote sensing image fusion, any calculation parameter is newly created from the orthogonal image pixel set, as shown in the following formula 3.4:

$$g_Q = \sum_{\lambda} \alpha(\lambda, Q) \rho_{\lambda} \quad (3.4)$$

2) *Feature normalization of remote sensing image.* The calculation in formula 3.4 can put any pixel into a suitable spatial position, as shown in formula 3.5:

$$h_Q = (T_Q)g_Q, Q \in Q_s \quad (3.5)$$

3) *Feature fusion and smooth synthesis of remote sensing image.* The result of formula 3.5 can be used as the inverse operation of image feature fusion boundary, as shown in formula 3.6:

$$\Delta_s f = \sum_{Q \in Q_s} \omega_Q - h_Q \quad (3.6)$$

4) *Time frequency subband reconstruction.* Incorporate formula 3.6, and use image pixel reconstruction formula to reconstruct and synthesize time and frequency, as shown in formula 3.7:

$$f = p_0(p_0 f) + \sum_{s>0} \Delta_s(\Delta_s f) \quad (3.7)$$

3.2. Image feature extraction method based on SVM and multi-feature fusion. Hard interval maximization support vector machine, also known as linear support vector machine, is the most primitive and simplest form of support vector machine [10]. As the basis of support vector machine theory (hereinafter referred to as SVM for short), it mainly aims at the problem of linearly separable dichotomous problems, as shown in Figure 3.1.

First, we combine SVM and DS evidence theory, extract three types of features of image shape, texture and fractal dimension after preprocessing the remote sensing image, and construct basic probability assignment with the SVM classification results of three types of nonlinear single features as independent evidence, and introduce DS fusion algorithm based on matrix analysis to simplify the complexity of decision level fusion algorithm [11]. Multi-feature fusion algorithm is introduced to calculate the spatial approximation of the original graphic pattern and feature vector, and the approximation is used as the fusion feature to complete the extraction of image features.

Fig. 3.1: Learning and application of classifier

3.2.1. Theoretical evidence of SVM . The main theoretical basis of the SVM calculation method is the certainty of the specific position of pixels in the dimension space of remote sensing image and the balance interval between each other during the post-processing of image capture. The spatial classification of any number of remote sensing image pixels in the shape, texture and fractal dimension of the image is carried out by using the formula of SVM classification and archiving. The specific method of discrimination is as follows 3.8:

$$f(x) = \text{sgn}\left(\sum_{x_i \in S_V}^n a_i y_i k(x_i, x) + b\right) \tag{3.8}$$

In the above formula, a_i is the Lagrange multiplier, S_V is the support vector, $k(x_i, x)$ is the kernel function, x_i and y_i are the basic support vector bases of the two calculation methods' functions, and b is the parameters determined according to the specific image pixel functions[12].

From the above formula, it can be seen that $k(k-1)/2$ SVM classification calculation methods are used to restore remote sensing image pixels. In the process of classifying image pixels, the computer defaults to counting once for each calculation, and sends data to all sets. Finally, the most counted image pixels are classified into a class of image pixel sets to build the theoretical evidence of SVM.

3.2.2. DS evidence theory. The basic principle of DS evidence theory is as follows: DS evidence theory fuses the trust functions corresponding to two or more evidence bodies and transforms them into a new function. The implementation process of DS evidence theory is described as follows:

Let Θ be the discriminant framework, define the function $m : 2^\Theta \rightarrow [0, 1]$ to satisfy the condition $M(\Phi) = 0$ (Φ is empty set), $\sum m(A) = 1(A \in 2^\Theta)$, and construct $m(A)$ according to the three characteristics of image shape, texture and fractal dimension, which is the fundamental probability assignment (BPA) on the framework Θ . $m(A)$ is the accurate level of trust in proposition A, and $M(\Phi)$ is the uncertainty of evidence. Assuming that m_1, m_2, \dots, m_n is BPA to distinguish different evidences on frame Θ , $m = m_1 \oplus m_2 \oplus \dots \oplus m_n$ can be converted into the following formula 3.9 and 3.10 according to $\sum m(A) = 1(A \in 2^\Theta)$:

$$m(A) = \sum_{A_1 \cap A_2 \cap \dots \cap A_n = A} \left(\prod_{1 \leq i \leq n} m_i(m_i(A)/(1-k)) \right) \tag{3.9}$$

$$k = \sum_{A_1 \cap A_2 \cap \dots \cap A_n = A} \left(\prod_{1 \leq i \leq n} m_i(m_i(A)) \right) \tag{3.10}$$

In the above formula, k is the uncertainty factor of credentials.

3.2.3. DS-synthesis algorithm with matrix analysis. This paper proposes a DS-synthesis algorithm based on matrix analysis to fuse the features of remote sensing images. In view of the situation of identifying

a target with n-type image features at the same time, the mutually independent fundamental trustable distribution values m_{ij} and uncertainty probability θ_{ij} of n-type features given to m image target categories can be described as the following formula 3.11:

$$M = \begin{bmatrix} m_{11} & m_{12} & \cdots & m_{1m} & \theta_1 \\ m_{21} & m_{22} & \cdots & m_{2m} & \theta_2 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ m_{n1} & m_{n2} & \cdots & m_{nm} & \theta_n \end{bmatrix} \tag{3.11}$$

Because the sum of the mutually independent fundamental trustable distribution value m_{ij} and uncertainty probability θ_{ij} given to the target category of m images by the same image characteristics should be 1, therefore, the sum of the elements in each row of the matrix should meet the normalization condition, as shown in the following formula 3.12:

$$m_{i1} + m_{i2} + \cdots + m_{im}\theta_i = 1 \tag{3.12}$$

Under the condition of normalization, a new matrix R with $(m + 1) \times (m + 1)$ is obtained by multiplying the transposition of one row of the matrix with another row, and the DS synthesis of matrix analysis is realized[13]. The following formula 3.13:

$$R = M_i^T M_j \begin{bmatrix} m_{i1}m_{j1} & m_{i2}m_{j2} & \cdots & m_{i1}m_{jm} & m_{i1}\theta_j \\ m_{i2}m_{j1} & m_{i2}m_{j2} & \cdots & m_{i2}m_{jm} & m_{i2}\theta_j \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ m_{im}m_{j1} & m_{im}m_{j2} & \cdots & m_{im}m_{jm} & m_{im}\theta_j \\ \theta_i m_{j1} & \theta_i m_{j2} & \cdots & \theta_i m_{jm} & \theta_i m_j \end{bmatrix} \tag{3.13}$$

where the uncertainty factor k is the sum of the non-diagonal elements of the first $m \times n$ sub-matrices in the matrix, that is, the following formula 3.14:

$$k = \sum_{p \neq q} R_{pq}(p, q = 1, 2, \dots, m) \tag{3.14}$$

Fusion of matrix analysis and image features under the DS evidence theory m algorithm: this algorithm completes the matrix multiplication calculation of m+1-dimensional column vector and m+1-dimensional row vector in each implementation process. The time required to obtain the fusion result is $T((m + 1)^2)$, and the time required to obtain the fusion result is $T((m + 1)^2n)$, which is approximately linear with the number of characteristic types n[14].

3.2.4. Proximity of remote sensing image features. The feature extraction of remote sensing images is based on the fusion results of image features calculated by the -synthesis algorithm of matrix analysis. The feature space corresponding to the image to be classified is regarded as the core point of the type. The core point is attractive to all feature points in the feature space of the shape, texture and fractal dimension of the remote sensing image. The closer the feature point is to the core point, the stronger the attraction. The attraction of the core point of each image feature type is only effective in a certain spatial range.

Definition 1. In the feature space of the n-dimensional remote sensing image, the attraction between the core point x_i and the feature point x_j is defined as the following formula 3.15:

$$G_{ij} = e^{-d_{ij}^2/2\sigma^2} \tag{3.15}$$

where $d_{ij}^2 = x_i - x_j$ is the Euclidean distance of the two remote sensing image feature vectors, and σ is the parameter that controls the influence range of the core point of the image feature parameters. The core points of remote sensing image feature parameters are attractive to feature points, and the core points also attract each other[15]. The attractiveness index between the core points constitutes the proximity matrix G.

Fig. 4.1: Classification accuracy of target samples detected by SVM classification

Definition 2. Suppose there are m samples in the n -dimensional feature space, and the proximity matrix G is defined as the following formula 3.16:

$$G = \begin{bmatrix} G_{11} & G_{12} & \cdots & G_{1m} \\ G_{21} & G_{22} & \cdots & G_{2m} \\ \cdots & \cdots & \cdots & \cdots \\ G_{m1} & G_{m2} & \cdots & G_{mm} \end{bmatrix} \quad (3.16)$$

Line i in G represents the attraction between the prototype model of image feature type and other prototype models of remote sensing image feature type, which qualitatively reflects the statistical relationship between all types of data and prototype models. G is a symmetric matrix whose diagonal elements are 1. For any remote sensing image sample feature y , it is necessary to calculate the attraction between y and the prototype model of each remote sensing image type. The feature proximity vector g of the image sample is formed by these attractive indicators, which represents the fusion feature of the remote sensing image sample y . The proximity vector is composed of the attraction between the feature vector and the primitive graphic pattern, and the Euclidean distance of the row vector in g and G is compared. If the distance between g and G is close, the feature type of the image sample can be determined to complete the feature extraction of the remote sensing image[16].

4. Result analysis. In order to prove the usefulness of the method in this paper, it is necessary to carry out experimental proof. In the experiment, 300 remote sensing images are used as target samples for testing. Among them, 150 remote sensing images are all kinds of terrain with different angles, and 150 images are other targets. 90 representative remote sensing images of grassland, road, lake and 60 other target images were selected for training after feature acquisition[17].

4.1. Image feature vector classification detection. This paper lists 10 images that are sent into the classifier to implement classification accuracy after the method changes in this paper, as shown in Figure 4.1.

After using this method, the output of its soft threshold classifier is as follows: 0.9865, 0.9965, 0.7852, 0.9921, 0.9847, 0.6879, - 0.5898, - 0.5678, - 0.6987, - 0.4785. The results show that the algorithm in this paper has a good discrimination of the shape features of the terrain image, and can extract the features of the terrain image more accurately.

The remote sensing image in the randomly collected target sample passes through the feature acquisition channel, and is brought into the optimal classification function to check whether it is a terrain image. In the case of no noise, the error of the extraction results of the three types of image features is around 0.0500[18]. Considering that the noise will affect the detection results, 0 2 Gaussian white noise is added to the original image, and its shape, texture and fractal dimension consequences are shown in Figure 4.2 to Figure 4.4.

Fig. 4.2: Shape feature error after adding noise

Fig. 4.3: Texture feature error after adding noise

It can be seen from Figure 4.2 to Figure 4.4 that the error range of the result after adding noise is basically the same as that of the noise-free case when the three types of feature vectors extracted by the algorithm in this paper are used for classification detection, with good noise resistance and robustness.

4.2. Comparison results with traditional methods. In order to verify the superiority of this method, we use this method and the traditional method to compare the images of the same sample set, and the results are shown in Figure 4.5 [19].

It can be seen from Figure 4.5 that the accuracy of feature extraction of the method in this paper is significantly higher than that of the traditional method when tested with the method in this paper and the traditional method respectively[20].

5. Conclusion. At present, in the post-processing of image capture, the restoration of image pixels is the key in the whole image processing process, and in the pixel restoration process, the key problem is feature extraction. In addition, the feature extraction of image pixels also has a significant impact on the subsequent

Fig. 4.4: Fractal dimension characteristic error after adding noise

Fig. 4.5: Comparison of image feature extraction accuracy between traditional method and this method

work of image restoration and image calculation. This paper proposes a feature extraction method of remote sensing image based on SVM and multi-feature fusion. The simulation results show that the speed and accuracy of feature extraction of the proposed method are significantly improved compared with traditional methods, which verifies the feasibility of the proposed method. The method of extracting dimensions from remote sensing images of terrain surveying based on nonlinear multi feature fusion has many future research possibilities and areas for improvement. Here are some directions that can be further explored and improved:

1. Feature selection and extraction algorithm: more advanced Feature selection and extraction algorithm can be studied to better capture relevant information in remote sensing image of topographic mapping. For example, automatic feature learning techniques in deep learning models can be explored, as well as specific feature extraction methods that are more suitable for terrain surveying.
2. Data augmentation and incremental learning: Remote sensing images of terrain surveying may have different variation patterns and uncertainties. Therefore, data augmentation techniques can be studied to increase the diversity of training data through operations such as synthesis, rotation, and scaling,

thereby improving the robustness and generalization ability of the model. In addition, introducing incremental learning methods can achieve rapid adaptation to new data and model updates to cope with constantly changing terrain conditions.

RESEARCH ON INTELLIGENT AGRICULTURE BASED ON ARTIFICIAL INTELLIGENCE AND EMBEDDED PERCEPTION ALGORITHMS

XINHUAN ZHAO*, FANG ZHANG† AND NA GAO‡

Abstract. In order to solve the problems of weak collection link, limited data coverage and poor real-time for big data in agriculture, smart agriculture by implementing artificial intelligence and embedded sensing is proposed. The front-end perceptron and wireless gateway were designed. A steady-state data collection system was constructed according to the characteristics of intelligent agricultural information data. Combining various algorithms such as data unification and data recognition, intelligent perception calculation parameters were extracted. The adaptive steady-state sensing model was designed relying on deep learning technology in the field of artificial intelligence. The experimental results show that the RMSE value of the designed system in the study is 0.028, which meets the requirements of intelligent agricultural information data perception accuracy. It is concluded that agricultural big data is a collection of data involved in the process of agricultural production, transportation and marketing, and data collection is the most important part of it.

Key words: artificial intelligence, embedded sensing, smart agriculture

1. Introduction and examples. The development of artificial intelligence in agriculture has changed people's thinking about agricultural management services. Based on the background of big data, the reasonable use of artificial intelligence can effectively monitor the production of agricultural products and build a management system that combines information monitoring and services. The system has the functions of early warning of natural disasters, prevention and control of pests and diseases, and prediction of market fluctuations, which effectively reduces the construction of agricultural platforms and creates new engines and dynamics of agricultural and rural modernization [1]. Intelligent agriculture refers to an agricultural model that utilizes modern technological means to improve agricultural production efficiency and agricultural product quality. Among them, the application of artificial intelligence and embedded perception technology can greatly improve the efficiency and intelligence level of agricultural production.

In order to accelerate the construction of digital agriculture, we should not only play the role of the government, but also mobilize the strength of all parties to form a joint effort to promote it. We should encourage and guide social capital to invest in agriculture and broaden the source of funds for agricultural and rural development. In accordance with the digital construction carried out by agricultural enterprises and new business entities, it is recommended that the government introduce relevant support policies to provide financial incentives to accelerate the process of digital platform construction. We should strengthen the construction of agricultural infrastructure, actively carry out the creation of modern agricultural parks, and fundamentally improve the conditions of agricultural practices. We should strengthen digital agriculture and rural business training, carry out digital agricultural talents to the countryside, popularize digital agriculture-related knowledge, digital technology application and management level of new business entities and high-quality farmers. We should play the role of scientific research institutions, universities, enterprises and other parties to speed up small farmers and digital agriculture interface, and accelerate the integration and application of agricultural data. At the same time, we should use digital technology to transform traditional industries in the countryside, attract outstanding urban talents to return to their hometowns for employment and entrepreneurship, inject new ideas, new thinking and new strategies into agricultural production, guarantee the scientific nature of agricultural business decisions, and further promote the high-quality development of digital agriculture [2,3].

2. Literature Review. With the Internet of Things, big data, artificial intelligence and other technology applications continue to sink into the social life of production practices, digital agriculture has become the focus of the development of the agricultural industry now and in the future. Artificial intelligence can improve the accuracy and speed of agricultural production decision-making by analyzing a large amount of agricultural data. For example, using machine learning algorithms to analyze and predict agricultural data can predict crop growth periods, diseases and pests, and take timely measures to protect crops and improve crop yield and quality. The deepening of the application of digital agriculture in China's agricultural production prompts significant changes in China's traditional agricultural production methods. More and more crude, mechanical and empirical production modes are developing towards intensive, intelligent and scientific. Today, digital applications have become the mainstream of industrial production and social life, while the application of digital technology in agricultural production is still in its infancy. The agricultural sector may be the last industry where information technology and digitalization are popularized. The reasons for the slow diffusion of digital technology applications in agriculture are multi-layered, the main reason of which is that the scattered production and operation mode in rural areas of China is not conducive to the concentration of data resources in the informatization system [3]. And with the continuous improvement of rural communication infrastructure, the gradual maturity of agricultural IoT technology, and the national vigorous promotion of the construction of modern agricultural industrial parks, data integration in the whole agricultural industry chain has become possible. Liu, S. et al. constructed an agricultural Internet of Things (IoT) management system to realize the integrated management of Internet devices, environmental data, video data and agricultural expert knowledge. Then, they introduced the current status of agricultural IoT from the perspective of sensing technology, transmission technology and three intelligent information processing technologies, analyzed the economic benefits of IoT for agricultural production, and proposed future research priorities and development directions for agricultural Internet in China [4]. Vermesan, O. et al. introduced ECAS vehicles through artificial intelligence (AI) in vehicle and infrastructure-level architectures based on evolution of distributed intelligence based domain controllers, regional vehicles and federal vehicle/edge/cloud centers, and the role of AI technologies and approaches in achieving different autonomous driving and optimization functions for sustainable green transportation [5].

Agricultural big data is the overall collection of data involved in the process of agricultural production, transportation and sales, and data collection is prominent as its most important link. Embedded perception technology can achieve real-time monitoring and data collection of agricultural production environment, such as temperature, humidity, lighting and other environmental factors. At the same time, it can also achieve real-time monitoring of crop growth, such as crop growth status, pests and diseases. These data can be used to improve the accuracy of agricultural production, thereby reducing waste and improving agricultural efficiency. In the early days, the degree of agricultural informatization was low, agricultural data was small and the mining value was low. However, in recent years, the development of agricultural artificial intelligence and embedded sensing technology has made agricultural data show a spurt growth. Although the current development of agricultural big data is a big improvement over the previous, there are still some problems in the data collection link:

1. The data collection in agricultural production is uneven, only in the more developed areas of communication, and data transmission is mainly wired network;
2. The data collection is mainly based on sensor text information, with less image and video information;
3. The cost of the existing intelligent agricultural monitoring system is high and the system integration is low, it is not applicable to areas where broadband is not laid, and it is difficult and costly to deploy.

By summarizing the previous research experience, artificial intelligence technology is adopted in this study to establish an embedded sensing system with artificial intelligence adaptive sensing model as the focus to realize the sensing of agricultural information.

3. Method.

3.1. Front-end perceptron design for artificial intelligence-based embedded sensing system for agricultural information. In order to realize the collection and transmission of agricultural information, the front-end perceptron is designed. The agricultural information embedded sensing system of artificial intelligence is a system that applies modern sensing technology, communication technology, computer technology, and artificial intelligence technology to the agricultural production process. The front-end perceptron is an important component of the system, mainly responsible for collecting various parameter information in the

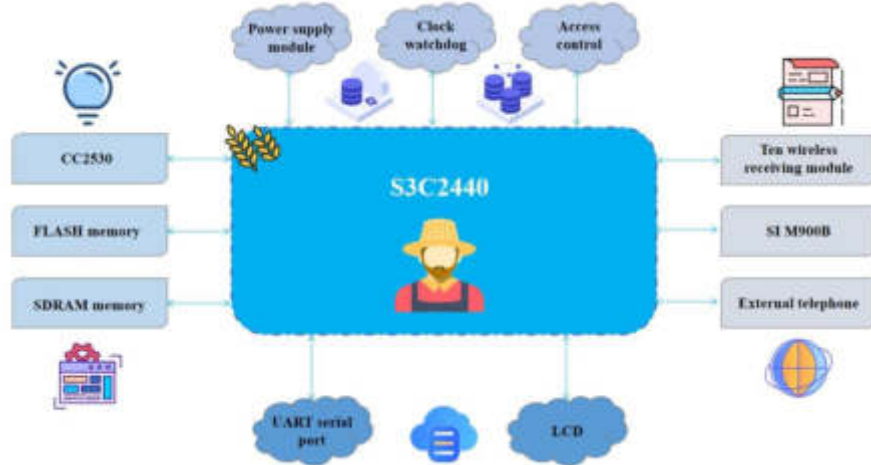

Fig. 3.1: Block diagram of the hardware structure of the gateway

agricultural production process and transmitting this information to the backend data processing center for processing and analysis. Considering the node power consumption and information reception sensitivity degree, the front-end sensing device designed in the study uses the CC2530 chip as the core, and connects the CC2530 chip to the microcontroller I/O port for the purpose of information exchange. Then it is combined with wireless transceiver module, clock module and other structures to complete the front-end sensing device design [6].

3.2. Wireless gateway design for artificial intelligence-based agricultural information embedded sensing system. The wireless gateway is designed mainly for data transmission, encapsulation and parsing. Through research, it is known that the S3C2440 microprocessor can operate at a maximum frequency of 400MHz, which can meet the working requirements of the sensing system. In this study, it is used as the design core of the wireless gateway, and then it is connected with components such as TFT-LCD display and remote control keypad. The actual hardware structure of the wireless gateway is shown in Figure 3.1.

In addition to the hardware structure of the gateway shown in Figure 3.1, the LM25965-5.0 switching voltage regulator is installed at the gateway power supply in order to enhance the stability of the gateway application.

3.3. Building intelligent agricultural information data collection system. The sensing of smart agriculture information needs to be based on data. The data collection structure of smart agriculture information shown in Figure 3.2 is designed in the study. The construction of an intelligent agricultural information data collection system requires consideration of multiple aspects, including the selection and configuration of hardware equipment, the design and implementation of data collection methods, data storage and processing, data display and analysis, etc.

In the acquisition structure shown in Figure 3.2, S denotes the data collector, C denotes the encoder, l_1 and l_2 denotes the channel length. In order to ensure the integrity of steady-state data acquisition, an in-depth analysis is conducted for the two phases of information transmission, and the acquisition information of a single data concentrator is clarified, and the acquisition information is calculated by the coding function to generate the input signal. A moment in the data acquisition structure shown in Figure 3.2 is selected, and the data acquisition channel is described by Equation 3.1.

$$Y_a = X_{ja} + Z_a, Z_a \in N \quad (3.1)$$

In Equation 3.1, X denotes the input signal, Y denotes the output signal, a denotes the acquisition moment,

Fig. 3.2: Structure of intelligent agricultural information data collection

m denotes the number of data acquisition points of intelligent agricultural information, and denotes a data collection point, Z denotes interference noise, and N denotes variance [7,8].

Setting the critical capacity of the channel to transmit information in line with the minimum coded transmission requirements, the channel upper limit is calculated as Equation 3.2.

$$Q = L_1 \sum_j^m \log\left(1 + \frac{P_j}{N_j}\right) + L_2 \left[\log\left(1 + \frac{P_f}{N_f}\right) + \log\left(1 + \frac{P_z}{N_z}\right) \right] \tag{3.2}$$

In Equation 3.2, Q denotes the upper limit of the channel, $P_j P_f P_z$ denotes the average noise power of the information transmission process, $N_j N_f N_s$ denotes the noise variance of the information transmission process. For each average noise power analysis, the power constraint of each information transmission stage can be derived.

$$\begin{cases} P_j \geq \frac{1}{n} \sum_{a=1}^n [X_{j1}(w_j, a)]^2 \\ P_f \geq \frac{1}{n} \sum_i^n (X_{12}, \dots, X_{m2}, i)^2 \\ P_z \geq \frac{1}{n} \sum_i^n Z_i^2 \end{cases} \tag{3.3}$$

In Equation 3.3, ω indicates the agricultural information state quantity. Combining with the constraints shown in Equation 3.3, the spacing of the front-end data collectors in the steady-state data collection structure is set to realize the overall collection of steady-state data.

3.4. Extraction of intelligent perception calculation parameters. Based on the results of agricultural information data collection, techniques such as data unification and data recognition are applied to extract the mainstream features of steady-state data. Considering that the collected data are associated with both time and space, a data unification multi-layer model is designed in the study to identify the data states. Each feature quantity for the collected steady-state data is recorded to form the following matrix.

$$D = \begin{bmatrix} d_{11} & \dots & d_{1\alpha} \\ \cdot & & \cdot \\ \cdot & & \cdot \\ d_{\beta 1} & \dots & d_{\beta z} \end{bmatrix} \tag{3.4}$$

In Equation 3.4, D denotes the acquisition matrix, d denotes the number of individual features of the acquisition data, $\alpha\beta$ denotes the number of columns and rows of the acquisition matrix.

$$\tilde{\omega}_\alpha = (v_1, v_2, \dots, v_\alpha) \tag{3.5}$$

In Equation 3.5, $\tilde{\omega}$ denotes a sequence of steady-state data vectors, v denotes the matrix column vector.

Considering that the frequency of steady-state data collection varies, some of the collected data have the problem of loss. In the study, a dynamic time programming method is used to calculate the similarity of discrete sequences, and complete the sequence expansion and compression to ensure the uniformity of the sequence scale. A column vector is randomly selected as the reference vector within Equation 3.5, and the Euclidean distances of other column vectors are calculated to generate multiple distance matrices.

$$O_k = \begin{bmatrix} B_{11} & \dots & B_{1\beta} \\ \cdot & & \cdot \\ \cdot & & \cdot \\ \cdot & & \cdot \\ B_{\beta 1} & \dots & B_{\beta\beta} \end{bmatrix} \tag{3.6}$$

In Equation 3.6, k denotes the column vector, O_k denotes the distance matrix, B denotes the Euclidean distance. The distance matrix is extrapolated to form several distance loss matrices to complete the calculation of the column vector similarity.

$$\theta = \begin{bmatrix} \varepsilon_{11} & \dots & \varepsilon_{1\beta} \\ \cdot & & \cdot \\ \cdot & & \cdot \\ \cdot & & \cdot \\ \varepsilon_{\beta 1} & \dots & \varepsilon_{\beta\beta} \end{bmatrix} \tag{3.7}$$

$$Q = \{Q_1, Q_2, \dots, Q_\beta\} \tag{3.8}$$

In Equation 3.7 and 3.8, θ denotes the distance loss matrix, ε denotes the degree of loss, and Q denotes the optimally adjusted sequence and also the set of shortest paths within the matrix. The distance between the steady-state data vectors is adjusted by dynamic regularization techniques to ensure the distance minimization.

Then, using principal component analysis, the validity of the steady-state data is evaluated, duplicate redundant information is removed, and the complexity is calculated. First, the normalization process is performed for the adjusted vector distances to obtain the normalization matrix shown below.

$$U = \xi - \frac{\xi}{\beta} \tag{3.9}$$

In Equation 3.9, U denotes the normalized matrix and ξ denotes the interval distance adjusted covariate data, and based on the calculation of Equation 3.9, the covariance matrix and singular value decomposition formulas are obtained as follows.

$$E = \frac{1}{\beta} U \tag{3.10}$$

$$svd(E)[H, R, F] \tag{3.11}$$

In Equation 3.10 and 3.11, E denotes the covariance matrix, svd denotes the singular value decomposition, H, R, F denotes the matrix formed after decomposition, H denotes the dimensionality reduction matrix, and the main data vectors are dimensionally reduced by using the dimensionality reduction matrix.

Relying on the above dimensionality reduction data, the intelligent perception parameters of a single sample are calculated in combination with support vector machines, and then the likelihood functions of the unknown parameters are calculated with reference to the independence of each observed object within the collection sample. In summary, the extraction of intelligent perception computational parameters is completed [9].

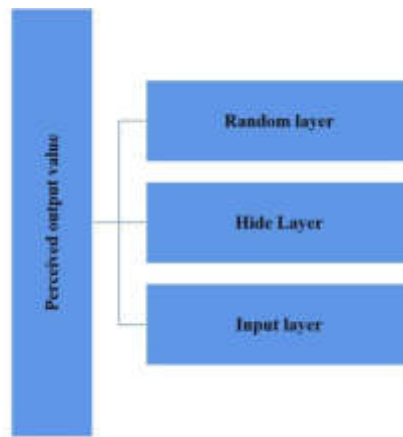

Fig. 3.3: Artificial intelligence-based adaptive perception model

3.5. Building an artificial intelligence adaptive perception model. The embedded sensing system designed in the study is centered on artificial intelligence technology, i.e., an artificial intelligence adaptive perception model is used as the focus of the research, and deep learning techniques within the field of artificial intelligence are applied to construct an adaptive perception model. The adaptive perception of the steady-state action behavior is divided into two parts, on the one hand, the input to output calculation of the AI neural network, and on the other hand, the parameter weights are modified based on the output perceived posture values. Deep learning technology is a machine learning method based on artificial neural networks. Its main feature is that it can automatically learn and extract features from data, and thus construct more accurate and efficient models. In embedded sensing systems, deep learning technology can be applied to the construction and optimization of perception models. By training and learning the data collected by sensors, more accurate and adaptive perception models can be constructed, improving the perception accuracy and stability of the system.

The adaptive perception model relying on artificial intelligence technology consists of four main layers of structure, as shown in Figure 3.3.

According to the schematic diagram of the perception model shown in Figure 3, it can be seen that the input layer includes the current steady-state condition of intelligent agricultural information, and according to the two parameters mentioned above, the input vector is described as:

$$\lambda(t) = (\lambda_1(t), \lambda_2(t), \dots, \lambda_2(t)) = \{\rho(t), \rho(t-1), \dots, \rho[t - (\partial - 1)\tau]\} \quad (3.12)$$

In Equation 3.12, $\lambda(t)$ denotes the input vector of the perceptual model in time input vector, ∂ denotes the attack time interval, ρ denotes the steady state condition of agricultural information data, τ denotes the time delay.

The information of the input layer of the adaptive perception model is passed to the hidden layer, which is computed via multiple hidden nodes to obtain.

$$\mu(t) = \frac{1}{1 + \psi^r} \quad (3.13)$$

In Equation 3.13, μ denotes the hidden layer output result, ψ denotes the constant, and r denotes the parameter weights.

The output results of the hidden layer are applied to the random layer to calculate the Gaussian distribution characteristics of the steady-state data as a way to describe the distribution of the output data. Considering the results of Gaussian distribution calculation for each hidden node, which is directly influenced by the intelligent perception parameters, the random layer output is expressed as:

$$\eta[\mu(t), r_0] = \frac{1}{1 + \psi^{\mu(t)r_0}} \quad (3.14)$$

In Equation 3.14, η denotes the random layer output result, r_0 denotes the hidden node parameter weights.

Finally, an adaptive reinforcement learning mechanism is added to the output layer to further analyze the output results of the stochastic layer, which is expressed as a one-dimensional Gaussian function. The steady-state perception results are obtained using intelligent perception calculation parameters, and then adaptive learning is performed for the deviations in the stochastic layer to update the parameter weights and obtain more accurate adaptive perception results for the steady-state operational behavior.

3.6. Developing the embedded sensing system. After the software design is completed, an embedded real-time operating system is used for software development. Its main feature is that it can respond to external events in real-time, while ensuring that the system can complete the processing of events within a specific time range. The application of embedded real-time operating system divides the software development into several subtasks and ensures that each subtask is responsible for the corresponding responsibilities and gives each subtask the corresponding operation order.

Considering that the perception system designed in the study is an embedded operating system, a comparative analysis of commonly used embedded real-time operating systems shows that the UCOS- system has free real-time characteristics and can support more than 250 tasks to be developed simultaneously. Therefore, UCOS- is chosen as the system software development platform in the study [10-11].

Usually, embedded real-time operating systems let the tasks in the front of the operation order run first during software development and can interrupt other tasks in the operation order for CPU preemption at any time. This development model optimizes the response time of software subtask development. This development model is applied to the development of the perception system, so as to make the functional software development into task-oriented software development and realize the simplification of the logical structure of the intelligent agricultural information data perception system. Finally, the software structure is set to three layers by using the embedded real-time operating system to avoid presenting the underlying hardware directly in the visualization interface, which facilitates the expansion of software and hardware respectively. So far, the overall design of the intelligent agricultural information data embedded sensing system is completed.

3.7. System test. In the study, the artificial intelligence technology is relied on to design an intelligent agricultural information data embedded sensing system. In order to verify the practical application effect of the system, a system test is conducted. During the test, the IEEE39 node system is used as an example to apply the system designed in the study to obtain steady-state sensing results and clarify the feasibility of the system designed in the study.

3.8. Building the test environment. Considering the embedded architecture of the design system in the study, the system testing process is based on Linux system, and multiple virtual machines are used to build the system testing environment to display the perception results in a visualized form in front of the user while the intelligent agricultural information data, and the system testing environment is shown as follows. Through the establishment and testing of the system test environment, the correctness and stability of the system can be verified, and the potential problems can be found and solved in time to ensure that the system can achieve the desired effect in practical application.

Combined with seven virtual machines, the test environment is completed by using Linux Ubuntu version of the operating system and JDK version programming components. Among them, four virtual machines act as Data Node slave nodes, two act as master nodes, and the remaining one is a management node. The actual configuration information is shown in Table 3.1.

According to the configuration information shown in Table 3.1, the IP address division of the virtual machine is realized, the programming components are installed on each virtual machine separately, and the environment variables are configured after the programming software is installed.

The configuration of environment variables starts from the settings of SSH protocol and Hadoop users. First, the SSH protocol is installed in each virtual machine, and a directory with the .SSH suffix is created to facilitate subsequent system startup and command execution. Then, the SSH protocol is used to generate keyless password pairs for Hadoop users and save them in the SSH directory. Finally, after the installation of Hadoop components is completed, the core component core-site.XML and MapReduce framework files are configured to complete the address configuration of slave and master nodes [12,13,14,15]. During this test, the

Table 3.1: Virtual machine address assignment

Nodes	IP Address
CDH Management Node	192.168.155.1
CDH Primary NameNode	192.168.155.2
CDH Secondary NameNode	192.168.155.3
CDH DataNode 1	192.168.155.4
CDH DataNode 2	192.168.155.5
CDH DataNode 3	192.168.155.6
CDH DataNode 4	192.168.155.7

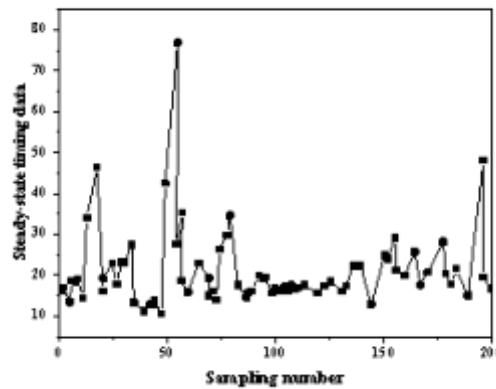

Fig. 3.4: Time-series data of agricultural information data

node system is the main result, which contains 10 generators, 46 lines and 19 load nodes in the system. In the above test environment, the sensing system proposed in the text is run to obtain intelligent agricultural information data.

3.9. Setting perceptual model parameters. In order to improve the accuracy of the test results, reasonable parameters are set for the artificial intelligence adaptive sensing model before the system is run. Running the IEEE39 node system is shown in Figure 3.4. The Nessus software is applied to scan the system acquisition characteristics, and the professional software is used to simulate network attacks during the scanning process to collect the 200 posture timing data shown in Figure 3.4.

As shown in Figure 3.4, agricultural information data can be regarded as nonlinear sequences, and agricultural information data situational awareness is accomplished by nonlinear mapping from different dimensional output spaces. Using the above 200 steady-state time-series data, 197 and 195 sets of test samples can be obtained when the dimensionality of the input vector is set to 3 and 5, respectively. The above data samples are applied to train the artificial intelligence adaptive perception model and compare the errors of the system output results under different parameters, so as to determine the final parameters of the model. It is known from the study that when the input vector dimension is set to 5, the number of nodes in the implicit layer of the model is 20, and the prediction results for the next time period of agricultural information data are more accurate [16,17,18].

4. Results and Discussion. After the parameters of the artificial intelligence adaptive sensing model are set, the embedded sensing system proposed in the study is applied to sense the steady-state operational behavior changes of the IEEE39 node system in one day, and the sensing results are combined with the actual detected state values to generate the line graph of the sensing results shown in Figure 4.1. The differences

Fig. 4.1: Line graph of sensing results

between the sensed and actual data are analyzed to clarify the application performance of the designed system in the study.

According to the sensing results shown in Figure 4.1, it can be seen that, compared with the intelligent sensing and condition sensing technology and application of substation equipment, the stable posture values obtained by the sensing system designed in the study match the actual posture values in most cases, and the sensed posture is opposite to the actual posture only at ten and fifteen points. In order to describe the application effect of the sensing system more intuitively, the accuracy of the sensed posture value is calculated by using the RMSE value index in the study.

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n |x_i - x_i|^2} = 0.028 \tag{4.1}$$

In Equation 4.1, RMSE denotes the mean square root error, n denotes the amount of steady-state action behavior data, i denotes a sample of steady-state data, x_i denotes the actual posture value, x_i denotes the perceived potential value. According to Equation 4.1, the RMSE value of the designed system in the study is, which satisfies the accuracy requirement of intelligent agricultural information data sensing [19,20].

5. Conclusion. In this study, it is proposed to realize intelligent agriculture by implementing artificial intelligence and embedded sensing. With the advancement of artificial intelligence technology, big data analysis can be more perfect. Secondly, artificial intelligence services provide a flexible infrastructure for agricultural big data analysis, which greatly simplifies the system scale of big data analysis and can be expanded according to demand, making it easy to manage workload. Finally, artificial intelligence services make users to perform big data processing without large-scale big data resources, which greatly reduces the big data system operation costs of agriculture-related enterprises and organizations and brings great value to agricultural development. In the era of big data, artificial intelligence is the strategic direction of future agricultural development, which can effectively improve agricultural production and quality, promote agriculture in the direction of green and ecological development, and then achieve the goal of smart agriculture.

The application of artificial intelligence and embedded sensing technology in intelligent agriculture can greatly improve the efficiency and quality of agricultural production, laying the foundation for the future development of intelligent agriculture. Firstly, through the application of artificial intelligence technology, intelligent agricultural management and decision-making can be achieved. For example, using artificial intelligence technology to analyze data such as farmland soil and crop growth status, predict crop growth trends and yields,

and provide more accurate and scientific decision-making basis for agricultural management. Secondly, the application of embedded sensing technology can achieve real-time monitoring and remote control of agricultural production. For example, using embedded sensors and controllers to monitor environmental factors such as weather, soil, and water quality, providing real-time feedback on data and controlling irrigation, fertilization, and other operations to improve crop production efficiency and quality.

THE APPLICATION OF INTELLIGENT WELDING ROBOTS AND VISUAL DETECTION ALGORITHMS IN BUILDING STEEL STRUCTURES

WEI ZHANG* AND JUNHUA LI†

Abstract. In order to understand the application of welding robots in building steel structures, the author proposes a research on the application of intelligent welding robots in building steel structures. The author first analyzed the characteristics of complex and diverse structural forms of building steel structure components, small batches, no repetitive components, diverse welding joint forms, low precision of components and assembly control, and proposed specific requirements for the application of intelligent welding robots, such as fast programming to meet diverse structural forms, rich and powerful welding process databases, and high adaptability to parts and assembly deviations. Secondly, it is described that existing welding robots have mature contact sensing and arc tracking functions, have offline programming software, and can achieve thick plate groove welding. They already have the technical foundation to achieve automatic welding in building steel structural components. Finally, combined with practical cases, taking a commercial building project as an example, the construction land area is 31689m², using Q460GJC steel, with a maximum plate thickness of 100mm, the steel structure includes extended arm honing frame, radial separation frame, ring separation frame, and other contents, and is connected to the core tube as a whole. Describe the application content and methods of robot technology in the manufacturing of building steel structures, including parameter selection, programming methods, welding processes, and more. In order to achieve the goal of automatic welding of building steel structure robots. According to the application results, compared with traditional manual welding, intelligent Robot welding welding has higher efficiency and better quality, which is worth popularizing and applying comprehensively. Comprehensive comparative analysis, compared with manual welding, intelligent Robot welding has the advantages of higher efficiency and more stable quality, and has the technical conditions for comprehensive promotion.

Key words: Intelligent welding, Robots, Building steel structure

1. Introduction. With the rapid development of the construction steel structure industry, there are more and more steel structures for large-span, venue, and super high-rise buildings, and the types of components are becoming increasingly complex. Their design and production accuracy requirements are high.

At present, the low efficiency and unstable quality of manual welding operations often become the biggest obstacles to improving production efficiency and product quality stability. The improvement of welding level, especially automatic welding level, in steel structure manufacturing enterprises is the key to achieving rapid development of steel structure technology, the actual production components are shown in Figure 1. Although the welding workload in the construction steel structure manufacturing industry is large, there are significant difficulties in achieving fully automated welding due to the current non-standard design of construction steel structures, multiple types of components, small batch production of single pieces, complex processes, and low cutting and assembly accuracy in the previous process; However, the continuous innovation of advanced welding technology in the steel structure manufacturing industry and the application of efficient and intelligent welding equipment are gradually improving the quality of steel structures. At present, the vast majority of steel structure enterprises are still in the wait-and-see stage in the application of welding robots, considering the high cost and immature application of welding robots. With the development of the welding robot industry, the application of robots in the welding of U ribs and plate units in bridge projects is relatively mature; And in non bridge projects, enterprises have already put welding robots and supporting tooling systems into actual component production lines; Under the booming trend of robotics, the emergence of small welding robots and emerging technologies is also driving the application of intelligent steel structure welding. Welding robots have been

Fig. 1.1: Application of Intelligent Welding Robot in Building Steel Structures

widely used in industries such as automotive manufacturing and medical devices due to their high efficiency, performance, and quality. These products have the characteristics of standardization and large batches.

At present, the level of welding automation in industrialized countries around the world has reached as high as 80%, resulting in significant advantages in terms of efficiency and quality. According to the estimated consumption of welding materials for manual and automatic welding, the nominal degree of welding automation is 30%, which is a significant difference compared to this. With the development of building welding structures towards large-scale, heavy-duty, and high-precision parameters, the low efficiency and unstable quality of manual welding operations often become the biggest obstacles to improving production efficiency and product quality stability. In order to meet the special requirements of high-strength, thick plates, and long welds, the improvement of welding level, especially automatic welding level, is the key to achieving the rapid development of steel structure technology. Therefore, rapidly improving the level of welding automation has become an urgent and important task [1].

2. Literature Review. Intelligence and interconnection have become the mainstream direction for the future development of welding robots. The so-called intelligence mainly refers to the precise tracking and sensing of welding seams. In order to replace manual welding operations, robots need to accurately track welding based on the actual situation of the groove. Therefore, the mainstream development trend is to shift from a single teaching type to a multi-sensor and intelligent flexible processing system centered on intelligence. At present, most of the intelligent welding robots retained in the market are still teaching type, and the precise tracking and sensing technology for welds is not yet mature, and there is still great room for improvement.

Compared to the slow progress of intelligence, there has been significant progress in the interconnection of welding robots. The welding robot regional interconnection technology introduced by China Construction Steel Structure Co., Ltd. has been successfully applied to the on-site installation of steel components. Interconnection technology connects welding robots and terminal devices through regional networks, enabling remote information operation of welding. This not only improves welding efficiency, but also ensures the safety of operators.

At the same time, the real-time operation of the welding site can also be synchronized to the company's monitoring system through the network, further strengthening the control of welding quality. The intelligent and interconnected development of welding robots is the overall trend of their future development, and they will also make significant progress in other areas, such as automatic cleaning of welding slag, welding of complex components, and long installation time before welding, which require step-by-step technological breakthroughs, these are not bottlenecks that constrain the development of welding robots. Driven by market demand, the future development potential will be enormous. The position of the steel structure industry in the national economic development system is irreplaceable. With the increasing domestic steel production year by year, the application of welding technology in construction is also becoming increasingly popular, which has a huge impact on engineering safety and functional applications. Diaz-Cano, et al., propose an online robot programming approach that eliminates the traditional unnecessary steps in robot welding, allowing the operator to complete

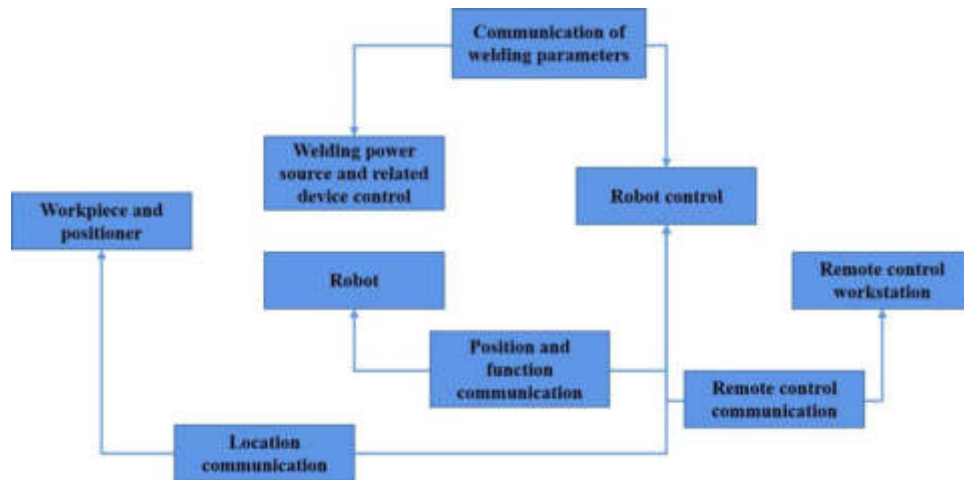

Fig. 3.1: Typical Welding Robot System Structure

the welding task by performing only three steps[2]. Canfield, S. L. et al., propose a collaborative robot model and model calibration strategy to aid teaching and monitoring of welding tasks. This method uses a torque estimation model based on robot momentum to create an observer to evaluate external forces [3,4].

At present, the structural form of steel structure buildings is complex. Introducing welding robots into the technology can lead the industry to gradually develop towards digitization and industrialization, fully meeting the requirements of technological innovation and environmental protection, and comprehensively improving the quality and efficiency of steel structure welding.

3. Research methods.

3.1. Technical methods for the application of intelligent welding robots . In the welding of structural components in industries such as bridges and construction machinery, there are problems such as large workpiece sizes and plate thicknesses, poor welding groove processing, and poor accuracy in workpiece assembly, in order to achieve good welding results, robots need to have sensing and tracking functions equivalent to human vision, touch, and other senses - that is, tracking and correction functions. The welding robot system can achieve functions such as finding the starting point of welding and tracking the weld seam through devices such as contact sensors, arc sensors, and laser tracking sensors (Figure 3.1).

3.2. Contact sensing function. The contact sensing function is a collection of starting point sensing, 3-directional sensing, welding length sensing, arc sensing, root gap sensing, multi-point sensing, etc. The robot senses voltage through the end of the welding wire (or welding gun nozzle), detects deviation and groove size of the welding workpiece, and remembers the position of the workpiece or weld seam.

Through the combined application of these functions, the welding process can be unaffected by errors caused by workpiece processing, assembly welding, and welding clamp positioning. It can automatically find the starting position of the weld seam and identify the weld seam situation, compensate for weld seam offset, deformation, length, and groove width changes, and ensure that the robot can weld smoothly. The principle is shown in Figure 3.2, and the contact sensing function is mainly used for locating the starting point of the weld and locating the groove [5,6].

(1) *Finding the starting point of the weld seam.* The starting point of the weld seam is located by sensing the surface of the workpiece in three directions, in order to perceive the actual position of the component weld seam to be welded [7,8]. The deviation between the actual position and the position of the component weld surface during teaching is calculated through a program, and then the deviation is added to the welding position during programming to find the correct welding position, correct the welding position deviation caused by assembly, assembly, and welding, and achieve the goal of ensuring welding quality.

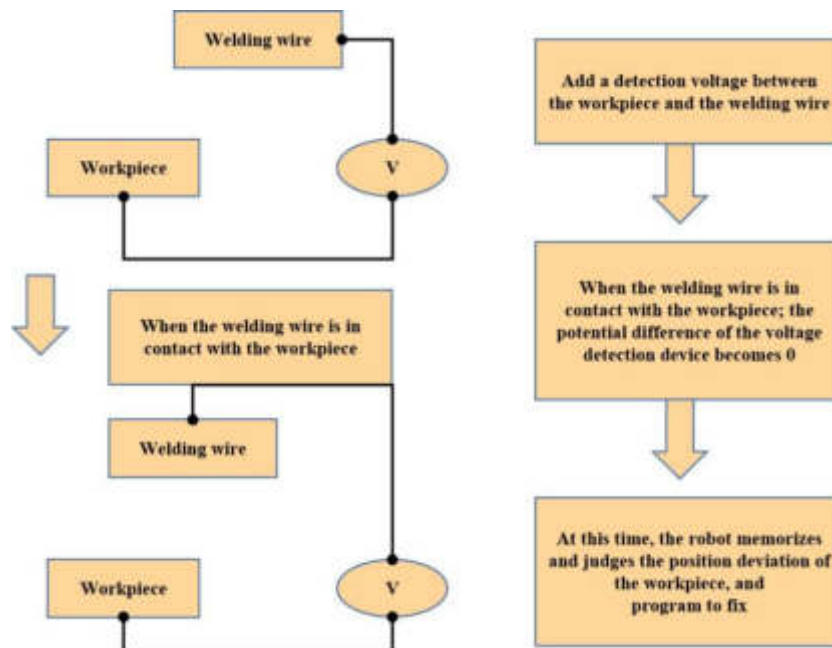

Fig. 3.2: Schematic diagram of contact sensing function

(2) *Groove sensing and groove positioning sensing.* Through the contact sensing of welding wire (or welding gun nozzle), the specific position of the weld groove can be quickly and conveniently found, and the width and depth of the groove can be automatically detected. At the same time, the groove angle can be calculated, which can be provided for the welding program to judge and adjust.

3.3. Arc tracking function . The arc tracking function is a function that searches for the center of the welding line, corrects the deviation of the welding workpiece in real-time, automatically detects the position of the welding line, and tracks the position deviation based on the feedback value of the welding current during swing welding. Especially in the multi-layer and multi-pass welding process, the workpiece change information obtained during the first layer of welding is utilized, and after the control system organizes and calculates, the results are directly applied to the welding after the second layer. Arc tracking is divided into welding line tracking (left and right direction tracking and up and down direction tracking) and groove width tracking [9].

(1) *Welding line tracking.* After the position of the starting point is determined, the correctness of the welding direction also needs to be ensured using the arc tracking function. Arc tracking refers to the real-time monitoring of welding voltage and current changes by the welding robot system through software during the welding process, analyzing and calculating the changes in arc length, and correcting the deviation of the weld seam through software adjustment of the robot's posture, thereby achieving seam position tracking.

(2) *Groove width tracking.* The arc welding robot system detects multiple points on the entire weld seam before welding, calculates the width of the weld seam groove through software, and then obtains the change in the width of the entire weld seam. During the welding process, by automatically adjusting the welding swing amplitude and welding speed, a weld seam with consistent height and shape is obtained, achieving the goal of improving welding quality [10,11].

3.4. Teaching Programming and Offline Programming. All welding robots have the function of teaching programming, which guides the welding gun to the starting point through the teaching box, and then determines the position, motion mode (linear or arc interpolation), swing mode, welding gun posture, and various welding parameters, at the same time, the movement speed of peripheral devices can also be determined through the teaching box. The welding process operations include arc striking, arc extinguishing, and filling

arc pits, which are also given through the teaching box. After the teaching is completed, the welding program can be produced. For the welding seams of structural components with complex structures, different shapes, and larger volumes, especially for the production of multi variety, small batch, and single variety, non batch welded structural components, online teaching will inevitably spend a lot of time, reduce equipment usage, and increase the labor intensity of operators. The method of online teaching directly restricts the application of welding robots, as is the case in the steel structure industry [12,13,14].

Offline programming technology utilizes 3D modeling software to copy the real work robot system into a computer, and then imports the component models generated by SolidWorks or ProE software into the robot scene in the computer. The workpiece can be programmed in an offline simulation environment, allowing the robot to complete welding programming independently on the computer without the need for the robot equipment itself. The program for on-site teaching and editing can be copied, translated, and other basic programs that can be read by offline programming software, greatly reducing the preparation time for welding programming and improving the utilization rate of intelligent robots [15].

4. Experimental analysis.

4.1. Project Introduction. Taking a certain commercial building project as an example, the construction land area is 31689m², using Q460GJC steel with a maximum plate thickness of 100mm. The steel structure consists of extended arm honing frame, radial separating frame, ring belt separating frame, etc., and is connected to the core tube as a whole. The steel used in this project is about 120000 tons, and the cotton frame layer structure is complex. In terms of design, high-strength bolts are used to connect with welding. The weight of a single component is 90 tons, and the welding quality and installation accuracy requirements are strict. The steel is mainly Q345GJC, which is a low alloy high-strength structural steel with a thickness range of 20-130mm. In actual construction, it is controlled according to foreign welding standards [16].

4.2. Application method.

4.2.1. Parameter determination. The robot in this building adopts a modular development route, with trajectories, actuators, multi degree of freedom welding guns, control platforms, and intelligent control modules, which can fully meet the on-site installation and welding needs of steel structures. In order to meet the various welding operation requirements on site, the main parameter selection is: in terms of technical parameters, the robot adapts to the welding position and supports horizontal, vertical, upward and 360° all position welding; Supports straight seams, circumferential seams, and irregular welds, supports circular workpiece sizes with a diameter exceeding 168mm, and the robot's walking speed is between 0-160cm per minute; The angle swing of the welding gun adopts a strip conveying method, with a swing speed of 0-255cm per minute and an amplitude of ±25mm; The horizontal tracking stroke is 200mm, the vertical tracking stroke is 150mm, and the programmable parameter adjustment amplitude is ±20%. In terms of melting efficiency, the efficiency of thick plate long weld welding is 1.5 times higher than that of arc welding; The magnetic adsorption type track of the robot is driven by friction, with a fine and compact body structure and convenient installation [17,18].

The comparative analysis of the technical performance of different mechanisms is shown in Table 4.1. Finally, a cage type positioner continuous flipping device was selected, and two workstations were arranged simultaneously. During welding operations, one workstation could be used for loading and unloading of vertical components, improving efficiency and the utilization rate of welding robots.

4.3. Programming method. This welding robot system supports three programming methods:

(1) *Online teaching programming.* Online teaching programming cannot be widely applied in building steel structures due to long equipment usage time and low efficiency, and can only be used as a supplementary application for on-site adjustment.

(2) *Offline teaching programming.* Through traditional offline teaching programming software, offline programming of all steel structure components can be achieved, meeting the requirements of welding usage. However, due to the numerous types of building steel structures, the standardization of welding structural components is not high, and the 3D models generated by the CAD software currently used by steel structure enterprises cannot be directly imported into offline programming software, and the 3D models of components need to be

Table 4.1: Comparative Analysis of Technical Performance of Different Mechanisms

Types	Work situation	advantage	disadvantage
L-type 90° flipping device	Build and purchase on the jig frame, and after welding on each side, flip the device with $N \times 90^\circ$ flip, experimental full position welding	Moderate price Can achieve continuous automatic welding	Unable to synchronize with robot control system
Continuous flipping of cage positioner	Built and loaded into a cage positioner, capable of achieving 360° continuous rotation	Can be linked with the robot control system to meet the requirements of continuous automatic welding	Relatively high price The system is relatively complex

rebuilt, it will consume a lot of time in modeling and editing robot action trajectories in offline programming software, so traditional offline programming software is difficult to meet the needs of actual production.

(3) *Intelligent rapid programming software.* In order to address the above issues, an intelligent and fast offline programming software has been developed. The rapid programming system adopts parameter driven, similar to building blocks, to construct a model of the welded part. The H-beam, box column, and cross column are defined as the main body of the workpiece, and the rib plate, bracket, and combined bracket are defined as modules, by inputting the size parameters of the main body of the workpiece, the size parameters and quantity of the module, and the parameters of the installation position on the main body of the workpiece, the two-dimensional model of the workpiece, the three-dimensional model that can be recognized by the offline teaching software, and the Robot welding implementation program are automatically generated. At the same time, according to the input size information, the welding database of the corresponding weld is automatically selected (Figure 4.1). The automatically generated robot program can be verified in an offline system.

The application of intelligent rapid programming software has greatly improved the welding programming time of building steel structure components, shortened the ratio of programming time to welding time, and laid an important technical foundation for the promotion and application of building steel structure welding robots. Online teaching programming requires a long investment time and low work efficiency, making it difficult to fully utilize in building steel structures and can only assist in on-site adjustments. In offline teaching, programming of all steel structure components can be achieved, fully meeting the requirements of welding applications. However, due to the variety of steel structure types, the standardization level of structural components is low, and the 3D model generated by the CAD software used by the enterprise cannot be directly imported into offline software. Therefore, it is necessary to rebuild the model and spend a lot of time editing the robot's motion trajectory, which is not in line with actual needs. In this regard, the building adopts intelligent offline programming software, which is parameter driven and similar to the principle of building blocks to construct a welded workpiece model. It uses box shaped columns and cross column workpiece bodies to support and strengthen modules such as plates, and automatically generates a two-dimensional model. By inputting parameters such as workpiece body parameters, size, quantity, etc., the offline teaching software of the three-dimensional model is recognized. Based on the input size information, a matching database is automatically selected, Enable the robot program to be verified in the offline system, saving more programming time, and effectively ensuring the welding efficiency of the steel structure of this project.

4.3.1. Welding process. This type of robot can walk along a predetermined route, repeatedly operate a certain process for a long time, and is easy to track and control. The system operation is stable and reliable, with high work efficiency. It is suitable for prefabrication and welding at various locations on site, and can effectively solve the problem of automatic welding for long welds and multi-position steel structure installation in construction projects. In this project, the application of welding robots includes the following content. In the welding of the extended arm truss, the truss layer of this project is a key and difficult welding point, mainly

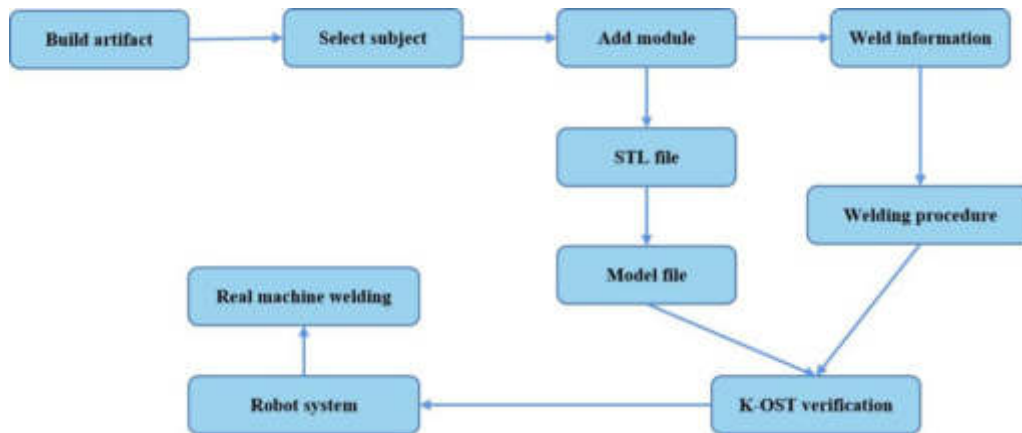

Fig. 4.1: Intelligent Fast Programming Process

Table 4.2: Welding flux parameters of damper quality box

project	numerical value
Number of steel cables	13 pieces
steel type	Q355B
Quality box quality	1100t
Steel plate thickness	85mm
Weld length	10m

made of Q390GJC material. The maximum length of the vertical weld seam of the extended arm truss is 4m, and the plate thickness is 140mm, one weld seam requires two welders to work continuously for 40 hours to complete. According to the relevant regulations for steel structure welding, the difficulty level reaches level D. This project includes a total of eight truss layers, each with a degree of 2-4m, a plate thickness of 80-140mm, and more than 50 welds. Due to the large amount of welding, low manual operation efficiency, and unstable welding quality, robot technology should be introduced to achieve high-altitude welding goals. The welding operator determines the length of the track based on the actual situation on site, configures the power control box, wire feeder, etc. required for automatic welding, and connects the cable to the welding trolley. The cable length is about 25 meters. This equipment can be placed at a high altitude around the car for welding. The welding protection gas cylinder can be connected to the control box through a gas pipe, ensuring that the center of the weld pool is the same as the weld seam during welding, optimizing and improving the welding parameters, and achieving the goal of continuous welding. In the welding of the damper quality box, the equipment is located on the 125th floor, with a height of 27m. There are 4 groups of 13 pieces suspended on the 125-131 floor, and the specific parameters are shown in Table 4.2 [19].

In order to ensure the reliability of root welding, a 5mm gap should be reserved during assembly. Generally, welding wires with a diameter of 5mm should be placed on both sides and in the middle during assembly, and then positioned for welding, the length of the weld seam is between 30-40mm, with a spacing of 400-500mm, it should be positioned at the small groove position, and the end should be spot welded and fixed before polishing smoothly, treat it as the arc starting point for robot operation. After the point welding is completed, use a flame gun to heat and remove the welding wire. Arrange the two robots symmetrically to minimize welding stress and deformation while ensuring welding progress and quality.

4.4. Application effect. In this project, the welding robot was used to achieve the welding objectives of the boom honing frame and the damper mass box. Under the same position and conditions, it has significant advantages compared to traditional welding modes, and the application effect is mainly reflected in: Firstly, the

welding quality is high, the appearance is beautiful, the weld seam is smooth with the base material, and the non-destructive testing results meet the standards[20]; Secondly, the welding efficiency is high, and automatic slag cleaning can be achieved during the welding process, achieving continuous operation, which doubles the efficiency compared to previous manual welding; The third is to greatly reduce the intensity of manual work. Technicians only need to adjust the welding parameters. After completing the weld seam teaching activity, the robot can automatically repeat welding, which is very convenient.

5. Conclusion. Currently, there are various forms of construction, and the types of steel structural components are becoming increasingly complex, with the characteristics of small batches without repetition, which puts forward higher requirements for the function of welding robots. In practical projects, appropriate parameters and programming methods should be selected based on the actual situation, advanced and reliable welding processes should be applied to achieve the goal of automatic welding of steel structure components, compensate for the quality defects of previous manual welding, and better meet the requirements of digitalization and technology in steel structure manufacturing, making component manufacturing more efficient and reliable. The application of intelligent and rapid programming software greatly improves the welding programming time of building steel structure components, reduces the ratio of programming time and welding time, and lays an important technical foundation for the promotion and application of building steel structure welding robots.

APPLICATION OF PHYSICAL MODELING AND VIRTUAL SIMULATION TECHNOLOGY IN MEASURING THE PERFORMANCE OF SUBWAY TRAIN TRACKING AND OPERATION

XIUXUAN WANG* AND HONGWEI LIANG†

Abstract. The purpose of this paper is to study the application of virtual simulation technology in the measurement of subway train tracking performance. Firstly, the safety braking model required by virtual reconnection technology is discussed around the operation simulation and performance measurement of virtual reconnection. The two trains are combined into "one virtual reconnection train set", the tracking train and the head train run with relative moving block, and the two run with the front train set with moving block. Then, according to the characteristics of Metro train tracking operation, a virtual reconnection model and an improved station tracking model are proposed for the bottleneck area of the station. Finally, the proposed model is verified by numerical calculation and computer simulation modeling. The simulation results reproduce the dynamic characteristics of train flow during metro train operation. The results show that the departure interval and minimum tracking interval of the train are all 58 s. The improved station tracking model has the moderate passing capacity as the relative moving block, and the virtual reconnection model has the largest passing capacity. After the initial delay of the system, the delay recovery ability of the virtual reconnection model is the strongest.

Key words: virtual reconnection, relative moving block, train tracking interval, performance measurement, simulation system, Subway operation system

1. Introduction and examples. Virtual simulation technology is Simulation technology and virtual reality technology combined product. It builds the whole system A complete virtual environment is typically characterized and integrated and controlled through the virtual environment Make a large number of entities. Entities interact in a virtual environment, or with a virtual Environmental effects are the real characteristics of the objective world.Virtual simulation means "true Real people manipulate virtual systems in a virtual environment while conducting simulations, in the most In recent years, the development has been very rapid, and a series of successful in a wider range of fields Apply.

Driven by information technology, simulation technology has developed into a universal and strategic technology for human beings to understand and transform the objective world, which requires it to further absorb and integrate other related technologies on the original basis. Virtual simulation technology is the combination of simulation technology and virtual reality technology. It is typically characterized by a unified and complete virtual environment of the whole system, and integrates and controls a large number of entities through the virtual environment [1]. The interaction between entities in the virtual environment or with the virtual environment is the real characteristics of the objective world. Virtual simulation refers to the simulation conducted by "real people manipulating virtual systems in virtual environment". It has developed very rapidly in recent years and has been successfully applied in a wide range of fields. Metro train operation system can ensure safe and smooth train operation. But it is a systematic process from design, construction to system commissioning, involving large quantities, high investment and complex system. So it is difficult to quickly find and handle problems only by virtue of experience. We combine virtual simulation technology with Metro train operation system to simulate a real subway operation environment on computer, which can be used for train operation control strategy, system integration scheme analysis, key subsystem testing and driving training. It has the characteristics of controllability, safety, repeatability and economy, which is of great significance for urban traffic development [2].

†Zhengzhou Railway Vocational & Technical College, Zhengzhou, Henan, 451460, China(HongweiLiang7@163.com)

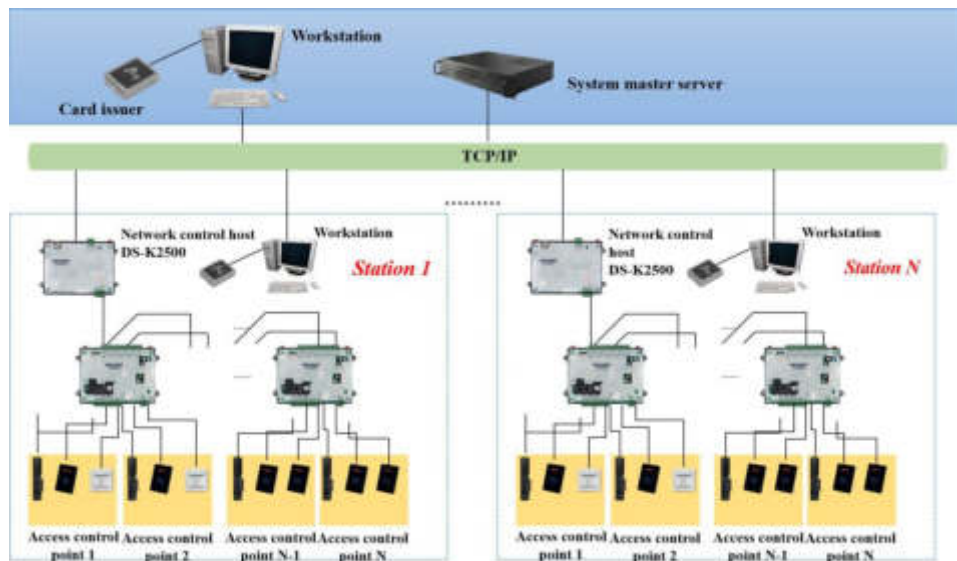

Fig. 1.1: Metro train tracking operation

The subway train operation system can ensure the safe and smooth operation of the train, but it is a systematic process from design, construction to system trial operation, which involves a large amount of engineering, high investment and complex system, and it is difficult to quickly discover and master the problem just by relying on experience. We combine virtual simulation technology with subway train operation system. To carry out research, simulate a real subway operating environment on the computer, can it be used for train operation control strategy, system integration scheme analysis, key subsystem test and driving training. It is controllable, safe, repeatable and economical. Sex and other characteristics are of great significance to the development of urban traffic.

In terms of the current development of the railway, on the main trunk lines of the railway line, with the increase of speed and traffic density, there will be mixed trains of different speed grades on the line at the same time, and their body weight and speed are different to some extent. Due to the different speeds of trains, it is impossible for trains to operate in an undisturbed environment. In most cases, multi-trains tracking operation with mutual influence (Fig. 1.1).

In this process, the operation of the two trains will affect each other. In case of failure or speed restriction of the current train during operation, the recommended speed curve and train schedule of ATO system are no longer applicable to the following train [3]. At this time, if the following train still operates according to the speed curve generated offline before leaving the station, it may produce unnecessary braking or parking, or even more serious accidents when receiving the fault information of the preceding train. After braking or parking, increasing speed or starting again will produce traction energy consumption, which increases the total energy consumption of the train.

According to the characteristics of section tracking operation, the following train obtains the position, speed and other information of the front train in real time through communication. Therefore, the impact of the front on the following should be taken into account in the energy-saving and optimized driving of the following train. So that it can update its target speed curve in time according to the actual situation, avoiding unnecessary deceleration or waiting. So as to reduce the total energy consumption of the train [4]. When the current train is disturbed during operation and has an impact on the following train, the ATO system of the following train will adjust or re-plan its operation speed curve in real time according to its current information and the information of the front train. It will adopt corresponding intelligent control methods to make the train take the updated speed as the operation basis, reducing delay and unnecessary energy consumption.

2. Literature review. The VR virtual simulation operation system of rail transit trains can help train operators to deal with various emergency situations, such as train accidents, equipment failures and so on. By simulating the actual situation, the operator can be trained in the virtual environment, familiar with the emergency handling procedures and operating procedures, improve the emergency response capacity and processing capacity, and greatly improve the operation safety. The VR virtual simulation operation system of rail transit trains can monitor and analyze the operation of trains in real time, identify potential faults and problems in advance by predicting and analyzing the operation status of trains, help dispatchers make reasonable operation plans and maintenance plans, and improve the reliability and operation efficiency of trains. The traditional training method needs to spend a lot of manpower, material resources and financial resources, and the VR virtual simulation operation system of rail transit trains can be trained in the virtual environment, which greatly reduces the training cost, and can also avoid accidents and losses caused by improper operation.

For this study, considering the constraints such as the actual line condition and speed limit of train operation, Z L ü et al. constructed the train operation strategy using genetic algorithm (GA), and gave the form of the optimal solution in ATO system and the minimized energy consumption of train driving control [5]. Liu, Y. et al. use the Lagrange multiplier and maximum principle method to obtain a set of optimal control and control conversion points of the train, and optimize the running time [6]. Song, H. et al. proposed a global optimal driving strategy for the train running on the track with different slopes, and calculated the local optimal switching point on each slope using the principle of local energy minimization. The algorithm can continuously update the optimal speed profile [7]. Considering the utilization of train regenerative braking energy, Zhang, M. et al. proposed a semi-analytical solution to discretize optimization problem of the train energy consumption, and applied the Lagrange multiplier algorithm to solve the speed optimization [8]. Dong, J. et al. proposed a distance based train speed trajectory search method, which uses the speed level of each preset position obtained during operation, and uses the search method combined with ant colony algorithm, GA and dynamic programming to search the train speed [9].

Based on the analysis of train energy-saving operation strategy, Zhanjun, W. proposed a fusion algorithm to optimize the global optimal operation strategy of train. The fusion algorithm is based on energy saving, meets the requirements of passengers, and can obtain the optimal timetable and optimal driving strategy of the train at the same time [10]. For multi train joint control, Li, Z. et al. proposed the corresponding controller and stability criteria. And the stability conditions of the proposed algorithm are given using Lyapunov stability criterion. The controller can use the information of the nearest train to ensure the operation performance of multi-train sequence [11]. Gao, R. et al. mainly studied the absorption of energy consumption generated by train regenerative braking and proposed the method of multi-train combination. That is, the energy consumption generated by the braking of the front train can be absorbed by other trains on the line [12]. Zheng, P. and others mainly used GA and particle swarm optimization algorithm to determine the train speed and minimize the error between it and the actual running speed. At the same time, Kalman filter is used to determine the position of transponder according to the changed parameters. When the transponder position reaches the optimum, the train speed error is also reduced [13]. Aiming at the train optimal control, Zhou, H. et al. firstly analyzed the stress of the train and established the train analysis model. Then, according to the selection principle of optimal coasting point and the energy-saving of regenerative braking, the single train interval operation optimization model and multi-train energy-saving operation model are established respectively. The particle swarm optimization algorithm based on Gaussian white noise disturbance variation is used to solve the above model, and the optimal control strategy of the train in each case is obtained. Finally, the energy-saving adjustment scheme under the condition of train delay is discussed [14].

3. Virtual simulation of train operation system. Scene model is the basis of simulation. Modeling is an essential part in the construction of virtual simulation system which needs to model the physical attributes and motion laws of virtual environment and virtual objects like visual appearance and surface friction. Its purpose is to give drivers and customers a sense of immersion in the actual scene around the current train.

(1) *Scene modeling content.* The modeling quality of scene model has a direct impact on the analysis and evaluation of the whole simulation system. After a high-quality model runs, users will have a strong sense of immersion [15]. Therefore, the three-dimensional model of subway track and trackside ancillary facilities must

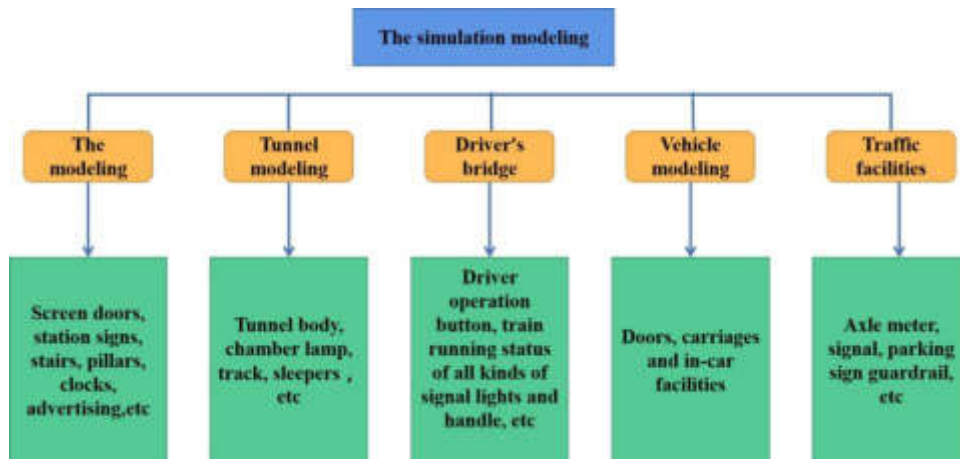

Fig. 3.1: Scene Modeling content

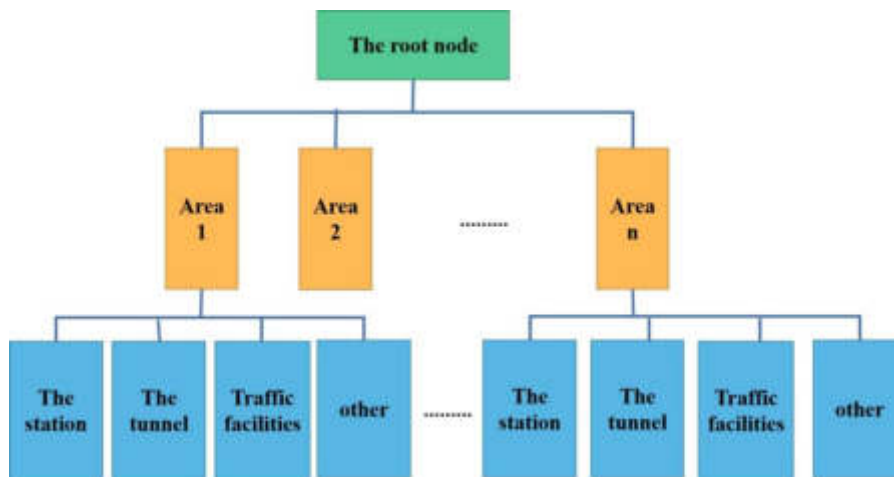

Fig. 3.2: organizational structure of scene model

be established according to the reconstructed line drawings of Beijing Metro Line 2. The design results can be observed and displayed from any angle, so as to realize the roaming function by interactively changing the position of viewpoint or preset motion route. We use the modeling software creator launched by American MultiGen paradise company for modeling. The virtual simulation modeling of the system mainly includes the following six modules, as shown in Figure 3.1.

(2) *Organizational structure of the model.* The organizational structure of scene model directly affects the operation efficiency of the system. The scene model is generally expressed in a multi-level tree structure. According to the characteristics of banded distribution of subway lines [16], the tree structure based on spatial location relationship is adopted to realize the establishment of scene model. The basic idea is to divide the whole scene into several regions along the line direction, which correspond to the first-level nodes in the scene model tree (Figure 3.2).

The idea of hierarchical modeling method is generally adopted for the modeling of the underlying facilities. It uses the tree structure to represent each component of the object. It not only provides a convenient natural segmentation method, which can arrange various levels of the database from large to small, but also is very

Fig. 4.1: Influence of station tracking interval on maximum operation speed under different tracking modes

beneficial to the modification of complex models [17]. Take the subway station model as an example: the independent modules such as platform, wall, roof, column and annunciator can be placed at the same level, while the stairs can be placed at a lower level than the platform because they are on the platform. The stair nodes include handrails, steps, etc., which are the next node of the stairs. This tree hierarchical scene modeling based on spatial location relationship can quickly realize various convenient operations on the scene model of the specified area from top to bottom, reduce mutual restraint and interference, have clear structure and clear hierarchy, and greatly improve the operation efficiency of the system.

The whole scene is divided into static scene and dynamic scene. The static scene is the fixed part of the scene, and the dynamic scene is the part that changes in the scene. In the simulation process, the dynamic scene should be controlled. The screen door, train door, signal and train operating status indicator in the station are all dynamic scenes, and we need to control them in real time according to the operation of the train, such as controlling the opening of the screen door and the train door, the color change of the signal and the indicator, and the movement of the virtual handle. The control of dynamic scenes can be achieved through the Switch node and DOF provided by Creator.

The system software mainly includes three parts: the model system initialization, the 3D model loading and management and the main program of vision generation. The initial configuration of the model was completed through the Vega graphical interface LynX, and the.adF file was formed. After the initialization work is completed, the virtual simulator loads the required 3D model from the file into the memory, and at the same time reads the signal device description file and determines the state of the device and the position of the moving object to operate the model accordingly.

4. Performance measurement and result analysis.

4.1. Steady state performance measurement. The simulation parameters are set as follows: train length $L_T = 140m$, protection section length, $L_S = 15m$, train starting acceleration $a = 1m/s$, train braking deceleration $b = 1m/s$, braking reaction time $T_R = 3s$ and stop time $T_R = 3s$. Based on formulas 4.1 to 4.4, the relationship between station tracking interval and train speed of moving block, relative moving block, virtual reconnection model and improved station tracking model can be obtained [18]. The simulation results are shown in Figure 4.1.

Under the condition of train tracking operation, the general formula for calculating the passing capacity of the line is:

$$T_1 = \frac{2a(L_T + L_S) + v_{max}^2}{2av_{max}} + T_R + T_D \quad (4.1)$$

Fig. 4.2: Influence of passing capacity on maximum speed under different tracking modes

Table 4.1: Comparison of station tracking interval and passing capacity under different tracking modes

Block system	The station tracking interval/s	Passing capacity/ (cars/h)
Moving block	60.21	54
Relative moving block	54.35	58
Virtual reconnection model	33.26	86
Improved station tracking model	54.46	88

$$T_2 = \sqrt{\frac{2b(L_T + L_S)}{a^2 + ab}} + T_R + T_D + \frac{v_{max}}{b} \quad (4.2)$$

$$T_1 = \frac{4a(L_T + L_S) + v_{max}^2}{2av_{max}} + T_R + T_D + \frac{v_{max}}{b} / 2 \quad (4.3)$$

$$T_4 = T_2 \quad (4.4)$$

$$N = \frac{3600}{t} \quad (4.5)$$

where: N refers to the maximum number of trains that can pass through the line within 1h, t is the minimum tracking interval of the train. The control value of the minimum tracking interval of the train generally occurs during the parking operation of the front train. When multiple trains travel in sequence along the same track and the same direction [19], there must be sufficient tracking interval between the follow-up train and the front train to ensure a certain safe distance between adjacent trains, so as to avoid abnormal braking, parking or collision of the follow-up train. Therefore, the tracking interval of the station is used to calculate the line passing capacity. The line passing capacity ignores many factors affecting the capacity in the actual line operation, so it is only discussed here as the upper bound of the theoretical capacity. The relationship between the line capacity and the maximum train speed under different tracking modes is shown in Figure 4.2.

See Table 4.1 for station tracking interval and passing capacity under different tracking modes when $v_{max} = 72km/h$. It can be seen from Figure 4.1 and Figure 4.2 that the station train tracking interval is not the greater the speed, the smaller the interval, but the minimum tracking interval under a special speed [20]. After exceeding this speed limit, the greater the speed is, the greater the tracking interval will be, and the corresponding

Fig. 4.3: Speed distance curve of tracking train under head train delay

theoretical passing capacity will be smaller and smaller. According to the simulation data in table 4.1, under the same maximum driving speed limit, the tracking interval of the moving block station is the largest, and the tracking interval of the improved station tracking model is the same as that of the relative moving block, while the station tracking interval of virtual reconnection model is the smallest. For the corresponding passing capacity, virtual reconnection model is the largest, the relative moving block is equal to the improved station tracking model, and the moving block is the smallest.

It can be seen that under the moving block system, adding the concepts of virtual reconnection model and improved station tracking model, will theoretically improve the line passing capacity (in the data in Table 4.1, the passing capacity of virtual reconnection model is 64.1% higher than that of moving block, and the passing capacity of improved station tracking model is 11.3% higher than that of moving block). This is only two train formation. If more trains are formed, the line passing capacity will be further improved [21,22,23]. But correspondingly, the train control system will be more complicated.

4.2. Dynamic performance measurement. The simulation scene and simulation parameters of the system are set as follows: $L_T = 140m$, $L = 2000m$. The total evolution time of the system is 2000 s, the acceleration and deceleration of the train are $1m/s^2$, maximum operating speed $v_{max} = 72km/h$, safety interval $L_S = 15m$. The system sets up a station at 1000m in the center, and the parking position of the locomotive in the station is 1000m. In particular, the simulation scene in this paper is that only the storage line and turn back line (or arrival departure site) are set at the end station, one station line is reserved in the upper and lower directions of the section transfer station, and there is no turnout connection with the section main line. Therefore, there is no "station arrival departure interval" at the station.

Figure 4.3 is the speed distance curve of follow-up tracking trains when the initial delay of the first train occurs at the station under moving block (the departure interval and minimum tracking interval of trains are all 58s). As can be seen in Figure 4.3, when the first train has no initial delay, the follow-up tracking train will slow down and stop evenly, and accelerate to leave the station after arriving at the station without interference by the first train [24]. However, when the head train is delayed, the tracking train will deviate from the planned speed distance curve. The longer the head train is delayed, the farther the tracking train deviates from the planned speed distance curve, and even stops outside the station waiting for the outgoing train, which is consistent with the actual situation.

In order to evaluate the delay propagation of initial delay in different systems under different tracking modes, the number of delayed trains caused by initial delay is calculated during simulation. Figure 4.4 is the relationship between different departure intervals and the number of train delays when the initial delay of the first train is 120s.

It can be seen from Figure 4.4 that appropriately increasing the departure interval can effectively reduce

Fig. 4.4: Relationship between departure interval and train delay number under different tracking modes

the number of follow-up train delays caused by the initial delay of the first train [25]. On the premise of a certain actual departure interval, the number of delayed trains is reduced to a certain extent compared with moving block under the conditions of improved station tracking model in most cases. The number of delays in the improved station tracking model is basically the same as that in the relative moving block. The virtual reconnection model has the least number of delayed disturbed trains.

5. Conclusion. Virtual reconnection technology is a technology to control the tracking operation of trains on the track in formation. This technology uses vehicle-to-vehicle communication to coordinate the operation of each train, so as to realize the operation of "safe space dimension and closer time dimension". It improves the flexibility of urban rail transit operation, so as to adapt to the changing traffic demand and improve the passing capacity of the line. Aiming at the bottleneck area of the station, a tracking interval model based on virtual reconnection is proposed: that is, the combination of two trains is "one virtual reconnection train set". The relative moving block is used between the tracking train and the head train, and between the train set and the front train set. Then an improved station tracking model is proposed: relative moving block tracking is adopted only in the station area and moving block tracking is adopted in the section.

Therefore, on the premise of large space in the station platform, the design of virtual reconnection technology for the station area is an effective and feasible method to improve the overall line passing capacity. Under the condition of limited space in the station platform, the improved station tracking model can further improve the line passing capacity. In the aspect of running time optimization, the train running time in the section is only required within the allowable error range. In actual operation, when the train runs in multiple stations (multiple sections), it cannot only ensure that a certain section meets the requirements of operation time, but also need to adjust the overall operation time. For example, when the train runs ahead, it needs to redistribute the excess time. Or when lagging behind, it needs to speed up to reduce the delay, Therefore, optimizing the timetable can better achieve the purpose of optimizing the speed of the train. This system can not only meet the needs of the subway train running simulation system, but also provide various reference information for the subway line designers to make decisions about its design. It has high fidelity and credibility to provide drivers with simulation training for driving under various signal systems on different lines.

THE EMPLOYMENT OF CARBON NANOTUBES IN BIOMEDICAL APPLICATIONS

JAJAAR FAHAD A. RIDA*

Abstract. Carbon nanotubes (CNTs), a prominent application of nanotechnology, find extensive use across various fields. Their electrical and optical characteristics, which are affected by the manufacturing process and any impurities introduced during production, are crucial in establishing their suitability for use. This research focuses on the utilization of carbon nanotubes in medical applications, exploring their properties both as electrical conductors and semiconductors, comparable to silicon used in precision medical equipment and devices. When functioning as electrical conductors, CNTs exhibit characteristics similar to traditional conductive materials. This property is harnessed in medical applications, particularly in targeted cancer treatments that minimize impact on healthy cells. CNTs' efficient conduction of electrical current makes them valuable components in medical devices and equipment. Furthermore, CNTs showcase semiconductor properties akin to silicon. This characteristic is crucial for developing advanced medical equipment, enabling accurate diagnostics and medical imaging. The semiconductor behavior allows the creation of intricate medical devices with enhanced precision. The research underscores the significance of CNTs in shaping the future of medical technology, especially when integrated with artificial intelligence applications. The ability of CNTs to function both as conductors and semiconductors highlights their versatility in the medical field, promising advancements in healthcare technologies. Their use holds potential for targeted cancer treatments, accurate diagnostics, medical imaging, and enhanced performance through integration with artificial intelligence.

Key words: Carbon Nanotubes, Biomedical Engineering, Nanotechnology Engineering, Bio- Nanotechnology, and Carbon Nanotube Applications

1. Introduction. Nanotechnology, emerging as an alternative to microtechnology, introduces the possibility of manufacturing nanoelectronic and electromechanical devices, drastically reducing their size compared to micro devices. This transformative innovation is anticipated to bring about significant advancements across various scientific and engineering disciplines. Enthusiasts foresee its broad influence on contemporary medicine, the global economy, international relations, and the daily lives of individuals. The potential to arrange matter particles in unprecedented ways at a lower cost sparks imaginations of supercomputers integrated into pen tips, and fleets of medical nanorobots administered to treat blood clots, tumors, and currently incurable diseases[[1], [2]]. The study highlights the contrast between micro and nano technologies, emphasizing nanotechnology's potential to revolutionize electronic and electromechanical devices. In contrast to micrometers, nanoelectronic and electromechanical devices can be reduced in size by a factor of a thousand, resulting in enhanced performance. This paradigm shift is not merely a theoretical concept; it has tangible applications across various industries. For instance, polymers in micro-devices lead to increased device longevity, while metals like gold, nickel, and aluminum contribute to the reliability of early devices [3], [4]. The discussion extends to the unique properties of nanomaterials, showcasing their exceptional hardness, transparency, and transformative effects on material behavior. Spherical nanoparticles made of silicon, ranging from 40 to 100 nanometers, exhibit hardness surpassing even that of sapphire and approaching that of diamond. Transparency, a characteristic of nanoparticles due to their dimensions being smaller than light wavelengths, opens up possibilities for applications like transparent packaging and cosmetic products [5], [6], [7].

Nanotechnology is acknowledged as the fifth generation of electronic technologies, following the progression from electronic valves to transistors, integrated circuits, and microprocessors. The development of nanoelectronic and electromechanical devices, facilitated by advancements in synthetic chemistry, holds promise for applications in health, medicine, information technology, and beyond. Notable examples include IBM's creation of a microscope for imaging and recording atoms at the Nano level and the aspiration to replace electricity with light ([8], [9], [10]) potentially leading to the advent of optical computers such as shown in figure 1.1.

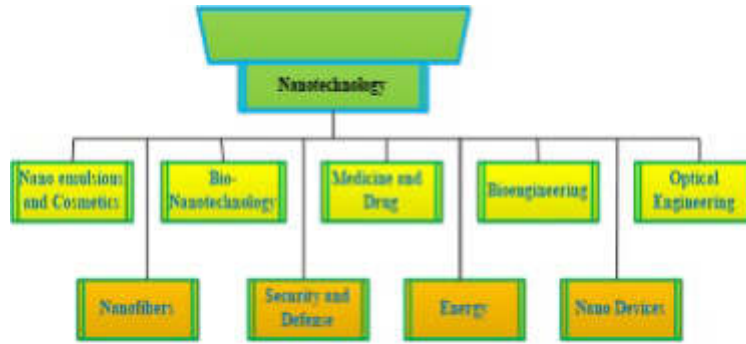

Fig. 1.1: Nanotechnology holds promising prospects and applications in many fields.

1.1. Overview of Carbon Nanotubes (CNTs). During the early 1990s, Sumio Iijima made a groundbreaking discovery of carbon nanotubes (CNTs), which brought about a significant transformation in numerous scientific and technical domains. Carbon, which is vital for human existence, serves as the fundamental building block for the bonding arrangement of diamond, graphite, nanotubes, and fullerenes. With a wide range of desirable properties, CNTs have become integral in structural science, material science, chemistry, biology, and electronics [11], [12]. CNTs, resembling stretched graphite strips, exhibit exceptional properties: tensile strength surpassing steel, superior thermal conductivity, and electrical conductivity equivalent to copper. Divided into single-wall (SWNTs) and multi-wall (MWNTs) categories, CNTs' key characteristics include diameter, chirality angle, and number of walls, each influencing unique physical and chemical properties. Fabrication techniques involve chemical methods and physical techniques such as chemical vapor deposition (CVD), arc discharge, and laser ablation. CNTs, incorporated into nanosystems like polymer electrical nano materials, possess a nanoscale diameter, contributing to their versatility. Electronic properties vary based on diameter and chirality, with approximately one-third exhibiting metallic structure and the rest being semiconducting. The optical properties of CNTs have garnered attention in photonics, showcasing a short recovery time and high third-order optical nonlinearity. Chiral nanotubes, categorized based on chiral vectors, contribute to the diverse landscape of carbon nanotubes. The interplay between valence electrons and the lattice in rigid covalent-bond materials impacts the electronic structure. Calculations show that around one-third of CNTs have a metallic structure, dependent on nanotube diameter and chiral angle [13], [11], [14].

The structure of single-walled carbon nanotubes (SWNTs) is intricately linked to their electrical properties, particularly influenced by the chiral vector (Ch), which determines the orientation of the honeycomb lattice. This unique parameter serves as the key characteristic affecting whether SWNTs behave like metals or semiconductors. The chiral vector, represented by (n, m) indices, defines the tube's structure, with n and m being integers that influence the nanotube's diameter and chirality angle (θ) . It is essential to comprehend the structure of the end of a single-walled carbon nanotube (SWNT), which is commonly described using Hamada indices (n, m) , as this knowledge is critical for accurately predicting and controlling the electrical characteristics of SWNTs. The chiral angle and the specific arrangement of carbon atoms significantly impact the electronic structure. The correlation between the electrical structure and geometry, as demonstrated in fullerenes, is proposed to be a universal trait in nanostructured carbon materials such as carbon nanotubes. This reliance is attributed to the enhanced interaction between valence electrons and the lattice in rigid C-C covalent-bond materials. In materials with stiff covalent bonds, valence electrons interact more strongly with the lattice, influencing the electronic structure based on geometrical details. The electrical energy band structure of a nanotube is intricately connected to the energy band structure generated by the 2D graphite honeycomb sheet used in the production of the nanotube. This connection highlights the significance of the underlying hexagonal lattice

Fig. 1.2: Full carbon nanotube (CNT) manufacturing process, from atomic carbon to graphite sheets to rolled-up form tubes.

structure in determining electronic properties. Calculations reveal that approximately one-third of carbon nanotubes exhibit a metallic structure, while the remaining two-thirds have a semiconducting structure [14][2][15]. This observation is contingent on factors such as nanotube diameter (dt) and the chiral angle (θ). Chiral nanotubes, categorized as zigzag and armchair nanotubes, represent another classification based on chiral vectors (Ch), adding to the diversity of carbon nanotube structures as observed in the figure 1.2.

Carbon nanotubes (CNTs) have potential biomedical applications in various fields. They have applications in antimicrobial materials, dentistry, drug delivery, biosensing, cancer therapy, tissue engineering, diagnostic imaging, and regenerative medicine. Carbon nanotubes (CNTs) have distinctive characteristics, including a large surface area, exceptional mechanical robustness, electrical conductivity, and thermal properties, which render them well-suited for these specific applications. Functionalization of CNTs enhances their biocompatibility and enables biomolecule loading for targeted drug delivery and immobilization support. Carbon nanotubes (CNTs) can undergo modifications with diverse functional groups to enable the concurrent transportation of many molecules, facilitating targeted delivery, therapeutic interventions, and imaging purposes. They have been employed for the delivery of tiny medicinal molecules, peptides, proteins, and genes and have demonstrated therapeutic effectiveness in both *in vivo* and *in vitro* experiments. In addition, carbon nanotubes (CNTs) have been utilised in the advancement of biosensors for the detection of biological and biomedical chemicals. However, there are challenges related to cytotoxicity and biodegradation that need to be addressed for their safe implementation in clinical trials [16], [17].

Properties of carbon nanotubes have High Strength that mains Carbon nanotubes are known for their exceptional strength, making them ideal for use in biomedical implants and scaffolds [3], [18], [19]. Electrical Conductivity is they exhibit excellent electrical conductivity, allowing for applications in bioelectronics and biosensors. Thermal Stability is with high thermal stability, carbon nanotubes are suitable for various biomedical applications, including heating-based therapies. Carbon nanotubes (CNTs) exhibit unique optical properties that make them highly valuable in various applications. Some key aspects of their optical properties include: Optical Absorption and Emission are CNTs demonstrate strong optical absorption in the near-infrared region. Their emission properties can be tuned based on the nanotube structure, offering possibilities for applications in sensors and imaging. Photoluminescence is Carbon nanotubes can emit light upon absorbing photons, a phenomenon known as photoluminescence. This property is influenced by the nanotube's diameter and chirality, providing opportunities for designing nanoscale light sources and devices [20]. Nonlinear Optical Behavior is CNTs exhibit nonlinear optical behavior, making them suitable for applications in nonlinear optics. Their response to intense light can be harnessed for developing optical switches and modulators. Optical Transparency is Depending on their structure, some carbon nanotubes are optically transparent. This transparency, combined with their excellent electrical conductivity, is advantageous for applications in transparent conductive films and coatings. Light Polarization can be Carbon nanotubes exhibit polarization-dependent optical prop-

erties. This polarization sensitivity is beneficial in designing devices for polarized light applications, such as in optoelectronics and photodetectors. Light Scattering and Reflection have CNTs can scatter and reflect light, and their interaction with light is influenced by factors like diameter and length. These properties are relevant in applications such as anti-reflective coatings and light-absorbing materials. Photoconductive Response have Carbon nanotubes can show a photoconductive response, meaning their electrical conductivity changes upon exposure to light. This property is utilized in developing light-sensitive devices like photodetectors and photovoltaic cells. Broadband Absorption: CNTs have broadband absorption capabilities, covering a wide range of the electromagnetic spectrum [13], [21], [22]. This feature is advantageous for applications in solar cells and broadband photodetectors.

Utilizing carbon nanotubes (CNTs) in biomedicine presents promising opportunities, but it also comes with several challenges and limitations that need to be addressed. Some key considerations include: Biocompatibility Concerns is the biocompatibility of carbon nanotubes is a significant challenge. Some studies have raised concerns about potential toxicity and inflammatory responses when CNTs interact with biological systems. Addressing these issues is crucial for safe biomedical applications. Functionalization and Surface Modifications are Pure carbon nanotubes may lack specific functional groups required for targeted drug delivery or interactions with biological molecules. Surface modifications are often necessary to enhance biocompatibility, solubility, and the attachment of biomolecules [3], [4], [23], [24]. Biodistribution and Clearance have Understanding the biodistribution and clearance of carbon nanotubes from the body is essential for their safe use. The long-term fate of CNTs, especially in terms of potential accumulation in organs or tissues, needs careful investigation. Regulatory Approval can be the regulatory approval process for medical applications involving carbon nanotubes is challenging. Establishing standardized protocols for testing and ensuring the safety and efficacy of CNT-based biomedical products is crucial for regulatory acceptance. Large-Scale Production is Scaling up the production of high-quality, well-characterized carbon nanotubes for biomedical applications remains a challenge. Ensuring consistency in size, structure, and purity is essential for reproducibility in research and clinical settings. Cost is the production and functionalization of carbon nanotubes can be expensive, limiting their widespread adoption in healthcare. Cost-effective manufacturing methods need to be developed to make CNT-based technologies more accessible. Limited Understanding of Long-Term Effects can be the long-term effects of exposure to carbon nanotubes, especially in the context of chronic diseases or repeated treatments, are not fully understood. Further research is needed to assess any potential cumulative impact on health over extended periods. Interaction with Immune System has the interaction between carbon nanotubes and the immune system is complex. Depending on their properties, CNTs can trigger immune responses, impacting their effectiveness and safety in biomedical applications. Intracellular Fate is understanding how carbon nanotubes behave inside cells and their intracellular fate is crucial. This includes investigating whether they remain intact, undergo degradation, or lead to the formation of toxic byproducts. Multifunctionality Challenges are while the multifunctionality of carbon nanotubes is advantageous, integrating multiple functionalities (e.g., imaging, drug delivery, and sensing) in a single platform without compromising performance remains a technical challenge. Carbon nanotubes (CNTs) possess unique properties such as large surface area, mechanical strength, electrical conductivity, and biocompatibility, making them ideal for biomedical applications. CNTs have been used as antibacterial agents, dental materials (scaffolds, bone-grafting, tissue engineering), and drug delivery systems for cancer therapy. The modifications of CNTs with metal and metal oxide nanoparticles, such as zinc oxide (ZnO), have enhanced their antibacterial properties [13], [22], [25], [26], [27].

The graphite's hexagonal mesh structure, which serves as the basis for carbon nanotubes, can be conceptualised as a cylindrical formation resembling rolled-up chicken wire, owing to the organisation of carbon atoms in stacked layers. Within the electrical density of states (DOS) of carbon nanotubes, there are singularities called Van Hove Singularities. Each nanotube possesses four distinct energy levels two for conduction and two for valence (CNTs). In contrast to metal carbon nanotubes, semiconducting carbon nanotubes exhibit a direct band gap that increases with the nanotube diameter, enabling them to efficiently conduct electrical current. Single-walled nanotubes generally exhibit sizes within the range of 1-2 nm, but multi-walled nanotubes can exhibit diameters ranging from 2-25 nm. Furthermore, nanotubes can vary in length, ranging from 0.2 to 5 micrometers, which provides a diverse array of structural options. Carbon nanotubes can exhibit either metallic or semiconducting properties, depending on their structure and orientation. This dual nature makes

them valuable for a wide range of electronic applications, from high-conductivity components to semiconducting devices in advanced technology and nanoelectronics [7], [21], [28], [29]. The authors Mohd et al. (2023) provided information. The user's text is empty. Carbon nanotubes possess significant potential for utilisation in several biomedical applications, including the fabrication of antibacterial materials, enhancement of dental operations, drug delivery, and the advancement of biosensors. The study conducted by K. Victor et al. (2022) highlighted the several potential biomedical uses of carbon nanotubes, which encompass therapeutic, tissue engineering, diagnostic, and imaging applications. Additionally, carbon nanotubes can be utilised for drug transport and exhibit antibacterial properties. [Sarika Verma et al, (2023)] described The potential biomedical applications of carbon nanotubes include their usage in diagnoses, tissue regeneration, selective drug delivery, and as tissue engineering scaffolds. [Mahdiah Darroudi et al, (2023)] explained Carbon nanotubes have the potential to be used in several biomedical applications, such as diagnosing, treating, and preventing infectious and neoplastic disorders. They can also be used for gene transfer and anti-inflammatory therapy. [Lopamudra Giri et al. (2023)] discussed the biomedical applications of carbon nanotubes, highlighting their potential in various biological applications. [Duygu Harmanaci et al. (2023)] discussed Carbon nanotubes (CNTs) show great potential for theranostic applications in various fields, including cancer diagnosis and therapy, infectious diseases, central nervous system problems, and tissue engineering. Functionalized carbon nanotubes (CNTs) have been successfully used in pharmaceuticals and medicine due to their unique properties . Study of the properties of carbon nanotube when it acts as a conductor of electric current or acts as a semiconductor, based on the materials added to the graphite material, as well as on the valence band and conduction in each nucleus and the opening between them. It is considered a carbon nanotube that is symmetrical, unlike semiconductors made of silicon, which are asymmetrical and the bias voltage is high. Compared to the effort required for carbon nanotubes. Single walled carbon nanotubes (SWNTs) have a single cylindrical wall. The typical diameter of the nanotubes falls within the range of 1 to 2 nm, although their length can vary from 0.2 to 5 μm , and in some cases, even extend to a few centimeters, as depicted in figure 3. It has been processed to have optical qualities that are compatible with optical systems. The photonic and biological research communities have been paying an increasing amount of attention to the possible uses of carbon nanotubes. The latter property has given rise to dreams of using nanotubes to make extremely dense electronic circuitry and the last year has seen major advances in creating basic electronic structures from nanotubes in the lab, from transistors up to simple logic elements. The volumes of SWNTs produced are currently small and the quality and purity are variable. Multi-walled carbon nanotubes have two or more cylinders within cylinders. Nanotubes typically have diameters in the range of two to twenty-five nanometers, and their lengths may vary anywhere from two to five micrometers or a few centimeters. The gap between the walls is 0.36 nm, and the spacing between walls is 0.36 nm. In these progressively more sophisticated systems, the several SWNTs that combine to form the MWNT could have quite different architectural compositions (length and chirality). MWNTs have an average length that is one hundred times greater than their width, and their outside diameters are almost always measured in the tens of nanometers. [5], [8], [10], [13], [22]. Despite the fact that it is simpler to produce significant quantities of multi-wall nanotubes than single-wall nanotubes, the structures of multi-wall nanotubes are not as well understood as those of single-wall nanotubes due to the greater complexity and variety of multi-wall nanotubes, as shown in figure 1.3.

2. Research Methodology. When a single sheet of graphite crystal is rolled up into a cylinder, the result is a single wall carbon nanotube (SWTN). This cylinder has a thickness of one atom and a relatively low density of atoms (2040 per micron in diameter and length) along its axis. The nanotube represented by the chiral vector C_h .

$$C_h = n * a_1 + m * a_2 \quad (2.1)$$

where n and m are two integers denoting the number of unit vectors $n * a_1$ and $m * a_2$ in the hexagonal honeycomb lattice contained in this vector, where $|a| = |a_1| = |a_2|$ and where $|b| = |b_1| = |b_2|$ and where $|c| = |c_1| = |c_2|$ Graphite lattice vectors a_1 and a_2 are a pair of real space vectors with the following values: $a_1 = (a, 0)$, $a_2 = (0, a)$, where $a = 0.246\text{nm}$, where $a_3 = (a, a)$, where $a_4 = (0, a)$ is the c - c bond length. As can be seen in Figure 1.3, the chiral vector may be used in conjunction with the zigzag or the direction to create an angle (the chiral angle. On a graphene sheet with a honeycomb structure, the vector connects two O and A sites that are crystallographically

Fig. 1.3: Schematic representation of rolling graphite to create single- and multi-walled carbon nanotubes.

Fig. 2.1: Clarification of the process through which graphite sheets are converted into carbon nanotubes

similar to one another. Each vertex of the honeycomb structure contains a carbon atom. The axis of the zigzag nanotube is located at the value $\phi = 0$ for the parameter, the axis of the armchair nanotube is located at the value $\phi = 30$ for the parameter, and the axis of the chiral nanotube is located at a value that is $0 < \phi < 30$. Attaching the line AB to the parallel line OB in figure 2.1 creates the smooth cylinder connection that the nanotube needs in order to function properly [30], [31], [32], [33]. The following is an equation that expresses the diameter of a nanotube, denoted by the notation d_t , in terms of the numbers n and m: equation 2.2.

$$d_t = \frac{|a| * \sqrt{(n^2) + n * m + m^2}}{\pi} \tag{2.2}$$

The distance between the two carbon atoms of the closest neighbor is 1.421 or 0.142 in graphite, C_h is the length of the chiral vector, and the chiral angle (ϕ) may be obtained by solving the following equation 2.3.

$$\phi = \tan^{-1} \frac{\sqrt{3} * m}{2n + m} \tag{2.3}$$

Thus, the (n, m) indices or their equivalent, d_t , may be used to describe a nanotube.

Figure 2.1 shows a) The unit cell of one-dimensional nanotubes is described using the nomenclature of the unit cell of the honeycomb lattice, which is often encountered in two dimensions; b) the Brillouin zone of two-dimensional graphite represented by rhombuses and a shaded hexagon; and c) The unit cell of one-

Fig. 2.2: Actual and reciprocal features of the structure's fundamental building block, the unit cell

dimensional nanotubes is described using the nomenclature of the unit cell of the honeycomb lattice, which is often encountered in two dimensions.

Figure 2.2's coordinates (x, y) are used to express the real space basis vectors a_1 and a_2 , which are written as equations 2.4 and 2.5 respectively.

$$a_1 = \left(\frac{\sqrt{3}}{2}a, \frac{a}{2}\right), a_2 = \left(\frac{\sqrt{3}}{2}a, -\frac{a}{2}\right) \tag{2.4}$$

and

$$b_1 = \left(\frac{2\pi}{\sqrt{3}a}, \frac{2\pi}{a}\right), b_2 = \left(\frac{2\pi}{\sqrt{3}a}, -\frac{2\pi}{a}\right) \tag{2.5}$$

where $a = |a_1| = |a_2| = 0.246\text{nm}$, a is the lattice constant of two-dimensional graphite, which is consequently the basis vectors b_1 and b_2 of the reciprocal lattice. b_1 and b_2 are the reciprocal lattice's basis vectors. The reciprocal ($b=2.949\text{nm A}$) hexagonal lattice has basis vectors b_1 and b_2 that are rotated by 30 degrees with respect to the real space hexagonal lattice's basis vectors a_1 and a_2 . To do this, we choose the shaded region of Figure 2.2 to represent the first brilluoin zone, the centers of Points K and M, and the corners of Figures 2.1 and 5 to represent the highest symmetry points. Calculations have been made to determine the energy dispersion relations for the MK triangle depicted in Figure 2.1 with dotted lines. As shown in figure 1.3, the unit cell is defined by the smallest repetition distance along the axis of the 1D nanotube, which is denoted by the letter OB. This allowed us to determine the translation vector (T).

$$T = t_1 * a_1 + t_2 * a_2 \tag{2.6}$$

The equation 2.7 the variables n and m are connected to the coefficients t_1 and t_2 , respectively.

$$t_1 = \frac{(2n + m)}{(dR)}t_2 = \frac{-(2n + m)}{(dR)} \tag{2.7}$$

where dR is the greatest common divisor of $(2n+m, 2m+n)$, and the equation 2.8 for dR may be obtained by clicking here.

$$dR = \begin{cases} d, & \text{if } n - m \text{ is not a multiple of } 3d \\ d3, & \text{if } n - m \text{ is a multiple of } 3d \end{cases} \tag{2.8}$$

where d is the greatest common divisor of all the other (n, m) . The magnitude of the translation vector T , equal to the vertical bar symbol.

$$|T| = \frac{\sqrt{3} * L}{dR} \quad (2.9)$$

The length of the chiral vector C_h is denoted by L , while the diameter of the nanotube is denoted by d_t . The region bounded by the vectors T and C_h is the area that is referred to as the nanotube's unit cell. The values (n,m) and the formula are used to determine the number of hexagons, N , that are contained within the one-dimensional unit cell of a nanotube. This number may be thought of as the number of individual nanotubes 2.10.

$$N = \frac{(2(n^2 + n * m + m^2))}{dR} \quad (2.10)$$

Two carbon atoms are added, which is represented by a single hexagon in the honeycomb structure shown in Figure 1.2. We chose carbon nanotubes with the following chirality ratios $(17, 0)$, $(12, 5)$, $(10, 10)$, $(16, 2)$, $(15, 0)$, and $(11, 11)$ based on the assumption that a $(c-c)=0.142$ nm. The nanotube has a larger real space unit cell compared to the 2D graphene sheet, resulting in a substantially smaller 1D Brillouin zone (BZ) for the nanotube compared to a single 2D graphene unit cell. The reason for this is that the actual spatial unit cell for the nanotube is far greater than that for the 2D graphene sheet. Brillouin Zone-folding methods have been extensively utilised to establish approximate connections between the dispersion of electrons and phonons in carbon nanotubes (n, m) possessing specified symmetry. The user's text is empty. The nanotube's crystal structure closely mimics that of a graphene sheet, which is why the Brillouin Zone is relatively modest. The vectors k_1 and k_2 may be calculated using the relationship. $R_i * K_j = 2 * i * j$, where the lattice vectors in real space are denoted by $R(i)$, and the vectors in reciprocal space are denoted by K_j . It is possible to write form k_1 and k_2 as

$$k_1 = 1/N(-t_2 * b_1 + t_1 * b_2) \text{ and } k_2 = 1/N(m * b_1 - n * b_2) \quad (2.11)$$

The reciprocal lattice vectors of a graphene sheet in two dimensions are represented by the symbols b_1 and b_2 , which are correspondingly indicated by the equation that describes them 2.5. Given a set of N wave vectors $k(1) (=0, \dots, N-1)$, it is feasible to compute N discrete k vectors in the circumferential direction. A one-dimensional band of electronic energy appears for each of the discrete values of the circumferential wave vectors, and phonon dispersion relations extend in six distinct directions depending on the value of $.$ Creating a nanotube from a graphite sheet by rolling it along the chiral vector C_h . The resulting nanotube is rolled (n,m) . Nanotubes can be characterised by their diameter (d_t) and chiral angle (π) in relation to the zigzag axis. Single-wall nanotubes (SWNTs) may be thought of as hollow cylinders that are formed by rolling a graphite sheet. It is possible to describe it in an unambiguous manner by a vector denoted by the letter C_h in terms of a set of two numbers denoted by the letters n and m , which correspond to graphite vectors a_1 and a_2 . It is possible to create two standard nanotubes from a single graphite sheet by rolling it in opposite directions. The nanotubes can exist in three different configurations: zigzag $(n, 0)$, armchair (n, m) when $n = m$, and chiral (n, m) . If n is a value greater than m and less than zero, the coordinates of the chiral nanotubes are as follows: $(17, 0)$, $(15, 0)$, $(12, 5)$, $(16, 2)$, $(10, 10)$, and $(11, 11)$. Both the lattice constant and the intertube spacing are essential requirements for the proper creation of a bundle of single-walled carbon nanotubes (SWNTs). Experiments and theoretical studies have reached the conclusion that the average length of C-C bonds in MWNT should be 0.34 nanometers, and that the spacing between tubes should also be 0.34 nanometers. In light of this, equations 2.1 and 2.2 may be used to simulate a variety of tube architectures and interpret experimental data. They are now taking into account the energetics or the stability of nanotubes. During the fabrication of a SWNT from a graphite sheet, the strain energy is equal to $1/d_t$ per tube, or $1/d_t^2$ per atom.

The diameter of SWNTs that are often seen in experiments ranges from 0.6 to 2.0 nanometers, however it may be as tiny as 0.4nm or as big as 10 nanometers (3.0nm). The electrical properties of a nanotube can

be determined by analysing the dispersion relation of a graphite sheet with wave vectors (k_x, k_y) , in the most basic scenario.

$$E(k_x, k_y) = \gamma \sqrt{4\cos((3 * k_x * a)/2)\cos((k_y * a)/2) + 4\cos^2((k_y * a)/2)} \quad (2.12)$$

Considering the stated values of $a = 0.246nm$, $\gamma = 2.5eV - 3.0eV$ (the lattice constant), and $a = 0.246nm$ (the closest neighbour hopping parameter), it is plausible that γ originates from many sources. In order to construct a nanotube from graphite, it is necessary to maintain a periodic boundary condition either around the circumference of the tube or in the C directions. This may happen either along the circumference of the tube or along the C directions [30], [31], [32], [34], [35], [36], [37], [38]. The two-dimensional wave vector $k = (k_x, k_y)$ is quantized in this direction due to the constraint $k.c = 2q$, where k that satisfies this condition is allowed when q is an integer. The following need, therefore, must be satisfied in order for metallic conductance to occur: equation 2.13

$$(n - m) = q_{metallic} (2n + m) = 3q \quad (2.13)$$

2.1. Semiconducting of Carbon Nanotubes . The valence energy band is located at the lower section of the energy curve, while the conduction energy band is located at the upper section of the energy curve. When s equals zero, the valence band and the conduction band become symmetric, adopting the shape of a ball, which is described by equation 2.12, and $\gamma = 2.9eV$. This occurs when the electron spin is equal to zero. 2D graphite is classified as a zero-gap semiconductor due to the conduction and valence bands intersecting at the six corners of the Brillouin zone, which are known as high symmetry sites $E = E_{sp}$ [30], [38], [39], [40]. The positive sign is used to represent the valence band, whereas the negative sign is used to indicate the conduction band. Graphene exhibits symmetrical conduction and valence bands in terms of both structure and distribution. On the other hand, silicon, which is an indirect band gap semiconductor, exhibits dissimilar band structures for both electrons and holes. The Fermi points are the places on the edges of the Brillouin zones where the energy troughs may be found. These sites are also known as the Brillouin zone corners. The vectors serve as the foundation for the reciprocal lattices b_j . The wave vectors were limited to the specified range as a direct consequence of the periodic boundary restriction that was applied in the circumferential direction .

$$k.c = 2 * \pi * q \quad (2.14)$$

where k is a wave vector that can be allowed, and q is an integer that denotes the quantum number. This may be allowed. The equation that describes the conductance of SWNT, MWNT rope, or SWNT cable is as follows 2.15:

$$G = G_O * M = ((2e^2)/h) * M \quad (2.15)$$

Since nanotubes' conductance is quantized, the resistance of nanotubes is equal to $6.5 * 10^3$ ohms; M is an apparent number of conducting channels that takes into account electron-electron coupling and intertube coupling effects in addition to the intrinsic channel $G = (6.5k_{ohm})^(-1)$ which is the value of the intrinsic channel. The results of the combined STM and STS studies are consistent with the following hypotheses: 1) approximately two-thirds of the nanotubes are semiconducting, and one-third of them are metallic; 2) the density of states exhibits van hove singularities, which is characteristic of the expectations for a one-dimensional system; and 3). The energy gaps of semiconducting nanotubes are proportional to the square root of the distance traveled over time $(1/d_t)$. An inductor's E_k value is determined by the extra kinetic energy associated with the current. This represents the equilibrium Fermi energy for electrons moving between the source and the drain of a field-effect transistor. This demonstrates that kinetic inductance has a ballistic origin. Therefore, making the right option while selecting the diameter is helpful. At a temperature of 300 kelvin, the typical values for the band gap are as follows: - (1.12 eV) for germanium; (0.67 eV) for silicon; and (1.43 eV) for GaAs. Electronic density of states (DOS) is measured in terms of the equilibrium Fermi energy per unit of nanotube length, whereas availability is expressed in terms of the number of electron-phonon pairs per unit of nanotube length. Both of these measures are independent of one another. Both of these measurements are expressed in nanotube length units. Due to the fact that the bias window only contains right-moving carriers, the density of states must be divided by two in the calculation for the mean number of electron-phonon couplings. This is because the bias window contains only the right-moving carriers [26], [27], [41], [42], [43].

2.2. Nanotechnology Applications in the Medical Sciences. Because of its close relationship to human life and health, nanomedicine is often regarded as one of the most significant uses of nanotechnology. Some even argue that it is the most significant application of all. This is the age of nanomedical technology, when the principles of illness prevention, diagnosis, and treatment have been rewritten in light of recent advances in nanotechnology. Whereas nanotechnology, by way of illustration, opens up novel pathways for drug carriers within the human body, allowing them to specifically target different cells, and to take on some of humanity's deadliest diseases, like cancer. This has spawned a great deal of nano research and experimental applications at labs all over the world. The nanosensors, on the other hand, may be surgically inserted into the brain of the paraplegic patient to give them the ability to move and walk again. Research indicates that it will appear on the farthest extent of techniques for repairing living cells, as well as nano-neural electronic links, and if this happens, a real revolution will occur in the world of treatment and therapy. There are a lot of applications in the field of health care and the manufacture of nanomedical devices. Using this method, it is possible to capture images of the body's cells with ease, akin to taking a conventional snapshot. Furthermore, these cells can be manipulated and moulded into various configurations [13], [14], [22]. An institute in California has set a general framework for what nanotechnology can offer us in the field of medicine, for those people who suffer from certain diseases, and for older people who suffer because of the incorrect sequence of atoms.

2.2.1. Delivery of the Drug to the Tissues. Delivery of drugs to tissues is one of the priorities of research in the field of nanomedicine, as it depends on the manufacture of micro-nanomaterials that improve the bioavailability of the drug. This means that the drug molecules are located in the targeted place in the body, where they work with maximum effectiveness, and thus the rate of drug consumption decreases and its side effects are reduced, as well as the total cost of treatment. Pharmacology is one of the sciences that needs high accuracy due to its connection to human health. A drug's efficacy is diminished and it causes undesired side effects if it is absorbed by healthy tissues along with the sick ones. For instance, we see that conventional approaches such as radiation and chemotherapy have serious adverse effects and are not very successful in treating cancer [11], [21], [44], [45]. As a result, anti-cancer medications need highly targeted administration in order to have any effect at all. Therefore, scientists are studying one of the future nano applications, which is represented in the drug delivery technology using one of the nano devices called dendrimer. Methods of drug delivery are based on nanotechnology, some of which depend on very small-scale tubes that have the ability to move and can be directed to the area to be treated. Others rely on smart systems of very small size that can be implanted inside the body and have the ability to control drug doses and the appropriate time for delivery. It appeared that carbon nanotubes could be used by linking them with peptide compounds to introduce them to the immune system in the body and thus use them in the delivery of traditional vaccines [43].

2.2.2. Pharmaceuticals and Therapeutic Drugs. A new term has now been introduced into the science of medicine, nanobiotics, which is the new alternative to antibiotics. Hangbang University researchers in Seoul successfully incorporated nano-silver into antibiotics. Silver possesses the capability to eradicate 650 pathogenic pathogens while maintaining the safety of the human body. This technology will solve a lot [5], [31], [46], [47], [48]. One of the problems of antibiotic-resistant bacteria that have caused mutations that prevent the effect of the antibiotic on these bacteria is that nanobiotics puncture the cell wall of bacteria or cells infected with the virus, allowing water to enter the cells and they are exterminated. This technique will eliminate the strains of bacteria that are resistant to antibiotics that have caused mutations to prevent them from affecting them. Where the nanobiotic punctures the cell wall of the bacteria or virus, and when millions of them enter the gel membrane of the bacterium, they are chemically attracted to each other and gather in the form of long tubes or many pins that puncture the cell membrane and other groups work to expand the hole in the bacterial cell wall so that it dies within minutes as a result. They dissipate the external electrical potential of her membrane and then destroy it within minutes, and she cannot adapt her immune system with it [4,44].

2.2.3. A Nano-Sized Robot is an Assistant in Surgical Operations. For use in delicate and high-risk procedures, Corv is has developed nanoport optical transducers with nanoscale scales. By using a specialized gadget, the surgeon may direct the robot to do the procedure with more precision and less human error than is possible with conventional approaches. The surgeon manipulates the robot arm, which holds the instruments and camera, via a joystick. Through this, huge motions may be reduced to micromanipulations, enhancing the

accuracy of surgical procedures. Because of its extreme hardness, scientists used carbon to create a nanopore only 1 millimeter wide, allowing it to pass through human blood arteries. Magnetic resonance imaging (MRI) and computed tomography (CT) scans may be used to track the robot while it works within the body to verify that it has reached the correct organ or sick tissue.

2.2.4. Diabetes Treatment. Niue University in the United States has successfully created a nanotechnology-based device that can regulate blood sugar levels in the body. This device offers an alternative to insulin injections for diabetic patients. Additionally, nanotechnology is being used in the treatment of kidney diseases. Specifically, researchers are studying the atomic-level formation of kidney proteins and using nanotechnology for imaging purposes. The aim was to study the biological processes that occur in kidney cells and the use of nanoparticles in the treatment of kidney diseases, where solutions to many kidney diseases can be reached by understanding the physical and chemical properties of kidney proteins, and many doctors dream of an artificial kidney using nanotechnology. The cell has the potential to improve the lives of many kidney patients significantly.

2.2.5. Medical Imaging of Medical Applications. Researchers and medical professionals now have the ability, thanks to nanoimaging, to monitor every movement that takes place inside the live tissue of the human body. This allows medical professionals to properly detect the movement of the medicine within the sick tissue. Studying some cells of the body is difficult, and from here scientists resort to coloring them. There is another problem, which is that the cells that emit light waves of different lengths do not always work in the same way or in the same way, which makes medical imaging processes face problems in terms of correct diagnosis. Scientists were able to solve this problem by using some nanoparticles that show reactions different due to the different wave frequencies arising naturally from the difference in the length of the face. Nanotechnology will contribute to advancing its development in terms of its efficiency, performance, speed of work, and increased safety, due to the entry of nanotechnology into the manufacture of electronic chips, electrical conduction circuits, and data processors used in these devices.

2.2.6. Diagnostic Applications of Nanotechnology Medical. The main goal is to discover the disease in the early stages so that it can be eliminated before it causes symptoms or complications. By using nanotechnology, biological tests to measure the presence or activity of the tested materials become faster, more accurate and flexible. The presence of specific molecules or microbes can be combined, and similarly, gold nanoparticles can be combined with short sections of DNA to identify a sequence of genes in a sample. There is also the technology of nano-holes to analyze DNA, which converts its sequence of units directly into electrical signals, and by using nanoparticles as contrast agents (as an alternative to dye), we obtain MRI and ultrasound images with better contrast and distribution, and even luminous nanoparticles can help the surgeon during the operation Surgical procedures to identify the location of the tumor and thus make the process of eradicating it more easily [4], [6], [17], [20], [25], [29], [30], [38], [45], [48], [49], [50].

3. Result and Discussion. The electrical characteristics of carbon nanotubes (CNTs) are determined by the chiral vector (C_h), which is calculated using Equation (1). Various arrangements of carbon nanotubes, such as (17, 0), (12, 5), (10, 10), (16, 2), (15, 0), and (11, 11), exhibit different chiral angles and integer pairs. For instance, the (17, 0) and (15, 0) nanotubes, known as zigzag nanotubes, can function as either metals or semiconductors, depending on the fabrication method. The focus of this paper is on chiral semiconducting nanotubes, specifically (12, 5) and (16, 2), with $n = 12, m = 5$, and chiral angles analyzed in the range of 0 to 30 degrees. Additionally, armchair nanotubes (10, 10) and (11, 11), with $n=m=10$ and a chiral angle ($=30$), operate as metals. Simulation results reveal nanotube diameters ranging from approximately 1.33 nm to 1.356 nm. The band gap in semiconducting nanotubes is determined by solving for the energy difference between the Fermi energy and electronic density of states (DOS). Equation 3.1 is employed to find the band gap (E_g) in semiconducting nanotubes by used MATLAB program. This is found by comparing the Fermi energy per carbon nanotube atomic unit cell to the electronic density of states (DOS) (unit measurement, arbitrary, unit) given by equation 3.1

$$E_g = \frac{2 * a(c - c) * \gamma_o}{d_t} = \frac{(0.8eV)}{d_t} \quad (3.1)$$

Fig. 3.1: An example of two van hove singularities in semiconductor carbon nanotubes

Figure 3.1 shows the energy band gap, denoted as E_g , for a semiconductor with two conduction bands and two valence bands, where the Fermi energy is $E_f = 2.9 eV$, and where two van Hove singularities are handled. The semiconducting properties of carbon nanotubes are described by the equation (2/3) if the condition that $2n+m = 3q$ is equation (3.13). The minimal value, which is provided by the equation, is used to compute the kinetic energy, denoted by E_k , of the lowest subband 3.2.

$$K(c,q) = \frac{2}{(3d_t)} \tag{3.2}$$

The equations that describe the energy output of carbon nanotubes, where d_t represents the diameter of the nanotube, are as follows: 3.3

$$(K_t) = \left(\frac{3 * a(c - c) * \gamma_o}{2} \right) * \sqrt{(k_t^2 + (2(3d_t)^2)} \tag{3.3}$$

and

$$E_o = \frac{(3 * a(c - c) * \gamma_o)}{2} \tag{3.4}$$

where E_o is the energy gap for graphite when it is at its standard temperature. After solving equations 3.3 and 3.4, we are left with equation 3.5, which describes E_{out} , also known as the output energy band gap.

$$E_{out} = \frac{(E(k_t))}{E_o} \tag{3.5}$$

Doping the electron density of states during manufacture has a direct impact on the output energy band gap of carbon nanotubes, which may be described as an equation 3.6.

$$D(E_k) = \frac{8}{(3 * \pi * a(c - c) * \gamma_o)} * \frac{(E(k_t))}{\sqrt{(E(k_t) - (E_g/2)} \tag{3.6}$$

The electrons in the valence band (v_2) are excited by the incident light (photon) and move into the conduction band (c_2), leaving a hole in the valence band (v_2), which allows an electron to move from the valence band (v_1) to the valence band (v_2), which in turn allows an electron to move from c_2 to the conduction band (c_1) and back to v_1 such as shown in figure 3.1.

Certainly, let's delve deeper into specific aspects of the electronic construction of carbon nanotubes (CNTs) and their implications:

Fig. 3.2: The energy gap to the DOS in this system in order to present the results for three distinct carbon nanotubes (17, 0), (12, 5), and (10, 10)

- *Chirality and Electronic Properties:* The chirality angle (θ) determined by the chiral vector plays a crucial role. Zigzag nanotubes ($=0$) exhibit unique properties, potentially serving as either metals or semiconductors. Semiconducting nanotubes with specific chiral angles (e.g., (12, 5), (16, 2)) offer controlled electronic behavior.
- *Simulation and Diameter Impact:* The simulation results showing nanotube diameters are vital. Diameters influence the electronic structure, affecting band gaps and conductivity. Understanding this parameter aids in tailoring nanotubes for specific applications.
- *Energy Band Gap in Semiconducting Nanotubes:* Equation 3.1 provides a direct link between the energy band gap and nanotube diameter. This relationship is essential for predicting and controlling the semiconducting properties crucial for electronic applications.
- *Visualization of Energy Band Gap (E_g):* Figure 3.1's visualization of the energy band gap is a key element. It illustrates the distinct bands and van Hove singularities, giving a comprehensive view of the electronic structure. This understanding is fundamental for designing nanotubes for specific electronic functionalities.
- *Output Energy Band Gap (E_{out}):* Equation (20) and the concept of E_{out} are critical. This parameter encapsulates the nanotube's output energy band gap, offering insights into its behavior and suitability for various applications. It aids in predicting the nanotube's response to external stimuli.
- *Impact of Doping on Electronic States:* Equation 3.6 underscores the impact of doping on the electron density of states. Doping introduces additional electronic states, influencing the output energy band gap. This insight is valuable for engineering nanotubes with tailored electronic properties.
- *Applications in Electronics:* The discussed parameters collectively contribute to the understanding of how carbon nanotubes can be harnessed in electronic devices. Their unique electronic properties, such as high conductivity and tunable band gaps, make them promising candidates for future electronic applications.
- *Challenges and Future Directions:* Despite their potential, challenges and limitations in utilizing carbon nanotubes in electronics should be acknowledged. Issues like uniformity, scalability, and reproducibility are areas of ongoing research. Future directions may involve overcoming these challenges for widespread implementation.

The electronic construction of carbon nanotubes, shaped by factors like chirality and diameter, offers a versatile platform for tailoring their behavior in electronic applications. The ability to control their electronic properties makes them valuable in the development of advanced electronic devices.

Figure 3.2 illustrates that carbon nanotubes can exhibit both positive and negative values for the energy band gap. This high level of symmetry is a unique characteristic, indicating the versatile electronic behavior

Fig. 3.3: Connection between energy gap and DOS for three distinct carbon nanotubes (16, 2), (15, 0), and (11, 11)

of nanotubes. Coordinates (17, 0) and (12, 5) in Figure 3.2 demonstrate the energy gap with two valence bands (v_1 and v_2) and two conduction bands (c_1 and c_2) according to van Hove notation. The presence of both positive and negative energy gap values highlights the tunable electronic states in these nanotubes. Unlike semiconductor nanotubes, (10, 10) nanotubes exhibit metallic behavior with only one conduction band and a valence band. The absence of a band gap in these nanotubes classifies them as metals. This behavior is critical for applications requiring high electrical conductivity.

Employing equations 3.2-3.5, another set of findings is presented in Figure 3.3, reinforcing the observation that carbon nanotubes can have both positive and negative energy gap values. This emphasizes the exceptionally high symmetry of carbon nanotubes' electronic structure. In Figure 3.3, coordinates (15, 0) and (16, 2) exhibit two conduction van Hove bands (c_1 and c_2) and two valence bands (v_1 and v_2). The symmetry of the energy gap in semiconductor carbon nanotubes is influenced by doping in the electronic density of states (DOS), resulting in either positive or negative energy gaps. For (11, 11) nanotubes, the band gap is zero, indicating metallic behavior. These nanotubes act as metallic carbon nanotubes with a continuous range of energy levels. Equations 3.7 and 3.8 provide insights into the behavior of carbon nanotubes as semiconductors (S) and metals (M) during a symmetric transition at $p=q$. The ability of nanotubes to operate in positive and negative bias with low bias is a crucial characteristic for certain applications. The equations suggest that the symmetric transition in the energy level occurs at $p=q$, allowing carbon nanotubes to operate under both positive and negative biases with low bias conditions (160 mV - 200 mV). This bias-dependent behavior is significant for practical electronic applications.

$$E_p p^S = \frac{(2 * \pi * a(c - c) * \gamma_o)}{d_t} \tag{3.7}$$

For semiconductance carbon nanotube,

$$E_p p^M = \frac{(6 * \pi * a(c - c) * \gamma_o)}{d_t} (6 * p * a(c - c) * o) / d_t \tag{3.8}$$

for metallic carbon nanotube.

Figure 3.2 and 3.3 and associated equations underscores the intricate electronic properties of carbon nanotubes, including their symmetry, tunability, and diverse behavior as semiconductors and metals under different conditions. These characteristics are fundamental for leveraging carbon nanotubes in a wide range of electronic applications. The synergy between nanotechnology and artificial intelligence (AI) represents a transformative leap in technology. Nanotechnology, with its ability to manipulate materials at the nanoscale, coupled with AI's data processing and analytical capabilities, promises enhanced precision and efficiency across various domains.

In the realm of medical devices and healthcare, the convergence of nanotechnology and AI holds great promise. The precision offered by nanoscale materials, such as carbon nanotubes, can be complemented by AI algorithms for more accurate diagnostics, treatment delivery, and monitoring of health conditions. Carbon nanotubes, with their remarkable electrical, thermal, and mechanical properties, stand out as a key component of nanotechnology. Their high conductivity, strength, and unique structure make them versatile for applications ranging from electronics to biomedical devices. The discussion emphasizes the significant role carbon nanotubes will play in the future of nanotechnology. In the biomedical field, these nanotubes have shown promise for drug delivery, imaging, and diagnostics due to their ability to penetrate cell membranes and interact at the molecular level. Carbon nanotubes, integrated with AI, can revolutionize healthcare by enabling advanced diagnostics, personalized medicine, and real-time monitoring. The combination of nanoscale materials and intelligent algorithms enhances the capabilities of medical devices for more accurate and timely interventions. The collaborative use of nanotechnology and AI in medical diagnostics can lead to highly accurate and efficient diagnosis. Nanoscale sensors, possibly incorporating carbon nanotubes, can detect biomarkers at ultra-low concentrations, while AI algorithms analyze complex datasets for disease identification. The statement underscores the belief that carbon nanotubes, as part of nanotechnology advancements, will significantly shape the future of healthcare. This suggests a transformative era where nanoscale materials, guided by AI, contribute to breakthroughs in diagnostics, treatment, and overall healthcare management. Alongside the potential benefits, it's crucial to acknowledge and address challenges and ethical considerations associated with the integration of nanotechnology and AI in healthcare. Ensuring the safety, privacy, and ethical use of these technologies is paramount for their widespread acceptance and positive impact. the convergence of nanotechnology, artificial intelligence, and the potential of carbon nanotubes holds immense promise for advancing healthcare. The precision, efficiency, and transformative capabilities offered by these technologies signify a future where medical devices are more accurate, personalized, and effective in improving patient outcomes. The difference is clear in Table No. 3.1 of the specifications and properties of carbon nanotube and its use, like semiconductors, silicon, and germanium, in terms of work, heat tolerance, and working with ultra-high frequencies up to THz. as well as form figure 3.2 and 3.3.

4. Conclusion. The development of nanoparticles, their size control, and the study of their physical properties have revolutionized medical diagnostics. The advancement has opened up possibilities for incorporating nanoparticles, specifically carbon nanotubes (CNTs), into well-established diagnostic techniques such as magnetic resonance imaging (MRI), ultrasound, CT scans, and nuclear medicine equipment. The ability to control nanoparticle properties enhances diagnostic efficiency, enabling early disease detection and providing detailed information about disease location, size, and progression. Around the world, ongoing studies focus on incorporating nanotechnology advancements into medical fields. These efforts include safety assessments for human use, aiming to turn these applications into a daily reality in hospitals. Nanotechnology applications span various sectors, including technology, electronics in medicine, biology, pharmaceutical industries, and disease detection. The enormous potential of CNTs in biological applications is evident. CNTs are highly adaptable molecules that show promise in diverse contexts, acting as sensors, drug transporters, imaging aids, bioelectrodes, and reinforcement for composites. CNT-based sensors are envisioned as simple, rapid, sensitive, and cost-effective tools for monitoring various analyses. Their design flexibility allows for tailoring to specific needs, surpassing the limitations of prior analytical methods. The construction of CNT-based sensors from scratch enhances simplicity and performance. These sensors are considered more straightforward to work with, exhibiting improved detection limits, sensitivities, specificities, and repeatabilities. The potential of CNT-based sensors as effective tools for monitoring targets is recognized, offering a feasible option to meet the urgent demand for numerous analyses. Future research on CNTs-based biosensing is expected to emphasize *in vivo* detection methods. These methods aim for minimal cytotoxicity, high sensitivity, and long-term stability to meet the requirements for reliable point-of-care diagnostics under physiological conditions. The continuous development of CNT-based technologies underscores their significance as a transformative tool in healthcare, contributing to disease treatment and human health preservation. While silicon remains the workhorse of the semiconductor industry, carbon nanotubes offer unique properties that make them attractive for certain applications, particularly in emerging fields such as flexible electronics and advanced sensors. Ongoing research aims to harness the strengths of both materials for future semiconductor technologies. Table No. 1 in the specs outlines the

Table 3.1: Comparison Carbon nanotubes (CNTs) and silicon are both materials with distinct semiconductor properties.

Serial No.	Criteria	Carbon Nanotubes (CNTs) Semiconductors	Silicon Semiconductor:
1.	Structure	CNTs have a tubular structure composed of carbon atoms arranged in a hexagonal lattice.	Silicon is a traditional semiconductor with a crystalline structure.
		They can be single-walled (SWNT) or multi-walled (MWNT), and their electrical properties depend on their structure and chirality.	It is widely used in the electronics industry, forming the basis of most semiconductors
2.	Electrical Properties	CNTs can exhibit either metallic or semiconducting behavior depending on their structure.	Silicon is typically a semiconductor with an indirect bandgap.
		Semiconducting CNTs have a bandgap that varies with their diameter and chirality.	Its electrical properties can be manipulated through doping.
3.	Advantages	High electrical conductivity, comparable to or even better than silicon.	Well-established technology with mature fabrication processes
		Exceptional mechanical strength, flexibility, and thermal conductivity.	Integrated into a variety of electronic devices and circuits.
4.	Applications	Widely explored for Nano electronics, including transistors and interconnects.	Dominant material in the semiconductor industry for integrated circuits and microelectronics.
		Promising in applications like flexible electronics and high-performance sensors.	Commonly used in transistors, diodes, and solar cells.
5	Bandgap Control	CNTs offer a tunable bandgap based on their structure.	Silicon bandgap is controlled through doping
6	Mechanical Properties	CNTs have superior mechanical properties	Silicon, providing flexibility and strength.
7.	Conductivity	CNTs can have higher electrical conductivity than silicon, making them suitable for specific high-performance applications.	Silicon has modest conductivity and is affected by temperature changes
8.	Fabrication Complexity	Large-scale production of CNTs is still an evolving challenge.	Silicon has well-established and mature fabrication processes

distinctions between carbon nanotubes and their applications in semiconductors such as silicon and germanium, focusing on factors including performance, heat resistance, and operation at ultra-high frequencies up to THz, as well as the result of this work paper.

DRIVER DROWSINESS DETECTION

ANN ZEKI ABLAHD*, ALYAA QUSAY ALORAIBI† AND SUHAIR ABD DAWWOD‡

Abstract. The state of the driver of being extremely tired or sleepy through the operation of the vehicle is called driver drowsiness. Different factors caused this state such as alcohol, lack of sleep, and the side effect of some medication. The drowsiness of drivers is a serious safety lead to accidents or fatalities on external and internal roads. The increased number of road accidents resulted from drowsy driving. A special smart, reliable, and accurate system, Using Python language 3.6 for Windows, was designed to build an alert system for drivers in detecting drowsiness driver. This system is crucial in reducing accidents road by the ability to concentrate, react quickly, and produce sound decisions through driving. This system implements a real-time detector that can monitor the states of drivers through driving.

Smart cameras with 16-megapixel were used to ensure that capturing photos have a high quality. These cameras were used in gathering the driver's dataset in different alertness states, including both alert states and drowsy. The collected dataset is processed by extracting all relevant features such as head movement, yawning, and eye closure, which were used in identifying the driver's drowsiness. Python's libraries such as TensorFlow, OpenCV, Keras, and Pygame are used for extracting all the above features. Viola-Jones algorithm is used in face eye region detecting and extracting from the image of the face in the proposed system. A Support Vector Machine (SVM) algorithm was used in classifying between drowsy and non-drowsy drivers. The system is tested and evaluated in the real world, to ensure that the system is reliable and robust; it has high performance and accuracy, and the accuracy is about 99.1%. This system can be used in manufacturing vehicles.

Key words: sensors, driver, drowsiness, driving, accident, smart camera

1. Introduction and Preliminaries. Driver Drowsiness considered a significant contributor to road accidents worldwide. To enhance road safety a special detection system was developed to detect driver drowsiness. Such a system becomes very crucial in enhancing road safety.

The proposed system can monitor the physiological signs and behaviors of drivers to detect drowsiness and alert the driver early before the accident occurs. Various techniques have been used in a proposed system including facial expression analysis, The proposed system can be used in eye tracking, and Viola-Jones algorithm; future in the car industry to reduce road accidents resulting from drowsy drivers and keep a safe driver.

2. Literature Review. The research on driver drowsiness contributed significantly to improving the safety of external and internal roads to increase safety and reduce or prevent all drowsy driving risks. These researchers try to identify the warning signs that cause driver drowsiness. This information is used in developing a different technology for detecting and preventing driver drowsiness such as physiological sensors, steering behavior analysis, and eye-tracking systems. Such technologies alert the drowsy driver through becoming incapacitated, to take control vehicle. The benefit of this is to reduce accidents number and save people's lives. With the increasing of road accidents number caused by drowsy driving has become a driver drowsiness detection system very important field in transportation safety. Through the availability of digital cameras, it has been increasing the amount of archived recorded videos around the world and it became an effectively growing processing of these video data. Different studies have been conducted to develop and evaluate several techniques in detecting driver drowsiness.

The most popular technique is using electromyogram (EMG) [1], electroencephalogram (EEG), and electrocardiogram (ECG) signals in monitoring the driver's muscle activity, brainwaves, and heart rate respectively. Dong and colleagues (2015) introduced a study that used EEG signals in detecting driver [2] drossiness, with

*Technical College Kirkuk, Northern Technical University (drann@ntu.edu.iq)

†University of Mosul, College of Computer Science and Mathematics, Software Department (dr.alyaa@uomosul.edu.iq)

‡University of Mosul, College of Administration and Economics, Department Management Information Systems (suhair_abd_dawwod@uomosul.edu.iq)

an accuracy of 94%. Lee and colleagues (2017) introduce a study that used a combination of ECG, EEG signals in detecting driver drowsiness, with an accuracy of 98%. Chakraborty (2019) [3] used the data of eye tracking in the detection of driver's drowsiness with an accuracy of 85%. Wu and colleagues (2021) applied facial expression analysis in the detection of driver's drowsiness with an accuracy of 87%. Different machine language algorithms have been used in the detection of driver's drowsiness by using data pattern recognition and deciding the accurate predictions. Malik (2019) [4] applied a support vector machine (SVM) classifier in the detection of driver's drowsiness with an accuracy of 92%. Vishwakarma used a process called object tracking of the saved video in his survey [5]. M. Zhang [6] used extensive hardware sensors in detecting. But C. Anil used the generalizability of models in enhancing the detection of drowsy by increasing the dataset size [7]. M. Jafari introduced a new technology for enhancing the accuracy of system detection [8]. M. Aljasim suggested an expensive experiment detection method [9]. A. M. Leeuwenberg used more complex algorithms that used more variables and increased the tested samples [10]. The accuracy of the previous works is low in more time and most of these papers are surveys, that why it prepared a real-world practical system to protect people from the high numbers of accidents. The real-world, low-cost cost with larger data sets proposed system is reliable and robust and is used in different scenarios like Viola-Jones algorithm, face eye region detecting and extracting from the smart camera's images. After evaluation of the proposed system, the accuracy is 99.1%. This system is more practical and it is easy to use in manufacturing different vehicles.

3. Architecture of the Proposed System. The proposed system consists of different steps; Figure 1 shows the steps of the proposed system. Input data: Input picked videos and images as a dataset to identify the driver's physiological signals, such as eye movement, and facial expression. Face Detection and Extract eye region: The identification of the driver's physiological signals is preprocessed for extracting the relevant features of him(her), such as eye blinking which are used to detect the driver's drowsiness. The Viola-Jones algorithm is used to detect each object in videos or images. This step is very important in improving the accuracy of the proposed system. Classification: All the extracted features are fed to the SVM (Support Vector Machine) classifier. This binary classifier is a supervised learning algorithm used for pattern identification to distinguish between (Drowsy, and non-drowsy) drivers based on input features. A sound will be produced by the proposed system to alarm drivers as a notification to stop driving and prevent accidents.

4. Dataset and Preprocessing. After collecting different data set images, the data is extracted from videos by cutting the continuous streams into discrete frames to identify the objects (face, mouth, eye,..., etc). The OpenCV technique is used. OpenCV is a Python library (tool for image processing) with the deep learning algorithm Support Vector Machine. The dataset of the proposed system depends on sequences of videos and images captures by webcam, which is based on eye estimation motion.

The Viola-Jones algorithm was applied to detect the parts of the face and eyes [11], [12]. While the area of eye motions was estimated frame to frame by sparse track from optical flow. Different adaptive thresholding values were used to decide whether the eyes were closed or opened.

The data preprocessing is an essential step in the detection of driver drowsiness, and it helps to prepare and clean data for analysis. The preprocessing steps that applied to the proposed system are:

Collection of data: Collect all captured camera videos or images of drivers exhibiting different levels of fatigue or drowsiness, to detect the face and extract the eye region, facial expression, [13] head position from the face images. Figure 4.1 represents the preprocessing of data.

Cleaning of data: Remove all irrelevant noisy data points that affect the analysis accuracy [14], [15].

Normalization: Try to normalize the captured data according to a common scale to be easier to analyze and compare.

Features selecting and extracting: Selecting and extracting most of the relevant features is important, because, not all extracted features are useful in drowsiness detection. So the selection of the most important features can improve analysis accuracy. Examples of data extraction like determining the location of eyes, blinking of eyes (closed, opened), etc. The Python libraries (dlib, OpenCv) are used in performing feature extracting. From every captured video the landmarks eyes were detected by eye aspect ratio

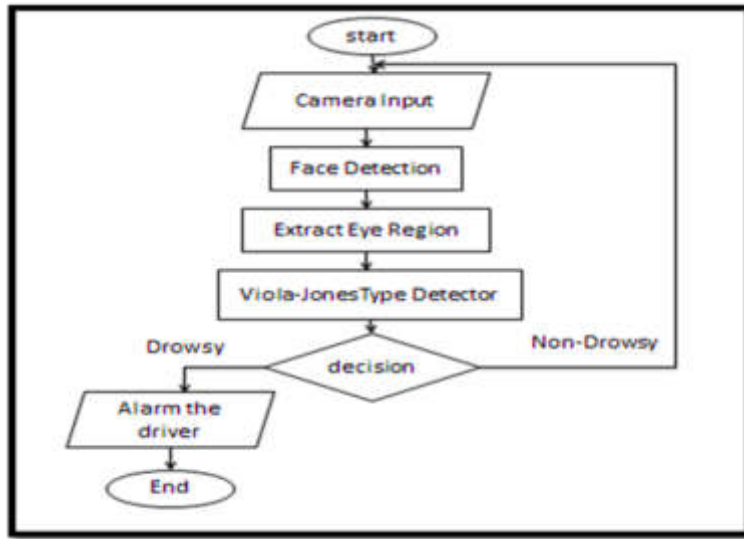

Fig. 4.1: Architecture of the Proposed System

Fig. 4.2: The preprocessing of data for Face detection

(EAR) between the width and height of the eye will be computed by using equation 4.1.

$$EAR = \frac{||P2 - P6|| + ||P3 - P5||}{2||P1 - P4||} \tag{4.1}$$

where $p1, p2, p3, p4, p5, p6$ are the landmark location of two dimensions drawn in Figure 3 [9].

The EAR ratio is mostly constant when the eye is opened and EAR=0 when the eye is closed. EAR ratio for an open eye has a small variance, in plane rotation of the face, and is fixed to a uniform scaling for each image [16], [17]. The blinking of each eye is performed synchronously by both eyes, and the EAR of them is averaged.

Figure 4.2 represents an example of signals of EAR over the video sequence.

Classifying of data: Classifying the data into two cases drowsy or drowsy by using the Support Vector Machine (SVM) algorithm. The last step is creating special samples of data by applying small variations or adding noise to existing data. This step is done to improve the accuracy and performance of this proposed system [18].

Evaluate the proposed system: The evaluation is done in real words by testing the dataset using some metrics such as precision, accuracy, and recall. The Python library sklearn. metrics used in performing the evaluation. This system can detect drowsy drivers to alert them to stop driving and take a rest.

Fig. 4.3: Closed and open eyes with 2D landmark location

5. Viola-Jones algorithm. This is the most algorithms popular today in object detection for digital videos and images. This algorithm applies a series of image classifications [14], [15]. At first, this algorithm will convert each image into ("Haar-like features) a series of rectangular sub-images. This algorithm used Haar-like features, Figure 5.1 represents these features. These sub-images a binary images that have different highlights in brightness between adjacent pixels. This algorithm is used to determine and detect the features of the object. Like detection of eyes in the face image, which is very high real-time framework training [21], [22].

There are three ideas that used in this algorithm for face detection:

1. Integral Image: This idea represents an image where each pixel value represents the sum of all the above pixels and the left of it. This idea is very useful for quickly computing all sum values of pixels in any rectangle region of the image.
2. The classifier AdaBoost: This is an algorithm used in classification tasks. It is work combining different weak classifiers to form a strong one. It has multiple iterations, each one assigns higher weights to misclassified samples and trains a new one to get the final classifier from the weighted sum of all weak classifiers.
3. Attentional cascade structure: This is an algorithm in computer vision used for object detection. The idea of this algorithm is to break down the problem of object detection to a sequence of smaller sub-problems that are solved by a special detector. Each detector is applied to a small region of an image to form a successful detector in object detection [23].

The Viola-Jones used features of rectangles instead of pixels in face detection. Generally, the details of the eyes and face are detected by this algorithm automatically. The eye motion is estimated by the differences in optical flow intensity frame after frame, to decide if the eyes are covered or not by eyelids [24], [25].

This algorithm is used in a wide range of applications because it is the speed and accuracy in detecting objects, especially faces [26], [27].

6. Support Vector Machine Algorithm. Support Vector Machines (SVM) is a supervised machine learning algorithm that is used in classification of Driver Drowsiness Detection to identify drowsy or non-drowsy drivers depending on all based features [28]. After this classification, a sound will generate to alarm and prevent the driver from accidents caused by drowsy driving. SVM is used in regression analysis. In the context of the proposed system, the SVM is trained on different of dataset-labeled examples. Each example has a set of extracted features from a driver's face [29]. The most important features are head pose, eye closure duration, and all other factors of drowsiness indication.

The goal of SVM is creating the best boundary line for segregating the space of n-dimensional into classes [30]. To easily put the new data in the correct group. The hyperplane of the SVM algorithm called for the best decision boundary created by choosing the maximum points or vectors. These points are called support vectors. Figure 6 shows two different groups that are classified by using a hyperplane.

The model of drowsy or non-drowsy drivers is created using the SVM algorithm by training this model using a lot of images of the driver with drowsy and non-drowsy by learning different features of them. So the SVM algorithm will create a boundary between these features (support vectors) to simplify the decision of

classification between drowsy and non-drowsy shown in Figure 6.1.

7. Python Language. This language is a powerful and easy, multi-programming language, often used for building an application of data science, machine learning, web applications, cyber security, and many development systems. The Python language is an Object Oriented Programming language that has an extensive standard modules library. The Python tools used in this proposed system are TensorFlow, OpenCV, eras, Pygame [32], [33]. These Python tools are used in detecting the closed eyes of drivers. TensorFlow is a free flexible open source library in Python. It was developed by specialists of the Google AI organization. This library has high support in deep neural networks like training and inference. OpenCV is a free open-source library in Python. It has a high performance in machine learning, computer vision, and image processing tasks such as object tracking, face detection, and many more tasks. It can recognize faces, eyes, and all objects from videos and images. This tool will monitor every image picked by the webcam and then feed this image into the proposed system model of deep learning to classify the eyes of the driver if it is opened or closed.

Keras is a free open-source library in Python. It is a built-in library that provides a high-performance Artificial Neural Network. This tool is used in building the proposed system classification model. Pygame is a free open-source library in Python. This tool is used to produce sound to alarm the drivers immediately to pay attention by detecting the driver's closed eyes. Figure 7.1 represents part of the Python code for the proposed system.

8. Smart cameras. Smart cameras are used in the proposed system to monitor the behavior of the driver and detect all the sign of drowsy or non-drowsy. 16-megapixel cameras were used for capturing the photos to be ensured photos with high quality. These cameras are equipped with the advanced of computer vision and image processing algorithms that responsible for analyzing different movement and facial features for detecting

```

import cv2
data = []
labels = []
for j in [60]:
for i in [10]:
vidcap = cv2.VideoCapture('drive/My Drive/Fold5_part2/' + str(j) + '/' + str(i) + '.mp4')
sec = 0
frameRate = 1
success, image = getFrame(sec)
count = 0
while success and count < 240:
landmarks = extract_face_landmarks(image)
if sum(sum(landmarks)) != 0:
count += 1
data.append(landmarks)
labels.append([i])
sec = sec + frameRate
sec = round(sec, 2)
success, image = getFrame(sec)
print(count)
else:
sec = sec + frameRate
sec = round(sec, 2)
success, image = getFrame(sec)
print("not detected")

```

Fig. 7.1: Part of Python code for the proposed system

all drowsiness signs. The most common features of driver are blinking eye rate, the duration of driver's eye closure and head pose. If the camera detect the closing of his eyes for period of time or his head was drooping, sound alarm will produce to stop driving and take a break. [34] [35] This type of cameras will combined with sensors and artificial intelligent or machine learning algorithms to increase the accuracy of this proposed system. Figure 8.1 shows the smart cameras.

Overall using of smart cameras in this proposed system can help in reducing the accidents risk that caused by drowsy driving and improve overall driver safety [36].

9. Alert device. The alert device is very important part in proposed system. The purpose of this part is to alert the driver when the system detects signs of fatigue and drowsiness. It is used in helping to avoid accidents caused by driver's inattention [37]. The alert device used in proposed system is Audible alerts that can include chimes, beep, or other sound that can triggered when the system detects signs of drowsiness. This type of alert is very effective at getting the attention of driver and can be customized and suitable for the driver's preferences. There are different factors the alert device used in this proposed system such as the type of vehicle, the preferences of driver, and the specific requirements of the system. The alert device that is choice is very powerful at getting the driver's attention to take action to avoid accident trough drowsiness.

10. Stacked deep convolution. This type of convolution called stacked con-volutional neural networks (CNNs) is used in the proposed system to improve the accuracy of this system. CNNs are a kind of deep learning algorithm was designed for processing all visual information such as videos and images. The stacking

Fig. 8.1: Smart cameras

Fig. 10.1: The images in different states Drowsy or None

with multiple CNN layers allows for more complex features to be detected and leads to high performance in classification. In the context of the proposed system this type of convolution used in analyzing video data and fed as CNNs input ,from the camera mounted on the vehicle dashboard , and the output of the proposed system is a prob-ability score indicating the driver's drowsy by producing a beep sound from an alert device. The CNNs are trained for detecting all drivers' features such as head nodding, changes in facial expression, and eye closure that are indicative of drowsiness [30]. Through building the proposed system using CNNs a dataset is gathered of images shows the drivers with open, closed eyes, and images that show drivers with different levels of drowsiness. In addition of that the images include different angles of driver position and lighting condition to ensure that CNN can recognize the drowsiness in different real world. Figure 10.1 shows the images in different states.

Also, CNN can be trained in learning all the features like (head nods, droopy eyelids, slower eye movements) that are indicative of drowsiness. CNN output has the ability of driver's classification as asleep, drowsy, or alert.

In this proposed system it is used a technique called data augmentation which include creating variations of the original images for increasing the dataset size.

Overall, CNN is a powerful tool for driver's drowsiness detection because it can be accurate in recognizing the patterns in real-time for indicating drowsiness and producing an alert to the driver to take action to prevent accidents.

Table 11.1: The experiment of the proposed system

Samples	Total	Training	Validation	Testing
Number	3000	1500	800	1500
Drowsy	1500	700	300	500
Non-Drowsy	1500	800	500	1000

Fig. 11.1: Chart represents experiment data of the proposed system

11. Experiments and Analysis. The proposed system "Driver Drowsiness Detection" is an important area of research that aims to prevent accidents caused by drivers fatigued. It used a deep learning algorithm and some Python tools for feature extraction and classification (drowsy or not). This system is prepared to analyze the driver's faces depending on dynamic sequences of captured photos. There are two types of experiments were performed here. The first experiment is collecting a dataset, it generates a dataset with 3000 images see Table 11.1. The second experiment is performed in videos.

Out of 3000 images used for the experiment in the proposed system, 1500 images are drowsy and others are non-drowsy. For experimenting, 1500 images were used for training, 800 images were non-drowsy, and 700 images were drowsy. A total of 800 images were used for validation samples, 300 images were drowsy, and 500 images were non-drowsy it was diagnosed in several milliseconds. An 1500 images are used for testing, out of 500 images are drowsy, and 1000 images are non-drowsy Figure 11.1 shows a chart for experiment data. The accuracy of the proposed system is about 99.1% after testing the dataset. During the second experiment, the video frame was captured through smart cameras and generated an alarm by an alert device when the proposed system predicts drowsy. The static images are used in the training phase, but through the testing stage, the keyframe is extracted from continuous videos captured by smart cameras.

12. Conclusion. In this paper a new tool was proposed as a saver strategy for vehicle drivers through taking alcohol, drugs, and lack of sleep to protect them from expected accidents. In this state, it builds a monitoring system for detecting drowsiness. This system distinguishes between non-drowsy and drowsy and generates an alarm sound when the eyes are closed.

There are different algorithms and materials are used in such detection. A Viola-Jones detection algorithm is used for detecting the face and eye portion. The learning phase includes extracting all features of the driver's face by using a neural network algorithm called stacked deep convolution. The accuracy of the previous works is low in more time and most of these papers are surveys, which is why it prepared a real-world practical system to protect the people from the high numbers of accents. Support Vector Machines (SVM) is a supervised machine learning algorithm that is used in the classification of Driver Drowsiness Detection to identify drowsy or non-drowsy drivers depending on all based features. An alert device is used proposed system to alert the driver when the system detects signs of fatigue and drowsiness. Smart cameras with 16-megapixel were used for capturing the photos and videos to ensure that the photos were of high quality to monitor the behavior of the driver and detect all the signs of drowsy or non-drowsy. Python tools are used in this system like TensorFlow,

OpenCV, eras, and Pygame. These Python tools are used to detect the closed eyes of drivers. The accuracy of the proposed system is about 99.1%. Out of 3000 images used for the experiment in the proposed system, 1500 images are drowsy and others are non-drowsy. Generating alarm sound from the alert the device effectively when the proposed system identifies drivers' drowsiness.

13. Acknowledgment. The authors would like to show their gratitude to the Universities of Mosul and Technical College Kirkuk, Northern Technical University in Iraq for providing encouragement and support. There was no funding for this study.

ENSEMBLE TRANSFER LEARNING FOR BOTNET DETECTION IN THE INTERNET OF THINGS

ALI AALSAUD*, SHAHAB WAHHAB KAREEM[†], RAGHAD ZUHAIR YOUSIF[‡] AND AHMED SALAHUDDIN MOHAMMED[§]

Abstract. Botnet attacks are just one security scalability problem that nearly comes as a default with each and every new IoT system launched into the real world. IoT devices, in particular, are tricky to locate on a network with standard methods of botnet detection due to their inherent volatility and system constraint developments. To this aim, we propose an ensemble method for botnet detection based on transfer learning that mitigates those drawbacks. The representation learning-based method is used to deliver a domain-adapt transfer of data between two domains (one that has traditional network data and other that contains IoT devices). Ensemble Method This technique improves the detection accuracy and robustness by employing pre-trained models and customizing them to the target IoT environment using many models working together. The ensemble transfer learning system includes low-level base classifiers (e.g., AlexNet, VGG16, inceptionV3, Mobile Net) that are trained on various IoT data and features. To utilize the domain-specific information effectively, the authors investigate model stacking and domain adaptation as two transfer learning strategies. The authors also consider feature engineering methods to determine signatures of IoT behavior and aid their models to distinguish between normal device behavior and botnet activities. The authors also perform extensive experiments on real-world IoT datasets to show the efficacy of the proposed ensemble transfer learning approach. In comparison to single-model techniques, the results show considerable gains in botnet detection accuracy, sensitivity, and specificity. The ensemble technique is also resilient to different IoT device types and network circumstances, making it appropriate for real-time deployment in various IoT contexts. In comparison to single-model techniques, the results show considerable gains in botnet detection accuracy, sensitivity, and specificity. The ensemble technique is also resilient to different IoT device types and network circumstances, making it appropriate for real-time deployment in various IoT contexts.

Key words: Deep Learning, Botnets, Detection, Transfer Learning, Internet of Things.

1. Introduction. The Internet of Things (IoT) has witnessed unprecedented growth, leading to an ever-expanding network of connected devices. This rapid expansion, while beneficial, introduces significant security vulnerabilities, particularly in the form of botnet attacks. Botnets, networks of compromised devices controlled by attackers, pose a substantial threat due to their capacity to execute coordinated cyberattacks, data breaches, or distributed denial-of-service (DDoS) operations. The IoT environment, characterized by its dynamic nature and diverse array of devices with varying capabilities, presents unique challenges for botnet detection. These challenges are compounded by the resource constraints inherent to many IoT devices, which limit the effectiveness of traditional botnet detection methods primarily designed for more static, homogeneous network environments [1][2].

Unlike traditional networks, IoT ecosystems comprise a wide variety of devices with different hardware configurations, communication protocols, and data generation patterns. This heterogeneity makes it particularly challenging for conventional botnet detection techniques to accurately identify malicious activities. The limitations of these methods in the context of IoT's diverse and dynamic nature necessitate an innovative approach to enhance the accuracy and efficiency of botnet detection. In response to these challenges, we propose a novel ensemble method that leverages the capabilities of transfer learning to improve botnet detection in IoT ecosystems. Transfer learning, a powerful deep learning paradigm, allows for the transfer and adaptation

of knowledge acquired in one domain (the source domain) to a new, relevant domain (the target domain), in this case, IoT environments [4][5]. Our ensemble approach intelligently utilizes pre-trained models from source domains, such as traditional network data, and optimizes them for effective functioning within the IoT domain. It incorporates multiple base classifiers, including renowned deep learning architectures like AlexNet, VGG16, InceptionV3, and MobileNet, each fine-tuned to the unique data and characteristics associated with IoT devices.

To effectively leverage knowledge from the source domain, our study explores various transfer learning strategies such as model stacking and domain adaptation. Additionally, we delve into feature engineering techniques specifically designed to capture the unique behaviour patterns exhibited by IoT devices. Existing botnet detection approaches in IoT environments often struggle with scalability, adaptability, and accuracy. These methods typically fail to account for the heterogeneous and evolving nature of IoT networks, resulting in suboptimal detection and increased false positives. There is a clear gap in developing detection techniques that can dynamically adapt to the IoT's varied landscape while maintaining high accuracy and low resource consumption. Our Contribution: Addressing these challenges, our research introduces a novel ensemble method leveraging transfer learning to improve botnet detection in IoT environments. This approach represents a significant advancement in several ways:

Adaptation to IoT Heterogeneity: By employing transfer learning, our method adeptly adapts knowledge from traditional network contexts (source domain) to the diverse IoT environment (target domain), a crucial step overlooked by existing methods.

Incorporation of Advanced Deep Learning Models: We use well-known architectures like AlexNet, VGG16, InceptionV3, and MobileNet, each fine-tuned to IoT-specific data characteristics, a strategy rarely adopted in conventional IoT security solutions.

Customized Feature Engineering: Our method involves developing feature engineering techniques tailored to the unique behavioral patterns of IoT devices, enhancing the precision in differentiating between normal operations and botnet activities.

We empirically validate our approach using a full validation to demonstrate the strength of our method in detecting anomalies at a higher level compared to existing approaches available with a single model, on a number of IoT datasets from our industry partners. **Flexibility and Range of Use:** Our ensemble method is extremely well-suited for real-time deployment across a wide range of IoT settings, and it is robust to different types of IoT devices and network conditions. This study aims to solve a critical deficiency in IoT security by building the new, efficient, and scalable botnet detection methodology. This work allowed us to set new baselines in Internet of Things (IoT) security and will continue to accelerate progress in this key area. **Large-scale Trials on Real-world Internet of Things Datasets to Evaluate Ensemble Transfer Learning Method Results** obtained illustrate significant improvements in botnet detection accuracy, sensitivity and specificity in comparison with common single-model methods. What's more, our ensemble approach is robust and can resistant to a wide range of IoT devices and network environments, which renders it a suitable choice for real-time transmission in a variety of IoT scenarios.

2. Literature Review. Traditional botnet detection algorithms do encounter some limitations when applied in IoT scenarios, simply because they can be stemming from more conventional network data. The diversity of IoT devices in their hardware configurations, connection protocols and data patterns make it difficult for traditional methods to properly detect botnet activities. In this paper, we provide solutions to these problems through presenting an ensemble-based transfer learning technique to achieve higher accuracy on IoT Botnet detection [6]. One major concern is that IoT systems are not built with security in mind, and this poses significant concerns for botnet attacks. The Internet of Things (IoT) is so diverse and constantly developing that it represents an issue for traditional botnet detection technology, because this technology was created to operate in environments that are more stable and homogenous. Such solutions are typically too inflexible to manage the huge array of hardware configurations, communication protocols, and the vagaries of data patterns in a IoT network. To this end, the current research gap calls for the development of detection techniques that are more flexible and reliable, which are able to take the unique characteristics of IoT devices into the account.

Our study proposes this new ensemble method which leverage transfer learning to advance the botnet detection in IoT ecosystems to address these problems. Transfer learning is a powerful deep learning technique

that allows knowledge gained in more general network environments (source domain) to be transferred to the IoT (target domain). This is must do for remediation of issues that are in mainstream practice which do not account with IoT network of hundreds of other protocols. applying an advanced ensemble-learning approach to reinforce the security of IoT devices. Bandara addressed the concern over increasing security threats, in particular scale-based botnet attacks, in the changing IoT landscape. How does a botnet work, and how might cybercriminals use botnets to carry out DDoS attacks, or cyber-attacks and data breaches? Traditional intrusion detection Approaches which are designed for static network data, find it hard to keep pace with a constantly changing and resource constrained nature of IoT devices. The authors propose a conceptual model for transfer learning in ensemble learning to address these issues.

Transfer learning is really the ability to generalize from one area to another. In this transference of data between classical networks and IoT devices, an advantage is that the capability of detecting botnets is enhanced [7]. This is echoed in the further security challenge in IoT contexts raised by the authors, namely the detection of attacks which could have significant impact on the available linked devices [8]. The model improves the efficiency and accuracy of identifying cyberattacks by modifying transfer learning towards the constrained nature of IoT networks. The collaborative part of the model of many Internets of Things (IoT) devices then shares to teach other devices to recognize threats. Each device adds its own strengths to the collective model, by tapping into the pool of knowledge accumulated by all other contributors. Zhang and his team used this type of collaborative learning to fine-tune the model to work with various IoT networks and devices. This research article uses realistic IoT network data going through the Deep Transfer Learning model. In [9] this research aims to improve the security of IoT networks in terms of an easy way to detect potential security vulnerabilities and attacks. Deep Transfer Learning: One DNN based approach, which uses transfer learning techniques and the idea is to shift from one domain to the other, one can be some common network traffic, but the other will be IoT devices. This helps the model to get better at detecting based on how the IoT devices behave and its unique properties. The performance of Deep Transfer Learning model is validated with the results from the experiments in this study. Results of statistical investigations using real-world IoT datasets show that our model can attain improved intrusion detection accuracy when compared to most traditional single-domain techniques.

Transfer learning is employed in the proposed IDS which refers of transfer learning and Optimized Convolutional Neural Networks (CNN), two vital methods. However, due to the number of threats in the IoV domain, transferring previously learned models to IoV environment improves the DL model. The data from the IoV can be easily and accurately extracted as features through the optimized CNN architecture. This paper examines the Transfer Learning and Optimized CNN-based IDS in the IEEE International Conference on Communications (ICC) 2022 and then evaluates its performance. In this section, we evaluate the intrusion detection performance of our model using IoV datasets from the real world. The findings indicate how efficient the design is in monitoring and blocking attacks in IoV networks. This is the brief introduction about the detection by deep learning according to the tabulated form Table 2.1. For example, article [11] likely expresses the depths of progressive neural networks can be applied to enhance the mechanism of IIoT security defense. This is may be an opening paragraph about how IIoT systems need better detection principles and a more complex threat landscape The next paragraph will provide examples of the neural network topologies of the most convenient architecture, consider in which patterns they are operating, their low-level responsiveness and accuracy of threat detection. Authors of this study [22] may have some experience detecting malware on IoT devices with machine learning. P1: New malware advancements make them harder for untrained eyes to know where they are, and security threats in IoT are always changing. Then the next paragraph could explain how IoT networks are deployed, which machine learning models are working and how well those models detect different types of malwares. The authors probably explore potential transfer learning uses in the domain of Internet of Things intrusion detection.

Next section will then discuss a definition of transfer learning, its traditional applications, and how it can be applied to the area of Security in the Internet of Things (IoT). The next part will likely detail the ways that transfer learning might raise robustness of anomaly detection of intrusion attacks against zero-day attacks and decrease the time needed for retraining take place [13]. This article provides an ensemble tree model which might help them to detect intrusions occurred in IIoT. Previously an explanation of why ensemble methods

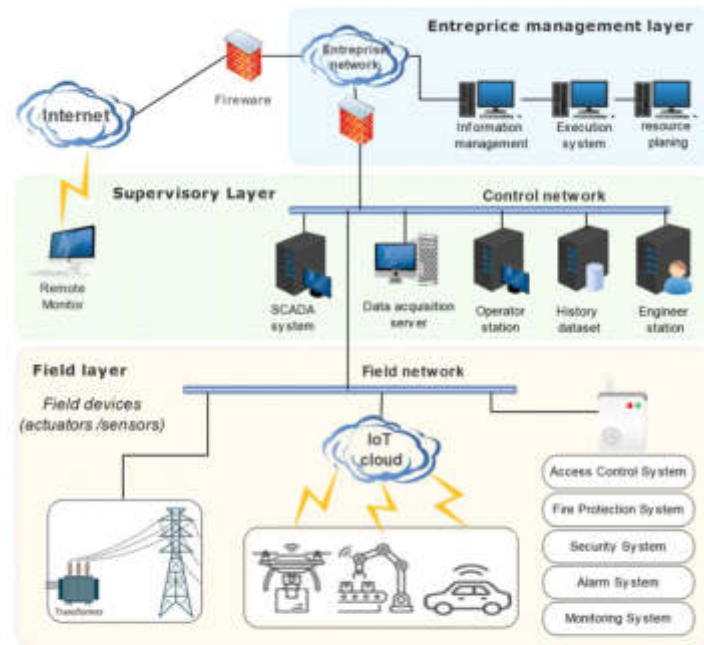

Figure 1 The general layout of an ICN.

Fig. 2.1: The general layout of an ICN

are so powerful for detection, please check the first paragraph. For example, paragraph one could cover the benefits of using an ensemble model rather than single model approach, the architecture of the model, and the performance of the model in different IIoT scenarios [14]. Threat Model for Smart Home Attack Detection using Transfer Learning is depicted in [15], hence, this article likely discusses SALT, as an approach to danger prediction in smart home settings, which is based on transfer learning. Perhaps even some notes on the use of transfer learning and on some of those security considerations that smart homes have. However, as you will see, this opens the door to a detailed description of SALT design and how it extends previous work, and where SALT is useful in a smart home scenario presents a hybrid IDS based on different techniques for the protection of IoT [16]. The first paragraph can list the advantages of hybrid systems, as well as provide an overview of how it works. You can expand more about the hybrid strategy which was used and how the different methodologies have been incorporated and categorize it more effective in the overall system in second paragraph [17].

3. Methodology. The Internet of Things (IoT) is an oven of problems the minute it grows into such rapid proportions where wreaking havoc through botnet attacks is a recurring theme from the security risks to devices that come about. This will include ensemble approach using transfer learning for to leverage IoT botnet discovery. By taking an ensemble approach to combine the intelligence of multiple models, the approach devised improves the robustness and accuracy of botnet detection. The goal of this approach it to combine the base classifiers so that the mistakes of one base classifier are corrected by the another in order to detect Internet of Things (IoT) devices participating in botnet activities.

Figure 3.1 shows the complete proposed model Transfer Learning is one such paradigm of deep learning in which the knowledge from one domain (source domain) is transferred to adapt and be used in the other domain. In this work, they propose to transfer from the source domain (conventional network traffic) to the target domain (IoT devices). This allows the models to adjust their conduct to carry out effectively in the IoT environment based on what they learned previously. Basic classifiers such as AlexNet, VGG16, inceptionV3, and MobileNet are employed to enhance the transfer learning process. These models have been adapted to

deal with data that is suitable for IoT and the IoT botnet-originating features. To fully utilize the learned information from the original domain, researchers are also exploring model stacking and domain adaptation-based transfer learning approaches, which stack multiple models and transfer one (trained) or few top layers respectively.

These techniques are aimed at enhancing the pre-trained ones to detect botnet activities on Internet of Things devices. The Technique, in its suggestion, solves the security issues arose by the rapid growth of Internet of Things (IoT) and the botnet attacks. The technique tackles these challenges by achieving significant improvement in botnet detection performance using feature engineering, pre-trained model adaptation, ensemble learning, and transfer learning. This versatility in how it handles various classes of IoT devices and networking environments gives the method greater practical value for IoT environments that companies will encounter in reality. The work offers a valuable perspective on IoT security from the aspect of botnet identification using deep learning. In this paper, an ensemble approach with transfer learning is recommended for detecting botnets in IoT environments. Traditional methods are ineffective at identifying botnets across diverse IoT use cases.

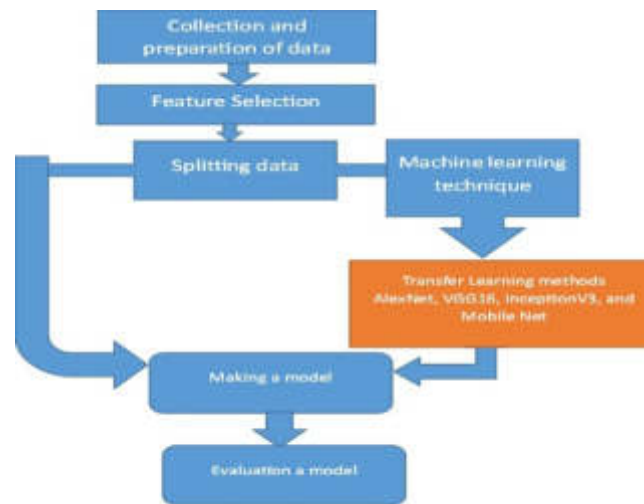

Fig. 3.1: Overall Proposed models

This strategy is designed to combat those limitations.

1. The ensemble learning method is used to increase the accuracy and robustness of botnet detection by aggregating different model intelligences. Ensemble learning is used to detect this botnet behaviour in IoT devices as ensemble learning is the process in which the strong model is built by combining multiple base classifiers.
2. This is a knowledge transfer and adaption approach A data can be transferred from one domain as traditional network data and can be adapted in to another domain, i.e. the domain of Internet of Things devices. Using their earlier training, the models can adjust to the IoT environment.
3. Use Of Pre-Trained Models: For peak performance with IoT data, leverage pre-trained models like AlexNet, VGG16, InceptionV3, MobileNet. These models have been further fine-tuned to detect botnets under IoST environment. Step Four: Repair Data Imbalances Which can easily fixed by using something like over- or under-sampling, or generating fake data in data preprocessing. Data normalization and feature engineering comes under cleaning and preparation for analysis phases
4. Model Training: Multiple Resources for training 75 To a quire model training use Transfer Learning technique because we do have to train a model on a training data. All the measurements e.g. accuracy, sensitivity, and specificity are executed in a testing set;
5. For the 5th step, the data has been separated into two groups 75 to be used for training and 25 for testing and apply Transfer Learning transfer learning to train the model using the training data. Evaluate the model on testing set using measures in terms of accuracy, sensitivity and specificity.
6. Model Optimization and Validation: Apply model stacking and domain adaptation techniques for optimization. Conduct extensive tests with the iot23 dataset to assess the models performance.

Experimental Flowchart:

- Step 1: Gather data from the iot23 dataset.
- Step 2: Address data imbalance and preprocess data.
- Step 3: Divide data into training and testing sets.
- Step 4: Implement Transfer Learning and train the model.
- Step 5: Test and evaluate the model.
- Step 6: Optimize the model using advanced transfer learning methodologies.

Contribution of the Methodology. Our methodology addresses the security issues posed by botnet attacks and the rapid growth of IoT. It significantly enhances botnet detection accuracy using ensemble learning and transfer learning techniques.

The methods adaptability makes it suitable for real-time deployment in various IoT environments.

The following is the architecture of AlexNet: AlexNet model is a deep convolutional neural network (CNN) based on 5 convolutional layers and 3 fully connected layers. The first convolutional layer applies 96 11x11 filters with stride 4, followed by a ReLU activation function and max pooling with 3x3 size and 2 stride. 2nd CONVOLUTIONAL LAYER -> RELU -> MAX POOLING (3x3 strides 2) Convolution Layer 2:256 5x5 filters, stride-1 the fourth and fifth convolutional layers have 256 filters each but they have a size of 3x3 and stride of 1. Each fully-connected layer has 4096 units after a dropout to curb overfitting, followed by a ReLU activation function. The last layer, with an sigmoid activation used for binary classification.

VGG16 is made up of 16 layers, of which there are 3 fully connected layers and 13 are convolutional. And a CNN which have deep learning functionality. Each convolutional layer is followed by a ReLU activation function and a 2x2 max-pool with a stride of 2. Similarly for each layer: 3 by 3 filters and stride of 1. Every fully connected layer has 4096 units following a dropout to prevent overfitting (and a ReLU activation function). Zeros layer: Binary classification with sigmoid activation The inception module, a dense layer containing filters of all possible sizes, is used in deep CNNs (eg, InceptionV3) to identify patterns when featurized data is streamed into our computation frames. By stacking these Inception modules we allow the model to learn even more complicated features. Global Average Pooling Layer is being used that instead of reduce the parameter counts and avoid overfitting i.e. replacing fully connected layers with average pooling. The simple example would be a single unit with sigmoid activation, as the last layer for binary classification. These models are each optimized using the Adam optimizer and trained using a 32-person batch size over 10 epochs. Accuracy is employed as the evaluation metric, while binary cross-entropy is the applied loss function. During the training process, the training data is divided into two portions: 75% for training and 25% for validation. With the iot23 dataset, the objective is to identify botnet activities as accurately as feasible.

4. Discussion and Result. The iot23 dataset is a benchmark dataset created especially for analyzing the performance of machine learning models in the context of intrusion detection and IoT (Internet of Things) network traffic analysis. To answer the demand for standardized and varied datasets for IoT-related security research, a team of researchers created it. The iot23 dataset is very useful for researching the security issues and dangers that IoT settings must deal with because it is made up of network traffic data that was gathered from actual IoT devices and scenarios. The dataset offers a thorough depiction of IoT network traffic because it covers a variety of IoT device types, communication protocols, and traffic patterns. The iot23 datasets accessibility has considerably advanced IoT security research, particularly in the areas of intrusion detection and network traffic analysis. This dataset is made available to network and IoT researchers, developers and the like to enable the advancement of robust and secure machine learning models and algorithms against the threats on networks and IoT devices. The ensemble approach is evaluated for botnet detection in IoT23 dataset, and the performance in terms of the accuracy, Precision, Recall, F1-Score are the performance criteria.

Check the Ensemble model how much good predicting overall. This calculates the number of times the event is accurately predicted (ie true positive and true negative) as a percentage of the total number of cases in the dataset. It means our ensemble model is predicting some substantial amount of our dataset correctly which lead to a high accuracy score. The accuracy of the ensemble model means how much it can spot the botnet instances while expecting them. It is the proportion of prediction cases in which botnet detection has been predicted to the total number of detection cases even wrong ones. Higher precision scores means that the ensemble is more likely to treat instances as a botnet accurately. Recall (also known as sensitivity, or true positive rate) is a metric which tells, what is the ensembled models ability to find all the botnet instances out of all the true botnet instances (labeled as true by the data owner). This is done by computing the number of true positives divided by the total number of botnet instances in the dataset (including the ones which were false negative). A good recall score means, the ensemble model is detecting most of the instances of botnet correctly.

The harmonic mean of recall and precision is known as the F1-Score. It offers a balanced measurement that accounts for both recall and precision. When the distribution of the classes is unbalanced, the F1-Score is helpful. It has a value between 0 and 1, with a higher number indicating better performance. Achieved results compared with related work [26][27] and [28].

The performance outcomes of various botnet detection algorithms using Accuracy, Precision, Recall, and

Fig. 4.1: Accuracy comparison of the proposed model

Fig. 4.2: F1_Score comparison of the proposed model

F1-Score as evaluation criteria. The accuracy is shown in Figure 4.1. It is the proportion of cases in the dataset that were successfully predicted to all other instances. The model is better able to produce accurate predictions the higher the accuracy. Accuracy = 71.72 KNN (K-Nearest Neighbours) for NB (Naive Bayes) [26] [26]: GBM (Gradient Boosting Machine) Accuracy = 97.51 [27]: MLP (Multi-Layer Perceptron) Accuracy = 99.452 [27]: Precision is 97.842. Accuracy of CNN 3D (3D Convolutional Neural Network) [28]: 98.13 Accuracy of proposed models: 99.95.

Figure 4.2 shows the f1-score, The F1-Score provides a balanced measurement that takes into account both measures because it is the harmonic mean of precision and recall. When the distribution of classes is unbalanced, it is helpful. Naive Bayes (NB) F1-Score is 52.01 in [26]. K-Nearest Neighbors (KNN) F1-Score is 97.05 in [26]. Machine for gradient boosting [27]: MLP (Multi-Layer Perceptron) F1-Score = Not Available (-) F1-Score = Not Available (-), [27] 3D Convolutional Neural Network or CNN 3D F1-Score is 98.1 in [28]. Models suggested: F1-Score = 99.25.

Figure 4.3 shows recall, The capacity of the model to accurately identify positive cases among all of the real positive examples in the dataset is measured by recall (also known as sensitivity or true positive rate). It measures the proportion of real positives to all actual positives. Naive Bayes (NB) [26]: KNN (K-Nearest Neighbours) Recall = 36.11 Recall = 96.44 [26], 3D Convolutional Neural Network, or CNN 3D Recall = 98.09 [28], suggested models 99.2 of the time.

Precision is a measure of the model's ability to reliably detect positive cases (such as instances of botnets) among those that it expected to be positive. It is the proportion of actual positive results to all expected positive results. Naive Bayes, or NB [26]: Exactness = 92.89 the K-Nearest Neighbours method [26]: Precision GBM (Gradient Boosting Machine) = 97.67 [27]: MLP (Multi-Layer Perceptron) Precision = Not Available (-)

Fig. 4.3: Precision comparison of the proposed model

Fig. 4.4: Recall the comparison of the proposed model

Precision = Not Available (-) [27], Using a 3D convolutional neural network, CNN 3D [28]: Exactness = 98.1, Precision = 99.08 for the proposed models, as shown in Figure 4.4.

5. Conclusion. An extensive and practical solution for botnet identification in IoT contexts is provided by the suggested ensemble transfer learning model. The suggested strategy provides a potential method for enhancing IoT security and reducing botnet threats in the changing environment of connected devices by utilising the power of transfer learning, customising previously trained models, and utilising ensemble methodologies. Instead of all that work, the ensemble-methods approach has been proposed to resolve the safety problems that throw up when Internet of Things (IoT) is getting into Its stride. There is a method that greatly increases botnet detection accuracy: this strives after feature engineering and then fits the pre-trained model in particular for your purpose in addition, it is suitable for real-world IoT applications as it can fit with diverse IoT device types and network settings. Numerical results for the method proposed are given, together with comparisons to relevant previous studies. The model's performance is evaluated by using accuracy, precision, recall and f1-score as metrics. Out> The results indicate that the proposed ensemble transfer learning approach is better than any of the other classic machine learning or deep learning models> mentioned in the study, with respect to accuracy, precision, recall and f1-score. In a word, for pure performance the suggestion is best: transferring learning approach It achieves good results on accuracy, precision, recall and F1-Score in a proof of its efficiency for detecting botnet action within the IoT scenario of context. Finally, there is the conclusion. The iot 23 dataset, which is used as a standard comparison data set for machine learning models in network traffic analysis and intrusion detection among the Internet of Things (IoT), has great significance here. The depiction in the dataset of a variety of different IoT device types, communication protocols, and traffic patterns benefits IoT security research greatly. By accurately identifying botnet activity, the ensemble approach with transfer

learning for deep learning-based botnet identification greatly improves IoT security.

SECURE MEDICAL IMAGE RETRIEVAL USING FAST IMAGE PROCESSING ALGORITHMS

SAMEER ABDULSTTAR LAFTA * AMAAL GHAZI HAMAD RAFASH † NOAMAN AHMED YASEEN AL-FALAH ‡
HUSSEIN ABDULQADER HUSSEIN § AND MOHANAD MAHDI ABDULKAREEM ¶

Abstract. Content Based Image Retrieval (CBIR) is a relatively new idea in the field of real-time image retrieval applications; it is a framework for retrieving pictures from diverse medical imaging sources using a variety of image-related attributes, such as color, texture, and form. Using both single and multiple input queries, CBIR processes semantic data or the same object for various class labels in the context of medical image retrieval. Due to the ambiguity of image search, optimizing the retrieval of a query picture by comparing it across numerous image sources may be problematic. The goal is to find a way to optimize the process by which requested images are retrieved from various storage locations. To effectively extract medical images, we propose a hybrid framework (consisting of deep convolution neural networks (DCNN) and the Pareto Optimization technique). In order to obtain medical pictures, a DCNN is trained on them, and then its properties and classification results are employed. Explore enhanced effective medical picture retrieval by using a Pareto optimization strategy to eliminate superfluous and dominant characteristics. When it comes to retrieving images by query from various picture archives, our method outperforms more conventional methods. Use the jargon of machine learning to propose a Novel Unsupervised Label Indexing (NULI) strategy for retrieving picture labels. To enhance the effectiveness of picture retrieval, we characterize machine learning as a matrix convex optimization using a cluster rebased matrix representation. We describe an empirical investigation on many medical picture datasets, finding that the search-based image annotation (SBIA) schema benefits from our suggested method. As a result, CT images of the lung region are explored in this study by constructing a content-based image retrieval system using various machine learning and Artificial Intelligence techniques. Real-world applications of medical imaging are becoming more significant. Medical research facilities acquire and archive a wide variety of medical pictures digitally.

Key words: Medical image, Image retrieval, Image processing

1. Introduction. Raw images captured by spacecraft, satellites, and cameras in our everyday environments may have their usefulness greatly enhanced by the use of image processing techniques. In the last ten years, several image processing programs have been created. Image processing systems are currently the most popular due to the ease with which personal computers can be maintained, the wide availability of graphics software, and the large capacity of memory devices, etc. [1]. Most of these methods were developed to make use of images obtained from unidentified space probes in real time. Image Processing relates Analogy: It describes the alteration of image via electrical data representation, example for this type of data representation is television, and television signal represents various amplitude to access brightness of image with significant pixel extraction [2].

Processing of digital image. Digital image computer processing with respect to different pixel dimensions, Image can be directed into different dimensions, it defines parallel data objects to serious of pixel operations to retrieve efficient results from original picture representation with image notations. The main advantage of digital image processing is to extract original data precision [3].

The main presentation of this approach is to define magnification of image for effective pixel identification and image. Image to image with different pixel factors in recent formations. Analysis of image is concerned with different measurements from image to image to extract image description with representation of image with pixels. Analysis of image approach describes the features of finding different objects on semantic image

feature representation [4].

In image segmentation process, divide image into different equal parts from input image, segmentation follows isolated applications with respect to interest of objects based on pixel value presentation of original image into sequential feature extraction from original data evaluation in pre-processing with autonomous contents in real time application development. Classification is the label of similar group pixel based on its grey value presentation, in information retrieval information classification is the main effective and mostly used method. Classification is set of pixels with multiple features of particular images [5].

Removable and reduction of degradation of image is called image restoration, it includes de-blurring of images, filtering noise pixel information and data presentation for efficient quality of image. Compression is an essential framework to achieve picture data and transfer to network maintenance in reliable pixel formation and presentation that uses Discrete Cosine Transformation (DCT) based on compression feature extraction. Based on these approaches present in image processing, different types of applications were developed in real time with preferable operation presentation [6].

After evaluation of image processing introduction with developing techniques and approaches with different pixel values. Our research mainly focuses image retrieval in image processing. Image retrieval is a foundational concept in the field of image processing, used to locate specific information using either a search query or an image's metadata. Various real-time applications, including healthcare, satellite data, video surveillance, and digital forensics, have made use of the vast amounts of multimedia data that have become available with the spread of multimedia and internet technologies. They were maintaining that multimedia-related data may be stored efficiently with varied characteristics [7] due to the specific needs of these domains. Text Based Image Retrieval (TBIR) is the most used method for retrieving information. Automatic and human picture retrieval from a variety of image sources form the basis of that search. Content Based Image Retrieval (CBIR) is a user-friendly image search retrieval approach that can extract data from many picture sources, unlike TBIR's human effort and time requirements for image retrieval. This is the fundamental architecture for retrieving images sequentially from many sources, with properties like color, shape, texture, and position supplied as feature vectors in several places. This retrieval method will manifest as indexed visual results in response to user queries. Finally, the indexing process is followed by an efficient searching technique of the picture database, and on the basis of this procedure, relevant user input is collected using a variety of visual processes [8].

Medical picture retrieval and searching using that term to get matching information from several medical image sources. The primary goal of this content-based method to medical image retrieval is to sift through a great quantity of data sources, each of which is characterized in terms of the query picture. In addition to the major component of medical images, features are also a key component to investigate utilizing feature matrix vectors to compare with medical image sources, contrasting various relevant and irrelevant characteristics based on original image sources with medical query picture. Challenges in retrieving medical images using various visual criteria, indexing, and clustering methods. For the purposes of this study, this is the primary issue statement for retrieving appropriate medical images from medical image databases [9]. A range of imaging modalities, such as CT, MRI, and X-ray, can be used to identify lung cancer. Due to decreased distortion and noise, the CT scan captures the features seen in distinct areas of the Lungs better than any other imaging modality, allowing radiologists to grasp and identify the occurrence of sickness [10].

Content-based picture retrieval has advanced significantly over the last decade, allowing for faster and more accurate image searches. Despite these advances, many issues remain unanswered. Semantic gap (occurs due to poor degree of pixel quality in feature presentation of pictures and also visual dimensional representation of image with varying index values) is the first challenge to extract data from multiple image sources. Some writers and academics have joined forces to find ways to close the semantic gap in picture retrieval. The large issue of the semantic gap in image retrieval may be broken down into a variety of smaller ones. Therefore, in this work, we single out such issues and provide adequate and practical remedies for them in the field of image retrieval [10]. The literature review is discussed in Part 2, the research methodology is outlined in Section 3, the study's findings and discussion are discussed in Part 4, and the study's conclusion and directions for future research are discussed in Part 5.

2. Literature review. Literature review in respect to Study of Secure Medical Image Retrieval Using Fast Image Processing Algorithms.

To improve picture recovery and recognizability evidence with content-based picture recognition, a method for extracting highlights through linearization of images is described in [11]. The developers tested their approach with 3688 images culled from two publicly available datasets. Regardless of the size of the image, this method reduced the number of highlights to 12. The factual measurements (with respect to correctness and review outcomes) were obtained for evaluation purposes. Misclassification of inquiry images might hinder the strategy's execution as compared to currently available alternatives for data recovery.

Band-based feature extraction and representation was suggested in [12]. If the image is altered, this method will dependably recover the data from the central (most important) objects. Fake neural networks were used for image recovery, with system performance and success measured using three publicly available informative indices (Coil, Corel, and Caltech 101), and recovery proficiency measured via exactness and review values.

Using statistical methods like Welch's t-tests and the F-ratio, [13] suggested a method for image recovery. The two completed visual information questions were reviewed for quality. While the full image is taken into account in the final product, the form is broken down into its component parts according to its orientation in the organized version. The F-ratio test is the first stage in the aforementioned procedure, with successful images moving on to the dynamic range test. The photographs were determined to be comparable if they passed both conditions. If nothing else, they are remarkable. The execution was approved and verified using a Mean Average Precision score. This enables us to create a system that isn't reliant on hand-crafted characteristics, which are typically necessary for other machine learning approaches.

So that surface and shading highlight extraction might have the same effect on CBIR, [14] developed a picture descriptor (Global Correlation Descriptor). The benefits of the structural component connection and insights from the histogram were included into the proposals for the Global Connection Vector and the Directional Global Correlation Vector, which are used to show surface and shading highlights, respectively. Approval was conducted on the Corel-10 K and Corel-5 K datasets, and performance was evaluated based on review and correctness.

In [15] a neighbourhood structure descriptor is proposed for picture recovery. Neighbourhood structure descriptor is made in light of the neighbourhood structures hidden hues; it has consolidated the shading, shape, and surface as one unit for recovery of pictures. Likewise, they proposed a calculation for include extraction which can separate nearby structure histogram utilizing neighbourhood structure descriptor.

In [16] proposed an approach known as picture recovery utilizing an intuitive hereditary calculation for figuring a high number of particular highlights at that point contrasting of related pictures for these highlights. The approach was tried on a gathering of 10,000 general pictures to demonstrate the effectiveness of the proposed approach.

In [17], a CBIR strategy was presented that combines Faster-Up Robust Features (SURF) and Scale Invariant Feature Transform (SIFT). Because SIFT is robust to rotation and scale shift and SURF is more robust to light fluctuations, depictions of these neighborhood highlights are used for recovery. The success of CBIR is enhanced when SURF and SIFT work together. All tests and evaluations were conducted on Corel-1500, Corel-2000, and Corel-1000 computers.

After settling on a visual list of capabilities, the next question is how to point them in the direction of precise image recovery. Over the last several decades, many novel architectural concepts have been put forward at the most fundamental level. Here, we will gloss over the techniques discussed in [18] and instead present a small subset of the more recent approaches.

In [19], a semantically-sensitive approach to content-based image recovery is presented. For effective image matching, a semantic organization (such diagram vs. photo vs. completed vs. non-textured) for extracting relevant elements is necessary, as is a location-based universal comparability measure. The speed with which this architecture can recover is crucial. Using region highlight bunching and the Most Similar Highest Priority (MSHP) guideline, the coordinating measure Integrated Region Matching (IRM) has been developed for faster recovery.

It has been proposed to use a highlight coordinating system for area-based picture recovery with the help of district codebooks and learned locale weights, and efforts have been made to fuse spatial similarity using the Hausdorff remove on limited measured point sets [20].

In [21], an alternative illustration is shown for protest recovery in chaotic images that does not need on

perfect division. A different approach to image restoration is area-based querying, which employs homogenous shading surface parts termed blobs. If a user recognizes at least one segmented blob as being similar to the concept "tiger," then her search may expand to include looking for tigers in other images, perhaps with different backgrounds. All things considered, this may lead to a more semantically accurate depiction of the client's inquiry objections, but it also involves more significant involvement from and dependence on her. Recovery may also be carried out without the client's explicit location marking for the purpose of locating images containing scaled or decrypted forms of inquiry items [22].

The use of multi-leveled perceptual collecting of primitive image highlights and their inter connections to characterize structure has been proposed as an alternative to picture division for the purpose of recovery [23].

Another idea, inspired by data compression and content-based methods, is to use vector quantization (VQ) on image squares to generate codebooks for depiction and recovery [24].

Protest-based image recovery using a windowed search over area and scale has been shown to be more effective than solutions based on erroneous division [25]. The client's inquiry Region-of-interest (ROI) is divided into rectangular parts for a coarser closer view/foundation, and then the frontal portions are used in a database search. Division is not fundamental for whole images. The Kullback-Leibler method for quantitatively analyzing models has been presented as a means of surface recovery through a combined presentation of highlight extraction and proximity estimate.

In [26], we find a proposal for yet another wavelet-based recovery method that makes advantage of striking focuses. It has been shown that image histograms based on fractal square codes are effective in recovering lost data from completed image databases.

In [27], it is explored how MPEG-7 content descriptors might be used to generate self-organizing maps (SOM) for the purpose of image recovery. A secure image recovery framework is one of the recent developments in the field. When tying things down, it's important to discover a group of agent "stay" images and choose the semantic proximity between a self-assertive picture match and these stays in terms of their comparability.

The evaluations for the standard photo recovery task are excellent. For literature published in the 1990s, please refer to [28]. While early frameworks saw widespread use of more elementary features like shade and surface, more advanced features like Significance and Scale Invariant Feature Transform (SIFT) have gained traction in recent years.

In this study, we choose the widely used Bag-of-Words (BoW) representation according to the neighborhood invariant SIFT features. The effectiveness of this component representation has been shown in a number of contexts. Since the focus of this study is on efficient research, this section provides an overview of the state of the art in terms of adept hunt systems, which may be roughly categorized into three groups: updated document, tree-based ordering, and hashing. It's still widely used for record recovery in the data recovery community that the changed file was initially offered [29].

BoW, for example, is quite similar to the sack of words representation of literary records, thus it was familiar with the area of image recovery. In this setup, a list of references to each record (image) for every content (visual) word is created, allowing for quick retrieval of relevant reports (images) in response to questions using just a few words. In any case, the written inquiries often include not very many words, which is a major difference between archive recovery and visual inquiry. For instance, Google online searches often only provide four-word answers.² In contrast to the BoW depiction, a single Medical Image may include several visual words, resulting in a large number of potentially useful images (from the revised data) that need pre-checking, a process often based on similarities to the original BoW highlights. Because of this, the utility of reorganized documents for a wide-ranging visual examination is severely limited. The number of applications may be reduced by increasing the visual vocabulary measure in BoW, which will also significantly raise memory use [30].

2.1. Research methodology. Here we offer a Novel Unsupervised Label Indexing (NULI) method for retrieving image labels, which is a term from the field of machine learning. In order to enhance the effectiveness of image retrieval frameworks, we describe machine learning as matrix convex optimization using cluster based matrix representation. Using the Search Based picture Annotation (SBIA) schema, we outline an empirical investigation on many different kinds of medical picture data sets, finding that our suggested technique provides superior outcomes.

2.2. Methodology. Web oriented medical image retrieval is the most efficient approach to handle processing of image with different structural analysis in real time medical healthcare systems. As World-Wide Web develops at a detonating rate, web crawlers end up noticeably imperative devices for any clients who look for data on the Internet, and web picture look is no special case. Web picture recovery has been investigated and created by scholastic analysts and business organizations; including scholastic models extra hunt measurement of existing web indexes.

The effective extraction of medical images from medical image sources has prompted the development of a number of machine learning-related methods. In real-time applications, such as various medical research identification of approximately matched medical pictures related to input query medical image, medical image annotation is a useful notion. Annotating medical images is a superior idea for retrieving near-perfect matches to a query medical picture. It takes a lot of time and effort to gather various sorts of label medical pictures from huge medical image data sets, which is why traditional medical image annotation systems were established.

Since a huge number of poorly labeled face medical photos are readily accessible on the World Wide Web (WWW), some recent research has attempted to develop an attractive search-based annotation design for facial medical picture annotation. The search-based medical image annotation (SBIA) design is meant to handle the automated face annotation process by utilizing content-based medical picture retrieval (CBIR) techniques, as opposed to coaching explicit classification designs by the standard model-based medical image annotation methods. The primary goal of the SBIA method is to properly align the input medical image's name labels. In particular, given a novel medical image for annotation, we first recover a narrow your search of top K most identical medical pictures from a weakly marked medical image data source, and then annotate the medical image by performing voting on appearance associated with the top K similar medical pictures. In this study, we offer a Novel Unsupervised Label Indexing (NULI) method for retrieving labels of medical pictures utilizing language from the field of machine learning so that we may access these characteristics in medical image retrieval from various medical image sources. The efficient image retrieval framework may be enhanced by defining machine learning as matrix convex optimization using cluster based matrix representation. Our experimental findings show improved performance compared to the status quo when it comes to real-time medical picture retrieval applications using traditional methods.

2.3. Semantic Signatures. Medical image re ranking in web based medical image retrieval with offline and online stages perform medical image reference classes operations to extract medical images automatically from different medical image pools. To avoid ambiguity in medical image query search retrieval from different medical image sources, our proposed approach follows semantic signatures for reference class verification to automatically retrieve medical images. Procedure of the semantic signatures presentation explained with following example.

For example implementation of N reference class labels from input query image q and then pre-processing those images based on sequential selection of trained medical images, multiple class reference classifiers on visual features of pictures are trained and then give M-dimensions vector p , which indicates the probability of newly generated picture I related to different class labels. P is used to describe the semantic image features of input query image Q and calculate the distance between each pixel from I_a and I_b with different pixel notations P^a and P^b .

$$d(I_a, I_b) = \|p^a - p^b\| \quad (2.1)$$

2.4. Separate Features. To separate different medical images based on image features are extracted and then pre-processed them using SVM classifier with following visual features like signature of the colour, Spatiality colour, wavelet pixel formation, invariant notation of histogram and gradient based histogram and GIST. Those medical images are characterized from different features like shape, colour and texture on combined M-dimensions.

A characteristic thought is to join a wide range of visual highlights to prepare a solitary intense SVM classifier which better recognizes diverse reference classes. In any case, the motivation behind utilizing semantic marks is to catch the visual substance of a picture, which may have a place with none of the reference classes, rather than ordering it into one of the reference classes. On the off chance that there are N sorts of autonomous visual highlights, it is in reality more successful to prepare to isolate SVM classifiers on various sorts of highlights

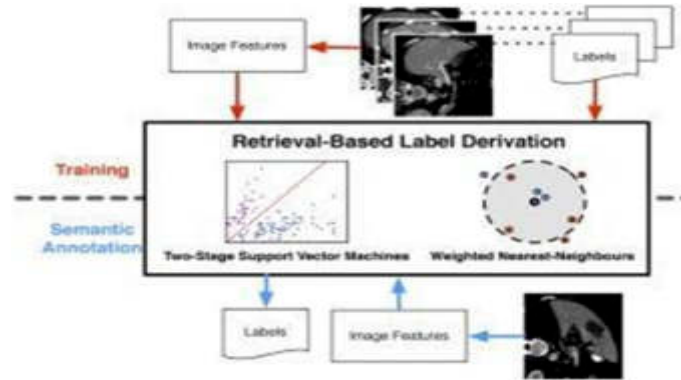

Fig. 2.1: Reference classes between input medical images with different dimensions.

and to consolidate the N semantic signatures $\{p^n\}^N$ = from n classifier present in N semantic signatures based on semantic features n 1 like shape, texture and dimension which describe different class labels in sharing of different images.

For instance, in Figure 2.1, given input as medical image relates to brain, liver with two reference class labels, if another image i.e. matched with source images based on verification of semantic signatures. If high amount of semantic signatures are matched with brain then retrieve relevant matched images with top matched brain images.

2.5. Medical image Reference Class Discovery. For each presented input query q , classify different image index labels. To describe this procedure, arrange images in sequential order i.e. $S(q)$ and describe the retrieved images based on index using query q describe the view of literary data. Query expansion found from different sources with sequential presentation of referable class labels with visual substance of image representation. Also contain subset of images explored with different instances matched with pixels of image at different dimensions.

Every idiom expansion e is used to obtain photos from the internet searcher and matched top $-k$ results with matching semantic keyword expansion for automated learning and retrieval of training medical images with reference classes. First the keyword q , retrieval relevant images sub sequentially extract relevant images matched by q . to find the similarity between images, use k-means clustering approach which are the images consists referable class labels. In this methodology similar group of average matched images are arranged in cluster and describe the exceptions from original images from medical image sources.

Here represents some of the keyword expansions like brain, liver and different keywords which consists identical and semantic visual features to increase the performance. To increase the computational cost in representation of image with different discriminative spaces between pixels in image. Estimate the referable class label index to learn parameters using SVM classifier to classify data into specified data relates to keyword with different pixel notations to find relevancy.

The first two basic training phases, Ai1 and Ai2, are used to extract m reference classes from the preceding procedures. Reference classes $D(i, j)$ will be obtained by using SVM classification learned from Ai1 and Ai2 to distinguish between reference classes i and j . The SVM calculates the likelihood of classifier score for the i class for each reference class. $D(i, j) = h((p_i + p_j)/2)$, where h is an increasing function, if the average score of Ai1 is p_i and the average score of the PJ across A2j is also determined. The production of a single binary bit is described as follows:

$$h(p_i) = 1 - e^{-1}(p_j) \quad (2.2)$$

While and remain fixed, the ratio of $(p_i + p_j)/2$ goes up as $h(p_i)$ goes down, and this trend holds true across all meaningful reference classes.

We describe the different referral class labels from n no. of users. Keyword expansion is used to extract reference class labels which explore mostly matched results with input image. Meanwhile, choose different referable class labels with different functions based on expansion of keyword. Distinct matrix $m \times n$ represents and its procedure in next sections with different parameters. Qualifying measures to solve optimization of image annotation based referable class label representation.

3. Medical image Indexing Implementation. This section describes general implementation NULI for accessing relevant images based on initial sequence factors in image retrieval in medical sources, conversation about problem development in medical picture annotation, criteria execution to catalog medical picture annotations, approximation collection process on function removal to determine medical picture recovery.

We describe $X = md$ is explored different medical features which consist different dimensions with pixels. $= m_1, m_2, \dots, m_n$ defines image labels with annotated pixel representations, m is the label of image. be the labelled matrix which consists weak label data which presents i th and j th rows and columns represents in sequential pixel Y_i formation of medical image $Y = [1, 0]^{m \times n}$. In NULI, individual medical query image from image source to gather relevant images based on label index.

Sequential matrix with class labels is used to illustrate the NULI method. Different values for x and y indicate the content of the label in matrix y . Use convex optimization based on the important features of the class labels to efficiently index photos for labelling. These procedures are used to achieve optimum performance when retrieving medical images based on relevance:

$$E_S(F, W) = \frac{1}{2} \sum_{i,j=1}^n W_{ij} \|F_{i^*} - F_{j^*}\|_F^2 = \text{tr}(F^T L F) \quad (3.1)$$

Matrix weight measure i.e., which comprises of optimal functions to build both "normal" and "fantastic" weight matrices. The following is a description of the representation of matrix regulations:

$$F^* = \arg \min_{F \geq 0} E_s(F, W) + \alpha \cdot E_p(F, Y) \quad (3.2)$$

Non-zero regulatory elements based on feature dimensions are specified by the following matrix parameter:

$$E_p(F, Y) = \|F_{i^*} - F_{j^*} \cdot S\|_F^2 \quad (3.3)$$

We supply an effective label index for each picture so that the development of a matrix of functions may be achieved. To maximize the evaluation in terms of accuracy and recall and others in real-time image processing applications, we will discuss the implementation of the NULI approach, the index label representation for various images, and the automated picture annotation.

3.1. Performance of Experiments. This section user interface implementation procedure of proposed NULI with hybrid approach in re-rank based image retrieval from image pools. Medical image sets are collected from different search engines defined in table 3.1. It describes medical image search engines and sample keywords with how many medical images retrieved from search engines with different keywords. photos. Anisotropic diffusion reduces noise while preserving significant sections of a picture. The lung region is segmented using morphological erosion.

As shown in table 3.1, discuss three publicly available data sets to test performance of proposed approach at various representations. Google image search contain 1000-10000 images to arrange in re-rank with searching relates to search optimizations. This search images spread search procedures with different objects like pixel dimension, calculation of pixel length, time, image patch and sequentially representation of image simultaneously. Data set 2 arrange results in re-rank procedure extracted images from image search of the label 2. Images are combined and get image data from Google search engine at different time frames, re-positioning based image retrieval with different label formation check whether it is present or not. As shown in table 3.1, collect medical images and then semantic signatures with reference classes labelled with different presentation shown in figure 3.1.

Table 3.1: Medical image data sets description with different search engines

Medical image Collection Procedure			
Medical image Data sets	Keywords	Medical images	Search Engine

II	50	1000	
III	20	500	Bing Medical image Search

Fig. 3.1: Relevant medical image for input query medical image based on visual semantic features.

4. Results and discussion.

Data sets. This section describes the set up environment of efficient image retrieval for different real time medical image processing applications. Different medical images taken from <http://www.imdb.com> URL which consist different feature related images, those images consists different labels i.e. data, path and image name. User search images based on name of an image which consist different label procedures. Based on collected data, using JAVA and Net beans software construct search engine to retrieve relevant images automatically whenever input image query matched with source image based on visual features in real time medical image network system. Using a variety of test cases, this section compares and contrasts the NULI method with the conventional method, i.e. a hybrid image retrieval framework. To demonstrate NULI’s efficacy in medical picture retrieval, this illustration contrasts NULI’s performance with that of the conventional method across a variety of metrics, including precision, recall, accuracy, and time. The following is a description of the quantitative analysis used to obtain medical pictures from several medical image sources:

$$\begin{aligned}
 precision &= \frac{No.of\ relevant\ images\ retrieved}{Total\ no.\ of\ images\ retrivd} \\
 Recall &= \frac{No.of\ relevant\ images\ retrieved}{Total\ no.\ of\ relevant\ images\ in\ database} \\
 Accuracy &= 2 \frac{precision * recall}{precision + recall}
 \end{aligned}$$

To obtain weak label medical pictures from many medical image sources, medical image sources include various medical images with various criteria such as labels and features. The findings of the NLUI methodology provide greater accuracy with weak label indexing of each picture from diverse image sources than the traditional approaches and procedures done on medical sources to obtain efficient images. Accuracy compared to conventional methods is shown in Figure 4.1.

Table 4.1: Average error rate and average computation time

Iterations	Average error rate			Average consumption time (sec)		
	Precision	Recall	False positive	F-Measure	Miss Rate	False negative
10	0.5375	0.4	0.35	0.018162	0.012237	0.014621

50	0.125	0.1	0.1	0.004663	0.000629	0.001296

Fig. 4.1: Different types of medical imaging accuracy

For both NULI and conventional methods, i.e. the hybrid strategy shown in Figure 4.2, accuracy is the primary metric for efficiently retrieving similarly matched images from medical sources.

In healthcare related image retrieval related application, recall for weak label image retrieval from medical image sources described in Figure 4.3.

Figure 4.4 shows the accuracy presentation of proposed approach with different image databases.

5. Conclusion and future work. Discussed in this article is a research proposal entitled "Novel Unsupervised Label Indexing for Efficient Image Retrieval from Medical Image Sources Based on Label Indexing Using a Re-rank Process Established Using a Search-Based Annotation Methodology." Various image notations are used to describe the arrangement of pictures in a convex optimization representation of image pixels. The findings indicate that the characteristics derived from the deep learning model point in the direction of developing an efficient CBIR system. This study will be extended in the future by training on a real-time dataset. The processing of various keywords for medical picture retrieval presentations is shown to improve accuracy, recall, and time efficiency in experimental findings. Weak label medical image classification is a potential future feature in medical image retrieval from all medical image sources, together with the further advancement of

ON SOFT STRONGLY B^* –COMPACTNESS AND SOFT STRONGLY B^* –CONNECTEDNESS IN SOFT TOPOLOGICAL SPACES

SAIF Z. HAMEED* ABDELAZIZ E. RADWAN† AND ESSAM EL-SEIDY‡

Abstract. In this research article, we present a new class of soft compact spaces and soft Lindelöf spaces, we identify the idea of soft strongly b^* –compact and soft strongly b^* –Lindelöf spaces and we supply multiple interesting examples. As well as we mention that the inaugurated spaces are conserved under soft strongly b^* –irresolute mappings and we look into definite of results which connect an extensive soft topology with the showing soft spaces. As well as we inquiry the features and attributive of soft strongly b^* –connected spaces and discuss and identify its relationship with soft connectedness.

Key words: soft strongly b^* –closed set, soft strongly b^* –open set, soft strongly b^* –compact, soft strongly b^* –Lindelöf spaces, soft strongly b^* –connected space

1. Introduction and Preliminaries. Molodtsov [1] used an acceptable parametrization. In 1999, he introduced the soft set theorem’s basic idea and disclosed the theorem’s first result. He had many experimenters working on the proposal. Topology is eminent in colorful divaricate of mathematics. Therefore, Shabir and Naz [2] were the pioneers who introduced the concept of soft topological spaces. Kannan [3] assigned soft generalized closed and soft generalized open sets in soft topological spaces. Akdag and Ozkan ([4], [5]) presented a conception of soft α –open, the soft b –open, and their respective continuous functions. Zorlutuna et al. inquiry soft interior point and soft neighbourhood and he first examined the compactness of soft topological spaces [6]. Connectedness [7] is an effective tool for topology introduced by Porter J. and Woods R.. Hussain [8] assigned and take a look at the features of soft connected space. Saif Z. et al. [9] introduced the soft bc –open set. The soft b^* –closed are introduced by Hameed, Saif Z. et al. [10]. Soft b^* –continuous functions, soft strongly b^* –closed and soft strongly b^* –continuous functions are studied by Hameed, Saif Z. et al. [11], [12].

In the present work, we define the soft strongly b^* –compact and soft strongly b^* –Lindelöf spaces. Also, we introduce the soft strongly b^* –connected spaces. The details of the properties, examples, and counterexamples that substantiate the concept are thoroughly discussed.

In this study, consider \mathcal{W} as an initial universe and $P(\mathcal{W})$ as the power set of \mathcal{W} . In addition, $\tilde{E} \neq \phi$ stands for the family of parameters that are being considered and $\phi \notin \varphi \subseteq \tilde{E}$.

DEFINITION 1.1. [1] (Ψ, φ) is referred to be a soft set over \mathcal{W} if Ψ is a map from φ to $P(\mathcal{W})$.

DEFINITION 1.2. [13] The soft set $(\mathcal{S}, \varphi) \in \mathcal{SS}(\mathcal{W}, \varphi)$, where $S(\nabla) = \phi$, for every $\nabla \in \varphi$ is stated A-null soft set of $\mathcal{SS}(\mathcal{W}, \varphi)$ and symbolize by $\tilde{\phi}$. The soft set $(\mathcal{S}, \varphi) \in \mathcal{SS}(\mathcal{W}, \varphi)$, where $S(\nabla) = \mathcal{W}$, for every $\nabla \in \varphi$ is stated the A-absolute soft set of $\mathcal{SS}(\mathcal{W}, \varphi)$ and symbolize by $\tilde{\mathcal{W}}$.

DEFINITION 1.3. [13] For two sets $(\Psi, \varphi), (\mathcal{S}, \Theta) \in \mathcal{SS}(\mathcal{W}, \varphi)$, then (Ψ, φ) is a soft subset of (\mathcal{S}, Θ) symbolize by $(\Psi, \varphi) \subseteq (\mathcal{S}, \Theta)$, if

1. $\varphi \subseteq \Theta$.
2. $\psi(\nabla) \subseteq S(\nabla), \forall \nabla \in \varphi$.

Then, (Ψ, φ) is stated to be a soft superset of (\mathcal{S}, Θ) , if (\mathcal{S}, Θ) is a soft sub-set of (Ψ, φ) , $(\mathcal{S}, \Theta) \subseteq (\Psi, \varphi)$.

DEFINITION 1.4. [2] Let (Ψ, φ) be soft set over \mathcal{W} , $z \in \mathcal{W}$. that’s what we call $z \in (\Psi, \varphi)$, whenever $z \in \psi(\nabla)$ for all $\nabla \in \varphi$. The soft set (Ψ, φ) over \mathcal{W} such that $\psi(\nabla) = \{z\}, \forall \nabla \in \varphi$ is stated singleton soft point and symbolize by z_φ or (z, φ) .

Fig. 1.1: Relationships of soft strongly b^* -closed

DEFINITION 1.5. [2] Let $\mathcal{Q} \subseteq \mathcal{SS}(\mathcal{W}, \wp)$. Then \mathcal{Q} is stated to be soft topological space (STS) if

1. $\tilde{\phi}$ and \tilde{W} belong to \mathcal{Q} .
2. Arbitrary unions of members \mathcal{Q} belongs to \mathcal{Q} .
3. Finite intersections of members \mathcal{Q} belongs to \mathcal{Q} .

It is symbolize by $(\mathcal{W}, \mathcal{Q}, \wp)$ (briefly \mathcal{W}).

DEFINITION 1.6. [2] Let $(\mathcal{W}, \mathcal{Q}, \wp)$ be a STS over \mathcal{W} , then the organ of \mathcal{Q} are stated to be soft open sets in \mathcal{Q} .

DEFINITION 1.7. [2] Let $(\mathcal{W}, \mathcal{Q}, \wp)$ be a STS over \mathcal{W} . A soft set (Ψ, \wp) over \mathcal{W} is stated to be a soft closed set in \mathcal{W} , if its relative complement (Ψ, \wp) belongs to \mathcal{Q} .

DEFINITION 1.8. [6] Let $(\mathcal{W}, \mathcal{Q}, \wp)$ be a STS and $(\Psi, \wp) \in \mathcal{SS}(\mathcal{W}, \wp)$. Then

1. The soft closure of (Ψ, \wp) is the soft set $cl(\Psi, \wp) = \cap\{(\mathcal{S}, \wp) : (\mathcal{S}, \wp) \in \mathcal{Q}^c, (\Psi, \wp) \subseteq (\mathcal{S}, \wp)\}$.

2. The soft interior of (Ψ, \wp) is the soft set $int(\Psi, \wp) = \cup\{(\mathcal{S}, \wp) : (\mathcal{S}, \wp) \in \mathcal{Q}, (\mathcal{S}, \wp) \subseteq (\Psi, \wp)\}$.

DEFINITION 1.9. A soft set (Ψ, \wp) of a STS $(\mathcal{W}, \mathcal{Q}, \wp)$ is stated to be

1. soft α -open [4] if $(\Psi, \wp) \subset int(cl(int((\Psi, \wp))))$,
2. soft pre-open [14] if $(\Psi, \wp) \subset int(cl((\Psi, \wp)))$,
3. soft semi-open [15] if $(\Psi, \wp) \subset cl(int((\Psi, \wp)))$,
4. soft β -open [14] if $(\Psi, \wp) \subset cl(int(cl((\Psi, \wp))))$,
5. soft b -open [5] if $(\Psi, \wp) \subset int(cl((\Psi, \wp))) \cup cl(int((\Psi, \wp)))$.

DEFINITION 1.10. [16] A soft set (Ψ, \wp) is called soft ω -closed in a STS $(\mathcal{W}, \mathcal{Q}, \wp)$, if $cl(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$ whenever $(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$ and (\mathcal{S}, \wp) is soft semi-open set in \mathcal{W} . The relative complement of (Ψ, \wp) is called soft ω -open in \mathcal{W} .

DEFINITION 1.11. [12] A soft set (Ψ, \wp) of a STS $(\mathcal{W}, \mathcal{Q}, \wp)$ is called a soft strongly b^* -closed (briefly sSb^* -closed) if $cl(int(\Psi, \wp)) \subseteq (\mathcal{S}, \wp)$, whenever $(\Psi, \wp) \subset (\mathcal{S}, \wp)$ and (\mathcal{S}, \wp) is sb -open. The complement of a sSb^* -closed set is stated to be sSb^* -open set.

THEOREM 1.12. [12] The following statements are correct:

1. Every soft open is sSb^* -open.
2. Every $s\alpha$ -open is sSb^* -open.
3. Every sSb^* -open set is sb -open.
4. Every $s\omega$ -open is sSb^* -open.

DEFINITION 1.13. [12] Let $(\mathcal{W}, \mathcal{Q}, \wp)$ be a STS. a subset $(\Psi, \wp) \subseteq \mathcal{W}$ is called a soft strongly b^* -neighbourhood (briefly sSb^* -nbd) of point $\nu \in \mathcal{W}$ if \exists an sSb^* -open set (Ψ, \wp) where $\nu \in \mathcal{W} \subseteq (\Psi, \wp)$.

DEFINITION 1.14. [12] Let $(\mathcal{O}, \wp) \in \mathcal{SS}(\mathcal{W}, \wp)$. Then $sSb^*int(\mathcal{O}, \wp) = \cup\{(\mathcal{L}, \wp) : (\mathcal{L}, \wp) \text{ is a } sSb^*\text{-open set and } (\mathcal{L}, \wp) \subset (\mathcal{O}, \wp)\}$.

DEFINITION 1.15. [12] Let $(\mathcal{L}, \wp) \in \mathcal{SS}(\mathcal{W}, \wp)$. Then $sSb^*cl(\mathcal{L}, \wp) = \cap\{(\Psi, \wp) : (\Psi, \wp) \text{ is a } sSb^*\text{-closed set and } (\mathcal{L}, \wp) \subset (\Psi, \wp)\}$.

DEFINITION 1.16. [12] A soft mapping $\Pi : \mathcal{W} \rightarrow \Sigma$, from $STS (\mathcal{W}, \mathcal{Q}, \wp)$ into $STS (\Sigma, \Omega, \Theta)$, is stated to be soft strongly b^* -continuous (briefly sSb^* -continuous) if the inverse image of every soft open set in Σ is a sSb^* -open set in \mathcal{W} .

DEFINITION 1.17. [12] A soft mapping $\Pi : \mathcal{W} \rightarrow \Sigma$ is stated to be soft strongly b^* -irresolute (briefly sSb^* -irresolute) if the inverse image of every sSb^* -closed set in Σ is a sSb^* -closed set in \mathcal{W} .

For are details, we refer to [12], [6], [7].

2. Soft strongly b^* -compact spaces. In this section, We offer the conception of soft strongly b^* -compact and soft strongly b^* -Lindelöf spaces and The significant structural properties.

DEFINITION 2.1. A collection $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$ of soft strongly b^* -open sets is called a soft strongly b^* -open cover of $(\mathcal{W}, \mathcal{Q}, \wp)$, if $\widetilde{\mathcal{W}} = \bigcup_{\epsilon \in \zeta} (\psi_\epsilon, \wp)$.

DEFINITION 2.2. A $STS (\mathcal{W}, \mathcal{Q}, \wp)$ is called soft strongly b^* -compact (resp. soft strongly b^* -Lindelöf), if each sSb^* -open cover of $\widetilde{\mathcal{W}}$ has a finite (resp. countable) soft subcover of $\widetilde{\mathcal{W}}$.

DEFINITION 2.3. A soft subset $(, \wp)$ of a $STS (\mathcal{W}, \mathcal{Q}, \wp)$ is called soft strongly b^* -compact in \mathcal{W} determined by for every collection $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$ of soft strongly b^* -open sets of \mathcal{W} where $(, \wp) \subset \cup\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\} \exists$ finite subset ζ_0 of ζ where $(, \wp) \subset \cup\{(\psi_\epsilon, \wp) : \epsilon \in \zeta_0\}$

DEFINITION 2.4. A $STS (\mathcal{W}, \mathcal{Q}, \wp)$ is called soft strongly b^* -space if every sSb^* -open set of \mathcal{W} is soft open set in \mathcal{W} .

COROLLARY 2.5. If $STS (\mathcal{W}, \mathcal{Q}, \wp)$ is a sSb^* -compact space and soft strongly b^* -space, then \mathcal{W} is soft compact space.

Proof. Assume that $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$ be soft open cover of \mathcal{W} . For each soft open set is sSb^* -open set, $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$ is sSb^* -open cover of \mathcal{W} . For \mathcal{W} is sSb^* -compact space and sSb^* -space, \exists finite subset ζ_0 of ζ where $\mathcal{W} \subset \{(\psi_\epsilon, \wp) : \epsilon \in \zeta_0\}$. Therefore, \mathcal{W} is soft compact space. \square

COROLLARY 2.6. If $\Pi : \mathcal{W} \rightarrow \Sigma$ is a sSb^* -continuous function and sSb^* -space, then Π is soft continuous function.

Proof. Assume $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$ be soft open set of Σ . whereas Π is sSb^* -continuous, $\{\Pi^{-1}((\psi_\epsilon, \wp)) : \epsilon \in \zeta\}$ is sSb^* -open set of \mathcal{W} and whereas \mathcal{W} is sSb^* -space, $\{\Pi^{-1}((\psi_\epsilon, \wp)) : \epsilon \in \zeta\}$ forms soft open set of \mathcal{W} . Thus, Π is soft continuous. \square

COROLLARY 2.7. Assume $(\mathcal{W}, \mathcal{Q}, \wp)$ be STS . If $(\mathcal{W}, \mathcal{Q}_\nabla)$ is a sSb^* -compact space, for each $\nabla \in \wp$, then $(\mathcal{W}, \mathcal{Q}, \wp)$ is a sSb^* -compact space.

Proof. Assume that $\wp = \{\nabla_1, \nabla_1, \dots, \nabla_n\}$ be a set of parameter and $(\mathcal{W}, \mathcal{Q}_\nabla)$ is sSb^* -compact space, for each $\epsilon = \overline{1, n}$. Suppose $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$ be sSb^* -open cover of \mathcal{W} . Since $\cup_{\epsilon \in \zeta} (\psi_\epsilon, \wp)(\nabla) = \widetilde{\mathcal{W}}$, for each $\nabla \in \wp$, and $(\mathcal{W}, \mathcal{Q}_\nabla)$ is a sSb^* -compact, \exists finite subset ζ_0 of ζ where $\cup_{\epsilon \in \zeta_0} (\psi_\epsilon, \wp)(\nabla) = \widetilde{\mathcal{W}}$. Hence, $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta_0\}$ is a finite subcover of $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$. Hence, $(\mathcal{W}, \mathcal{Q}, \wp)$ is a sSb^* -compact space. \square

COROLLARY 2.8. Every sSb^* -compact (resp. sSb^* -Lindelöf) space is soft compact (resp. soft Lindelöf).

In the next example, indicates that the inclusions of the Corollary 2.8 is not necessarily correct.

Example 1. Consider $\wp = Q^c$ is the set of irrational numbers. Let $\mathcal{Q} = \{\widetilde{\phi}, \widetilde{\mathcal{W}}, (, \wp)$ when $(\nabla) = \{1\}, \forall \nabla \in \wp$ be a STS on $\mathcal{W} = \{1, 2\}$. clearly, $(\mathcal{W}, \mathcal{Q}, \wp)$ is soft compact. furthermore, a family $\{(\delta, \Theta) : \delta(v) = \{1\}, \forall v \neq \nabla\}$ is a sSb^* -open cover of $\widetilde{\mathcal{W}}$. For has not a soft countable subcover of $\widetilde{\mathcal{W}}$. Thus, $(\mathcal{W}, \mathcal{Q}, \wp)$ is not a sSb^* -Lindelöf space.

THEOREM 2.9. Every sSb^* -compact space is a sSb^* -Lindelöf.

Proof. Clear. \square

In the next example, indicates that the inclusions of the Theorem 2.9 and Figure 2.1 is not necessarily correct.

Example 2. Let $\mathcal{Q} = \{\widetilde{\phi}, \widetilde{\aleph}, (\delta, \wp)\}$ and $\wp = \{\nabla_1, \nabla_1, \dots, \nabla_n\}$. such that $\delta(\nabla) = \{1\}, \forall \nabla \in \wp$ be a STS on the set of natural numbers \aleph . Since \wp and \aleph are soft countable, then $(\aleph, \mathcal{Q}, \wp)$ is a sSb^* -Lindelöf. furthermore, a family $\{(\mathcal{S}, \Theta) : \mathcal{S}(v) = \{1, x\}, \text{ for each } v \in \Theta, x \in \aleph\}$ is a sSb^* -open cover of $\widetilde{\aleph}$. For has not soft finite subcover of $\widetilde{\aleph}$. Thus, $(\aleph, \mathcal{Q}, \wp)$ is not a sSb^* -compact.

Fig. 2.1: Relationships

THEOREM 2.10. *The soft union of two sSb^* -compact (resp. sSb^* -Lindelöf) sets is sSb^* -compact (resp. sSb^* -Lindelöf).*

Proof. Let (ψ, \wp) and $(, \wp)$ be two sSb^* -compact sets. Assume that $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$ is a sSb^* -open cover of $(\psi, \wp) \cup (, \wp)$. Then, $\{(\psi_\epsilon, \wp) : \epsilon \in \zeta\}$ is a sSb^* -open cover of (ψ, \wp) and $(, \wp)$. Since (ψ, \wp) and $(, \wp)$ are sSb^* -compact, there exist finite subfamilies ζ_0 and ζ_1 of ζ such that $(\psi, \wp) \subseteq \{(\psi_\epsilon, \wp) : \epsilon \in \zeta_0\}$ and $(, \wp) \subseteq \{(\psi_\epsilon, \wp) : \epsilon \in \zeta_1\}$. Hence, $(\psi, \wp) \cup (, \wp) \subseteq (\cup\{(\psi_\epsilon, \wp) : \epsilon \in \zeta_0\}) \cup (\cup\{(\psi_\epsilon, \wp) : \epsilon \in \zeta_1\})$. It follows that, $(\psi, \wp) \cup (, \wp) \subseteq \cup\{(\psi_\epsilon, \wp) : \epsilon \in \zeta_0 \cup \zeta_1\}$. Thus, $(\psi, \wp) \cup (, \wp)$ is a sSb^* -compact.

The proof of the case of sSb^* -Lindelöfness is similar. \square

THEOREM 2.11. *Every sSb^* -closed subset (\mathcal{L}, \wp) of sSb^* -compact $(\mathcal{W}, \mathcal{Q}, \wp)$ is a sSb^* -compact.*

Proof. Assume that (\mathcal{L}, \wp) be a sSb^* -closed subset of sSb^* -compact space $(\mathcal{W}, \mathcal{Q}, \wp)$. Then (\mathcal{L}^c, \wp) is a sSb^* -open. Let $\{(\underline{\epsilon}, \wp) : \underline{\epsilon} \in \ell\}$ be a sSb^* -open cover of (\mathcal{L}, \wp) . Therefore, $\{(\underline{\epsilon}, \wp) : \underline{\epsilon} \in \ell\} \cup (\mathcal{L}^c, \wp)$ is sSb^* -open cover of \mathcal{W} . For \mathcal{W} is sSb^* -compact space, \exists finite subcover $\{(\underline{\epsilon}, \wp) : \underline{\epsilon} \in \zeta_0\} \cup (\mathcal{L}^c, \wp)$ for \mathcal{W} . Now, $\{(\underline{\epsilon}, \wp) : \underline{\epsilon} \in \zeta_0\} \cup (\mathcal{L}^c, \wp) - (\mathcal{L}^c, \wp)$ is a finite subcover of $\{(\underline{\epsilon}, \wp) : \underline{\epsilon} \in \zeta\}$ for (\mathcal{L}, \wp) . So, (\mathcal{L}, \wp) is sSb^* -compact. \square

THEOREM 2.12. *Every sSb^* -closed subset (\mathcal{S}, \wp) of sSb^* -Lindelöf space $(\mathcal{W}, \mathcal{Q}, \wp)$ is sSb^* -Lindelöf.*

Proof. Assume that (\mathcal{S}, \wp) be sSb^* -closed subset (\mathcal{S}, \wp) of sSb^* -compact space $(\mathcal{W}, \mathcal{Q}, \wp)$ and $\{(\Psi_\epsilon, \wp) : \epsilon \in \zeta\}$ be sSb^* -open cover of (\mathcal{S}, \wp) . Therefore, (\mathcal{S}^c, \wp) is a sSb^* -open and $(\mathcal{S}^c, \wp) \subseteq \cup_{\epsilon \in \zeta} (\Psi_\epsilon, \wp)$. Therefore, $\widetilde{\mathcal{W}} = (\Psi_\epsilon, \wp) \cup (\mathcal{S}^c, \wp)$. Since $\widetilde{\mathcal{W}}$ is a sSb^* -Lindelöf space, then $\widetilde{\mathcal{W}} = \cup_{\epsilon \in \zeta} (\Psi_\epsilon, \wp) \cup (\mathcal{S}^c, \wp)$. This implies that $(\mathcal{S}, \wp) \subseteq \cup_{\epsilon \in \zeta} (\Psi_\epsilon, \wp)$. Hence, (\mathcal{S}, \wp) is a sSb^* -Lindelöf. \square

COROLLARY 2.13. *If (δ, \wp) is a sSb^* -closed subset of $\widetilde{\mathcal{W}}$ and (Ψ, \wp) is a sSb^* -compact (resp. sSb^* -Lindelöf) subset of $\widetilde{\mathcal{W}}$. Then, $(\Psi, \wp) \cap (\delta, \wp)$ is a sSb^* -compact (resp. sSb^* -Lindelöf).*

Proof. Let (Ψ, \wp) be a sSb^* -compact set, consider $\{(G_\epsilon, \wp) : \epsilon \in \zeta\}$ is sSb^* -open cover of $(\Psi, \wp) \cap (\delta, \wp)$. Then $\{(G_\epsilon, \wp) : \epsilon \in \zeta\} \cup (\delta^c, \wp)$ is sSb^* -open cover of (Ψ, \wp) . For (Ψ, \wp) is a sSb^* -compact. So, \exists a soft finite subfamily ζ_0 of $\zeta \ni (\Psi, \wp) \subseteq \cup_{\epsilon \in \zeta_0} (G_\epsilon, \wp) \cup (\delta^c, \wp)$. Hence, $(\Psi, \wp) \cap (\delta, \wp) \subseteq \cup_{\epsilon \in \zeta_0} (G_\epsilon, \wp) \cap (\delta, \wp) \subseteq \cup_{\epsilon \in \zeta_0} (G_\epsilon, \wp)$. Therefore, $(\Psi, \wp) \cap (\delta, \wp)$ is sSb^* -compact.

The same evidence applies to sSb^* -Lindelöf space. \square

In the next example, indicates that the inclusions of the Theorem 2.12 is not necessary correct.

Example 3. Let $\mathcal{W} = \{h_1, h_2\}$ and $\wp = \{\nabla_1, \nabla_2\}$. Consider

$\mathcal{Q} = \{\widetilde{\mathcal{W}}, \phi, (\Psi_1, \wp), (\Psi_2, \wp), (\Psi_3, \wp)\}$ where $(\Psi_1, \wp), (\Psi_2, \wp)$ and (Ψ_3, \wp) defined as following manner:

$(\Psi_1, \wp) = \{(\nabla_1, \{h_1\}), (\nabla_2, \phi)\},$

$(\Psi_2, \wp) = \{(\nabla_1, \phi), (\nabla_2, \{h_2\})\}$ and

$(\Psi_3, \wp) = \{(\nabla_1, \{h_1\}), (\nabla_2, \{h_2\})\}.$

Then $(\mathcal{W}, \mathcal{Q}, \wp)$ is a *STS* over \mathcal{W} . Obviously, $(\mathcal{W}, \mathcal{Q}, \wp)$ is sSb^* -compact. furthermore, a soft set $(\Pi, \wp) = \{(\nabla_1, \{h_1\}), (\nabla_2, \mathcal{W})\}$ is a sSb^* -compact, even so it is not a sSb^* -closed.

THEOREM 2.14. *A $(\mathcal{W}, \mathcal{Q}, \wp)$ is sSb^* -compact (resp. sSb^* -Lindelöf) if and only if each collection of sSb^* -closed subsets of $(\mathcal{W}, \mathcal{Q}, \wp)$, satisfying the soft finite (resp. soft countable) intersection property, $\cap_{\epsilon \in \ell} (\Psi_\epsilon, \wp) \neq \phi$.*

Proof. Let $(\mathcal{W}, \mathcal{Q}, \wp)$ is a sSb^* -compact, and $\{(\xi_\epsilon, \wp) : \epsilon \in \ell\}$ be a family of sSb^* -closed subsets of $\widetilde{\mathcal{W}}$. Let $\cap_{\epsilon \in \ell} (\xi_\epsilon, \wp) = \phi$. Then $\widetilde{\mathcal{W}} = \cup_{\epsilon \in \ell} (\xi_\epsilon^c, \wp)$. For $\cup_{\epsilon \in \ell} (\xi_\epsilon^c, \wp)$ is a collection of sSb^* -open sets covering $\widetilde{\mathcal{W}}$. As $(\mathcal{W}, \mathcal{Q}, \wp)$ is sSb^* -compact, then \exists a soft finite subset ℓ_0 of $\ell \ni \cup_{\epsilon \in \ell_0} (\xi_\epsilon^c, \wp) = \widetilde{\mathcal{W}}$ then $\cap_{\epsilon \in \ell_0} (\xi_\epsilon, \wp) = \phi$. Which gives contradictions. Therefore, $\cap_{\epsilon \in \ell} (\xi_\epsilon, \wp) \neq \phi$. Conversely, let $\{(\gamma_\epsilon, \wp) : \epsilon \in \ell\}$ be a family of sSb^* -open cover of $\widetilde{\mathcal{W}}$. Let for every finite subset $\ell_0 \subset \ell$, we have $\cup_{\epsilon \in \ell_0} (\gamma_\epsilon^c, \wp) \neq \widetilde{\mathcal{W}}$. Then $\cap_{\epsilon \in \ell} (\gamma_\epsilon^c, \wp) \neq \phi$. Thus, $\{(\gamma_\epsilon^c, \wp) : \epsilon \in \ell\}$ satisfies the finite intersection property. By definition get $\cap_{\epsilon \in \ell} (\gamma_\epsilon^c, \wp) \neq \phi$ which implies $\cup_{\epsilon \in \ell_0} (\gamma_\epsilon, \wp) \neq \widetilde{\mathcal{W}}$ and this contradicts that $\{(\gamma_\epsilon, \wp) : \epsilon \in \ell\}$ is a sSb^* -open cover of $\widetilde{\mathcal{W}}$. Hence, $(\mathcal{W}, \mathcal{Q}, \wp)$ is a sSb^* -compact space. \square

THEOREM 2.15. *Let $\Pi : \mathcal{W} \rightarrow \Sigma$ be a sSb^* -continuous function. If \mathcal{W} is a sSb^* -compact space, then the image of \mathcal{W} under the Π is a soft compact.*

Proof. Assume $\Pi : \mathcal{W} \rightarrow \Sigma$ is a sSb^* -continuous, $\{(G_\epsilon, \wp) : \epsilon \in \ell\}$ is a soft cover of Σ . For Π is a sSb^* -continuous, therefore $\{\Pi^{-1}((G_\epsilon, \wp)) : \epsilon \in \ell\}$ is a sSb^* -open cover of $\widetilde{\mathcal{W}}$ and \mathcal{W} is a sSb^* -compact, \exists a soft finite sub-set ℓ_0 of $\ell \ni \{\Pi^{-1}((G_\epsilon, \wp)) : \epsilon \in \ell_0\}$ composes a sSb^* -open cover of $\widetilde{\mathcal{W}}$. Thus, $\{\Pi^{-1}((G_\epsilon, \wp)) : \epsilon \in \ell_0\}$ composes a soft finite soft open cover of $\widetilde{\Sigma}$. Therefore, Σ is a soft compact. \square

THEOREM 2.16. *Let $\Pi : \mathcal{W} \rightarrow \Sigma$ be a sSb^* -irresolute surjection and \mathcal{W} is a sSb^* -compact space, then Σ is a sSb^* -compact.*

Proof. Suppose $\Pi : \mathcal{W} \rightarrow \Sigma$ be a sSb^* -irresolute surjection, \mathcal{W} be a sSb^* -compact $(\mathcal{W}, \mathcal{Q}, \wp)$ to (Σ, Ω, Θ) . A soft open cover $\{(\delta_\epsilon, \wp) : \epsilon \in \zeta\}$ of Σ . Then $\{\Pi^{-1}((\delta_\epsilon, \wp)) : \epsilon \in \zeta\}$ is a sSb^* -open cover of $\widetilde{\mathcal{W}}$. For \mathcal{W} is a sSb^* -compact, then \exists a finite subset ζ_0 of ζ such that $\{\Pi^{-1}((\delta_\epsilon, \wp)) : \epsilon \in \zeta_0\}$ composes a sSb^* -open cover of $\widetilde{\mathcal{W}}$. Therefore, $\{\Pi^{-1}((\delta_\epsilon, \wp)) : \epsilon \in \zeta_0\}$ composes a finite sSb^* -open cover of $\widetilde{\Sigma}$. Hence, Σ is a sSb^* -compact. \square

THEOREM 2.17. *The sSb^* -irresolute image of a sSb^* -compact (resp. sSb^* -Lindelöf) set is a sSb^* -compact (resp. sSb^* -Lindelöf).*

Proof. Assume that $\Pi : \mathcal{W} \rightarrow \Sigma$ be a sSb^* -irresolute and let $(, \wp)$ be a sSb^* -Lindelöf subset of $\widetilde{\mathcal{W}}$. Let $\{(\Psi_\epsilon, \wp) : \epsilon \in \zeta\}$ is sSb^* -open cover of $\Pi(, \wp)$. Then $\Pi(, \wp) \subseteq \cup_{\epsilon \in \zeta} (\Psi_\epsilon, \wp)$. Then, $(, \wp) \subseteq \cup_{\epsilon \in \zeta} \Pi^{-1}(\Psi_\epsilon, \wp)$ and $\Pi^{-1}(\Psi_\epsilon, \wp)$ is sSb^* -open, for every $\epsilon \in \zeta$. by assumption, $(, \wp)$ is a sSb^* -Lindelöf, then $(, \wp) \subseteq \cup_{\epsilon \in \zeta} \Pi^{-1}(\Psi_\epsilon, \wp)$. Therefore, $\Pi(, \wp) \subseteq \cup_{\epsilon \in \zeta} \Pi(\Pi^{-1}(\Psi_\epsilon, \wp)) \subseteq \cup_{\epsilon \in \zeta} (\Psi_\epsilon, \wp)$. Thus, $\Pi(, \wp)$ is sSb^* -Lindelöf space. The same proof in case sSb^* -compact space. \square

3. Soft strongly b^* -connected spaces. One of the most important properties of soft strongly b^* -connected space is discussed and explored in this section.

DEFINITION 3.1. *Let $(\mathcal{W}, \mathcal{Q}, \wp)$ be STS, and $(\Psi, \wp), (\mathcal{L}, \wp)$ are sSb^* -open sets over $\widetilde{\mathcal{W}}$. Then, (Ψ, \wp) and (\mathcal{L}, \wp) are stated to be soft strongly b^* -separated sets iff $sSb^*cl(\Psi, \wp) \cap (\mathcal{L}, \wp) = \phi$ and $(\Psi, \wp) \cap sSb^*cl(\mathcal{L}, \wp) = \phi$.*

THEOREM 3.2. *If (Ψ, \wp) and (\mathcal{L}, \wp) are sSb^* -separated sets then they are disjoint.*

Proof. $(\Psi, \wp) \cap (\mathcal{L}, \wp) \subseteq sSb^*cl(\Psi, \wp) \cap (\mathcal{L}, \wp) = \phi$. \square

THEOREM 3.3. *If (Ψ, \wp) and (\mathcal{L}, \wp) are sSb^* -separated subsets of \mathcal{W} and $(\Gamma, \wp) \subseteq (\Psi, \wp)$ and $(\Upsilon, \wp) \subseteq (\mathcal{L}, \wp)$ then (Γ, \wp) and (Υ, \wp) are also sSb^* -separated.*

Proof. Suppose (Ψ, \wp) and (\mathcal{L}, \wp) are sSb^* -separated subsets of a space \mathcal{W} , by definition 3.1; $sSb^*cl(\Psi, \wp) \cap (\mathcal{L}, \wp) = \phi$ and $(\Psi, \wp) \cap sSb^*cl(\mathcal{L}, \wp) = \phi$. Since $(\Gamma, \wp) \subseteq (\Psi, \wp)$, we have $sSb^*cl(\Gamma, \wp) \subseteq sSb^*cl(\Psi, \wp)$ and since $(\Upsilon, \wp) \subseteq (\mathcal{L}, \wp)$, then $sSb^*cl(\Upsilon, \wp) \subseteq sSb^*cl(\mathcal{L}, \wp)$. Hence, $(\Gamma, \wp) \cap sSb^*cl(\Upsilon, \wp) = (\Psi, \wp) \cap sSb^*cl(\mathcal{L}, \wp) = \phi$ and $sSb^*cl(\Gamma, \wp) \cap (\Upsilon, \wp) = sSb^*cl(\Psi, \wp) \cap (\mathcal{L}, \wp) = \phi$. Therefore, (Γ, \wp) and (Υ, \wp) are also sSb^* -separated. \square

THEOREM 3.4. *Two soft separated sets are soft sSb^* -separated sets.*

Proof. Assume (ϑ, \wp) and $(, \wp)$ be two soft separated sets over \mathcal{W} , so $sSb^*cl(\vartheta, \wp) \cap (, \wp) = \phi$ and $(\vartheta, \wp) \cap sSb^*cl(, \wp) = \phi$.

As

$$sSb^*cl(\vartheta, \wp) \subseteq cl(\vartheta, \wp).$$

$$sSb^*cl(\vartheta, \wp) \cap (, \wp) \subseteq cl(\vartheta, \wp) \cap (, \wp) = \phi.$$

$$\text{and similarly, } (\vartheta, \wp) \cap sSb^*cl(, \wp) \subseteq (\vartheta, \wp) \cap cl(, \wp) = \phi.$$

Hence, (ϑ, \wp) and $(, \wp)$ are sSb^* -separated sets.

\square

Remark 1. If (ϑ, \wp) and $(, \wp)$ are disjoint. Then, require not be sSb^* -separated.

Example 4. Consider $\mathcal{W} = \{\varsigma_1, \varsigma_2\}$ and $\wp = \{\nabla_1, \nabla_2\}$. Consider $\mathcal{Q} = \{\widetilde{\mathcal{W}}, \widetilde{\phi}, (\vartheta, \wp)\}$ where $(\vartheta, \wp) = \{(\nabla_1, \{\varsigma_1\}), (\nabla_2, \{\varsigma_2\})\}$, let $(, \wp) = \{(\nabla_1, \{\varsigma_1\}), (\nabla_2, \{\varsigma_2\})\}$ and $(\mathcal{S}, \wp) = \{(\nabla_1, \{\varsigma_2\}), (\nabla_2, \{\varsigma_1\})\}$ be two soft sets over \mathcal{Q} . Then $(, \wp)$ and (\mathcal{S}, \wp) are soft disjoint sets but they are not sSb^* -separated.

DEFINITION 3.5. Let $(\mathcal{W}, \mathcal{Q}, \wp)$ be STS over \mathcal{W} . Then $(\mathcal{W}, \mathcal{Q}, \wp)$ is stated to be sSb^* -connected, if \mathcal{W} cannot be intimated as the union of two sSb^* -open sets. Else, $(\mathcal{W}, \mathcal{Q}, \wp)$ is stated to be a sSb^* -disconnected.

Example 5. Consider $\mathcal{W} = \{r, t, d\}$ and $\wp = \{\nabla_1, \nabla_2\}$. Consider

$$\mathcal{Q} = \{\widetilde{\mathcal{W}}, \widetilde{\phi}, (\Gamma_1, \wp), (\Gamma_2, \wp), (\Gamma_3, \wp), (\Gamma_4, \wp), (\Gamma_5, \wp)\}$$

where $(\Gamma_1, \wp), (\Gamma_2, \wp), (\Gamma_3, \wp), (\Gamma_4, \wp)$ and (Γ_5, \wp) are sSb^* -open sets over \mathcal{W} , define as follows:

$$(\Gamma_1, \wp) = \{(\nabla_1, \{t\}), (\nabla_2, \{r\})\},$$

$$(\Gamma_2, \wp) = \{(\nabla_1, \{t, d\}), (\nabla_2, \{r, t\})\},$$

$$(\Gamma_3, \wp) = \{(\nabla_1, \{r, t\}), (\nabla_2, \mathcal{W})\},$$

$$(\Gamma_4, \wp) = \{(\nabla_1, \{r, t\}), (\nabla_2, \{r, d\})\} \text{ and}$$

$$(\Gamma_5, \wp) = \{(\nabla_1, \{t\}), (\nabla_2, \{r, t\})\}.$$

Then $(\mathcal{W}, \mathcal{Q}, \wp)$ is STS on \mathcal{W} . Thus, $(\mathcal{W}, \mathcal{Q}, \wp)$ is a STS over \mathcal{W} . Intelligibly, \mathcal{W} is a sSb^* -connected.

THEOREM 3.6. Let $(\mathcal{W}, \mathcal{Q}, \wp)$ be a STS and (Ψ, \wp) is a sSb^* -connected. Let (\mathcal{L}, \wp) and (\mathcal{S}, \wp) are sSb^* -separated sets. If $(\Psi, \wp) \subseteq (\mathcal{L}, \wp) \cup (\mathcal{S}, \wp)$. Then either $(\Psi, \wp) \subseteq (\mathcal{L}, \wp)$ or $(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$.

Proof. Suppose (Ψ, \wp) be a sSb^* -connected and $(\mathcal{L}, \wp), (\mathcal{S}, \wp)$ are sSb^* -separated sets such that $(\Psi, \wp) \subseteq (\mathcal{L}, \wp) \cup (\mathcal{S}, \wp)$. Let (Ψ, \wp) not subset of (\mathcal{L}, \wp) and (Ψ, \wp) not subset of (\mathcal{S}, \wp) . Suppose $(P_1, \wp) \subseteq (\mathcal{L}, \wp) \cap (\Psi, \wp) \neq \phi$ and $(P_2, \wp) \subseteq (\mathcal{S}, \wp) \cap (\Psi, \wp) \neq \phi$. Then $(\Psi, \wp) = (P_1, \wp) \cup (P_2, \wp)$. Since $(P_1, \wp) \subseteq (\mathcal{L}, \wp)$, hence $sSb^*cl(P_1, \wp) \subseteq sSb^*cl(\mathcal{L}, \wp)$. Since $sSb^*cl(\mathcal{L}, \wp) \cap (\mathcal{S}, \wp) = \phi$ then $sSb^*cl(P_1, \wp) \cap (P_2, \wp) = \phi$. Since $(P_2, \wp) \subseteq (\mathcal{S}, \wp)$, hence $sSb^*cl(P_2, \wp) \subseteq sSb^*cl(\mathcal{S}, \wp)$. Since $sSb^*cl(\mathcal{S}, \wp) \cap (\mathcal{L}, \wp) = \phi$, then $sSb^*cl(P_2, \wp) \cap (P_1, \wp) = \phi$. But $(\Psi, \wp) = (P_1, \wp) \cup (P_2, \wp)$. Therefore, (Ψ, \wp) is not a sSb^* -connected. This is a contradiction. Then either $(\Psi, \wp) \subseteq (\mathcal{L}, \wp)$ or $(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$. \square

THEOREM 3.7. Let (Ψ, \wp) be a sSb^* -connected set. If $(\Psi, \wp) \subseteq (\mathcal{L}, \wp) \subseteq sSb^*cl(\Psi, \wp)$ then (\mathcal{L}, \wp) is also a sSb^* -connected.

Proof. If (Ψ, \wp) be not a sSb^* -connected, then \exists two soft sets $(\mathcal{S}, \wp) \subseteq (G, \wp)$ such that $sSb^*cl(\mathcal{S}, \wp) \cap (G, \wp) = (G, \wp) \cap sSb^*cl(\mathcal{S}, \wp) = \phi$ and $(\mathcal{L}, \wp) = (\mathcal{S}, \wp) \cup (G, \wp)$. Since $(\Psi, \wp) \subseteq (\mathcal{L}, \wp)$, thus either $(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$ or $(\Psi, \wp) \subseteq (G, \wp)$. Suppose $(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$ then $sSb^*cl(\Psi, \wp) \subseteq sSb^*cl(\mathcal{S}, \wp)$, thus $sSb^*cl(\Psi, \wp) \subseteq (G, \wp) = sSb^*cl(\mathcal{S}, \wp) \cap (G, \wp) = \phi$. But $(G, \wp) \subseteq (\mathcal{L}, \wp) \subseteq sSb^*cl(\Psi, \wp)$ thus $sSb^*cl(\Psi, \wp) \cap (G, \wp) = (G, \wp)$. Therefore, $(G, \wp) = \phi$, so is a contradiction. Hence, (\mathcal{L}, \wp) is a sSb^* -connected. Similarly, if $(\Psi, \wp) \subseteq (\mathcal{L}, \wp)$, then $(\mathcal{S}, \wp) = \phi$. Which again a contradiction. Hence, (\mathcal{L}, \wp) is a sSb^* -connected. \square

THEOREM 3.8. If (Ψ, \wp) is a sSb^* -connected set then $sSb^*cl(\Psi, \wp)$ is a sSb^* -connected.

Proof. Let (Ψ, \wp) is a sSb^* -connected set then $sSb^*cl(\Psi, \wp)$ is not. Then there exists two sSb^* -separation sets (\mathcal{S}, \wp) and (δ, \wp) such that $sSb^*cl(\Psi, \wp) = (\mathcal{S}, \wp) \cup (\delta, \wp)$. But $(\Psi, \wp) \subseteq sSb^*cl(\Psi, \wp)$, then $(\Psi, \wp) = (\mathcal{S}, \wp) \cup (\delta, \wp)$ and since (Ψ, \wp) is sSb^* -connected set, then by theorem 3.6 either $(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$ or $(\Psi, \wp) \subseteq (G, \wp)$. If $(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$ then $sSb^*cl(\Psi, \wp) \subseteq sSb^*cl(\mathcal{S}, \wp)$. But $sSb^*cl(\mathcal{S}, \wp) \cap (\delta, \wp) = \phi$. Hence, $sSb^*cl(\Psi, \wp) \cap (\delta, \wp) = \phi$. Since $(\delta, \wp) \subseteq sSb^*cl(\Psi, \wp)$, then $(\delta, \wp) = \phi$. So is a contradiction. If $(\Psi, \wp) \subseteq (\mathcal{S}, \wp)$ we can prove $(\mathcal{S}, \wp) = \phi$ as the same, that is a contradiction. Hence, $sSb^*cl(\Psi, \wp)$ is a sSb^* -connected. \square

THEOREM 3.9. If (Ψ, \wp) and (\mathcal{S}, \wp) are two sSb^* -connected sets where $(\Psi, \wp) \cap (\mathcal{S}, \wp) \neq \phi$. Therefore $(\Psi, \wp) \cup (\mathcal{S}, \wp)$ is also a sSb^* -connected set.

Proof. Assume that, if possible, $(\Psi, \wp) \cup (\mathcal{S}, \wp)$ be sSb^* -disconnected set, then $(\Psi, \wp) \cup (\mathcal{S}, \wp) = (\vartheta, \wp) \cup (\delta, \wp)$, where $(\vartheta, \wp) \neq \phi, (\delta, \wp) \neq \phi \ni (\vartheta, \wp)$ and (δ, \wp) are sSb^* -separation. Since $(\Psi, \wp) \subseteq (\Psi, \wp) \cup (\mathcal{S}, \wp) = (\vartheta, \wp) \cup (\delta, \wp)$, Therefore, $(\Psi, \wp) \subseteq (\vartheta, \wp) \cup (\delta, \wp)$. Hence, by Theorem 3.6, we have either $(\Psi, \wp) \subseteq (\vartheta, \wp)$ or $(\Psi, \wp) \subseteq (\delta, \wp)$. Again, either $(\mathcal{S}, \wp) \subseteq (\vartheta, \wp)$ or $(\mathcal{S}, \wp) \subseteq (\delta, \wp)$. Thus, we have four choices either $(\Psi, \wp) \subseteq (\vartheta, \wp)$ and $(\mathcal{S}, \wp) \subseteq (\vartheta, \wp)$ or $(\Psi, \wp) \subseteq (\vartheta, \wp)$ and $(\mathcal{S}, \wp) \subseteq (\delta, \wp)$ or $(\Psi, \wp) \subseteq (\delta, \wp)$ and $(\mathcal{S}, \wp) \subseteq (\vartheta, \wp)$ or $(\Psi, \wp) \subseteq (\delta, \wp)$ and $(\mathcal{S}, \wp) \subseteq (\delta, \wp)$. If $(\Psi, \wp) \subseteq (\vartheta, \wp)$ and $(\mathcal{S}, \wp) \subseteq (\vartheta, \wp)$ or $(\Psi, \wp) \subseteq (\delta, \wp)$ and $(\mathcal{S}, \wp) \subseteq (\delta, \wp)$, then $(\Psi, \wp) \cup (\mathcal{S}, \wp) \subseteq (\vartheta, \wp)$ or $(\Psi, \wp) \cup (\mathcal{S}, \wp) \subseteq (\delta, \wp) \Rightarrow (\vartheta, \wp) \cup (\delta, \wp) \subseteq (\vartheta, \wp)$ or $(\vartheta, \wp) \cup (\delta, \wp) \subseteq (\delta, \wp) \Rightarrow (\vartheta, \wp) \cup (\delta, \wp) = (\vartheta, \wp)$ or $(\vartheta, \wp) \cup (\delta, \wp) = (\delta, \wp) \Rightarrow (\delta, \wp) = \phi$ or $(\vartheta, \wp) = \phi$, then is a contradiction. So $(\Psi, \wp) \subseteq (\vartheta, \wp)$ and $(\mathcal{S}, \wp) \subseteq (\delta, \wp)$ or $(\Psi, \wp) \subseteq (\delta, \wp)$ and $(\mathcal{S}, \wp) \subseteq (\vartheta, \wp)$, then in both the cases, $(\Psi, \wp) \cap (\mathcal{S}, \wp) \subseteq (\vartheta, \wp) \cap (\delta, \wp) = \phi \Rightarrow (\Psi, \wp) \cap (\mathcal{S}, \wp) = \phi$. So, is contradiction again to the given supposition that $(\Psi, \wp) \cap (\mathcal{S}, \wp) \neq \phi$. Hence,

we have $(\Psi, \wp) \cup (\mathcal{S}, \wp)$ is also a sSb^* -connected set. \square

THEOREM 3.10. *If $(\mathcal{W}, \mathcal{Q}, \wp)$ is a sSb^* -connected space, then it is a soft connected.*

Proof. Suppose $(\mathcal{W}, \mathcal{Q}, \wp)$ not sSb^* -disconnected. Therefore, \exists nonnull soft sets (\mathcal{L}, \wp) and (\mathcal{S}, \wp) , where $\mathcal{W} = (\mathcal{L}, \wp) \cup (\mathcal{S}, \wp) \ni cl(\mathcal{L}, \wp) \cap (\mathcal{S}, \wp) = \phi$ and $(\mathcal{L}, \wp) \cap cl(\mathcal{S}, \wp) = \phi$. Since $sSb^*cl(\mathcal{L}, \wp) \subseteq cl(\mathcal{L}, \wp)$. Thus, $sSb^*cl(\mathcal{L}, \wp) \cap (\mathcal{S}, \wp) \subseteq cl(\mathcal{L}, \wp) \cap (\mathcal{S}, \wp) = \phi$. Hence, $sSb^*cl(\mathcal{L}, \wp) \cap (\mathcal{S}, \wp) = \phi$. Similarly, $(\mathcal{L}, \wp) \cap sSb^*cl(\mathcal{S}, \wp) = \phi$. Hence, $(\mathcal{W}, \mathcal{Q}, \wp)$ is a sSb^* -disconnected. So, is a contradiction. Therefore, $(\mathcal{W}, \mathcal{Q}, \wp)$ is a soft connected. \square

THEOREM 3.11. *If $\Omega : \mathcal{W} \rightarrow \Sigma$ be a sSb^* -continuous surjection and \mathcal{W} is a sSb^* -connected space, then Σ is soft connected.*

Proof. Assume that Σ is not soft connected. Let $\Sigma = (\Psi, \wp) \cup (\mathcal{L}, \wp)$ where (Ψ, \wp) and (\mathcal{L}, \wp) are disjoint nonempty soft open sets in Σ . Since Ω is a sSb^* -continuous and onto, $\mathcal{W} = \Omega^{-1}(\Psi, \wp) \cup \Omega^{-1}(\mathcal{L}, \wp)$ where $\Omega^{-1}(\Psi, \wp)$ and $\Omega^{-1}(\mathcal{L}, \wp)$ are disjoint nonempty sSb^* -open sets in \mathcal{W} , which is contradiction to \mathcal{W} is a sSb^* -connected. Therefore, Σ is a soft connected. \square

THEOREM 3.12. *If $\Omega : \mathcal{W} \rightarrow \Sigma$ is a sSb^* -irresolute surjection and \mathcal{W} is a sSb^* -connected, then Σ is a sSb^* -connected.*

Proof. Assume Σ is not sSb^* -connected and $\Sigma = (\Psi, \wp) \cup (\mathcal{L}, \wp)$ where (Ψ, \wp) and (\mathcal{L}, \wp) are disjoint nonempty sSb^* -open sets in Σ . Since Ω is a sSb^* -irresolute and onto, $\mathcal{W} = \Omega^{-1}(\Psi, \wp) \cup \Omega^{-1}(\mathcal{L}, \wp)$ where $\Omega^{-1}(\Psi, \wp)$ and $\Omega^{-1}(\mathcal{L}, \wp)$ are disjoint nonempty sSb^* -open sets in \mathcal{W} , which is contradiction to \mathcal{W} is a sSb^* -connected. Therefore, Σ is a sSb^* -connected. \square

4. Conclusion. In this article, we presented some of conception of soft sets and soft topological spaces are investigated. The basis of paper is to establish and introduce soft compactness and soft Lindelöfness, namely, sSb^* -compactness, sSb^* -Lindelöfness. Examining some properties of these spaces allows us to prove some of our results and varied introduce the relationship between spaces and illustrate our main findings. Moreover, We define and explore the soft strongly b^* -connected spaces and discuss its relation with soft connectedness spaces. Also, the properties of sSb^* -connected and sSb^* -disconnected with examples are studied.

SPORTS EVENT DATA MANAGEMENT SYSTEM AND ITS APPLICATION IN COMPETITION ORGANIZATION

ZHENYU LI*

Abstract. Traditional sports competition data management systems have poor security and reliability in management results. The author proposes a new sports competition data management system based on a network platform. Integrating internal and external services to handle system business, designing pages using JSP dynamic page technology. Utilize network platforms to transmit data, and verify the transmission of data on the network platform through hardware and software firewalls. Realize data transmission between the system and the client through the designed network platform. Analyzed data backup and recovery methods to ensure data security. Track important business and operations of the system through the log tracking layer, and provide UML modeling for competition data management. The experimental results show that the recovery speed of the system is significantly faster than SSH and MDA systems, indicating strong data recovery performance of the system. It has been proven that the competition data management results of the designed system are reliable and the system performance is strong.

Key words: Online platform, Sports competitions, Data management system, JSP dynamic page technology

1. Introduction. The organization of large-scale sports events is a huge systematic project, especially the management of competition data, which is the core link of event organization work. However, with the continuous increase in the scale of sports events, not only have the operating costs of sports events become increasingly high, but the data management process of sports competitions has also become more complex, leading to increasing risks in organizing sports events. With the vigorous development of computer technology, powerful solutions have been provided for the complex management process of sports competition results. Currently, the management of sports competition results cannot be separated from the support of computer software systems [1].

The development of competition data management software systems is generally based on the relevant competition management regulations and rules formulated by sports event organization and management institutions, and other management technical specifications. However, different sports events generally have different competition management regulations and rules, so different sports event organization and management institutions also use their own competition management regulations and rule management software systems, which leads to the current sports competition data management system's weak universality and poor adaptability [2].

The sports event data management system is an information system that integrates data collection, storage, analysis, and display functions, widely used in the organization and management process of various sports events. With the continuous improvement of electronic technology and information technology, the application of sports event data management systems has become an indispensable part of modern sports organizations [3]. Through comprehensive, accurate, and real-time management of competition data, this system can provide better competition experiences and services to event organizers, participants, and spectators. The core function of a sports event data management system is data collection. During the competition, the system can collect real-time game data, including game results, scores, goals scored, fouls committed, etc., through various sensors and devices such as timers, scoreboards, cameras, etc [4]. These data are transmitted to the central server through wireless transmission or wired connections, achieving real-time updates and storage of data. Through data collection and storage, the sports event data management system can perform data analysis. The system can perform various statistics and calculations based on competition data, generating competition reports, data charts, and event analysis reports. These reports can help event organizers understand the overall situation of

*College of Physical Education, Baicheng Normal University, Baicheng, Jilin, 137000, China (Corresponding author, lizhenyu8188@163.com)

the competition, identify the strengths and weaknesses of athletes, and develop more scientific and reasonable training and competition strategies.

The sports event data management system also has the function of data display. Through the internet and mobile terminals, the system can display real-time competition data to the audience and participating players. Viewers can watch live matches through devices such as television, computers, and mobile phones to understand the progress and results of the matches. Contestants can view their competition results and rankings, as well as the performance of other contestants, through their mobile phones or computers. This real-time display method makes the competition more open and transparent, improving the fairness and credibility of the competition [5]. The application of sports event data management system can greatly improve the organization and management efficiency of sports events.

Traditional manual recording and statistical methods suffer from human errors and inaccurate data, while sports event data management systems can automate data collection, storage, and analysis to ensure accuracy and timeliness. This not only saves labor costs, but also improves the efficiency and accuracy of data management.

In addition, the sports event data management system can also provide more commercial value for event organizers. By analyzing and mining competition data, the potential and market value of athletes can be discovered, providing more business cooperation opportunities and sponsorship resources for event organizers. At the same time, through the display and promotion of event data, it can attract more audiences and fans, improve the visibility and influence of the event [6]. However, the application of sports event data management systems also faces some challenges and problems. Firstly, data security and privacy protection are important considerations. The competition data includes personal information and performance data of athletes, and strict security measures need to be taken to prevent data leakage and abuse. Secondly, the stability and reliability of the system are also key issues. Once the system malfunctions or data is lost, it will have a serious impact on the organization of the event and the participating players. Finally, the popularization and promotion of sports event data management systems also need to overcome technical barriers and cost issues, so that more sports organizations and events can enjoy the convenience and advantages of information management. In summary, the application of sports event data management systems has become an important component of modern sports organizations [7]. By comprehensively, accurately, and in real-time managing competition data, the system provides better event experiences and services for event organizers, participants, and spectators. With the continuous development and innovation of technology, it is believed that the sports event data management system will play a more important role in the future, promoting the development and progress of the sports industry. For this purpose, a new sports competition data management system based on a network platform has been designed.

2. Sports Competition Data Management System on Network Platform.

2.1. Overall System Design. The designed sports competition data management system based on network platform is described in Figure 2.1.

Design a system that combines internal and external services to handle system business, and use JSP dynamic page technology to design pages, thereby reducing the complexity of page code writing.

In order to ensure the timeliness and security of the system, this section uses the network platform to transmit data, verifies the transmission requests of the network platform through hardware and software firewalls, intercepts abnormal requests, and only allows legitimate requests to access the system. Simultaneously utilizing different technological constraints to ensure data integrity [8].

2.2. Network Platform Design. The network platform is mainly used to achieve data transmission between the system and the client, consisting of server clusters, gateways, firewalls, and other network infrastructure devices. Due to the large amount of sports competition result data, in order to improve transmission efficiency, the system chooses a distributed processing system, adopts ASP technology and B/S architecture, and operates in a local area network and external network environment. The B-end is mainly used for inputting, managing, and outputting data, while the S-end is mainly used for saving, accessing, and processing data. The network platform structure is shown in Figure 2.2.

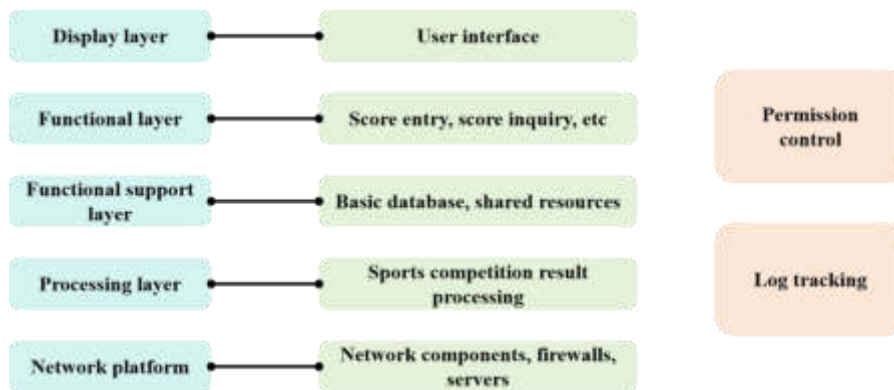

Fig. 2.1: Overall structure of the system

Fig. 2.2: Structure of the network platform

2.3. Functional Support Layer and Functional Layer Design. The functional support layer refers to the data center of the sports competition data management system and other network support, including components such as data storage and caching. Before athletes register online, the system administrator will publish the sports competition items and corresponding numbers, athlete grouping settings, and relevant information, making it easier for athletes to register independently [9].

During the competition, the system will promptly release competition information, and athletes can check their competition results through their own information. During the competition, the administrator inputs the competition results in real-time based on the competition status, and implements operations such as athlete grouping and competition result summary through the system. Users mainly include all sports competition staff, management personnel, athletes, etc., and can perform real-time queries on competition results[10]. The data flow diagram of the designed sports competition data management system is described in Figure 2.3.

During sports competitions, there are a large number of athletes, managers, and staff entering information, resulting in a large scale of data and heavy workload. Manual input can lead to data errors. In order to prevent these phenomena from occurring, data backup and recovery functions are provided in the design of the system to ensure the reliability of results. A detailed analysis will be conducted in the following text [11].

Before sports competitions, the administrator sets the competition items according to the requirements of the competition and processes the data based on the athlete's registration situation. The competition committee can check the athlete's competition results through online platforms, confirm them to be correct, and then output the results.

The functional layer contains several different types of functional modules, mainly responsible for imple-

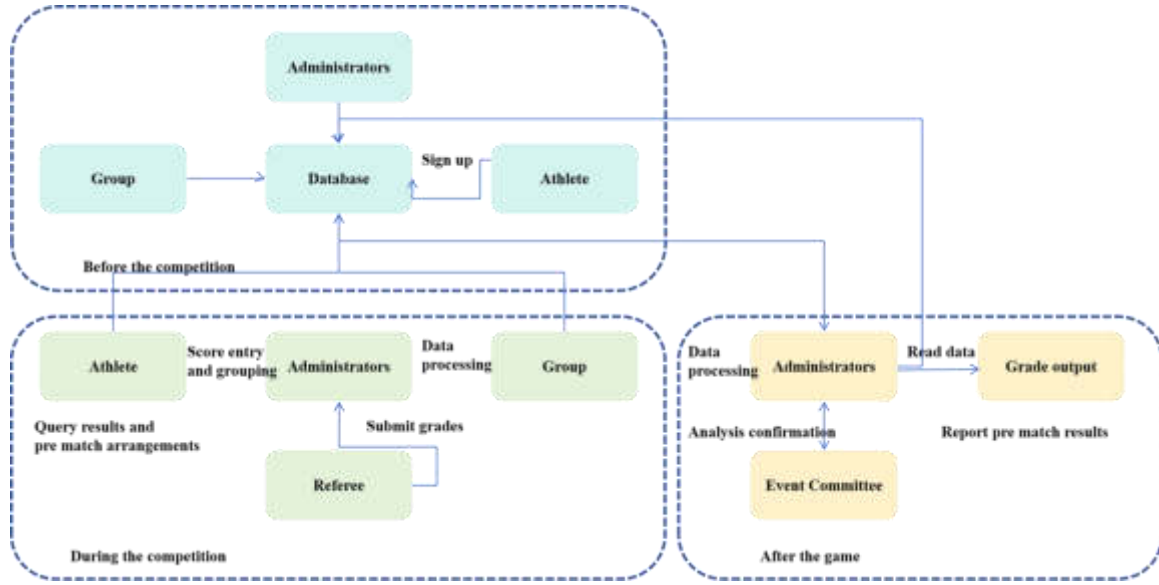

Fig. 2.3: Flow diagram of the system data

menting various business processes. By utilizing the interaction between the functional support layer and the data layer, corresponding business processing can be achieved, which not only displays information to users but also collects information from them[12].

2.4. Design of permission control layer. When designing the system, a firewall will be installed, with corresponding log records for all businesses in the system, mainly including operators and detailed operation information, for easy query.

In order to ensure the security of sports competition results, the system provides data backup and recovery functions. The system can autonomously backup data and recover it in the event of a failure, avoiding data loss [13].

When backing up sports competition data, encapsulate the request as a backup record and transfer it to the cache. The backup record mainly includes information such as the processing object, write length, and detailed data. The format is as follows:

$$R_{backup} = \{ \langle tid, offset, len, data \rangle \mid tid \in N, offset \in N, len \in N, data \in (0, 1)^t, t \in N \} \tag{2.1}$$

In the formula: tid is used to describe the excessive task identifier; $Offset$ is used to describe the offset address of the data to be processed; Len is used to describe the length of written data; $Data$ is used to describe writing data to a disk; N is used to describe a set of natural numbers. The process of recovering sports competition data is as follows:

1. Segmentation of sports competition data blocks and allocation of recovery tasks.
2. Calculate the summary values of different data and transfer the task record R_{task} to different remote backup servers for recovery. The task format is as follows:

$$R_{task} = \{ \langle tid, offset, len, LTH_i \rangle \mid tid \in N, offset \in N, len \in N, LTH_i \in N \} \tag{2.2}$$

In the formula: $LTH_i = H(L_i)$; H is used to describe the summary value function obtained; L_i is used to describe sports competition data to be restored.

3. After obtaining task records, read the object data block R_i from the remote backup server using a predetermined offset and data block size.

Fig. 2.4: Performance management: UML modeling

4. Find the summary values of different data blocks and compare them with the summary values transmitted by the local server. If they are inconsistent, it is considered that the data at both ends of the data block is different and needs to be restored; Otherwise, it is considered unnecessary to restore it[14].
5. Encapsulate the corresponding data blocks of different remote backup servers into recovery records and transmit them to the local server. The recovery record format is as follows:

$$R_{recovery} = \{ \langle tid, offset, len, data \rangle \mid tid \in N, offset \in N, len \in N, data \in (0, 1)^t, t \in N \} \quad (2.3)$$

6. After receiving data records, the local server transfers the data to the corresponding location on the disk through offset to achieve data recovery.

2.5. Log tracking design. The log tracking layer is mainly responsible for tracking important business and operations of the system, and recording relevant information in the form of logs, mainly including operation time, operator information, and specific operation information, in order to avoid losses caused by misoperations [15].

2.6. Processing layer design. The processing layer is mainly responsible for sports competition data management and is the core of the entire system. After the completion of different stages of the competition, the processing layer is responsible for inputting, processing, modifying, and printing the athlete's competition results, and grouping subsequent competitions based on the competition results. Detailed UML modeling is described using Figure 2.4.

3. Experiments and Result Analysis. The experiment tested the system from two aspects: The effectiveness of competition data management and system performance. In order to verify the effectiveness of the system, the SSH architecture system and MDA system were compared to manage the results of the men's 200m competition. The comparison results of the data management of the three systems are shown in Table 3.1.

Table 3.1: Management results of the three systems

Ranking	Actual grades	This article systematically announces the results	SSH system releases results	MDA system releases results
First place	2054	2054	2052	2054
Second place	2123	2123	2123	2123
Third place	2159	2159	2159	2146
Fourth place	2216	2216	2235	2223
Fifth place	2259	2259	2255	2259
Sixth place	2312	2312	2312	2312

Fig. 3.1: Time delay comparison results of the three systems

According to Table 3.1, the results published by the system are completely consistent with the actual results of the athletes, while the SSH system has three results that do not match the actual results, and the MDA system has two results that do not match the actual results. This indicates that the data management results of the system are reliable and effective.

During the testing process, the memory usage of the system remained within the range of 1-2 GB, and the memory growth remained stable without any memory leakage, effectively ensuring that the server provided real-time services to users [16]. In order to verify the timeliness of the system, a comparison was made on the query latency of competition results for 100 athletes in different events under the system, SSH system, and MDA system. The results are shown in Figure 3.1.

Analyzing Figure 3.1, it can be seen that the query latency of the system is significantly lower than that of SSH and MDA systems, indicating that the system not only has high management reliability but also good query timeliness [17-20].

The data recovery performance is a security factor that affects the security of system data. The data recovery speeds of this system, SSH system, and MDA system are compared below, and the results are described in Figure 3.2. Analyzing Figure 3.2, it can be seen that the recovery speed of the system is significantly faster than that of SSH and MDA systems, indicating that the system has strong data recovery performance and high security.

4. Conclusion. The author has designed a new sports competition data management system based on a network platform, provided the overall structure of the designed system, and introduced the design process at each level. The sports event data management system is a software system that integrates multiple functions,

Fig. 3.2: Comparison of the data recovery speed of the three systems

which can help match organizers efficiently collect, store, and analyze match data. The basic principle of this system is to collect various data during the competition, such as competition time, scores, statistical data, etc., through various sensors and devices, and then store these data in a database for subsequent analysis. The experimental results show that the designed system has reliable competition data management results and strong system performance. This system has high practical value and can be applied to various sports events to improve the management efficiency and accuracy of competition results. With the continuous development of technology, there is still room for further development and improvement of the system in the future.

THE INTEGRATION OF PERSONALIZED TRAINING PROGRAM DESIGN AND INFORMATION TECHNOLOGY FOR ATHLETES

PENGHUI HAO* AND KUN QIAN†

Abstract. In order to integrate the training of athletes with information technology, this paper proposes a method for evaluating the performance of athletes using training technology. HR, O₂, and hemoglobin were selected as input vectors of SVM, and the corresponding values were used as outputs to generate the training model. Adjust the support vector machine to minimize measurement error based on the learning objective. Support vector machines are used to study training patterns and develop models to evaluate athletes' performance. College athletes were taken as research subjects and the effects of training were examined in five sports: football, basketball, basketball, swimming, and running. The results show that the relative error of this type is less than 1 when measuring the performance of various sports subjects; Relative errors in measuring the academic performance of athletes in various sports using physical fitness standards and sport-specific skills 1. The proposed model proves that the athlete's training index is incorrect and has a useful application.

Key words: Machine learning algorithms, Training effectiveness, Support Vector Machine, High dimensional feature space, Indicator matrix

1. Introduction. With the rapid development of information technology, its application in various fields is becoming increasingly widespread. In the field of sports training, the design of personalized training programs is crucial for the growth and development of athletes. Traditional training programs are often based on general templates and cannot meet the individual differences and special needs of each athlete. Therefore, how to integrate information technology with the design of personalized training programs for athletes has become a focus of current research. The application of information technology in the field of sports training has achieved significant results [1]. The design of personalized training programs for athletes needs to fully consider factors such as their physical condition, technical level, and training objectives, in order to develop the most suitable training plan for them. Traditional training program design is usually formulated by coaches based on experience and routines, but this approach cannot meet the unique needs of each athlete.

The application of information technology provides new possibilities for the design of personalized training programs. By utilizing sensors, monitoring devices, and data analysis techniques, real-time physical data and performance of athletes can be obtained. These data can help coaches more accurately evaluate the training effectiveness of athletes and adjust training plans in a timely manner. For example, sports tracking devices can record the athlete's movement trajectory and speed, heart rate monitoring devices can understand the athlete's physical condition, and strength testing devices can evaluate the athlete's muscle strength.

The analysis and integration of these data can provide targeted training suggestions for coaches, helping them develop personalized training plans. In addition, information technology can also provide online teaching platforms, allowing athletes to train anytime, anywhere. Through video teaching, virtual reality and other technological means, athletes can receive guidance and guidance from professional coaches to improve the effectiveness of training. This approach not only saves time and costs, but also breaks geographical restrictions, allowing more athletes to benefit from professional guidance [2].

In addition, information technology can also provide a platform for coaches and athletes to communicate and share. Through social media, online forums, and other channels, athletes can communicate with other

*Police Skills and Tactical Training Department, Criminal Investigation Police University of China, Shenyang, 110035, China (Corresponding author, hph333666@163.com)

†College of Sports Science, Shenyang Normal University, Shenyang 110034, Liaoning, China (Corresponding author, qiankun20232@163.com)

athletes and coaches, share experiences and insights. This way of communication and sharing can stimulate innovation and cooperation, promote individual growth and team development of athletes. However, information technology also faces some challenges in the design of personalized training programs. Firstly, the accuracy and reliability of data are the core issues [3]. The body data of athletes needs to be collected through reliable sensors and devices, and the accuracy and stability of these devices have a significant impact on the credibility of the data. In addition, data analysis and processing require professional knowledge and technical support to ensure the extraction of useful information and guidance from massive amounts of data. Secondly, privacy and security issues also need to be taken seriously. The personal data involved in the design of personalized training programs needs to be legally and securely protected to avoid abuse or leakage. Relevant privacy policies and security measures need to be fully developed and implemented to safeguard the rights and interests of athletes and coaches.

In summary, the application of information technology in the field of sports training has brought new opportunities and challenges to the design of personalized training programs [4]. By using sensors, monitoring devices, and data analysis techniques, it is possible to more accurately evaluate the condition and training effectiveness of athletes, and develop personalized training plans for them. The establishment of online teaching platforms and communication sharing platforms also provides athletes with more learning and communication opportunities. However, data accuracy and privacy security issues need to be taken seriously and addressed. In the future, with the continuous development and innovation of information technology, the design of personalized training programs will be further improved, promoting the growth and development of athletes.

2. Analysis of the Application of Information Technology in Sports Training.

2.1. Information technology drives athlete selection through data-driven and evidence-based approaches. Scientific selection is based on the disciplines of life sciences such as biochemistry, biomechanics, and genetics, and utilizes modern scientific and technological means to comprehensively select athletes in terms of their physical form, physiological functions, physical fitness, psychological qualities, and sports skills according to their own characteristics and project characteristics [5]. It scientifically and reasonably selects outstanding athletes for high-level sports training. By combining modern information technology with biological data models, we aim to develop material selection criteria that are consistent with project characteristics, and strive to achieve rational, data-driven, and scientific material selection.

2.2. Information technology enables sports assistive devices to have intelligent brains. With the rapid development of modern science and technology such as electronic information technology, intelligent sensing technology, internet big data, cloud computing, artificial intelligence technology, etc., primitive traditional sports and fitness equipment that used to have no emotional color and no data feedback, such as barbells, treadmills, power extenders, etc., now have a "brain" that can interact and communicate with sports participants through the implantation of information technology, and automatic detection of physical fitness indicators functions such as automatic provision of training plans, real-time monitoring of exercise processes, and automatic feedback evaluation of exercise effects [6].

2.3. Information technology enhances the diversification of sports training forms and promotes scientific transformation. Information technology, as a product of technological development, has rapidly penetrated into people's daily work and life, and its impact is gradually expanding. The concept of the Technology Olympics not only increases people's expectations for modern sports events, but also makes them more visually appealing. The use of information technology for auxiliary training can make the training methods more scientific, diverse, and effective. In a sense, it is technology that makes sports more attractive, keeps sports up with the times, and makes sports more meaningful. Coaches use information processing technology to quickly and efficiently develop training plans, outlines, and lesson plans; Reasonably utilizing text processing technology, image editing technology, and video capture technology, the training content and methods are transmitted to the athlete's audio-visual system through technological means, improving the training experience in a new way, stimulating training motivation, and enhancing training effectiveness [7].

As one of the sports powerhouses, the United States has achieved impressive results in applying computer information processing technology to various fields of track and field training. For example, by loading a video into the system, the trajectory of the high jump athlete's movement before takeoff, the takeoff point, and

various posture changes, angles, speeds, etc. of the body after takeoff are recorded [8]. These data are then compared with various data from world-renowned high jump athletes in the database to identify gaps, identify problems, and provide solutions. Through repeated recording and playback of technical movements, combined with simulation teaching of information technology, athletes can intuitively, three-dimensional, actively, and comprehensively master standardized and correct technical movements, thereby improving the scientific and effective nature of sports training, reducing the training cycle of athletes, improving the success rate, and effectively increasing the scientific output of sports results. The application of information technology can not only improve training effectiveness, enhance competitive level, refresh sports performance, but also reduce sports injuries and extend sports lifespan. Information technology has broken the traditional mode of sports competition and training. Traditional sports training requires coaches to conduct planned, purposeful, and organized speech and actions through language or physical means. However, various data during training often better illustrate the actual competition ability of athletes.

3. Evaluation of Athlete Training Effectiveness Based on Machine Learning Algorithms.

3.1. Machine learning algorithms. Let $F(z)$ be a probability measure that exists in space z , with a set of functions $Q(z,a)$ and $a \in \Lambda$, which can achieve the goal of minimizing the risk functional or machine learning. The formula is as follows:

$$R(a) = \int Q(z, a)dF(z) \tag{3.1}$$

In the formula, the probability measure $F(z)$ is unknown, but there are fixed independent distribution samples. The formula for obtaining the loss function is as follows:

$$L(y, f(x, a)) = \begin{cases} 0, & y = f(x, a) \\ 1, & y \neq f(x, a) \end{cases} \tag{3.2}$$

Using the hazard function to justify the function $f(x, a)$ and the probability of exit from the trainer, it is necessary to obtain the function with the minimum distribution error based on the knowledge configuration.

The support vector machine method finds the final model result with the best learning ability, low complexity and high generalizability based on limited sample data. Support vector machine has a high degree of generality, suitable for large-scale, small-sample and non-data fields. Choosing support vector machines as a way to measure sports performance can fully understand the advantages of support vector machines for processing small data. By obtaining the best surface distribution from a small sample size, the surface distribution obtained was the best, reducing the cost of sports performance analysis.

Use (x_i, y_i) to represent training data, and satisfy $i = 1, 2, \dots, l, x \in R^d, y \in \{1, -1\}$, where l represents the number of samples. Assuming the existence of hyperplane H , there is the following formula:

$$w \cdot x + b = 0 \tag{3.3}$$

Using hyperplane H to separate positive and negative data, the hyperplane spacing formula is as follows:

$$\frac{2}{\|w\|} = d_1 + d_2 \tag{3.4}$$

In the formula, the euclidean norm of w and the two types of samples closest to H are represented by $\|w\|$ and d_1, d_2 , respectively. Using support vector machine method to search for hyperplanes with the maximum interval, the expression is: $\min_{w,b} \frac{1}{2}\|w\|^2, s.t. y_i(x_i \cdot w + b) - 1 \geq 0$, in the formula, $i = 1, 2, \dots, l$. The optimal classification surface problem is transformed into its dual problem through Lagrangian optimization method, and the formula obtained is as follows:

$$Q(\alpha) = \frac{1}{2} \sum_{i,j=1}^l \alpha_i \alpha_j y_i y_j (x_i \cdot x_j) - \sum_{i=1}^l \alpha_i \tag{3.5}$$

Using $\sum_{i=1}^l y_i \alpha_i$ and $\alpha_i \geq 0, i = 1, 2, \dots, l$. as constraints, use the Lagrange multiplier α_i corresponding to the sample to solve for the minimum value of Equation 3.5. The sample corresponding to α_i that is not 0 in the obtained result is the support vector[9].

The final optimal classification function is as follows:

$$f(x) = \text{sgn}\{(w \cdot x) + b\} = \text{sgn}\left\{\sum_{i=1}^l y_i \alpha_i (x_i \cdot x) + b^*\right\} \tag{3.6}$$

In the formula, b^* represents the classification threshold.

When the experimental sample is linearly inseparable, add a relaxation term; The method for obtaining $\xi_i \geq 0$ in Equations 3.5 and 3.6 is as follows:

$$\min_{w,b} \frac{1}{2} \|w\|^2 + C \sum_{i=1}^l \xi_i, \text{ s.t. } y_i(x_i \cdot w + b) - 1 + \xi_i \geq 0 \tag{3.7}$$

If the penalty factor $C > 0$ for the degree of punishment for correctly and wrongly divided samples is constant, then the dual problem condition is transformed into $0 \leq \alpha_i \leq C$.

The objective function obtained is as follows:

$$Q(\alpha) = \frac{1}{2} \sum_{i,j=1}^l \alpha_i \alpha_j y_i y_j K(x_i \cdot x_j) - \sum_{i=1}^l \alpha_i \tag{3.8}$$

At this point, the optimal classification function is as follows:

$$f(x) = \text{sgn}\left\{\sum_{i=1}^l y_i \alpha_i K(x_i \cdot x) + b^*\right\} \tag{3.9}$$

Different types of nonlinear decision surface support vector machines can be implemented through differential kernel functions. The radial basis kernel function is selected as the kernel function for evaluating the training effectiveness of athletes, and its formula is as follows:

$$K(x_i \cdot x) = \exp\left(-\frac{\|x - x_i\|^2}{2\sigma^2}\right) \tag{3.10}$$

3.2. Evaluation of Athlete Training Effectiveness. The physiological information during athlete training can reflect the training effect and showcase more information that the previous athlete training evaluation system could not evaluate.

Use $X = \{x_1, x_2, \dots, x_n\}$ and $Y = \{y_1, y_2, \dots, y_n\}$ to represent the athlete training sample set and the test indicator set that can reflect the physiological indicators of athlete training effectiveness, such as heart rate, oxygen uptake, hemoglobin, creatine kinase, etc. The matrix $A = (a_{ij})_{n \times m}$ represents the indicator matrix of the athlete training sample set X for the measurement indicator set Y, and the indicator values of the athlete training sample x_i for the measurement indicator y_j are represented by $a_{ij} = y_j(x_i) (i = 1, 2, \dots, n; j = 1, 2, \dots, m)$.

The input unit for evaluating athlete training effectiveness is the athlete training sample x_i , and the measurement vector $(r_{i1}, r_{i2}, \dots, r_{im})$ under physiological measurement index y_j . If the evaluation result u_i of athlete training effectiveness x_i is used as the output unit, there exists a non-linear mapping between the normalization matrix R and the evaluation result, as shown in F, and its formula is as follows:

$$u_i = F(r_{ij}) \tag{3.11}$$

Select athlete training effect sample $x_i(r_{i1}, r_{i2}, \dots, r_{im})$ as the input vector of the support vector machine, select training effect sample evaluation value as the regression target value U of the support vector machine, establish a learning sample set, represented by $G = \{(x_i, u_i)\}_i^n$, and obtain the regression function as follows:

$$u = \sum_{k=1}^s (\alpha_k - \alpha_k^*) K(x, x^k) + b \tag{3.12}$$

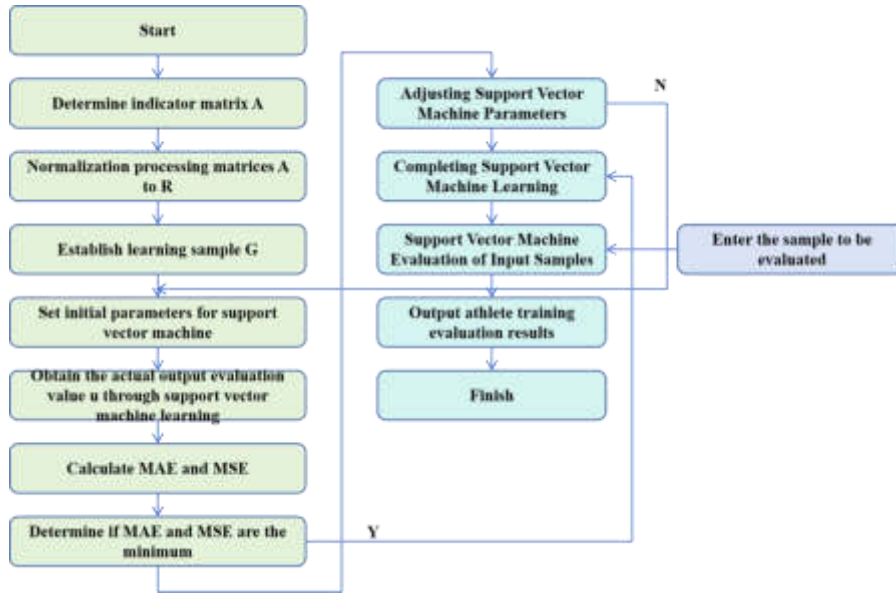

Fig. 3.1: Structural diagram of athlete training effect assessment

In the formula, X^k and s represent support vectors and the number of support vectors, respectively, $x^k = (r_{k1}, r_{k2}, \dots, r_{km}), k = 1, 2, \dots, s$.

Implement athlete training sample x_i through the above process; The non-linear mapping F between the measurement vector $(r_{i1}, r_{i2}, \dots, r_{im})$ of physiological indicators y_j and the evaluation value u_i of training effectiveness[10].

The structure diagram of evaluating athlete training effectiveness using the support vector machine method in machine learning algorithms is shown in Figure 3.1.

The process of evaluating the effectiveness of athlete training is as follows:

1. Determine the evaluation index matrix A for athlete training effectiveness based on physiological indicators that affect athlete training effectiveness;
2. Convert the indicator matrix A for evaluating the training effectiveness of athletes to a normalized matrix R ;
3. Establish a learning sample set $G = \{(x_i, u_i)\}$ using athlete training effect sample $x_i = (r_{i1}, r_{i2}, \dots, r_{im})$ and evaluation value u_i , and randomly select samples from the learning sample set to establish a training and validation set for support vector machine learning.
4. Select the radial basis kernel function as the support vector machine kernel function to obtain the regression function formula. The criteria for selecting parameters for evaluating the training effectiveness of athletes are as follows:

$$\begin{cases} MAE = \frac{1}{l} \sum_{i=1}^l |u_p^i - u_{SVM}^i| \\ MSE = \frac{1}{l} \sum_{i=1}^l (u_p^i - u_{SVM}^i)^2 \end{cases} \quad (3.13)$$

In the formula, MAE and MSE represent the average absolute error and mean square error of the validation samples, u_p^l and u_{SVM}^l represent the expert evaluation value and support vector machine calculation value of the validation samples, and l represents the total number of samples to be evaluated.

5. On this basis, SVM is used to evaluate the training results. By inputting the physiological testing indicator vector $(r_{i1}, r_{i2}, \dots, r_{im})$ of the training effect sample x_i of the athlete to be evaluated, the final support vector machine's athlete training effect evaluation result u_{SVM}^i can be obtained.

Fig. 4.1: Relative error in the number of different indicators

4. Example Analysis. Ten athletes majoring in sports training from a certain sports university were selected as the research subjects, and they were trained in five sports: football, basketball, volleyball, swimming, and running. This method was used to evaluate the training effects of the ten athletes. Heart rate and lung capacity were collected before and after each exercise training, and morning venous blood was collected for the training cycle.

Out of a total of 10,000 samples collected, 2,000 were used as research samples and the remaining 8,000 were used as test samples. Select radial root kernel function as support vector machine kernel function, use winSVM software to solve support vector machine problem, this software is optimized for Windows operating system, fully support vector machine classification and regression problem.

The training samples are divided into 10 groups of 200 each, and finally the parameters of the support vector machine are determined as $C=150$, $\sigma^2 = 0.016$, and the final decision is used to train the support vector to carry the vector and get the number of support vectors and the parameter b . 30 and -0.228 for the regression function [11]. To assess sports performance, heart rate, maximal oxygen uptake, hemoglobin, creatine kinase, and blood lactate are selected as physical parameters. This method was used to estimate the relative error of measuring the academic performance of athletes in various sports when only heart rate, heart rate, maximal oxygen uptake, and hemoglobin were used as measures of physical fitness five physical parameters used. From the experiments in Figure 4.1, it can be seen that as the number of physical parameters increases, the relative error of sports evaluation results decreases. This suggests that adding more physical parameters to the machine learning algorithm can improve the accuracy of sports analysis. The main reason is that many physical parameters improve the various results of sports analysis and improve the accuracy of sports analysis [12,13,14,15].

The output results of evaluating the training effects of 5 sports for 10 athletes using this method are shown in Figure 4.2.

Based on the evaluation of sports training results shown in Figure 4.2, the results of expert evaluation were selected as the correct decision criteria for sports performance evaluation, and five types of sports were analyzed in this type of performance analysis: football, basketball, and basketball. swimming and archery. To justify this type of performance assessment, physical activity and sport-specific skills were chosen as the model for comparison. Figure 4 shows a comparison of the relative errors in measuring the fitness index of athletes in five sports using different models[16,17,18,19]. From the comparison results in Figure 4.3(a)-(e), it can be seen that when selecting the expert evaluation the basis of performance evaluation, the relative error of this type is less than 1 when evaluating the training of athletes of various sports; Relative errors in measuring academic performance of athletes in various sports using fitness standards and sport-specific skills 1. Comparison of the results shows that this type has a good performance in sports evaluation. Analyzing the results of this type

Fig. 4.2: Results of the training effect evaluation of the athletes

of measurement can help coaches develop training plans for soccer performance. This type can be used to objectively evaluate soccer performance.

5. Conclusion. The training effect of athletes determines their final competitive performance, which is influenced by factors such as training methods and personal qualities, resulting in a wide range of fluctuations in athlete performance. Evaluate the training effectiveness of athletes using physiological indicators, and achieve the evaluation of athlete training effectiveness through the support vector machine method with higher evaluation performance in machine learning algorithms. Support vector machines have high learning and generalization abilities, the effectiveness of using the proposed method to evaluate the athletic performance of athletes through sports such as football has high guiding significance for improving the training effectiveness of athletes.

DIAGNOSIS AND TREATMENT SYSTEM BASED ON ARTIFICIAL INTELLIGENCE AND DEEP LEARNING

XIAOXI ZHENG*, QILI FAN† AND GENG WANG‡

Abstract. This paper designs an assisted diagnosis and treatment system based on deep learning algorithms and medical knowledge to solve the problem of poor use efficiency of massive electronic medical information. First, the disease data in the medical database is segmented to get the reverse order search table. Secondly, the similarity between the obtained clinical manifestation data and the corresponding diseases is analyzed and classified to obtain the clinical diagnosis. Then, the feedback-query method is used to analyze the weighted ratio of the original and feedback data, and the optimal fault diagnosis is carried out. The method of implicit semantic modeling is used to give the diagnosis scheme of the disease. The search method based on inference rules is introduced to realize personalized diagnosis and treatment resource recommendations to users. In this way, the specific attributes of medical resources based on individual information are effectively combined. Experiments show that the initial diagnosis recognition rate of the proposed method is 95%, the correct rate is 85%, and the recognition rate is 95% after optimization.

Key words: Deep learning; Medical knowledge base; Artificial intelligence; Electronic diagnosis and treatment; Lingo model

1. Introduction. Many patients with complicated diseases will come to first-tier cities to seek better treatment. There are many online information platforms to make the masses better understand the relevant medical information. In the past, access to medical information was mainly based on keyword-based information retrieval. However, due to the rapid development of medical data, this approach rarely meets the needs of patients. Many intelligent recommendation algorithms have recently been applied to medical data retrieval. Literature [1] provides a collaborative screening algorithm for patients with a particular disease, which can effectively solve the problem of personalized diagnosis and treatment of patients. Literature [2] proposes a medical knowledge recommendation method based on cooperation, which generates a trusted factor through the evaluation of medical services and introduces the trusted factor into the recommendation algorithm of joint filtering to realize personalized recommendations for physicians. This method not only overcomes the "information overload" of doctors but also improves the recommendation effect. Literature [3] extracts user data from user text, constructs a medical data knowledge map, and then carries out medical service resource recommendations based on collaborative filtering. Hidden semantic models such as matrix decomposition, probabilistic cryptology analysis, and implicit Dirichlet distribution effectively find hidden data. Reference [4] applies matrix decomposition to the prescription problem to discover the combination mode. However, the biggest drawback is that its parameter scale depends on the sample size, which can easily cause overfitting. Reference [5] provides the implicit semantic analysis method. They use the hidden tree method to find the hidden structure of the disease and construct the objective diagnostic criteria. The study used only disease data, not drug data, which is integral to the dialectics. Previous studies focused on the analysis of clinical manifestations. Yet, each case includes a set of symptoms and a set of medications. This project intends to use implicit-semantic modeling and case analysis methods to realize the association analysis of drug - pathogenesis. Then, the network platform provides personalized medication recommendations for patients.

2. Diagnosis and treatment based on the medical knowledge base. Reference [6] gives an architecture for assisting disease diagnosis and treatment. The system mainly includes the following parts: 1) Analysis of disease information through the characteristics of the disease segmentation operation to analyze the disease

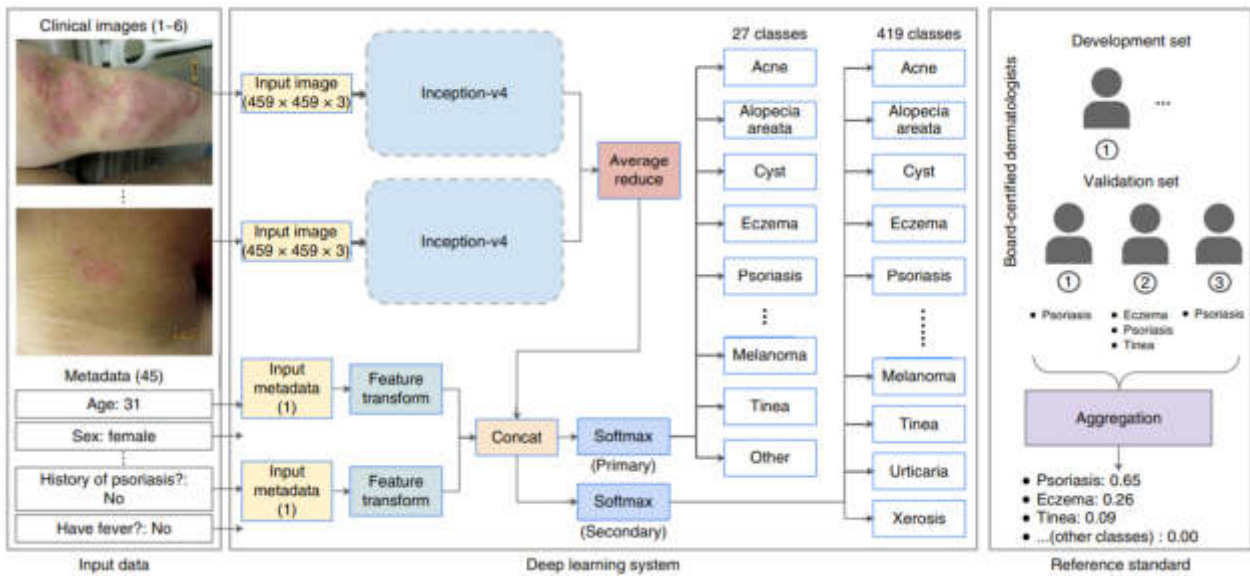

Fig. 2.1: Structure of diagnosis and treatment system based on deep learning.

information; 2) Disease index table an inverted index table can be constructed based on the analysis of disease information. 3) The condition assistance diagnosis module can input patient information into the system and judge the condition. 4) Diagnostic results and information feedback module displays diagnostic results. The optimal diagnosis of the disease is combined with the user’s opinion. 5) The case data analysis module can obtain the detection methods related to the disease. 6) Check the suggestion form to develop the diagnosis method according to the case analysis. 7) Diagnosis The diagnostic suggestion module displays the detection patterns and diagnostic possibilities. 8) The disease association information module displays disease-related information, such as etiology, diagnosis, and treatment mode. The system analyzes the relevant information on the disease in the medical database and generates the disease search form and diagnosis mode suggestion form in the background. Secondly, based on the clinical manifestation data of the patients, the suspected disease was diagnosed, and the correlation analysis was carried out. Then, if the user has feedback on their condition, the optimal diagnosis will be made, and the details of the condition and further tests can be seen.

3. Auxiliary diagnostic technology. This section discusses specific embodiments of the assisted diagnostic techniques described in Figure 3.1.

1. Perform the same segmentation on the clinical manifestations of the input patients and compare the segmentation results with the search table. All eligible cases are entered into the potential outcome set, and the total number of these cases is called N.
2. A symptom index table was used to calculate the degree of correlation of each condition in the potential outcome set for each case and ranked according to the degree of correlation.

Use $S = \frac{1}{t} \sum (q * d)$ to express the correlation function. A similarity measurement method based on the vector space model is proposed starting from the internal product method of the vector space model. Here S represents the degree to which the patient’s condition is related to the input. t is the number of types of diseases occurring in the disease, which is used to balance the matching probability of diseases with more significant symptoms in the disease database [7]. This solves the problem that the weight of the disease is too large due to the wide range of the disease. Where q is the proportion of each condition in different keywords. Treat the condition as the first possible condition. d represents the weight of each condition, again increasing the weight of the likely primary condition [8]. The correlation degree obtained by this function does not have a specific upper limit. For the convenience of calculation, the maximum and minimum values are standardized, so the correlation degree presented in the end is a relative value.

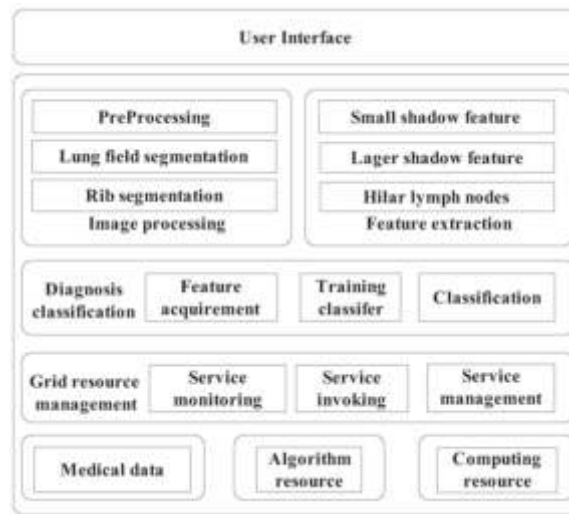

Fig. 3.1: Deep learning-based assisted diagnosis and treatment system flow.

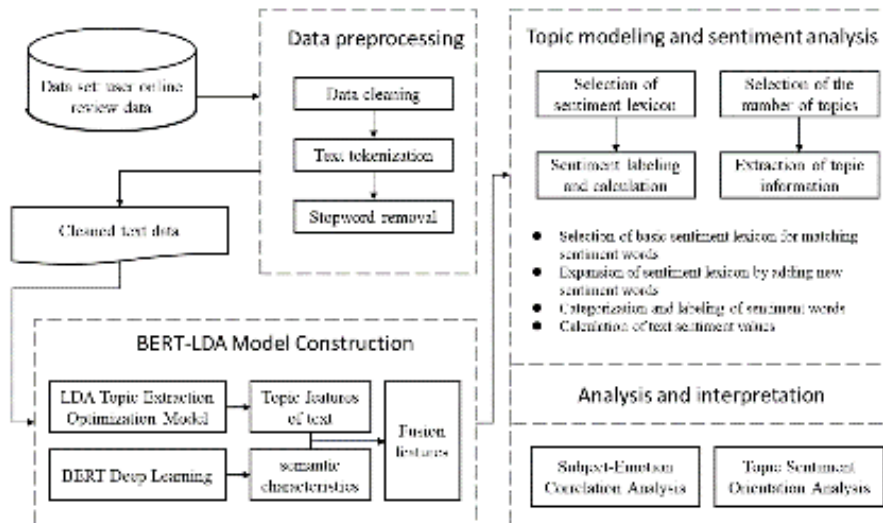

Fig. 4.1: Linear discriminant model flow.

4. The linear discriminant model was used to analyze medical case samples.

4.1. Introduction of Linear Authentication Mode. The implied Dirichlet distribution was first established in the multi-level Bayesian model by Blei et al. in 2003. The linear authentication pattern flow (Healthcare. MDPI, 2023, 11 (15):2142) is shown in Figure 4.1. This method was initially used in word processing and has been widely used in many data mining applications. The linear discrimination model is a typical topic model, which is to build θ and ϕ and discover.

A topic is a set of interrelated words that can be used to illustrate the topic. The words in the document are expressed in terms of conditional possibilities related to the topic [9]. Each topic contains words that have a high probability and are highly relevant to that topic. One word can have many different topics at the same time. Therefore, this paper proposes the "document-topic-vocabulary" correlation based on the generation

pattern. The method produces a topic with a certain probability and then a word with a certain probability. The probability of each word γ appearing in A document s can be calculated by the following formula:

$$| f(\gamma | s) = \sum_t f(\gamma | t)f(t | s)$$

t is the topic of this passage. In linear discrimination mode, the text contains the assignment of topics, and the topic contains the assignment of keywords [10]. Think of each prescription as a document that records the patient's condition and the medication the doctor prescribes. If symptoms and drugs are treated as "words" without distinction, they can be clustered through a linear identification pattern. Each group in the cluster contains several words, which can be a disease or a drug. Theoretically, explaining the rationality of such a cluster model is also problematic. Etiology is the subject of the model in the diagnosis problem related to conditions and both types of literature. If the two documents can be classified, establishing a link between the disease and the cause can better describe the problem.

4.2. Multiple linear discrimination model. Because of the existing methods in the aspect of data analysis of the connotation of the project plans to build a more linear differential model (figure 4.2) and reveal the whole process of production (PeerJ Computer Science, 2023, 9: e1016), the case will be regarded as files, including disease vocabulary r and γ two different types of vocabulary [11]. Given the pathogenesis, the distribution of these two types of words is independent and determined by the subject of the prescription, that is, the pathogenesis. c is a twovariable observation. There are only two values for the font: SYMPTOM or HERB. If it is $c = SYMPTOM$, the resulting word is the symptom word r . If it is $c = HERB$, the resulting word is the medical word γ . This project proposes a linear identification method based on multiple connotations. Case and drug words have the same topic, and there is a certain correlation between the two words under a specific topic. The spatial distribution of the problem c is obtained by using polynomial distribution characteristics. The post-disease word can be obtained according to the polynomial distribution lattice consistent with the problem. The medical word γ is derived from a polynomial distribution that agrees with the topic. It is the polynomial distribution lattice ζ and δ is the Dirichlet priori of χ .

After the distribution parameter $\varepsilon, \varphi, \delta$ is known, the joint probability of the "prescription - disease" distribution β , "disease - disease" distribution ζ , and "disease - drug" distribution χ is obtained as follows:

$$\begin{aligned} f(r, \gamma, c, \varepsilon, \beta, \zeta, \chi | \varepsilon, \varphi, \delta) = \\ f(\zeta | \varphi)f(\chi | \delta)f(\beta | \varepsilon)f(r, \gamma, c, \varepsilon | \zeta, \chi, \beta) = \\ f(\zeta | \varphi)f(\chi | \delta)f(\beta | \varepsilon)f(r, \gamma, c, \varepsilon, \zeta, \chi) \\ f(c | \varepsilon, \beta)f(c) \end{aligned}$$

The Gibbs sampling method is used to identify the parameters in the system [12]. In the multi-connotation linear identification model, the possibility of disease $f(r_i | r'_i)$ and drug $f(\gamma_i | \gamma'_i)$ belonging to topic $c = \{1, 2, L, K\}$ was calculated for the drugs for disease $r = (r_1, r_2, L, r_S)$ and disease $\lambda = (\lambda_1, \lambda_2, L, \lambda_W)$ in the observed samples respectively, and iteration was carried out for each stage.

5. Data online assisted diagnosis and treatment algorithm. A multi-connotation linear identification method obtained the corresponding relationship between disease and drug. A reasonable medication plan can be obtained using the established mathematical model for clinical diagnosis and then taking the clinical manifestations of patients as input. First, the "pathogenesis" is extracted based on the known disease characteristics, and then the drug is administered according to the cause [13]. The second method establishes a "disease-drug" matrix to obtain the corresponding relationship between each disease and each drug. In order of the conditions provided, get the corresponding medication recommendations. Therefore, this project intends to adopt a hybrid model to merge the two algorithms and improve the recommendation accuracy.

5.1. Pathology-based drug recommendation methods. Assuming that the clinical manifestation of the patient is $r = (r_1, r_2, L)$, the "disease-topic" distribution ζ , "drug-topic" distribution χ and prior parameters obtained by the multi-connotation linear identification model, then the etiological drug recommendation method can be expressed as:

Enter: A list of the patient's symptoms.

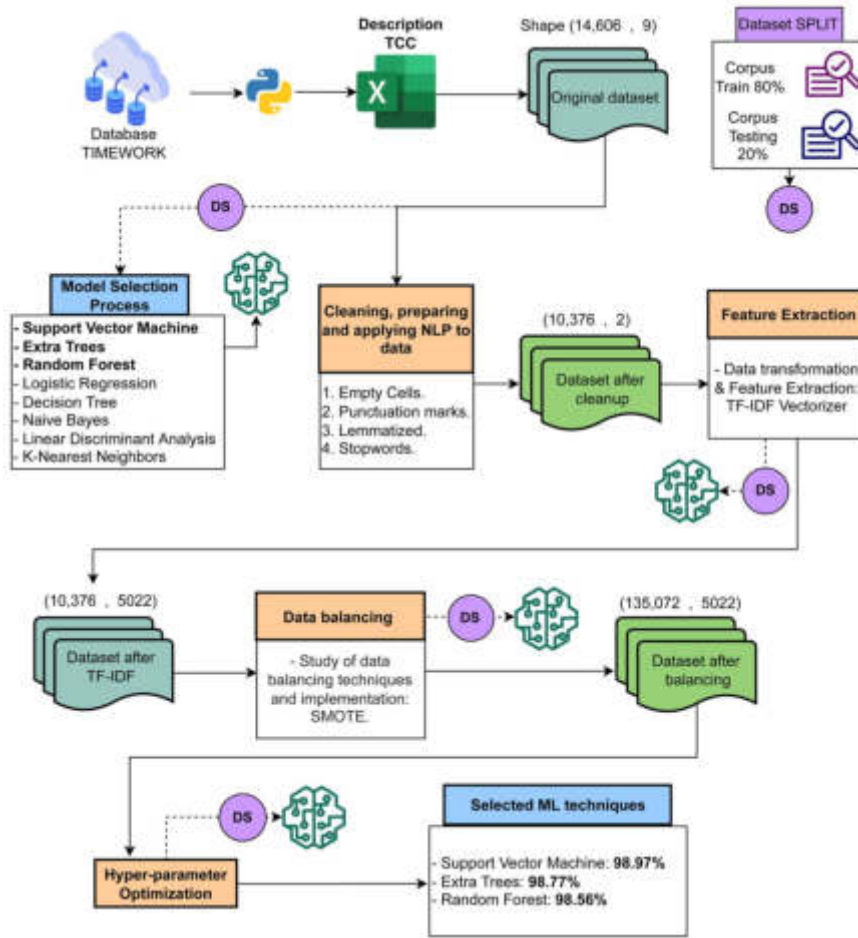

Fig. 4.2: Multi-content linear discriminant probability graph model.

Output: According to the patient W disease, medication is recommended.

1. Random initialization: Each current disease r will be randomly assigned a topic number c .
2. According to the sampling equation, the current file is tested again. For each disease r , the topic is sampled again.
3. The above treatment is repeated until the sampling convergence is achieved.
4. This paper determines the pathogenesis of the disease based on the distribution of the obtained topics. Top N drugs related to this disease are listed as recommendations [14]. First, the clinical manifestations of patients are regarded as the new document topic, then the disease information in the new literature is obtained by inference algorithm, and then the drug related to this disease is selected according to probability. The sampling equation to be used in the second step of the method is:

$$f(c_{i_r} = t \mid c = SYMPTOM, c_{-i_r}, r, \gamma) \propto \frac{W_{r_m}^{(t), -i_r} + W_{\gamma_m}^{(t)} + \varepsilon_t}{\sum_{t=1}^K (W_{r_m}^{(t), -i_r} + W_{\gamma_m}^{(t)} + \varepsilon_t) \sum_{f=1}^S (W_{r_t}^{(f), -i_r} + \varphi_f)}$$

$W_{r_m}^{(t)}$ and $W_{\gamma_m}^{(t)}$ represent the symptoms section in document m . The number of diseases listed in the

title t and the number of drugs used. $W_{r_t}^{(f)}$ is the number of disease words with an average f number in the topic t .

5.2. Drug recommendation methods based on clinical manifestations. The process of drug recommendation based on disease is shown in Figure 5.1, with a set of conditions and weights of patients as their inputs. It can be expressed as an n -dimensional vector. The default value is 1 ; otherwise, it is 0 . When the medical record rights are entered, the corresponding value is the input value [15]. This method expresses the correspondence between each disease and each drug by establishing a "disease-drug" matrix. Finally, according to the clinical manifestations of the patients, the most closely related to the clinical manifestations of the drug regimen.

Input: A set of symptoms for the patient and the proportion of each symptom.

Output: According to the patient W disease, medication is recommended.

1. Establish an "etiology - drug use" model. The information in column j , row i , of the matrix is $f(\gamma_j | r_i)$, which is the likelihood of taking the drug j when disease i occurs.
2. The rank value of each drug was calculated according to the clinical manifestations of patients and corresponding weights.
3. The drugs were ranked according to the rank, and the top W ranked drugs were recommended to patients. The formula used to construct the first step of the matrix is:

$$f(\gamma_j | r_i) = \sum_{c=1}^K f(\gamma_j | c) \cdot f(c | r_i)$$

c represents the topic in multinomial linear discrimination mode. K is the number of topics. The expression of $f(\gamma_j | c)$ as the parameter χ , $f(c | r_i)$ in the multi-connotation linear discrimination model is as follows:

$$f(c | r_i) = \frac{f(r_i, c)}{f(r_i)} = \frac{f(r_i | c) \cdot f(c)}{f(r_i)} \propto f(r_i | c) \cdot f(c)$$

$f(r_i | c)$ is the parameter ζ in the multi-content | model. $f(c)$ is the subject of the disease, which is obtained by the model derivation process. The grade value of each drug γ_j is calculated using the following formula:

$$\text{rank}(\gamma_j) = \sum_{i=1}^S f(\gamma_j | r_i) \cdot \text{weight}(r_i)$$

$\text{weight}(r_i)$ is a weighting of symptoms r_i provided by the user.

By default, conditions that have been typed have a weight of 1, and conditions that have not been typed weight of 0.

The first medication method analyzes the pathogenesis based on the disease and prescribes reasonable medication according to the cause. The latter is to give the corresponding treatment plan for the patient's condition [16]. The focus of the two types of treatment is different. In treatment, the doctor will start with the cause and then prescribe the corresponding drug to the patient. This paper intends to design a hybrid recommendation algorithm. Take the intersection of the two as the final recommendation.

6. Experimental results and analysis.

6.1. Data Sets. 900 cases were obtained by eliminating invalid samples based on the information of 1000 patients in the modern pharmacological database [17]. Instead of measuring each case, the paper classifies each case into a class or category of diseases.

6.2. Baseline Method. The benchmark method chosen in this article is the most popular drug recommendation method. Recommend the most popular products to customers [18]. The drug recommendation questions were all for cases of lung cancer patients, so several commonly used drugs were found based on the analysis of these cases.

Table 6.1: *Statistics of modern medical records.*

Project name	Quantity
Caseload	900
Number of disease species	85
Total number of medicinal materials	123

Fig. 6.1: *Results of confusion degree experiment.*

6.3. Degree of confusion of multiple linear discrimination modes. The results of multi-content linear discrimination are compared with those of traditional linear discrimination. It can be seen from Figure 6.1 that the effect of the multi-content linear discrimination model is significantly better than that of traditional linear discrimination [19]. In addition, the degree of ambiguity decreases with the increase of the number of categories Z , which indicates that the degree of ambiguity tends to converge, which is consistent with the theoretical argument. Increasing Z will not improve the efficacy after Z is large enough to cover all the hidden causes.

7. Conclusion. The improved linear identification model was used to analyze clinical cases and find hidden causes. Find out the internal relationship between recessive cause, syndrome and medication. Two methods of drug recommendation based on symptom were designed using the correlation between symptom, pathogenesis and drug. The algorithm's effectiveness is verified by testing the modern medical case base.

THE INTEGRATION AND INNOVATION OF SPORTS SOCIAL PLATFORMS AND INFORMATION TECHNOLOGY

YONGJUN CHEN*

Abstract. In order to better achieve the integration and innovation of sports social platforms and information technology, the author proposes an SFD (Sport Friend Discover) sports friend recommendation model based on physical testing big data. The core idea of this model is to use physical measurement data to match the similarity between athletes and recommend suitable exercise partners. Specifically, we collected a large amount of physical measurement data, including height, weight, body fat percentage, muscle mass, etc. Then, through data mining algorithms, these data are transformed into feature vectors of the movers. Next, we use a similarity algorithm to calculate the similarity between different athletes and find the most matching motion partner with the user. The results show that the SFD method outperforms the other two traditional recommendation methods on the dataset, with P @ 10, P @ 20, P @ 30, and P @ 40 of SFD reaching 0.099, 0.095, 0.085, and 0.591, respectively. SFD not only utilizes more neighboring information than FOAF based on local graph structure, but also compared to TRW based on global graph structure method, at the same time, the importance of the node itself is also considered, resulting in higher accuracy. It has been proven that the SFD sports friend recommendation model based on physical testing big data has achieved good results in recommending sports partners. Users can quickly find sports partners with similar body types and health conditions, improving the fun and effectiveness of exercise.

Key words: Recommendation algorithm, Sports and social interaction, Integrated innovation

1. Introduction. With the continuous development and popularization of information technology, sports social platforms are playing an increasingly important role in today's society. Sports social platform refers to a platform that combines sports and socializing through the internet and mobile applications. They provide a convenient way for people to share their sports experiences, challenges, and achievements, and interact and communicate with other sports enthusiasts. In the past few years, the number of users on sports social platforms has grown rapidly, attracting more and more people to join [1]. These platforms provide a virtual community where people can find like-minded partners and share their sports experiences and insights. By posting their own exercise records and achievements, users can receive praise and encouragement from others, which is crucial for improving their motivation to exercise and persevere [2]. In addition, sports social platforms also provide many useful features, such as sports data analysis, training plan development, and health advice, to help users better manage and improve their exercise status.

However, there are currently some issues and limitations with sports social platforms in the market. Firstly, for users, existing platforms often lack personalized and customized functions, which cannot meet the needs of different users. Everyone has different sports hobbies and goals. Some people like running, some like cycling, and some like exercising. Existing platforms often only provide some basic functions and cannot meet the personalized needs of users. Users hope to customize their exercise plans and training content based on their interests and goals [3]. Therefore, future sports social platforms need to strengthen the development of personalized and customized functions to meet the diverse needs of users. Secondly, for platform operators, there are difficult to solve privacy protection and data security issues. Sports social platforms involve users' personal information and exercise data, which are very important to users. However, due to the lack of effective privacy protection mechanisms, users' personal information and exercise data may be abused or leaked. In addition, data security is also an important issue.

Sports social platforms store a large amount of user data, which may be exploited by hackers or criminals without appropriate security measures. For platform operators, protecting user privacy and data security is an

*School of Physical Education, Chaohu University, Hefei, 238024, Anhui, China (chenyongjun@chu.edu.cn)

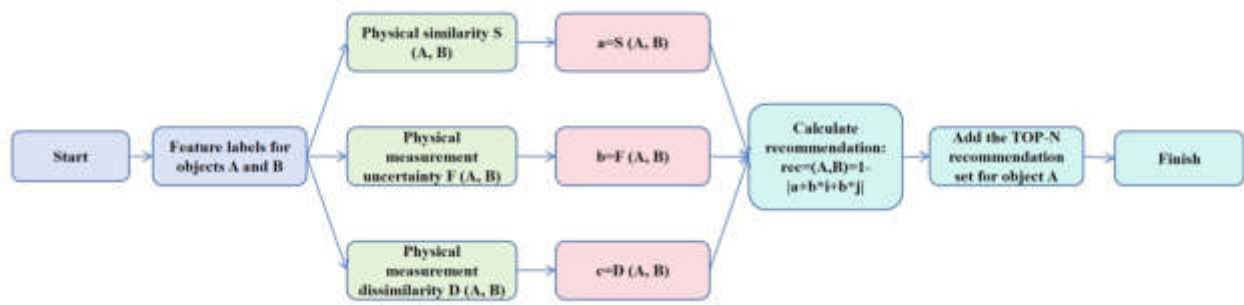

Fig. 2.1: Algorithm flow of college student physical examination

important responsibility, and they need to strengthen technical and management measures to ensure that user information is fully protected.

In addition, due to technological limitations and operational strategies, the functionality and experience of sports social platforms still need further improvement and innovation. At present, sports social platforms mainly focus on user interaction and sharing, but often overlook the needs of users for professional knowledge and guidance. Many users hope to receive professional sports advice and guidance to help them better engage in sports training. Future sports social platforms can strengthen cooperation with professional sports coaches and health experts, providing users with more comprehensive and professional services. In addition, sports social platforms can also combine virtual reality and augmented reality technology to provide a richer and more immersive sports experience [4].

In summary, sports social platforms play an important role in today's society, providing people with a convenient way to share sports experiences, challenges, and achievements, and interact and communicate with other sports enthusiasts. However, there are currently some problems and limitations with sports social platforms in the market, such as a lack of personalized and customized functions, privacy protection and data security issues, as well as limitations in functionality and experience [5].

Future sports social platforms need to strengthen the development of personalized and customized functions, as well as measures to protect privacy and data security, simultaneously enhancing functionality and experience to meet the diverse needs of users. Only in this way can sports social platforms better play their role in promoting health and social interaction.

2. SFD Sports Friend Recommendation Algorithm.

2.1. Overall Algorithm Design. The college student physical testing recommendation algorithm is specifically designed based on the big data of college student physical testing, and the algorithm process is shown in Figure 2.1. The concept of set pair analysis was introduced in this study to transform the traditional similarity. In the recommendation process, the first step is to calculate the similarity, uncertainty, and dissimilarity between two objects. Then, based on the theory of set pair analysis, the set pair recommendation degree $rec(A, B)$ needs to be calculated. Finally, the set pair recommendation degree is used to select suitable recommended objects and make recommendations [6].

2.2. Data preprocessing. Before designing the recommendation algorithm, in order to calculate the physical fitness recommendation between two objects, it is necessary to rate the physical fitness test items of college students according to the National Physical Fitness Standards, standardize the data of student physical test items into percentages, and classify the physical condition of students: The scores for explosive, endurance, flexibility, and strength categories are calculated based on the scores of student physical testing items with different weights [7].

Then, through threshold grading, different groups of strong, medium, and weak students are determined. Finally, it is necessary to fit the textual sports characteristics and give definitions: {"Strong": 1, "Medium": 2, "Weak": 3}.

Assuming the existence of objects A and B, their motion features are represented as feature vectors, that is $A = \langle a_1, a_2, a_3, a_4 \rangle, B = \langle b_1, b_2, b_3, b_4 \rangle$, the difference between the features of A and B can be represented by $|a_k - b_k|$, where $k \in \{1, 2, 3, 4\}$,

$|a_k - b_k| = 0$, indicating that A and B have similarity

$|a_k - b_k| = 1$, indicating that A and B have uncertainty

$|a_k - b_k| = 2$, indicating that A and B have a degree of dissimilarity.

This study will design the similarity, dissimilarity, and uncertainty of physical measurements in the context described above[8].

2.3. Set pair recommendation . Unlike traditional similarity calculation recommendation algorithms, it is necessary to consider the similarity between users, the differences between users, and the uncertain factors between users. Therefore, the concept of set pairs is introduced in the similarity calculation of recommendation algorithms, and the following definitions exist:

$$rel(A, B) = a + b \times i + c \times j \quad (2.1)$$

Among them, $rel(A, B)$ represents the correlation between A and B, $rel \in [-1, 1]$, the larger the rel , the higher the similarity, and vice versa, the lower the dissimilarity. a represents the physical similarity between A and B, that is $a = S(A, B)$; b represents the measurement uncertainty between A and B, that is $b = D(A, B)$; c represents the physical measurement dissimilarity between A and B, that is $c = F(A, B)$, and satisfies $a + b + c = 1$. i is the uncertainty marker and j is the dissimilarity marker. During the operation, i and j are both coefficients involved in the operation, and a constant value of -1 is specified for j , the value of i in the range of $[-1, 1]$ depends on the situation[9]. Set pair recommendation is a transformation based on the correlation degree rel , which comprehensively considers the factors of similarity, difference, and uncertainty to avoid errors caused by high similarity or difference, and is defined as follows:

$$rec(A, B) = 1 - |a + b \times i + c \times j| \quad (2.2)$$

$rec(A, B)$ represents the set pair recommendation degree between A and B, $rec \in [0, 1]$, the closer rec approaches 0, the less likely it is to be recommended; The closer it approaches 1, the easier it is to be recommended[10].

(1) *Physical similarity.* Similarity is a numerical measure of the degree of similarity between two objects, and is an important reference indicator in personalized recommendation systems. Traditional similarity is calculated based on user ratings of items and recommendations using relevant formulas. The calculation method of physical similarity in this study is different from traditional methods[11]. It refers to obtaining student physical measurement data, analyzing and processing the data to extract and describe the movement characteristics of students, calculate similarity by comparing the eigenvalues of different students through certain methods. If there are objects A and B in the recommendation system, the recommended objects A and B have the following similarity:

$$S(A, B) = \frac{N(a_k = b_k)}{n} \quad (2.3)$$

Among them, $S(A, B)$ represents the physical similarity between objects A and B, n is the total number of feature attribute types, and a_k and b_k represent the feature values of the two objects, respectively. By using certain rules, students' grades are divided into different levels. When two students have equal levels of physical education grades, it is considered that they have a certain degree of similarity, that is, $N(a_k = b_k)$ is the number of features that two objects have the same characteristic value[12].

(2) *Physical measurement dissimilarity.* Dissimilarity is a numerical measure that describes the degree of difference between two objects. In the recommendation problem based on physical fitness test scores, it is often unreasonable to only recommend based on similarity, if the two recommended parties only have similarity, it means that there is very little knowledge that both parties can learn from each other, so there needs to be a certain degree of difference between them. Only when there are two different parties can there be the possibility of learning from each other[13]. If there are two objects A and B with dissimilarity in the recommendation

system, then the recommended objects A and B have the following dissimilarity:

$$D(A, B) = \frac{\sum_{k=1}^n ||a_k - b_k| - 1| - N(a_k = b_k)}{n} \tag{2.4}$$

In the formula, D (A, B) represents the degree of dissimilarity between objects A and B, n is the total number of feature attribute types, and ak and bk represent the feature values of the two objects, respectively. It $\sum_{k=1}^n ||a_k - b_k| - 1| - N(a_k = b_k)$ is the number of distinct features that two objects have, among them, $\sum_{k=1}^n ||a_k - b_k| - 1|$ is the sum of the number of similar and different features of two objects, $N(a_k = b_k)$ is the sum of similar features of two objects, and n is the type of feature attribute[14].

(3) *Physical measurement uncertainty.* If there are objects A and B in the recommendation system, when one party's sports performance is average and the other party's performance is strong or weak, it cannot be used to determine whether the gap between the two parties is really large enough to teach the other party, thus there is uncertainty. In set pair theory, the sum of similarity, dissimilarity, and uncertainty is 1, that is, a+b+c=1. Therefore, there are the following uncertainties for recommended objects A and B:

$$F(A, B) = 1 - \frac{\sum_{k=1}^n ||a_k - b_k| - 1|}{n} \tag{2.5}$$

(4) *Determination of connectivity i.* The value of the difference uncertainty coefficient i corresponding to the set pair recommendation degree of objects A and B in the recommendation system is a key point that needs to be determined. As the value of i approaches 1, the similarity between the two objects increases. Therefore, using cosine similarity, a method for determining the value of i using computational value method is proposed, which has the following definitions:

$$i = \frac{1}{1 + d/s} \tag{2.6}$$

where s is the cosine similarity of objects A and B, the formula is as follows:

$$S = \frac{\sum_{k=1}^n (a_k \times b_k)}{\sqrt{a_k} \sqrt{b_k}} \tag{2.7}$$

d is the cosine dissimilarity of objects A and B. Under certain conditions, cosine dissimilarity can be transformed from cosine similarity. Use the following formula to transform similarity:

$$d = e^{-s} \tag{2.8}$$

d represents the degree of dissimilarity between two objects, s represents the degree of similarity between two objects. The larger the value of s, the smaller the value of d, and the closer i approaches 1; On the contrary, the further i moves away from 1 [15].

(5) *Calculation of Top-N Recommendation Set and Friend Recommendation.* The Top-N recommendation algorithm sorts data according to certain rules and selects the largest or smallest N data from the sorting list for recommendation. Different rules can be formulated for different social environments to filter the data in the recommendation set. Based on the study of university student groups, multiple factors need to be considered when making friend recommendations. Based on the obtained user set for the recommendation set, the average recommendation degree between the user and the recommended user is calculated as the threshold r. Recommendations greater than the threshold are stored in the user's Top-N recommendation set, as shown in Figure 2.2.

Due to the fact that in the process of friend recommendation, not only do we need to consider the recommendation level between users, but there are also some practical issues that need to be considered, such as the user's class, gender, and distance between living areas. When recommending, we filter based on the user's needs [16].

Fig. 2.2: Determination of Top-N recommendation set and friend recommendation

Table 3.1: Partial Physical Examination Data for Male Students

number	height /cm	weight /kg	vital capacity /ml	long jump /cm	sit-and-stand reach /cm	50 m/s	1 km/s	Pull up /piece
Male 1	173.5	55.2	3235	252	8.6	7.3	213	7

Table 3.2: Partial Physical Examination Data for Female Students

number	height /cm	weight /kg	vital capacity /ml	long jump /cm	sit-and-stand reach /cm	50 m/s	800 m/s	Sit ups /piece
Female 1	159.4	69.7	3012	154	18.5	10.2	270	33
Female 2	156.8	45.8	2462	176	14.8	9.5	246	26
Female 3	151.6	41.7	2063	160	19.9	10.2	300	32
Female 4	157.5	50.7	3035	194	26.8	8.6	227	44
Female 5	152.4	45.6	2323	186	23	8.4	237	45

3. Experimental results. The selected data is taken from the physical examination results of college students in a certain university, which are true and reliable, and only the part of the physical examination results is retained, the identification information such as name and student ID have been deleted. The student physical examination results are shown in Tables 3.1 and 3.2.

According to the National Physical Fitness Standards, calculate the physical test scores of students in Tables 3.1 and 3.2, as shown in Tables 3.3 and 3.4.

Based on the actual situation, provide the weight coefficients of the physical testing project for the features, and calculate the four major feature scores of students according to the weights, as shown in Figure 3.1.

In order to evaluate the effectiveness of the newly proposed SFD friend recommendation algorithm, the author compared SFDH with some typical local and global methods: FOAF: If two vertices have more com-

Table 3.3: Partial Physical Examination Results for Male Students/score

number	BMI	vital capacity	long jump	sit-and-reach	50m	1km	pull-up
Male 1	18.34	60.58	81.25	66.29	77	84.38	20
Male 2	23.67	71.7	60	82.35	63	52.5	0
Male 3	22.36	81.28	80	68.43	90	94	20
Male 4	21.16	75.18	67	55.69	15	76	
Male 5	20.36	58.59	75	72.86	72	66	85

Table 3.4: Female Partial Physical Examination Results/score

Female 3	18.14	60.26	76	81.33	60	32	65
Female 4	20.44	79.7	88.57	100	76	78	77
Female 5	19.63	65.46	82.86	91.5	78	74	78

Fig. 3.1: Male and female partial feature scores/score

mon friends, they are more likely to become friends. Global Walkthrough Algorithm (TRW): Preserves all path structures in the network, investigates all structural information, and calculates node similarity. The performance of the three algorithms on the mathematical data of ScienceNet is shown in Figure 3.2.

As shown in Figure 3.2, the SFD method outperforms the other two traditional recommendation methods on the dataset, with P @ 10, P @ 20, P @ 30, and P @ 40 of SFD reaching 0.099, 0.095, 0.085, and 0.591, respectively [17,18,19].

SFD not only utilizes more neighboring information than FOAF based on local graph structure, but also considers the importance of nodes themselves, resulting in higher accuracy compared to TRW based on global graph structure method.

4. Conclusion. The author proposes a friend recommendation model based on set pair theory, which innovates extensively in the formulas of similarity, dissimilarity, and uncertainty. The cosine similarity calculation method and its transformation are used to determine the value of connectivity i , ultimately obtaining the rec-

Fig. 3.2: Performance comparison of methods on the Science Network dataset

ommendation degree between users. The experimental results demonstrate that the designed recommendation method is more targeted and complementary, and the quality of recommended users is improved. Due to the relatively small number of feature attribute types and feature grading levels, the degree of difference between users is not significant, which has a better effect on users with larger differences. Therefore, in future research, more feature attributes will be added, such as user gender, user grade, and other personal information, and the formula will be further improved to further improve recommendation accuracy and rationality.

THE APPLICATION OF INFORMATION TECHNOLOGY FOR ATHLETE DATA ANALYSIS AND AUTOMATIC GENERATION OF TRAINING PLANS

SHULI YUAN*

Abstract. In response to the demand for scientific training of sports athletes, the author combined data mining technology to study an improved sports training mode decision support evaluation system. In this regard, the author analyzed the characteristics of association rule algorithms and elaborated on their functions in data preprocessing, data mining, and pattern evaluation. Based on the software design of decision support systems, the characteristics of system operation were analyzed. At the same time, the author focused on explaining the data fusion processing of association rules in sports evaluation decision support systems, and proposed an improved Apriori algorithm output mode to improve the effectiveness of system evaluation. Compared with other algorithms such as Apriori, DC Apriori and Apriori, this algorithm has higher reliability. When the minimum confidence is increased, the advantage of prior information will gradually disappear, and the final result will be obtained. Experimental results show that this method can effectively provide support for sports training decision-making.

Key words: Data mining technology, Association rules, Sports training evaluation, Data fusion processing

1. Introduction. In modern sports competition, the analysis of athlete data and the formulation of training plans are crucial for improving competitive level and achieving excellent results. With the development of technology and continuous innovation in data collection technology, more and more athletes and coaches are using information technology to collect, analyze, and apply sports data. The training plan for athletes has gradually shifted from subjective experience in the past to objective decision-making based on data, making training more scientific and efficient. The application of data analysis in sports competitions has become a trend. By analyzing athlete data, coaches can understand their performance during training and competition, identify their strengths and weaknesses, and then develop targeted training plans [11]. For example, in basketball games, coaches can evaluate a player's performance in offense and defense by analyzing their shooting percentage, rebounds, and assist data, and provide targeted technical and tactical training. Through data analysis, coaches can discover the potential abilities of athletes and assist them in personalized training to improve their competitive level.

Data analysis can not only help coaches develop training plans, but also help athletes understand their performance and improve their space. By analyzing their own sports data, athletes can gain a deeper understanding of their strengths and weaknesses, identify their problems in the competition, and find ways to improve. For example, in track and field competitions, athletes can analyze their speed, endurance, and technical data to identify their weaknesses in training and conduct targeted training to improve their competitive level. Data analysis can enable athletes to have a more comprehensive understanding of their performance and potential, thereby formulating more scientific and effective training plans. In addition to data analysis, the application of information technology in sports training also includes data collection and application [4]. With the continuous advancement of technology, athletes can use various sensors and devices to collect exercise data, such as heart rate, step frequency, exercise trajectory, etc. These data can help athletes and coaches have a more comprehensive understanding of their sports status and performance, enabling more precise training and adjustments. For example, in football training, athletes can monitor their heart rate and movement track by wearing smart bracelets or chest bands, so as to adjust their intensity and rhythm in training. Through data collection and application, athletes and coaches can more scientifically manage training and competitive processes, and improve training effectiveness [1]. The application of data analysis and information technology has not only changed the training methods of athletes, but also put forward new requirements for the role of coaches. Traditionally,

*Zhengzhou University of Technology, Zhengzhou, 450044, China (mylifeyuan@163.com).

Fig. 2.1: Data mining process.

coaches relied mainly on their own experience and intuition to develop training plans, but now they need to have certain abilities in data analysis and information technology application. Coaches need to learn to collect, process, and analyze sports data, obtain valuable information from it, and apply it to training programs. This poses new requirements for the comprehensive quality of coaches, who need to constantly learn and update their knowledge to adapt to the needs of technological development and data analysis.

In summary, the application of data analysis and information technology in modern sports competitions has become a trend. Through data analysis, coaches can develop targeted training programs to help athletes improve their competitive skills. Athletes can also analyze their sports data to identify their problems and engage in targeted training. Data collection and application can help athletes and coaches have a more comprehensive understanding of sports status and performance, and improve the scientificity and effectiveness of training. The use of data analysis and information technology not only changes the teaching process, but also places new demands on the effectiveness of teachers. With the continuous development of techniques and technology, the use of statistical data and information technology in sports competitions is becoming more and more popular, challenging many methods and approaches to athletes and coaches.

The author aims to explore the application of information technology in athlete data analysis and automatic generation of training plans, and evaluate its impact on athlete training and competitive performance. By collecting and analyzing physiological, technical, and competitive data of athletes, combined with advanced data mining and machine learning algorithms, we hope to automatically generate personalized training plans to help athletes better tap into their potential, improve training effectiveness, and achieve better results in competitions. Through this study, we will be able to gain a deeper understanding of the current status and potential of the application of information technology in athlete training and competition, providing scientific training guidance and decision support for athletes and coaches [15].

2. Decision support system for sports training mode.

2.1. Overview of Association Rule Mining Algorithms. The most crucial aspect of data mining technology is the association rule algorithm, and the Apriori algorithm is a classic algorithm in association rule algorithms. At present, there are various ways to classify association rules, and the most common one is to classify them according to the dimensions of the data types in the association rules [7]. It can be classified into one-dimension and multiple-attribute. There are a lot of influential factors in practice for athletes' physical training, and the data types obtained are much bigger than that of 3D ones. Therefore, the multi-dimension association rules must be taken into account in the design of the DSS of sports training model. Multi-dimensional association rules are more complicated than single-dimension association rules. Usually, multidimensional association rules include data preprocessing, data mining, and model assessment. The concrete data mining process is illustrated in Figure 2.1.

The preprocessing stage in the data mining process mainly involves collecting, processing, and transforming data, which takes the longest time throughout the entire data mining process; The data mining stage mainly analyzes the data in the preprocessing stage through selected association rules, neural network techniques, etc [12]. The evaluation stage of the pattern mainly involves presenting the information obtained from data mining to users, or providing a visual program for real-time viewing and analysis.

2.2. Data Fusion Processing of Sports Training Evaluation Decision Support System. In the evaluation of sports training model based on large data mining, the related data should be integrated into the

DSS. This paper focuses on the classification of the extracted data by neural networks.

2.2.1. Fusion and Clustering of Sports Evaluation Decision Information. The data feature identification function of the sports evaluation decision support system is:

$$P_c = \sum_{i=0}^n \sum_{j=0}^n \alpha(i, j) P(i, j) \tag{2.1}$$

Assuming that the starting symbol for each of the above attributes is: $C_0 = C_{N/2} = 0, C_{N-n} = C_n^*, n = 0, 1, 2, \dots, N/2 - 1$, the model relationship between sports training evaluation decision data and cluster center distribution is:

$$P_r = \frac{P_t}{(4\pi)^2 \left(\frac{d}{\lambda}\right) r} \left[1 + \alpha^2 + 2\varepsilon \cos\left(\frac{4\pi h^2}{d\lambda}\right) \right] \tag{2.2}$$

Based on the association criteria of sports training modes, feature recognition of sports decision support systems is carried out based on the different types of data obtained. Among them, the attribute categories of association criteria in the system are:

$$R_\beta X = U\{E \in R \mid c(E, X) \leq \beta\} \tag{2.3}$$

$$R_\beta X = U\{E \in R \mid c(E, X) \leq 1 - \beta\} \tag{2.4}$$

For different data block types m_i and m_j combined with the association criteria of sports training modes, the iterative process of sports training decisions obtained by using the fuzzy mean method in the data types is as follows:

$$S_b = \sum_{i=1}^e p(\omega_i) (u_i - u) (u_i - u)^T \tag{2.5}$$

$$S_\omega = \sum_{i=1}^e p(\omega_i) E \left[\frac{(u_i - u) (u_i - u)^T}{\omega_i} \right] \tag{2.6}$$

$$S_i = S_b + S_\omega \tag{2.7}$$

In the formula, $p(\omega_i)$ is the set of association rule vectors for the sports training decision system. Based on the above calculation formula, the fusion of information in the sports training mode decision support system is achieved [14].

2.2.2. Improve Apriori algorithm output. It is necessary to create a policy organization that presents the information only during the request for information that will be used to make design decisions for sports training models. The author created a collection of sports training standards organization standards using a modified weight system, and the last important rule is the only product that accepts weight products.

$$\omega_{sij} (n_0 + 1) = \omega_{sij} (n_0) - \eta_{sij} \frac{\partial J}{\partial \omega_{sij}} \tag{2.8}$$

Through the similarity analysis of relevant data in the DSS, the adaptive learning process can be obtained as follows:

$$\alpha_{desira}^i = \alpha_1 \cdot \frac{Density_i}{\sum_i Density_i} + \alpha_2 \frac{AP_i}{AP_{init}} \tag{2.9}$$

Rearrange the relevant data stored in the system in quintuples to obtain the probability density function used for data mining:

$$P_s = P_{2D}^k (1 - P_{2D})^{N-1-k} \sum_{i=1}^{\infty} \lambda_s^i = \frac{\lambda_s}{1 - \lambda_s} \tag{2.10}$$

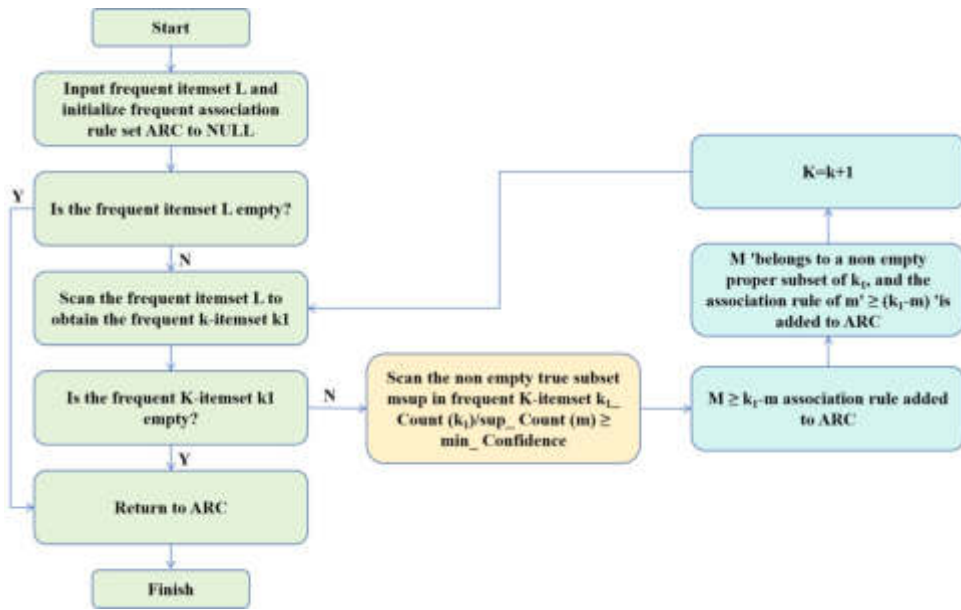

Fig. 2.2: Improved Apriori algorithm for frequent association rule process.

In the formula, λ_s and P_{2D} represent the correlation dimension of the data and the probability that the data can be effectively detected. The motion training model determines that the data clusters in the support system differ in the following ways:

$$\text{DisSim}(A, B) = 1 - \left| \frac{\text{SameDis}(A) - \text{SameDis}(B)}{\text{Dis}(A) + \text{Dis}(B)} \right| \quad (2.11)$$

In summary, the author can establish a system database model by mining the data of the sports training mode decision support system and extracting its association rules, and design the corresponding system in combination with software development [5].

2.3. Software Design. The decision support system for sports training mode is based on modern computers and uses computer and programming languages to simulate the sports training effects of athletes through human-computer interaction. It mainly addresses decision-making issues for managers during the implementation of plans. Decision systems can provide athletes with the convenience of obtaining real-time sports data, while also assisting in guiding and tracking the effectiveness of sports.

The author chooses the improved Apriori algorithm with frequent association rules as shown in Figure 2.2 to design the human-computer interaction system. Its main functions include:

1. The human-computer interaction system can provide a more convenient computer environment for decision-makers in sports training. It can check the physical fitness indicators of each athlete based on the front-end display settings, and use computers for tracking and processing.
2. Visually display the operational status of the decision support system, allowing users to fully understand the data changes during the system's operation and make timely adjustments.
3. Based on the output results of the system, targeted adjustments can be made to the training plan, and the simulation can be calculated to form the optimal training plan.
4. The human-computer interaction system can also correct erroneous information and perform preliminary verification and judgment on input data [6].

On the basis of analyzing the decision support system algorithm, the author integrated data mining technology with the system program through algorithm compilation to design a sports training mode decision support system [2]. The main functional modules of the system include communication module, program module,

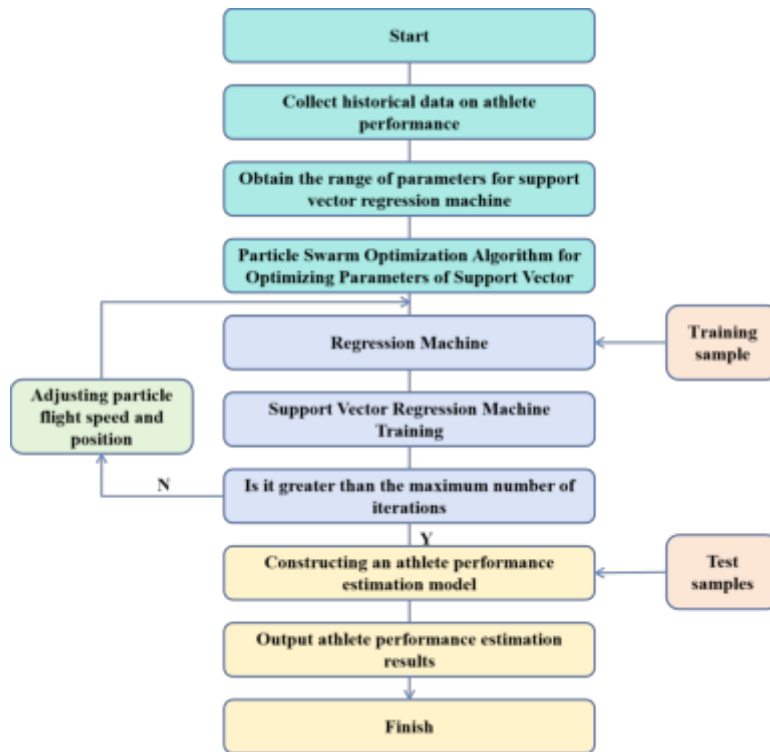

Fig. 2.3: Flow chart of athlete performance modeling and estimation.

database module, and data output module. Using Conti-ki bus technology to transmit and coordinate the data types of the sports training mode decision support system, meanwhile, combining VIX integrated control technology can achieve integrated control of the system. The data perception of decision support systems is built based on the 6LoWPAN protocol stack. The design of the wireless sensor network system adopts Atmel1284P as the main chip to control the overall IoT address allocation and mobilization of the sports training mode decision-making system. After the taskbar address is determined, the system’s human-computer interaction is achieved through the TaskBasic interface program.

2.4. Athlete Performance Modeling and Estimation. The workflow of athlete performance modeling and estimation based on big data analysis technology is shown in Figure 2.3.

The steps for modeling and estimating athlete performance using big data analysis technology are as follows:

1. Collect historical data of athlete performance, process the historical data of athletes to obtain the range of athlete performance:

$$x_i'' = \frac{x_i - x_{\min}}{x_{\max} - x_{\min}} \tag{2.12}$$

In the formula, the maximum value of the athlete’s score is x_{\max} , and the minimum value of the athlete’s score is x_{\min} .

2. On this basis, a support vector machine model based on PSO is proposed [10].
3. Train athletes according to each set of parameters and implement learning through support vector regression machine.
4. If the number of iterations exceeds the set maximum value, the algorithm ends; If the number of iterations is less than the set maximum value, adjust the flight speed and position of the particle swarm.

Table 3.1: Data related to the badminton team training in a certain place

Type	Tid	Item	Avg
Data	5401	114	38

Fig. 3.1: Comparison of execution times at minimum support.

Fig. 3.2: Comparison of execution times at minimum confidence.

5. Increase the number of iterations of particle swarm optimization algorithm.
6. Retrain athlete performance through the optimal parameters of the support vector regression machine, and obtain the optimal parameters of the support vector regression machine through the optimal solutions pbest and gbest. Construct an athlete performance estimation model based on support vector regression machine.
7. Test and analyze the performance of the athlete performance estimation model through athlete performance test samples, and output the final athlete performance estimation results [3].

3. Simulation experiment analysis. On this basis, Apriori algorithm, DC Apriori algorithm and modified Apriori algorithm are compared, the results show that the algorithm is feasible. Most of the time during the experiment, programming was done in the Java language. In this paper, a badminton team in the relevant training data as the research object.

The “Tid”, “item”, and “quantities” in Table 3.1 represent the specific types of training items, the total

number of data items, and the average level per training.

In Figures 3.1 and 3.2, the change in system runtime is shown as minimum support and minimum confidence increase.

Figure 3.1 shows the reaction speed of the modified Apriori algorithm proposed in this article under the minimum support, which shows that it is a more efficient method [9, 13, 8]. As you can see in Figure 3.2, the improved Apriori algorithm has better performance when the minimum confidence is low. As the minimum confidence level increased, the advantages of Apriori faded and the same effect was achieved.

4. Conclusion. In order to improve the competitive level of athletes, we must constantly improve the competitive level. Based on information technology, this paper studies the problem of decision support in sports teaching mode. On this basis, a method of physical education based on network is proposed. Secondly, using Apriori, DC Apriori, Apriori and other classical algorithms to test and verify the Apriori algorithm, the Apriori algorithm can better support training decisions, with high practical value.

DEEP LEARNING MODEL CONSTRUCTION OF URBAN PLANNING IMAGE DATA PROCESSING AND HEALTH INTELLIGENCE SYSTEM

CAN XU*

Abstract. In order to study the deep learning model of urban planning image data processing and health intelligent system, based on existing remote sensing image change detection methods, the author introduces and proposes the use of deep belief networks in deep learning to classify high-resolution remote sensing images and analyze urban expansion change detection. Compared with traditional methods, deep learning has the highest overall accuracy and Kappa coefficient. Deep learning has the highest producer accuracy and relatively low misjudgment rate, making it the most suitable for studying the trend of urban built-up areas. By calculating the information entropy of the image to predict the number of hidden layer nodes, the time for deep learning is greatly reduced. Under the same experimental conditions, the training time for each image can be shortened by 12 525 seconds has improved classification efficiency and made a significant contribution to research on urban expansion applications. Finally, the improved deep belief network was applied to classify and detect changes in the three phase remote sensing images of Beijing, and the urban expansion trend and characteristics of Beijing were analyzed. Provide technical reference and inspiration for urban planning and land use protection.

Key words: Deep learning, Deep belief network, Remote sensing images, Urban planning, Image data processing

1. Introduction. In the evaluation process of urban master planning methods, how to use practical and feasible evaluation methods to accurately and efficiently evaluate a large number of planning schemes is a practical problem faced by every urban planner [1]. As one of the deep machine learning methods, deep learning technology can extract features within samples and transform them. It has the outstanding advantage of strong learning ability and is widely used in fields such as image classification, object recognition, and object evaluation.

The commonly used deep learning techniques include automatic encoding, sparse encoding, deep belief networks, etc. These deep learning techniques utilize layer by layer feature transformation to transform meta spatial features into another space, facilitating feature classification and evaluation. Urban planning is a comprehensive work that not only considers the construction of tangible entities such as urban space, but also considers multiple aspects such as economy, society, environment, culture, etc. Throughout history, the formulation of urban planning has relied heavily on qualitative analysis and empirical judgment. Planners often fail to provide objective explanations for phenomena, and the scientific nature of the planning discipline has long been questioned, one important reason for this is the non collectability or non quantifiability of data. Nowadays, the emergence of intelligent planning has brought immeasurable vitality and change to the development of urban planning discipline.

Intelligent planning and design, with the assistance of computers, is particularly effective in saving manpower and computational costs, and the calculation and analysis results can also ensure absolute objectivity.

Remote sensing change detection is a technology that quantitatively analyzes the characteristics and information of land surface changes based on remote sensing images obtained at different times in the same region. It has become an important direction in current remote sensing image processing and analysis, and is widely used in many fields such as land use, vegetation cover, urban planning, crop growth monitoring, and disaster assessment and prediction.

At present, the change detection methods for remote sensing images mainly include algebraic operations, image classification, feature description, and other methods. In the field of urban expansion, due to the need to determine how urban land is transformed from other land uses, the research in this direction adopts the

*School of Economics and Management, Hubei Polytechnic University, Hubei, 435000, China (xu1982can@163.com)

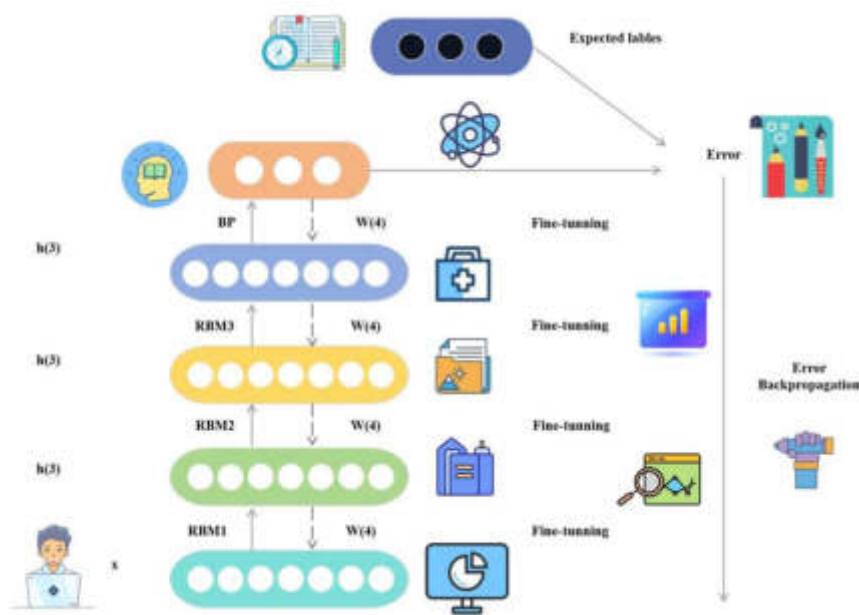

Fig. 2.1: DBN schematic diagram

method of image classification and change detection, which is more intuitive.

Image classification based methods can provide the types of surface changes and reduce the impact of external factors such as lighting and atmosphere on detection accuracy. However, in practical operations, a large number of learning samples need to be obtained, and the training time is relatively long. Therefore, how to obtain learning samples and reduce the training time of classification is an urgent problem that needs to be solved in the field of urban expansion.

The author takes urban expansion as an example and introduces a classification method of deep learning. After image classification, multi temporal change detection is performed. The accuracy index is compared with existing change detection methods, and information entropy is used to improve the efficiency of deep learning, achieving fast, efficient, and accurate change detection [2].

2. Methods. The deep learning method utilizes Deep Belief Network (DBN) for data classification and has made breakthrough progress. Subsequently, various research and engineering fields have adopted deep learning methods for application experiments [3]. In recent years, deep learning methods have also been continuously applied in the classification and recognition fields of videos, images, speech, etc. The essence of deep learning is a multi-level neural network, which improves the accuracy of results by extracting features from each layer to form final features suitable for classification.

Deep learning is applied in the field of remote sensing, utilizing deep belief network models for road target recognition in airborne images. But so far, there is still a lot of research space to apply this method to the classification of remote sensing images in large regions.

A deep belief network is composed of a multi-layer unsupervised Restricted Boltzmann Machine (RBM) network and a layer of supervised Backpropagation (BP) network, as shown in Figure 2.1 [4]. The experimental process of DBN includes two steps. Firstly, the input data is pre trained, and the output of the lower layer Boltzmann machine is used as the input of the higher layer, which is trained layer by layer.

In the fine-tuning stage, supervised learning is used to train the neural network layers, and the obtained errors are passed down to fine tune the weights of the deep belief network. The pre training stage actually initializes the weights of the neural network, thereby avoiding the drawbacks of local optima caused by random initialization.

Unlike traditional neural networks and shallow learning, deep learning methods generally have multiple layers, ranging from 4-7 layers to more than 10 layers. Moreover, through layer by layer feature extraction, they make classification and prediction results more accurate. However, the difficulty of using deep learning methods for classification lies in determining the depth of the network and the number of hidden layer nodes. Therefore, how to improve computational efficiency is an urgent problem that needs to be solved.

3. Experiments and Analysis.

3.1. Research Area and Data Sources . The author chose City A as the research area. The remote sensing image data used in the study includes LandsatTM and ETM+data with imaging times in 2009, 2015, and 2022, as well as auxiliary data such as A city topographic map, A city center administrative area map, and A city yearbook statistical data.

3.2. Land use classification standards and training sample selection. Appropriate classification standards and the number of training samples are the basis for accurate classification. Generally, a hierarchical classification system is adopted. The national standard GB/T21010-2007 "Classification of Land Use Status" stipulates that land use is divided into three categories: agricultural land, unused land, and construction land, each of which is further divided into several primary and secondary categories. Based on the research purpose and in combination with the provisions of national standards, the author categorizes land use consolidation into 5 categories [5]. Farmland, forests, and grasslands can also be merged into vegetation. A sufficient number of training samples and their representativeness are key to image classification. The selection method of training samples will affect the accuracy of classification, such as using pixel method, polygon method, etc. The mixed pixels in medium and low resolution remote sensing images contain complex information. Considering the complexity of land use in the study area, high-resolution remote sensing images should be selected for training sample selection.

The author used high spatial resolution images as training samples, randomly selected a training area with a sample size of 200, of which 100 samples were used for training the model and 100 samples were used for detecting model accuracy, each sample contains 10 pixels, accumulating 1000 pixels. For each class of samples, 213 are selected for unsupervised training, and the remaining 1/3 is used for fine-tuning in the network. As the author is studying the changes in the built-up areas of Beijing, it is advisable to select as many construction land as possible when selecting training samples to improve the classification accuracy of construction land.

3.3. Parameter Setting and Experimental Process . The restricted Boltzmann machine used in DBN only allows connections between hidden layer neurons and visible neurons, and there is no connection between two visible neurons or between two hidden layer neurons. In RBM, the energy equation is shown in Equation 3.1:

$$Energy(v, h) = h'Wv + b'v + c'h \tag{3.1}$$

In the formula, W represents the weight matrix of the neuron connections between the hidden layer and the visible layer, and b and c are the bias vectors on the visible and hidden neurons, respectively. When training Boltzmann machines, we input to the network through visible layer neurons, with the goal of updating and adjusting weights and biases, so that when training data is used as input, the configuration energy is minimized. Training RBM first inputs training vectors to the visible layer, and then compares and disperses them by alternately sampling hidden layer units and visible layer units. When using RBM, we do not need to calculate the joint probability and it is easy to sample. After only one Gibbs sampling iteration, we can reset (update) the weights and biases of RBM, as shown in Equation 3.2:

$$\begin{cases} W_{kj} = W_{kj} - \alpha(\langle v_{k0}h_{j0} \rangle - \langle v_{k1}h_{j1} \rangle) \\ b_k = b_k - (\langle v_{k0} \rangle - \langle v_{k1} \rangle) \\ c_j = c_j - (\langle h_{j0} \rangle - \langle h_{j1} \rangle) \end{cases} \tag{3.2}$$

In the formula, α is the learning rate, v_0 is sampled from the training sample, h_0 is sampled from $P(h|v_0)$, v_1 is sampled from $P(v|h_0)$, and h_1 is sampled from $P(h|v_1)$. We repeat this update operation on several

Fig. 3.1: Classification accuracy of different DBN layers

samples of the training data, and then iteratively train each next layer by using the activity of the hidden units in the previous layer as input data/visible units for the first layer.

For each pixel to be classified on an image, it is necessary to consider a region that includes its surrounding neighboring pixels. Assuming the neighborhood window size is $winsize$, it can be expanded into a one-dimensional vector with a $winsize \times winsize$ dimension. For DBN, the input data consists of three processed Pauli parameters, namely the diagonal elements of the correlation matrix ($0.5 | HH+VV12$, $0.5 | HH-VV12$, and $2 | HV12$), which can be assembled into a data vector for the first phase, therefore, for the data of period m , the dimension of the input vector is $winsize \times winsize \times 3 \times Em$. Calculate the spectral and texture feature vectors of the three bands synthesized by pseudocolor separately, and combine the three feature vectors into one feature vector as the input. The input dimension is 147. The experimental parameters are set as follows: The learning rate is initially set to 0.01, W is all random numbers from a normal distribution, and the hidden layer bias is initialized to 0. Due to the fact that the number of input and output nodes in the experiment is 147 and 5 (to be classified), the hidden layer nodes of the Boltzmann machine are set to take values of 5 to 147, respectively, when the error is minimized, it is the number of nodes in the first hidden layer, and so on for the remaining hidden layer nodes. The depth of the deep belief network is set to 1-6 layers, and the misclassification error, omission error, producer accuracy, user accuracy, overall accuracy, and Kappa coefficient are calculated to evaluate the classification accuracy. The results show that the highest accuracy is achieved when the network depth is 3, as shown in Figure 3.1 [6].

The experimental method is to preprocess remote sensing images; Based on the analysis of existing data and the establishment of interpretation criteria, the main land types in Beijing are extracted using computer classification methods; For smaller land classes, set an area threshold for neighboring merging; Extract boundaries of various land uses after merging, and correct incorrect boundaries through visual interpretation; Overlay the classification results of each image for later analysis and evaluation.

3.4. Classification Results and Analysis. The experiment focuses on the detection of changes after classification, using the ISODATA method in unsupervised classification, the maximum likelihood classifier in supervised classification, and deep learning methods to classify and analyze remote sensing images. The accuracy of the three methods is evaluated using measurement indicators such as classification accuracy, overall accuracy, and Kappa coefficient. The results are shown in Tables 3.1 to 3.4 [7,8].

The results showed that the overall accuracy and Kappa coefficient of deep learning were the highest, followed by the maximum likelihood classifier, and ISODATA was the worst. Deep learning has the highest producer accuracy and Kappa coefficient, with a relatively low misjudgment rate, and is most suitable for studying the trend of changes in built-up areas. The possible reason is that deep belief networks avoid ran-

domly assigning initial values to neural networks and better overcome the problem of local optima through pre training methods. Therefore, deep belief networks combine the advantages of unsupervised neural networks and supervised classification, which can improve classification accuracy and efficiency.

3.5. Determining the number of hidden layer nodes by calculating information entropy. Deep learning methods have high classification accuracy, but it is difficult to determine the number of hidden layer nodes and the number of hidden layer layers, which requires continuous attempts to determine [9,10]. While ensuring that the feature dimensions are maintained within a small range, it is also necessary to ensure that

Fig. 3.2: Comparison of Calculation Time between Information Entropy Estimation of Hidden Layer Nodes and Traditional DBN Algorithm

there is sufficient classification information in the features. Therefore, we need to estimate the number of hidden layer nodes and the number of hidden layer layers to improve classification efficiency, save time and labor costs. During the calculation process, we found that for images with richer content, their information entropy increases, on the contrary, images with more uniform terrain types have relatively lower information entropy. Therefore, we attempt to apply information entropy to determine the number of hidden layer nodes used for classification, which greatly shortens the calculation time and improves classification efficiency. In order to verify the above proposed ideas, we conducted experiments using the following preset training parameters and compared the calculation time between traditional methods and estimation methods. The experiments were conducted more than 20 times. The running time results are shown in Figure 3.2.

The experiment compared the calculation of information entropy to estimate the number of hidden layer nodes and the training time of traditional DBN algorithms. When the maximum training period is set to 100, the method of calculating information entropy to estimate the number of hidden layer nodes has an average training time of 68.427 seconds, while the traditional DBN algorithm network training time is 80.952 seconds. Compared with traditional methods, the training time is shortened by 12.525 seconds, greatly reducing the training time and improving classification efficiency.

4. Conclusion. The author applied the DBN model in deep learning to conduct change detection research on City A and compared it with traditional classification methods. The experiment shows that deep learning has the highest producer accuracy, overall accuracy, and Kappa coefficient, with a relatively low misjudgment rate, and is most suitable for studying the trend of urban expansion and change. By calculating the information entropy of the image to predict the number of hidden layer nodes, the time of deep learning is greatly reduced. When the maximum training cycle is set to 100, the method of calculating the information entropy to predict the number of hidden layer nodes reduces the training time by 12.525 seconds compared to traditional methods, improving the efficiency of classification. The experiment proves that this method is suitable for the classification and change detection of urban expansion. Accurately characterizing the characteristics of urban expansion changes is of great significance for identifying its expansion regularity, further explaining the coordination between built-up area expansion and socio-economic development, analyzing the spatiotemporal evolution process, and predicting future evolution trends. On the basis of change detection, further analysis of the characteristics and mechanisms of urban expansion, analysis of influencing factors, and prediction of change trends can be carried out in the future.

SPORTS DATA PRIVACY PROTECTION AND INFORMATION SECURITY MANAGEMENT

BIAO JIN*

Abstract. In order to achieve the protection of personal privacy, the author proposes research on sports data privacy protection and information security management. The author used the two-dimensional fractional Fourier transform (2D-FRFT) method to encrypt the detected human body parts, which can be decrypted when needed for viewing. Compared to traditional Fourier transform, Fractional Fourier Transform (FRFT) can better express the time-frequency characteristics of signals and is very sensitive to the order of the transform. It is widely used in image encryption systems. 2D-FRFT increases the range of keys, further enhancing the security of the system. The author achieved encryption by extracting the detected human body parts and then performing a certain order of FRFT in the x and y directions respectively; When decrypting, use the same order of encryption to perform inverse fractional Fourier transform. Finally, based on research on pedestrian detection and encryption technology, the author designed a human-machine interaction interface that integrates the functions of detection and encryption interfaces, making the entire operation more intuitive and concise.

Key words: Pedestrian detection, Fractional Fourier transform, Interactive interface, Information Security Management

1. Introduction. Human body detection refers to the use of computers to detect human targets in image files, which has been studied and developed for many years. However, it is affected by factors such as shooting angle, human posture, background and lighting intensity, occlusion, and pedestrian gathering, its detection algorithm still needs continuous improvement [1]. At present, human body detection technology has been widely applied in intelligent video surveillance, robotics, virtual reality, and safe driving of vehicles. With the rapid development of society, more and more unstable factors have emerged. For safety reasons, intelligent video surveillance has been successfully applied in many public places, such as security checks, highways, elevators, banks, shopping malls, etc. When the system detects abnormal emergencies, it can understand, analyze and judge the behavior of the detection target, timely alarm and respond to corresponding measures, in order to ensure the safety of people's lives and property, and then minimize losses. Intelligent robot technology has been widely applied in various industries in society. Currently, intelligent robots are mainly used to complete high difficulty and high-risk actions that are not easy to manually complete. For example, in the event of an earthquake disaster, intelligent robots can be used to participate in search and rescue work, which to some extent improves search and rescue efficiency [2-3]. And the positioning of these disaster victims can be achieved through human detection technology. With the increasing number of private cars year by year, the time and space distance between people has been shortened, but the negative impact cannot be ignored. For example, traffic safety accidents that may occur at any time can threaten people's life and property safety. Therefore, research on safe driving of automobiles is particularly important. If a camera is installed on the vehicle that can collect information in front of the vehicle's line of sight, it can detect and recognize whether there are pedestrians in front, whether they are within a safe range, understand and analyze pedestrian behavior, predict the possibility of collision, and provide relevant information to the driver in a timely manner, so that the driver can make timely and correct responses and prevent frequent traffic accidents. Virtual reality is a high-tech that has developed in recent years. Its main principle is to use computer technology to construct a three-dimensional simulation space, providing users with simulations of visual, auditory, and tactile senses, giving them a sense of firsthand experience. There is enormous potential research value in medical surgery, entertainment games, military aerospace, and other fields. Among them, relevant positioning requires pedestrian detection technology to support. Human beings have always been in a dominant position in social activities, and they are also a

*Beijing University of Technology, Beijing, 100000, China (ab2023000@163.com)

key object of object detection. With the development of human detection technology, it has provided practical convenience for many fields and has broad development and application prospects.

Human detection is a research topic with strong practical application value. Many scholars at home and abroad have conducted in-depth research and achieved certain research results [4-5]. Since 1997, the US Defense Advanced Research Projects Agency has funded a major research project on visual surveillance technology and video understanding, with the participation of many universities. The European Union has also increased funding for pedestrian detection related technology research since 2000. Compared to foreign research in this field, China's development research is later. However, in recent years, the discovery of potential application value has attracted the attention of many domestic universities and scientific research institutions, and in-depth research has been carried out in this field. The State Key Laboratory of Pattern Recognition of the Chinese Academy of Sciences has made many outstanding achievements in this field. The effectiveness of pedestrian detection has a significant impact on the stability of video surveillance systems. So far, there are many methods for pedestrian detection, but there is no universal algorithm, and each method has its own characteristics. These methods mainly include frame difference method, background difference method, template matching method, optical flow method, and machine learning based detection method. The frame difference method mainly determines whether a pixel belongs to a foreground point by subtracting the corresponding grayscale values of the two frames in the video sequence, in order to determine the motion target that appears in the video sequence. But this method is limited to only pedestrians in the moving target. The background subtraction method is to subtract the current image frame from a known background model, in order to determine whether the pixels in the current image frame are foreground points. This algorithm has a simple principle and good real-time performance, but if there is no movement of pedestrians in the image, the detection will fail.

The template matching method requires prior knowledge of the characteristics of the detected object, such as contours, edges, etc. The principle is to compare these feature templates with the video image frames to be detected. If the template's features are met, it can be determined as the detection target. However, due to the fact that humans are non rigid bodies and have different postures, the actions presented at different times are not uniform, making it impossible to form an accurate and effective template, resulting in low accuracy in pedestrian detection. The optical flow method can detect independent moving targets without prior knowledge of any background prior. However, the optical flow method requires high hardware requirements for the equipment and has certain limitations in areas with high real-time requirements. Machine learning based methods can overcome many unfavorable conditions and have good stability. Due to the differences in height, posture, movement, clothing, skin color, lighting conditions, and background, pedestrian detection poses great difficulties. It is difficult to find a unified detection algorithm that meets real-time requirements and has a high recognition rate. In order to overcome these difficulties, pedestrian detection methods based on statistical learning are often used more frequently. This method mainly consists of three steps. Firstly, it extracts the features of pedestrians. Currently, the commonly used features include grayscale directional histogram features, hall features, and edge contour features, each with its own characteristics and suitable application scenarios; Then, the classifier is selected to train the extracted features and obtain file data that can be used for final classification; Finally, send the image to be detected to the classifier for detection. Many domestic scholars have conducted extensive research on statistical learning based pedestrian detection methods, which have the advantage of adapting to the variability of non rigid detection objects, and the accuracy of detected pedestrian targets is high and relatively stable. The disadvantage is that a large number of training samples are required. Sometimes, due to the high dimensionality of sample features, it takes a long time to train the classifier and use it for detection, and the real-time performance is not ideal.

With the deepening of research, the technology of pedestrian detection has achieved many achievements so far, but it still lacks a wider application and more stable performance. This is mainly due to the particularity of the pedestrian object, and its main difficulties are as follows: pedestrians are located with different backgrounds, which will also have a greater impact on the detection results. Some images have a single background, such as in the grassland, desert, open vision, etc., relatively pedestrians are relatively easy to detect. Some images have a complex background, such as in shopping malls, squares, tourist attractions and crowded roads and streets, the flow of people gathers, so there will inevitably be pedestrian blocking phenomenon, so that only a part of the human body can be seen in the image, so that enough information can not be obtained from the

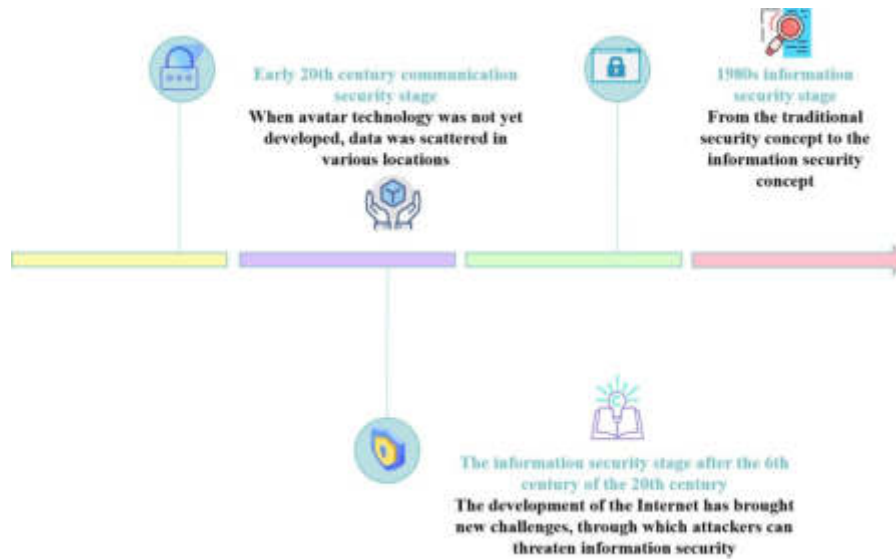

Fig. 1.1: Information Security Management and Privacy Protection Diagram

image, which affects the detector for analysis and judgment. At the same time, in some special backgrounds, some backgrounds are similar to the human body, such as tree trunk, telephone poles, etc., these disturbing background objects can easily be mistaken for the human body by the detector, thus reducing the detection accuracy. Camera can from the front, side, the back of the pedestrian, the results have the very big difference, and the influence of the distance between the camera and people, showing the pedestrian size is very different, and body parts also have difference, and in large traffic, sometimes in order to make the view more broad, need to improve the height of the camera, lead to the clarity of the photo is not quite the same. Because people are not rigid body, to a certain extent, both a certain rigidity, and a certain flexibility. Lead to the human body can show a rich change of posture, such as: upright, squatting, etc., even if the same person shows different movements, the test results-like also has a relatively large impact. At the same time, there are also differences in height, weight, clothing, etc., these characteristics will also bring some difficulties to detection. Even in the same place and under the same background, due to the different moments of photo collection, there can also be some differences in the light intensity. Some photos are brighter and some are darker. The differences in these rays will directly lead to the different image information extracted, which will ultimately affect the classification results. Therefore, the effect of reducing light intensity is also an aspect worth studying. Commonly used to describe the characteristics of the human body have edge, contour, texture features, gradient direction histogram features and the features back, these features can be used for pedestrian detection, but the results of different characteristics are often different, some feature detection results in addition to the algorithm used, will also be affected by the detection of image properties. So choosing a suitable feature is very important for the accuracy of the detection. In practical application, the system is often required to have good real-time, can quickly detect the human body part, and the corresponding understanding and analysis. However, the calculation amount of the algorithm directly restricts the real-time performance of the system, so the accuracy of detection is not affected as much as possible. It is very necessary to select a suitable algorithm above.

The author designed a concise human-computer interaction interface, which mainly includes image reading, detection of pedestrian parts, extraction of detected human parts, and encryption and decryption. The interface integrates all steps, making the operation of the entire privacy protection system more concise, intuitive, and user-friendly. Finally, the time complexity of all process modules in the system, including pedestrian detection, encryption, and decryption, was analyzed. Figure 1.1 shows information security management and privacy protection [6].

2. Methods. With the rapid development of computer and internet technology, network-based information exchange platforms have provided great convenience for the dissemination of digital works. However, the protection of property rights of digital works is also an issue that cannot be ignored [7]. Due to the intuitive and informative nature of image information, as well as the confidentiality requirements in certain specific fields, encryption and protection technologies for the growing demand for image information transmission are receiving increasing attention.

2.1. Introduction to the Development of FRFT. The reason why FRFT can be quickly and widely applied in the field of optics is because it is relatively easy to achieve this transformation based on optical devices [8,9]. Although FRFT has strong practical value in signal processing, this transformation lacks effective physical explanations and has low algorithm efficiency, resulting in it not receiving enough attention in signal processing. Nowadays, with the continuous in-depth research and development of FRFT, a large number of related research results have emerged.

2.2. Main Applications of FRFT. The unique properties of FRFT have attracted the attention of many learners and researchers. Nowadays, FRFT has been widely applied in many fields of scientific theory research and engineering application technology, such as wavelet transform, quantum mechanics, optical signal processing, artificial neural networks, video analysis, etc. The following mainly introduces some typical applications of FRFT in different fields.

(1) *Chirp class signal detection and parameter estimation.* The traditional Fourier transform is a transformation within the overall range that obtains the entire spectrum of a signal [10]. And FRFT can be seen as the decomposition of signals on orthogonal chirp basis, so FRFT is particularly suitable for the analysis and processing of chirp signals. In the detection of moving targets by radar, most of the received echo signals are chirp signals. The convenient processing of chirp signals by FRFT greatly improves the performance of signal processing systems in detecting moving targets and estimating their parameters.

(2) *Filtering.* The FRFT of a signal refers to the rotation of the signal at a certain angle in the time-frequency plane, which is very beneficial for the processing of non-stationary signals [11]. Traditional filtering methods mainly perform windowing operations in the frequency domain, but when the time-frequency coupling between the signal and noise is strong, it is difficult for traditional filtering methods to completely separate them. At this point, if the signal is rotated at a specific angle in the time-frequency plane, causing the signal and noise to lose coupling in the new Fourier domain, they can be separated well.

(3) *Neural networks.* Compared to traditional Fourier transform, FRFT has an additional transformation order p and can be freely selected from 0 to 1, making the transformation more flexible. In this case, if the neural network is in this domain, it can have a more stable effect [12].

(4) *Digital watermark.* The so-called digital watermark refers to embedding relevant marks in certain digital works in a specific way to verify copyright ownership. At the same time, this information should be ensured to be invisible and not perceived by anyone, and can only be detected by the copyright owner through special technical means. Digital watermarking technology is mainly aimed at protecting digital media. When property disputes arise, relevant information in the watermark can be extracted to verify copyright ownership. Due to the sensitivity of FRFT to the order of transformations, watermarking techniques based on FRFT correspond to different transformations at different orders. By adding key parameters, the security of the watermarking system is improved without knowing the order of transformations.

2.3. Definition of FRFT. The traditional Fourier transform is well-known to everyone, and its theoretical research and development are relatively mature, and it has been well applied [13]. And FRFT is based on the theoretical foundation of traditional Fourier transform, which is a refinement and supplement to it. The traditional Fourier transform can be regarded as a linear operator that rotates the angle $/2$ counterclockwise from the time axis to the frequency axis, while FRFT can be regarded as an operator that rotates any angle a . Compared to traditional Fourier transform, FRFT has greater advantages in application. It not only possesses some properties of traditional Fourier transform, but also adds some new characteristics related to its own properties. There are various definitions of FRFT based on different perspectives, but each definition has a certain inherent connection. Defining FRFT from different perspectives can help us have a more comprehensive understanding of it.

2.4. FRFT Properties and Characteristics.

(1) *The properties of FRFT.* FT represents the differential operator acting on the function, and F^P is the p-th power of FT, which means that if the function is rotated by an angle p, the p-th order FRFT can be understood as treating FP as an operator to generate FRFT [14]. The main properties of FRFT are as follows: Interchangeability: Perform FRFT on a function with order P1 first, after performing FRFT with order p2, the result is the same as performing FRFT with order P2 first and then FRFT with order p1, that is: $F^{P1}F^{P2} = F^{P2}F^{P1}$.

Order additivity: For different p1 and p2, there is always $F^{P1}F^{P2} = F^{P1}F^{P2}$.

Linear transformation: Satisfies the superposition principle, that is $F^P|\sum c_n f_n(u)| = \sum c_n|F^p f_n(u)|$.

Periodicity: According to $a=pr/2$, the period of order p is 4, which is $F^{p+4} = F^p$.

Reversibility: After performing p-order FRFT on a function, followed by-p order FRFT, the original function can be obtained. There are: $(F^p)^{-1} = F^{-p}$ [15].

(2) *The main characteristics of FRFT.* From the definition form of FRFT, it can be seen that FRFT reflects a time-frequency information of the signal, which is an extension of traditional Fourier transform and particularly suitable for processing non-stationary signals. Moreover, it has an additional transformation order p, making the transformation angle more flexible. Moreover, the discrete algorithm of FRFT has high efficiency and fast speed. Compared to traditional Fourier transform, FRFT mainly has the following characteristics:

The transformation order of FRFT can continuously increase from 0 to 1, demonstrating the continuous time-frequency variation characteristics of the signal, providing a better platform for time-frequency analysis of the signal [16].

FRFT can be seen as a decomposition of chirp groups. In radar signal processing, most of the echo signals for detecting moving targets are chirp signals, which is beneficial for improving the performance of signal processing systems in detecting moving targets and estimating their parameters.

FRFT has an additional transformation order p compared to traditional Fourier transform, which increases the value space of the key and improves the security performance of the system in image watermarking and encryption systems.

FRFT is a linear transformation without cross interference, which has advantages in the presence of additive noise.

FRFT is easy to achieve through optical transposition and has a wide range of applications in the field of optics.

The development of FRFT is relatively mature, with fast and efficient discrete algorithms, and it provides fast discrete algorithms for fractional convolution and other applications. At the same time, it also makes it easier to promote in practical applications.

2.5. 2D-FRFT. Perform one FRFT on f (x, y) in the x and y directions respectively to obtain 2D-FRFT. 2D-FRFT is implemented based on FRFT, and its kernel function can be expressed as:

$$K_{p1,p2}(x, y, u, v) = \frac{\sqrt{1 - j\cot\alpha}\sqrt{1 - j\cot\beta}}{2\pi} \times \exp\left[\left(\frac{x^2 + u^2}{2\tan\alpha} - \frac{xu}{\sin\alpha}\right)j\right]\exp\left[\left(\frac{y^2 + v^2}{2\tan\beta} - \frac{yu}{\sin\beta}\right)j\right] \tag{2.1}$$

In the above equation, $\alpha=p1n/2$, $\beta= P2 /2$ represents the two rotation angles of 2D-FRFT, respectively. If the corresponding transformation orders p1 and p2 are given, 2D-FRFT can be represented in the following form:

$$F^{p1p2}(u, v) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} K_{p1p2}(x, y, u, v) f(x, y) dx dy \tag{2.2}$$

Similar to FRFT, the inverse transformation of 2D-FRFT only requires taking the opposite order of the

corresponding order. As shown in the following equation:

$$f(x, y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} K_{-p_1-p_2}(x, y, u, v) F^{p_1 p_2}(u, v) dudv \quad (2.3)$$

From equation 2.1, it can be seen that the transformation kernel of 2D-FRFT can be separated, which is:

$$K_{p_1, p_2}(x, y, u, v) = K_{p_1}(x, u) \times K_{p_2}(y, v) \quad (2.4)$$

The two-dimensional discrete FRFT can be seen as the result of two one-dimensional discrete FRFTs. The transformation process is as follows:

1. Firstly, perform discrete FRFT on the two-dimensional discrete signal in the x-direction to obtain F1;
2. Then perform discrete FRFT on the two-dimensional discrete signal in the y-direction to obtain F2;
3. Finally, by transposing F2, a two-dimensional discrete FRFT can be obtained.

When $\alpha = \beta$ When, it is symmetric 2D-FRFT; If $\alpha = \beta = /2$ is the traditional 2D-FRFT; When $\alpha \neq \beta$ When, it is an asymmetric FRFT [17].

3. Results and Analysis. The author designed and implemented a demonstration system that can integrate human body detection and privacy protection functions. This system can perform human body detection on input images and extract the detection part for encryption and decryption. The input image can be a real-time image captured by the camera or a pre saved image in the hardware device.

3.1. Introduction to System Interface Function Modules. As a demonstration system, it is required to be able to interact with users. Based on basic functional requirements, the interface of this demonstration system includes four parts: input area, functional area, display area, and operation instruction area. Input area: By inputting in the x and y directions, the detected pedestrian part can be encrypted and decrypted with any order of fractional Fourier transform. Functional area: Mainly realizes the input of images (supports real-time shooting or opening of saved images from the camera), detects pedestrians in the images, encrypts and decrypts the detected pedestrian parts, and has the function of exiting the system. The included function buttons include: Turn on the camera, turn off the camera, take and save photos, open pictures, save pictures, pedestrian detection, encryption, decryption, and exit. Display area: Mainly displays the input image, as well as the results of pedestrian detection, encryption, and decryption of the input image. Operation Instruction Area: This area mainly provides an operation instruction for the entire demonstration system and provides a brief summary of the system principles.

3.2. Demonstration System Design Principles. This interface is designed based on the GUI (Graphical User Interface) module of MATLAB. Human body detection is implemented on the open-source platform OpenCV. MATLAB is currently one of the most widely used mathematical software, but due to its use of line interpretation to execute code, it to some extent limits the execution speed of the code. The open-source code of the OpenCV class library is written in C and C++, and the code execution efficiency is high [18]. Combining the advantages of these two languages and leveraging their respective strengths often yields better results. When calling a cpp file in MATLAB, it is necessary to first convert the cpp file into a mex file in a certain format. The mex file is developed in C/C++ language, after being compiled in a certain way, it can be called by the m language interpreter in MATLAB.

Compared to interface software packages such as MFC, the GUI functions in MATLAB are simple, and the message mapping mechanism is concise, making it particularly suitable for system interface design that is not particularly demanding. MATLAB integrates an efficient interface development environment called Guide, which includes various MATLAB supported control objects, and users can choose different interface appearances and set different action response methods for controls. A complete GUI creation, firstly, it involves the selection of controls and spatial layout in interface design. Then, in order to respond to certain operations, it is necessary to write callback functions. Through callback functions, the specified functions of the controls can be achieved.

Table 3.1: Human detection time

Image size (pixels)	648*384	463*636	301*488	364*556
mean time to detect (ms)	2139.42	2865.59	1629.19	1927.04

Fig. 3.1: Human detection time chart

Table 3.2: Detected encryption time of human body parts

Image size (pixels)	191*383	210*420	142*283	116*232
mean time to detect (ms)	834.15	1211.41	311.49	195.65

3.3. Experimental section. Firstly, load the saved image from the hardware device using the "Open Image" button, and use the "Pedestrian Detection" button to detect the human body part of the input image. After detecting pedestrians, the system extracts the human body part. Then, by setting the order in the x and y directions, the corresponding order of encryption can be achieved for the human body part.

A time complexity analysis was conducted on the human body detection, encryption, and decryption parts of the entire system, as shown in Tables 3.1, 3.2, and 3.3. The computer system used in the experiment was Windows 7 flagship version, and the software versions used were vs2010 flagship version, OpenCV2.44, and MATLAB 2013a. The main hardware environment of the computer is: Intel Pentium dual core T4300@2.10CHz Processor, memory 3.00GB [19].

The following table lists the image size and corresponding operation time. From Table 3.1 and Figure 3.1, it can be seen that the detection speed is related to the image size, and the larger the image, the longer the required time [20]. Detecting a $648 * 384$ image requires 2139.41 milliseconds, which takes a long time and has low real-time performance, this is because the selected HOG features have a dimensionality of 3781 and require complex computation. In order to ensure both detection rate and real-time performance, this is a major challenge that needs to be overcome in the current field of pedestrian detection. Tables 3.2, 3.3, Figure 3.2, and 3.3 respectively encrypt and decrypt the pedestrian parts detected in the images in Table 3.1. It can be seen from the tables that real-time performance is still a challenge that cannot be ignored. So, there are still many areas that need to be improved and enhanced for pedestrian detection and encryption in real-time videos.

4. Conclusion. The author mainly implemented it based on 2D-FRFT, not only analyzing the principle of FRFT for image encryption, but also providing the encryption and decryption effects of different orders in the x and y directions through experiments, as well as the slight deviation of the decryption order relative to the encryption order, which affects the decryption effect of the image. Enable readers to fully understand

Fig. 3.2: Encrypted time graph of detected human body parts

Table 3.3: Decryption time for encrypted parts

Image size (pixels)	191*383	210*420	142*283	116*232
mean time to detect (ms)	831.56	1017.9	374.82	200.20

Fig. 3.3: Decryption time graph for the encrypted part

that different orders of FRFT have significant differences in image encryption and decryption effects. In the system design section, the author utilized the GraphicalUserInterface module in MATLAB, fully considering functional requirements and interface aesthetics, in order to design an interface that can take real-time photos and save, as well as both pedestrian detection and encryption and decryption of pedestrian parts. It has the characteristics of simple operation, complete functions, and beautiful interface.

DATA COLLECTION AND ANALYSIS BASED ON SENSOR TECHNOLOGY IN SPORTS TRAINING

XIANBIN SHI* AND HUAGANG ZOU†

Abstract. In order to realize the automatic monitoring of physical fitness index in athletic training, a new method of automatic monitoring and identification is put forward in this paper. In this paper, a network structure model is designed to automatically monitor the physical fitness index in sports training based on IOT and WSN. The collected a number of physical parameters in sports training, including heart rate, maximal oxygen absorption, respiration entropy, and load parameters. Then, by monitoring heart and lung function data, Cooper's method was used to measure the maximal oxygen intake, and EQO₂ was used as the training index. Then, the dynamic parameters of physical fitness index were extracted, and the change of gas metabolism and critical threshold were analyzed. This paper builds a system structure model to monitor the physical fitness index of physical training, and realizes the modular design of the system. The experiment results indicate that the system is not very different from the real one, and it can be used to automatically monitor the physical performance index in sports training. Practice has proved that the system has good stability and reliability, and is suitable for physical monitoring in the process of sports training.

Key words: Sensors, Sports training, Physical fitness indicators, automatic monitoring

1. Introduction. With the continuous progress of technology, the application of sensor technology in sports training is becoming increasingly common. Sensors, as an advanced technological tool, can collect and analyze athlete data, provide precise motion details and real-time feedback, thereby helping coaches and athletes improve training methods and technical levels. The development of sensor technology has brought tremendous changes and innovations to sports training [1]. The application range of sensor technology is very wide, which can be applied to various sports, including football, basketball, athletics, swimming, etc. Sensors can be embedded into the equipment of athletes, such as shoes, jerseys, protective gear, etc., or directly fixed on the sports field. Through real-time monitoring and data collection of sensors, coaches and athletes can obtain a large amount of information about the athlete's body posture, strength output, speed, acceleration, heart rate, and other aspects. These data can be used to analyze whether the athlete's technical movements are correct, whether the training intensity is appropriate, and whether their physical condition is good.

The application of sensor technology has revolutionized traditional observation and recording methods. Sensors can provide more objective and accurate data, reducing subjective interference. Sensors can monitor the movements of athletes in real-time, transmit data to computers or smart devices, analyze and process them through software, and generate visual results and reports [2]. Coaches can use this data to accurately analyze and evaluate athletes, develop targeted training plans, help athletes improve their technical skills, reduce injury risks, and optimize training outcomes. The application of sensor technology can also provide real-time feedback, helping athletes adjust their movements and postures in a timely manner. Sensors can transmit information to athletes through sound, light, vibration, and other means, guiding them to perform correct actions [3]. For example, in football training, sensors can remind athletes of the appropriate kicking force through vibration, indicate the correct angle when passing the ball through sound, and display the accuracy of the athlete's movement through light. This real-time feedback can help athletes correct mistakes faster, improve the accuracy and efficiency of technical movements.

The application of sensor technology can also promote communication and confrontation between athletes. Sensors can compare and analyze data from multiple athletes, helping coaches understand the differences and advantages among different athletes and develop corresponding training plans. At the same time, sensors can

†School of Physical Education, Anhui Normal University, Wuhu, Anhui, 241002, China

Fig. 2.1: Sensor Layout

also share data, allowing athletes to engage in real-time confrontation and competition [4].

For example, in swimming competitions, sensors can monitor the speed and posture of athletes in real-time, display data on screens next to the swimming pool, and allow the audience and coaches to clearly see the performance of each athlete, and compare and evaluate them. However, the application of sensor technology also faces some challenges and limitations. Firstly, the cost of sensors is relatively high, which may be difficult for some economically disadvantaged sports and athletes to afford. Secondly, the reliability and accuracy of sensors also need to be continuously improved and enhanced [5]. In the complex environment of sports fields, sensors may be subject to interference, resulting in inaccurate data. In addition, for some special sports such as gymnastics, judo, etc., the application of sensors may face technical difficulties. Due to the complex and varied actions of these projects, sensors may not be able to accurately capture and analyze relevant data.

Overall, the application of sensor technology in sports training has brought about significant changes and innovations. Sensors can collect and analyze athlete data, provide precise motion details and real-time feedback, thereby helping coaches and athletes improve training methods and technical levels. However, the application of sensor technology still faces some challenges and limitations, which require continuous improvement and refinement. With the further development of technology, it is believed that sensor technology will play a more important role in sports training, providing better support and guidance for the growth and progress of athletes [6]. The purpose of this study is to explore the application of sensor based data collection and analysis in sports training. By collecting sports data of athletes, such as posture, speed, strength, and other indicators, combined with real-time feedback provided by sensor technology, we can understand the performance of athletes and conduct scientific analysis. By collecting and analyzing data, more comprehensive and accurate training evaluations and guidance can be provided for coaches and athletes, thereby improving training effectiveness and competitive performance.

2. Overall System Architecture. In order to realize the automatic monitoring of the fitness index in the multi-sensor sports training, the overall structure of the system is based on the combination of the heart rate, the maximal oxygen absorption, the breathing entropy, and the collecting and analyzing of the load parameters. The ZigBee Network Sensor Monitoring System is used to build an auto-extracting model of Physical Fitness Indicator Parameters in Physical Training [7]. Combining with Physiology Parameter Recognition and Information Monitoring, a Hardware Device System for Monitoring and Detecting Physical Fitness Index in Sports Training with Wearable Device, Establishes Information Exchange Model and Command Transmission Control Model for Sports Training in XML and Web Middleware.

Wearable sensors such as oxygen, carbon dioxide and piezoelectric thin film sensors are used to collect heart rate, maximum oxygen uptake, respiratory entropy and load parameters, and video sensors are used to collect video data on exercise training as shown in Figure 2.1.

The maximum amount of oxygen is achieved by running or cycling with a mask on, depending on the difference between the data from the oxygen sensor and the CO₂ sensor; Calculate respiratory entropy based on the ratio of carbon dioxide production and oxygen consumption at the same time; When hemodynamic changes

occur, light enters the human body and undergoes predictable scattering. Using this principle, piezoelectric thin film sensors generate PPG waveforms for measuring heart rate and use heart rate data as basic biological characteristic values to ensure the accuracy of heart rate, load parameters, and other physiological parameter measurement results [8]. Arrange video sensors in the athlete training venue to collect athlete training video data, laying a solid data foundation for automatic monitoring of physical fitness indicators in subsequent sports training.

Among them, VO_2 , CO_2 emission (VCO_2), HR, etc., are the most important parameters in the automatic monitoring of ECG. The monitored the physical performance index of the sports training, which is divided into the primary and the secondary. Based on the change of gas metabolism and critical threshold, it can be used to automatically monitor the performance index in different sports programs and situations. Based on the general structure of the Physical Fitness Index Automatic Monitoring System in Sports Training, the SOA Framework Protocol is used. The automatic monitoring system of physical fitness index in physical training is composed of the main circuit control module, the data processing terminal module, the human-machine interaction module, and the bus output control module. Using JMS and HTTP protocols, we set up a system of service structure to monitor the performance index of sports training [9]. This article introduces an automatic monitoring system based on XML and Web middleware, which can monitor physical fitness index based on the M flag in the RTP header during exercise training. In sports training, we established an evaluation index called PE index and constructed a control model on the web service client to manage the components of PE index in sports training. In order to implement this system, we adopted a three-layer architecture design, which is the network layer, information fusion layer, and data output layer. Below, we will provide a detailed introduction to the functions and roles of these three levels.

Firstly, the network layer is responsible for handling communication between the system and external devices. In our system, motion training data is obtained through the M flag in the RTP header and transmitted to the information fusion layer for processing. The network layer is also responsible for communicating with web service clients, receiving and sending relevant data. Next is the information fusion layer, which is the core part of the system. In this layer, we use XML to encode and decode motion training data, and determine the type of motion based on the M flag. By analyzing and calculating exercise data, we can obtain the evaluation results of physical fitness index [10]. At the same time, the information fusion layer is also responsible for transmitting these evaluation results to the data output layer for users to view and analyze. Finally, there is the data output layer, which presents the evaluation results of physical fitness index to users in a visual form. Through the web service client, users can easily view and monitor changes in their physical fitness index. In addition, we can also control and adjust the composition of the PE index according to user needs to achieve better training results.

Through a three-layer architecture design, we have achieved effective communication and data processing between the network layer, information fusion layer, and data output layer. This system provides a scientific, convenient, and visual monitoring method for sports training, which helps to improve training effectiveness and the physical fitness level of athletes. Figure 2.2 shows a three-layer structural system [11].

On the basis of the three layers structure of the system, the dynamic parameters of the physical fitness index are extracted. Based on the change of gas metabolism and critical threshold, this paper establishes the structural model for the monitoring of the physical fitness index. Based on the data collection of HRMS and the physical function analysis, the data is synthesized in the sensor. In the application layer, the exchange of data is carried out, and in the network layer, the information exchange, the data fusion, and the characteristic output of the physical fitness index are realized [12]. The system's functional module architecture is illustrated in Figure 2.3.

The physical fitness index is one of the important indicators for measuring a person's energy level. By extracting and monitoring the dynamic parameters of physical fitness index, it is possible to better understand and evaluate an individual's physical and health status. To achieve this goal, this article proposes a physical fitness index monitoring system based on a three-layer system structure [13].

Firstly, at the bottom of the system, we construct a structural model of the stereoenergy index by analyzing gas metabolism and changes in critical thresholds. Gas metabolism is an important indicator of energy metabolism during human movement. By monitoring and analyzing gas metabolism, the individual's physical

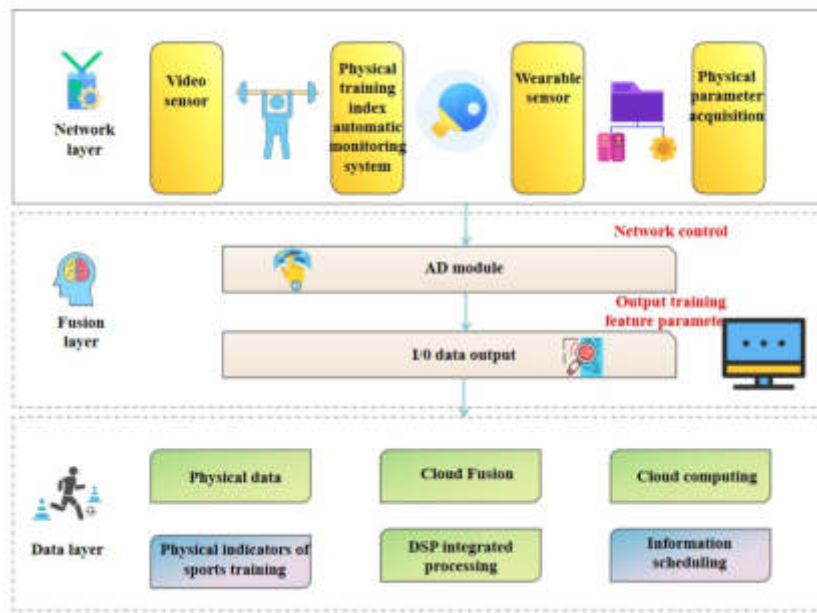

Fig. 2.2: The three-layer structural system of the system

Fig. 2.3: System Function Module Structure

adaptability and ability level can be inferred. The critical threshold refers to the critical value of physical fitness index at a specific exercise intensity, exceeding which may lead to physical fatigue and overtraining. By comprehensively analyzing gas metabolism and critical thresholds, we can obtain an accurate physical fitness index model for monitoring an individual's physical condition [14].

Secondly, in order to collect and analyze data, we introduced HRMS (Exercise Physiology Monitoring System) as a data collection tool. HRMS can monitor individual physiological parameters such as heart rate, blood pressure, and body temperature in real-time, and transmit these data to the system's sensors. By analyzing and processing these data, we can obtain information on individual movement status and physical fitness. At the application layer of the system, we conducted data exchange and processing [15]. Through data

	female	0. 73

Fig. 3.1: Experimental Test Objects

transmission with HRMS, we can obtain real-time physiological parameter data of individuals and transmit it to the network layer for processing. At this level, we obtained the physical fitness index of individuals through data fusion and feature extraction. The physical fitness index is an evaluation index that takes into account individual physiological parameters, exercise ability, and physical condition, and can objectively reflect an individual's physical fitness level and health status.

Finally, at the network layer of the system, we achieved feature output for information exchange, data fusion, and physical fitness index. The network layer serves as a bridge for data transmission and processing, integrating and analyzing data from sensors, and outputting the final evaluation results. Through the operation of the network layer, we can achieve real-time monitoring and evaluation of individual physical fitness index [16].

3. System data analysis and experimental testing.

3.1. Experimental Method and Object. In the data analysis, the maximal oxygen uptake was measured by Cooper's method, and EQO_2 was used as the training target. In this paper, the distribution of physical fitness index was established, and the differences of the maximal oxygen uptake VO_{2max} , O_2 Pmax and $METS_{max}$ were analyzed. Physical fitness index monitoring was performed, and the original VO_{2MAX} monitoring profile of each group was given, as shown in Table 3.1.

Sports such as Sanda, tennis, badminton, sports dance, martial arts, and roller skating were selected as the test subjects, and the distribution of test participants is shown in Figure 3.1.

Based on the distribution of test subjects in Figure 3.1, this paper presents a method to monitor the performance of physical fitness index in the design of the automatic monitoring system. The participants were classified into two categories: technology, combat, long and short distance running, and ball. Figure 3.2 illustrates the distribution of monitoring information density for sensor sampling for various projects [17].

Fig. 3.2: Concentration distribution of monitoring information sampled by sensors of different projects

Fig. 3.3: Comparison of Various Indicators for Men’s Long Distance Running in Various Events

Table 3.2: Comparison of Various Indicators for Long Distance Running in Comprehensive Projects

	Technical and combat oriented categories	Short distance running category	Long distance running category	Balls
VO_{2max}	43.9 ± 2.54	32.4 ± 3	31.41 ± 2.23	30.3 ± 2.54
S	2032.46 ± 155.43	1852.11 ± 245.12	1546.46 ± 143.43	1653.32 ± 145.3
METs	932 ± 0.6	8.35 ± 1.6	8.12 ± 14.34	8.21 ± 0.46

According to the analysis chart, using this method for monitoring physical fitness indicators in sports training, the correlation between the feature distribution and $P < 0.05$ and $P < 0.01$. Meet the functional monitoring requirements for sports training indicators. Based on this, the comparison of various indicators for long-distance running in each project is shown in Figure 3.3. The comparison of various indicators for long-distance running in various projects is shown in Table 3.2 [18,19,20].

We test the accuracy of the training performance curve obtained as shown in Figure 3.4.

Through analyzing the above monitoring results, we can draw a conclusion that there is little difference between the monitoring of physical fitness index and the real one. The system can be used to automatically

Fig. 3.4: Detection performance curve

monitor the physical performance index in physical training, and it is very adaptable to the environment and the individual.

4. Conclusion. An automatic monitoring system of physical fitness index in physical training is designed on the basis of multiple sensors. The whole structure and function modules of this system are expounded in detail. On this basis, a health index monitoring system based on wireless sensor network is proposed. Through the statistical analysis of large sample data, it is proved that the method has high credibility, can adapt to the personalized monitoring of large-scale sports activities and enhance the dynamic monitoring of BMI.

INTRODUCTION TO THE SPECIAL ISSUE ON NEXT GENERATION PERVASIVE RECONFIGURABLE COMPUTING FOR HIGH PERFORMANCE REAL TIME APPLICATIONS

C. VENKATESAN*, YU-DONG ZHANG†, CHOW CHEE ONN‡ AND YONG SHI§

The evolution of scientific computing is reshaping the hardware and software requirements, emphasizing the need for high-performance platforms adaptable to real-time applications. Traditional methods with general-purpose processors often lack the agility needed for swift modifications and fast computations during real-time tasks. Reconfigurable computing offers a compelling solution by integrating hardware speed and software flexibility on a unified platform. This technique promises significant acceleration across diverse applications like image processing, encryption, decryption, runtime operations, and intensive computing tasks such as sequence searching and matching in smart environments.

For high-performance applications, software-programmed microprocessors offer versatility. Artificial Intelligence (AI) has proven more robust than traditional methods in noisy environments, relying on reconfigurable designs for efficient operation. Hybrid machine-learning techniques enhance system reliability without compromising performance. Reconfigurable computing systems have recently accelerated intensive algorithms compared to software-optimized versions, leveraging parallel topologies. Deep Neural Architectures with adaptable computation patterns excel in computer vision tasks. Artificial Neural Networks (ANNs) are crucial for pattern recognition, high-performance machine learning, data manipulation, security threats, data mining, signal processing, and other applications, driving ongoing research into reconfigurable hardware and software implementations for ANNs.

It is a privilege for us to introduce the Special Issue on “Next generation pervasive reconfigurable computing for high-performance real-time applications”. Among the numerous research papers we received (49 in total), we meticulously selected 22 papers for publication. The overarching objective of this special issue is to investigate the recent advancements and disseminate state-of-the-art research related to reconfigurable computing for high-performance real-time applications and the technologies that make this possible. This special issue represents a showcase of new dimensions of research, offering researchers and industry professionals an illuminating perspective on pervasive reconfigurable computing. We sincerely hope that the contributions in this special issue will not only inform but also inspire future research endeavours, leading to a deeper understanding of the multifaceted world of speed computation during real-time applications.

The paper titled “Vulnerability Detection in Computer Networks Using Virtual Reality Technology” by Songlin Liu, traditional network security challenges are tackled through virtual reality integration. Optimization calculations are employed to extract network security vulnerability attributes, with adjustments made using a web crawler and a detailed analysis of attack characteristics. This approach facilitates automated detection within a virtual reality framework. Empirical results show a significant reduction in detection delay to 75.33 milliseconds, compared to 290.11 milliseconds and 337.30 milliseconds in conventional methods, highlighting the efficiency of the proposed approach.

“Computer Malicious Code Signal Detection Based on Big Data Technology” by Xiaoteng Liu improves

*Department of Electronics and Communication Engineering HKBK College of Engineering, Bangalore, Karnataka, India. (venkatesanc.ec@hbk.edu.in)

†Chair in Knowledge Discovery and Machine Learning, Department of Informatics, University of Leicester, United Kingdom (yz461@leicester.ac.uk)

upon traditional methods by using big data for detecting malicious software behaviour. The approach tackles challenges in mobile malware detection through mean-variance feature selection and advanced techniques like PCA, KLT, and ICA for feature extraction. A decision tree-based multi-level classification model enhances accuracy and addresses data imbalance issues, leading to notable accuracy improvements of 3.36% to 6.41% across different Android detection methods, highlighting the effectiveness of the proposed malware detection technology.

"Network Security with VR-Based Antivirus Protection and Reduced Detection Delays" by Chunna Song et al., addresses delays in traditional systems by leveraging VR technology. It aims to decrease detection delays, enhance efficiency, and optimize security feature identification. The method includes web crawling for an injection list and virtual protection blocks to mitigate threats, achieving a detection delay of 75.33 milliseconds, surpassing traditional delays of 290.11 ms and 337.30 ms. Empirical evidence supports the efficacy of automatic detection in VR, promising improved network security responsiveness and effectiveness.

Xiaohong Li et al., in the paper titled "Computer Network Virus Defense with Data Mining-Based Active Protection" presents a novel approach to enhance computer network virus defence beyond traditional technologies. Utilizing Object-Oriented Analysis (OOA) mining, the method analyzes Win API call sequences in PE files to detect deformed and unknown viruses. Experimental results demonstrate the Data Mining-based Antivirus (DMAV) system's superiority with higher accuracy in deformed virus detection, effective defence against unknown viruses (92% recognition rate), improved efficiency, and reduced false alarms for non-virus files. The research introduces an OOA rule generator to optimize feature extraction, bolstering system intelligence and resilience in enhancing computer network security.

"Application of Nonlinear Big Data Analysis Techniques in Computer Software Reliability Prediction" by Li Gao and Hai Wang addresses challenges in using artificial neural networks for software reliability prediction, focusing on improving the PSO-SVM model. Comparative experiments with a Backpropagation (BP) model highlight the PSO-LSSVM model's rapid reduction in training error within 200 generations, compared to BP's 1,733 generations. The optimized PSO-LSSVM model demonstrates superior efficiency with small sample sizes, offering accelerated training and enhanced prediction accuracy for software reliability assessments.

"Enhancing Industrial Control Network Security through Vulnerability Detection and Attack Graph Analysis" by Yan Liao addresses communication attack defence gaps in industrial control networks. The study proposes using attack graphs to improve security and vulnerability assessments, providing detailed construction methodologies. Experimental evaluations using the "earthquake net" virus identify four main attack routes for the "Zhenwang" virus, each with specific loss values and attack success probabilities. This research emphasizes the need for systematic vulnerability analysis to enhance overall industrial control network security.

Chunmei Ji et al., in the paper titled "Improving Semantic Analysis in Visualization with Meta Network Representation and Parsing Algorithm" introduces the semantic Meta Network (MNet) for advanced semantic analysis in visualization. MNet employs a hierarchical framework to integrate semantic elements, relationships, and attributes, facilitating comprehensive understanding from phrases to complete texts. The study presents a construction algorithm for MNet and parsing methods tailored for natural language interface parsing, validated through empirical experiments. This research enhances semantic analysis capabilities, particularly in interpreting SCADA system instructions, contributing to improved natural language understanding and semantic analysis in visualization contexts.

"Hybrid optimization for high aspect ratio wings with convolutional neural networks and squirrel optimization algorithm" by Pengfei Li presents an efficient approach for optimizing lightweight high-aspect-ratio wings. The study combines a hybrid binary unified coding description, one-dimensional convolutional neural networks for aeroelastic modelling, and the squirrel optimization algorithm for computational efficiency. Experimental results demonstrate a 4.1% reduction in wing weight, showcasing the effectiveness of this hybrid method in optimizing complex wing structures.

"Computer Software Maintenance and Optimization Based on Improved Genetic Algorithm" by Ming Lu aims to enhance software maintenance and network performance using an advanced genetic algorithm. The study refines network architecture through enhanced genetic operations and evaluates satisfaction and fitness index functions with controlled data iterations. Results show network reliability initially improves with iterations but stabilizes due to hardware limitations, highlighting a peak reliability of 0.894 achieved at 100

iterations. This research provides a foundational framework for optimizing computer network reliability with a balanced genetic algorithm approach.

Jing Wang et.al., in the paper titled "Research on Intelligent Transformation Platform of Scientific and Technological Achievements Based on Topic Model Algorithm and Its Application" enhances the conversion of scientific breakthroughs into practical applications using the LDA theme model. The study improves efficiency by extracting pivotal terms and thematic phrases, facilitating information management, retrieval, and recommendations for academic and business sectors. The platform evaluates transformation results and operational efficiency in advancing scientific and technological achievements.

"An Emotional Analysis of Korean Topics Based on Social Media Big Data Clustering" by Yanhong Jin introduces the Online Topic Emotion Recognition Model (OTSRM) to enhance emotional analysis accuracy in Korean social media. Utilizing the Online Latent Dirichlet Allocation (OLDA) model, OTSRM integrates emotion intensity and employs an innovative emotion iteration framework. It introduces an affective evolution channel and distribution matrices for characteristic and affective words, advancing understanding of emotional context. Validation experiments demonstrate OTSRM's effectiveness with emotion recognition accuracy rates of 85.56% and 81.03%, improving precise emotional dynamics assessment in Korean social media.

Xiangying Liu et. al., in the paper titled "Application of Artificial Intelligence Technology in Electromechanical Information Security Situation Awareness System" proposes leveraging AI and big data to enhance predictive capabilities in information security. Using LSTM-RNN and variant GRU models, the study achieves high accuracy with LSTM-RNN showing MAPE of 8.79%, RMSE of 0.1107, and RRMSE of 8.47% on test data. This research highlights AI's potential in developing robust information security situational awareness systems, comparing LSTM and GRU models for effectiveness and efficiency in predictive analysis.

Wenjuan Yang in the paper titled "Analysis and Application of Big Data Feature Extraction Based on Improved K-means Algorithm" addresses challenges in handling large volumes of data by proposing an enhanced K-means algorithm. Focused on mitigating errors, the study applies this algorithm to monitor power equipment, achieving an error rate below one per cent and consistently high accuracy exceeding 95%. The research underscores the algorithm's effectiveness in improving clustering accuracy and efficiency, emphasizing its practical application in big data analysis for energy systems.

"Intelligent Prediction of Network Security Situations Based on Deep Reinforcement Learning Algorithm" by Yan Lu et al. introduces a novel approach using deep learning to enhance network security assessment. The study develops a deep self-encoding model for effective network attack detection and integrates a unique oversampling weighting algorithm to improve pattern detection with limited training data. Experimental results demonstrate significant performance gains over traditional methods like DT, SVM, and LSTM, achieving higher F1 scores by approximately 2.77, 10.5, and 5.2, respectively. This research emphasizes improved accuracy and efficiency in predicting and measuring network security situations.

Min Yan and Hua Zhang in the paper titled "Interface Control and Status Monitoring of Electronic Information Equipment Based on Nonlinear Data Encryption" proposes an advanced system ensuring information fairness, objectivity, and security in traffic accident investigations. The study develops a robust security strategy with PC-based platforms for efficient data acquisition, secure processing, transmission, and storage using nonlinear data encryption methods. Performance tests with files ranging from 3MB to 10MB show a significant 25% average speed improvement over the original platform. This system enhances data integrity during transmission, aids in accurate equipment identification post-accident, and addresses critical security challenges in traffic accident investigations.

Yongqiang Shang in the paper titled "Detection and Prevention of Cyber Defense Attacks Using Machine Learning Algorithms" examines the rise in cyber threats fueled by enhanced computing power, big data utilization, and advanced machine learning techniques. The study explores both defensive and offensive uses of machine learning in cybersecurity, focusing on mitigating attacks targeting machine learning models. It underscores the pivotal role of artificial intelligence in enhancing digital security through tasks like malware analysis, network vulnerability assessment, and threat prediction amidst rapid global digitization.

Zhixiong Xiao in the paper titled "Minimizing Overhead Through Blockchain for Establishing a Secure Smart City with IoT Model" explores the integration of blockchain technology with IoT to enhance security while addressing resource constraints. Traditional blockchain deployments are impractical for IoT due to their

high storage and computational demands. This study proposes an optimized blockchain framework tailored for IoT devices, ensuring essential security measures like authenticity, credibility, confidentiality, availability, and non-repudiation. The approach aims to bolster security without imposing excessive resource burdens, making it suitable for smart city applications.

"Security and Privacy of 6G Wireless Communication Using Fog Computing and Multi-Access Edge Computing" by Ting Xu, Ning Wang, Qian Pang, and Xiqing Zhao addresses data confidentiality challenges in forthcoming 6G networks. The study explores blockchain's potential for enhancing security and incorporates machine learning (ML) to manage vast data volumes. It reviews strategies for protecting automotive communication systems and assesses confidentiality approaches within 6G architecture. The research emphasizes safeguarding private data in the Internet of Everything (IoE) era and proposes ML solutions for data processing challenges, underscoring blockchain's role in securing 6G communications.

"Sustainable Development in Medical Applications Using Neural Network Architecture" by Shuyi Jiang aims to enhance risk management in healthcare through machine learning. The study uses social media data analysis to identify and assess threats, aiding informed decision-making in healthcare management. It employs machine learning algorithms to visualize risk categories and simplifies data processing for efficiency. Empirical analysis of Consumer Value Stores (CVS) reveals operational, financial, and technological risks, categorized by severity. The study highlights the framework's effectiveness in threat identification and mitigation, offering insights for safer healthcare environments.

"Target Image Processing Based on Super-Resolution Reconstruction and Machine Learning Algorithm" by Chunmao Liu proposes a method to enhance the resolution of medical images using super-resolution reconstruction and machine learning. This approach integrates nonlocal autoregressive learning into the reconstruction model, exploiting inherent data similarities in medical images. Additionally, a clustering algorithm refines classification dictionaries to improve efficiency. Experimental results, conducted on CT/MR images, demonstrate significantly improved peak signal-to-noise ratios and structural similarity values compared to other methods, achieving a peak value of 31.49. This study validates the efficacy of combining super-resolution reconstruction and machine learning for enhancing medical image resolution.

"Group Intelligent City Mobile Communication Network's Control Strategy Based on Cellular Internet of Things" by Jiazheng Wei explores enhancing mobile communication networks in urban areas using an improved particle swarm optimization (PSO) algorithm. This study refines PSO to tackle specific network challenges and achieves robust optimization results through simulations. The Grad-PSO algorithm effectively improves network performance with optimized parameters, demonstrating its suitability for enhancing mobile communication efficiency in urban environments.

Shuiquan Zhu presented the paper titled "Performance evaluation of micro automatic pressure measurement sensor for enhanced accuracy" focuses on enhancing the accuracy of micro-automatic pressure measurement sensors through design improvements and rigorous performance testing. The sensor achieved high detection accuracy (0.0452%) and met reliability standards with features such as sensitivity (0.0582%), nonlinearity (0.0741%), hysteresis (0.0266%), and repeatability (0.0625%). It also demonstrated reduced response times compared to traditional sensors, though the study highlights the necessity for additional real-world testing to optimize its performance further.

In summary, this special issue of Scalable Computing: Practice and Experience explores emerging trends in scientific computing that influence hardware and software requirements. It underscores the need for high-performance platforms capable of real-time architectural updates. Traditional computing struggles with adaptability and speed in real-time applications, while reconfigurable computing integrates hardware speed and software flexibility in a unified platform. This approach accelerates applications like image processing, encryption, and machine learning, especially Artificial Neural Networks (ANNs). The issue highlights advancements in reconfigurable computing systems and their impact on enhancing performance in intensive computing domains such as signal processing and computer vision.

ML-CSFR: A UNIFIED CROP SELECTION AND FERTILIZER RECOMMENDATION FRAMEWORK BASED ON MACHINE LEARNING

AMIT BHOLA* AND PRABHAT KUMAR†

Abstract. Sustainable and substantial crop production is essential globally, especially considering the increasing population. To achieve this, selecting appropriate crops and applying necessary fertilizers are pivotal for ensuring satisfactory crop growth and productivity. Farmers have relied heavily on intuition when choosing which crops to cultivate and suitable fertilizers to use in a given season. However, this traditional approach often needs to consider the significant impact of current environmental and soil conditions on crop growth and yield. Overlooking these factors can have far-reaching consequences, impacting not just individual farmers and their households but also the entire agricultural sector. The integration of machine learning offers a promising avenue for addressing these challenges and providing practical solutions. The core contribution of this research lies in proposing a unified framework termed Machine Learning-enabled Crop Selection and Fertilizer Recommendation (ML-CSFR). This framework's primary objective is to predict appropriate crops accurately and subsequently suggest corresponding fertilizers based on specific agricultural conditions. The initial phase involves the identification of proper crops for individual farmlands, considering local input variables. This phase employs artificial neural networks (ANN) to filter crops effectively using the available choices. The next phase utilizes soil and environmental parameters to anticipate the optimal fertilizer for the selected crops. This phase leverages the XGBoost (XGB) model to predict the most suitable fertilizers accurately. This two-phase approach ensures a comprehensive and effective recommendation system for enhancing agricultural outcomes. Experimental results demonstrate the effectiveness of this framework, achieving an accuracy score of 99.10% using ANN and 97.66% for XGB. The framework's capability to deliver tailored recommendations for individual farms and its potential to integrate real-time sensor data positions it as an effective tool for improving agricultural decision-making.

Key words: Machine learning, Fertilizer recommendation, Digital agriculture, Crop selection, Neural network

1. Introduction. Agriculture stands as the foundation of our society, fulfilling the nutritional requirements of billions worldwide. With the relentless growth of the world's population, the assurance of a consistent and reliable food source has become paramount. The significant role of agriculture is highlighted by its substantial contribution to India's GDP, amounting to 18.3% during the fiscal year 2022-2023 [1]. Additionally, this sector serves as the source of livelihood for approximately 50% of the country's workforce [2]. Despite its importance, the agricultural industry has experienced a decline in its performance in recent times. According to the Food and Agriculture Organization of the United Nations (FAO), approximately one-third of all food produced for human consumption across the globe is lost or wasted each year [3]. Insufficient land holdings, soil depletion, improper crop choices, inadequate fertilization, climate variations, and plant disease influence these losses.

Emerging technologies like Machine Learning (ML) [4], [5], Deep Learning (DL) [6], [7], and the Internet of Things (IoT) [8] have proven highly advantageous for the agricultural sector. These advancements offer the potential to enhance productivity and simultaneously ensure ecological sustainability by fortifying conventional farming practices. However, many small and marginal farmers still employ traditional or customary agricultural methods. For instance, these farmers often rely on their rudimentary knowledge to select crops and suitable fertilizers, usually favoring traditional or popular crops within their locality. Consequently, this reliance on traditional methods can compromise crop yields and soil fertility [11] due to insufficient scientific insights [15]. An adverse consequence of such practices is increased soil acidity, inappropriate selection and crop-specific fertilizers, and inadequate soil nutrient management. Additionally, the quality and productivity of crops are influenced by environmental conditions, climate variations, soil attributes, and water levels, further underlining the complexity of agricultural outcomes.

*Computer Science and Engineering Department, National Institute of Technology Patna, Bihar, India. (amitb.phd19.cs@nitp.ac.in).

†Computer Science and Engineering Department, National Institute of Technology Patna, Bihar, India. (prabhat@nitp.ac.in).

Selecting suitable crops and appropriate fertilizers tailored to filtered crops is pivotal in augmenting agricultural output and enhancing quality. Driven by the challenges above, this study aims to identify and tackle the intricacies of crop production by proposing a machine learning enabled Crop Selection and Fertilizer Recommendation (ML-CSFR) framework. This framework is designed to navigate the complex decision-making process of crop selection and appropriate fertilizer recommendation. It achieves this by considering various influential factors, including temperature, humidity, pH, rainfall, and soil nutrient levels. Notably, soil nutrients like Nitrogen (N), Phosphorus (P), and Potassium (K) are paramount for promoting plant growth and enhancing yield [16]. Concurrently, pH governs chemical reactions within the soil by determining its acidic or alkaline nature. Moreover, the development of plants is significantly influenced by electrical conductivity (EC), which also indicates soil fertility, water quality, and salinity.

The government has taken initiatives to enhance agricultural productivity by issuing Soil Health Cards (SHC) to individual farmers after assessing their farm's soil composition. These cards provide details about the soil's macro and micro nutrient levels. However, the conventional farming practices followed by farmers often fail to capitalize on this valuable information, resulting in suboptimal agricultural productivity. The ML-CSFR framework is proposed as an accessible and cost-effective solution to address these challenges. This framework suggests crops and corresponding fertilizers based on localized parameters by leveraging machine learning techniques. The ML-CSFR framework encompasses two distinctive phases: crop filtration and fertilizer recommendation. In the initial phase, crops are filtered based on local and regional variables. This filtration process involves the selection of 'n' crops that align with the soil and weather conditions while excluding those less suitable. Subsequently, tailored fertilizer recommendations are provided for each filtered crop in the second phase, guided by the soil's specific parameters. This research offers several noteworthy contributions:

1. The study introduces a two-phase Machine Learning-based Crop Selection and Fertilizer Recommendation (ML-CSFR) framework designed to provide farmers with optimal crop selection and fertilizer recommendations to enhance their returns. The initial phase of this framework involves assisting in selecting appropriate crops by filtering them based on the specific soil nutrient levels and the prevailing regional weather conditions associated with each farmland. Subsequently, the second phase generates fertilizer predictions for each filtered crop, considering the localized soil parameters.
2. Extensive experiments are conducted to demonstrate the efficacy of the proposed framework.
3. The first phase is evaluated on six benchmark models, including Decision Tree (DT), Support Vector Machine (SVM), Random Forest (RF), K-Nearest Neighbour (KNN), XGBoost (XGB), and Artificial Neural Networks (ANN), for crop filtration. The evaluation results highlight that the proposed Artificial Neural Network (ANN) model attains the highest accuracy scores of 99.07% for validation and 99.10% for testing, while 99.13% precision and 99.24% recall, surpassing the performance of all other studied models.
4. The second phase evaluates eight benchmark models for fertilizer prediction: Logistic Regression (LR), DT, Gaussian Naive Bayes (GaNb), LrSVM, XGB, and RF. The evaluation results emphasize that the proposed XGB model excels, achieving outstanding accuracy scores of 99.23% for training and 97.66% for testing.
5. This empirical analysis validates that the proposed crop filtration in the first phase aligns with improved crop intensity and productivity. Furthermore, the framework's fertilizer recommendations in the second phase undergo validation through credible sources referenced in citations, thereby justifying the credibility and reliability of the framework's output.

The subsequent sections of this paper are organized as follows: In Section 2, a comprehensive overview of related works is provided. Section 3 outlines the methodology for the proposed framework. Section 4 discusses the experimental setup, data analysis, and methods used. The results and discussion are presented in Section 5. Lastly, Section 6 concludes the findings and discusses potential avenues for future research.

2. Related works. Numerous researchers have made contributions to devising diverse solutions to enhance crop productivity. Machine learning [10] and Deep learning have made their way into agriculture to enable more innovative and accurate crop selection decisions and improve yield through precise fertilizer recommendations [12]. Automated systems equipped with IoT [27] are also facilitating farmers in monitoring processes and receiving alerts, including weather conditions and soil moisture updates [17].

Agriculture has seen notable advancements in its pursuit of real-time crop selection [36] and fertilizer prediction [13], [14]. Cheema et al. [18] introduced a diverse crop model leveraging multiple soil parameters for

identifying suitable crops. The proposed approach harnessed a Quantum Value-based Gravitational Search Algorithm (GSA) to discover optimal solutions. Soil attributes such as pH, salinity, texture, nitrogen, phosphorous, and potassium were explored and employed as inputs for crop selection. Bakhavatchalam et al. [19] presented a crop prediction system that relies on various attributes and utilizes a multilayer perceptron (MLP), JRip, and decision table classifier. A range of machine learning models was implemented on the WEKA platform, with the most effective MLP model achieving an accuracy of 98.22%. Jain et al. [20] devised a soil-based machine learning comparative analytical framework for predicting crop yield production. This framework employed soil characteristics and climatic factors to categorize crop yield predictions as high, low, or medium. Gupta et al. [21] introduced a crop recommendation system integrating MapReduce and K-means clustering. This model considered crop yields per acre for distinct regions based on different varieties cultivated in the target zone. Mariammal et al. [22] proposed a feature selection method called Modified Recursive Feature Elimination (MRFE) for crop prediction, aiming to select vital features from crop data. This method employed a ranking algorithm to identify significant attributes. The results highlighted that MRFE outperformed various wrapper-based feature selection techniques, achieving an accuracy of 95%.

Senapaty et al. [23] introduced an IoT-enabled soil nutrient classification and crop recommendation (IoTSNA-CR) model to assist farmers throughout the cultivation process. The model employs sensors to gather real-time data on soil moisture, temperature, water, and nutrient levels. This work is comparable to Bhola et al. [25], where the model helps in optimal crop selection and reduces fertilizer usage. The innovative hybrid algorithm, MSVM-DAG-FFO, which combines a multi-class SVM with directed acyclic graph optimization and fruit fly optimization, achieved a remarkable 97.3% accuracy, surpassing the SVM and Decision Tree performance. Swaminathan et al. [24] address the challenge of fertilizer recommendations based on soil nutrients through a nutrient-centered deep collaborative filtering approach. This research aims to create an advanced recommender system called the Nutrient-centered Deep Collaborative Filtering (NDCF) method. The proposed method achieved root mean square and mean absolute error of 0.8411 and 0.655 on the collected dataset, respectively. The study by Khan et al. [26] presents a real-time context-aware fertilizer recommendation system utilizing ML and IoT technology. The model suggests suitable fertilizers for specific soil and crop types by capturing real-time soil fertility context through IoT-assisted mapping. The proposed IoT-assisted fertility mapping aligns well with standard soil chemical analysis, demonstrating mean differences of 0.34, 0.36, and -0.13 for Nitrogen, Phosphorous, and Potassium, respectively. Machine learning models are employed for context-aware fertilizer recommendation, including Logistic Regression, Support Vector Machine, Gaussian Naïve Bayes, and K-Nearest Neighbor. The Gaussian Naïve Bayes model exhibited the highest accuracy, reaching 96% and 94% for training and testing datasets.

Further, integrating modern technologies like the IoT and Artificial Intelligence (AI) in agriculture is crucial for efficient and quality crop production. Swaminathan et al. [27] introduce a four-layer architectural model encompassing sensors, networks, services, and applications to establish an energy-efficient farming system. The application layer employs deep learning for a fertilizer recommendation system aligned with expert opinions. The entire system is accessible through a user-friendly mobile application for farmers. This work underscores the significance of IoT-driven agricultural sensors and AI applications to enhance crop yield and sustainability, addressing the increasing demands of a growing population. The proposed approach showcases its potential to improve crop yield through fertilizer recommendations based on chemical properties. It includes integrating more sensors for comprehensive farm management. Thorat et al. [34] focus on integrating AI and sensor technology in agriculture to enhance insecticide, fertilizer recommendation, and soil nutrient analysis. The proposed approach employs Transition Probability Function (TPF) and Convolutional Neural Network (CNN), achieving over 90% accuracy. Indeed, the suitability of a particular soil type for various crops is significant, but unfavorable crop selection in a given location can negatively impact crop yield. This study addresses the identified limitations by introducing suitable crop selection and crop-specific fertilizer prediction architecture.

3. Methodology. Farmers are grappling with reduced crop yields and profits due to a limited understanding of crop selection intricacies and the factors influencing crop growth. Given that crop selection and the corresponding fertilizer stand as pivotal factors for maximizing yield and profitability, the primary objective of this study is to devise a Crop selection and Fertilizer recommendation framework to enhance agricultural returns.

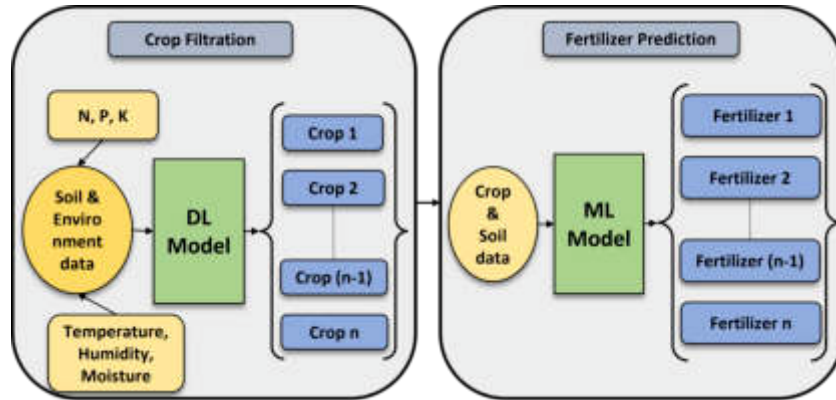

Fig. 3.1: Proposed framework

Consider a set of ‘ i ’ distinct crops denoted as $\{C_1, C_2, \dots, C_i\}$ and a collection of ‘ j ’ diverse farmlands denoted as $\{F_1, F_2, \dots, F_j\}$. It is assumed that each farmer possesses a Soil Health Card (SHC) for their farmland ‘ F_j ’, containing information about soil nutrient levels, alongside regular meteorological updates provided by government agencies. The objective is to determine appropriate crops and their corresponding fertilizers for each farmland based on inputs related to soil and weather conditions. The proposed framework, as depicted in Figure 3.1, employs a two-phase approach to suggest a variety of crops and associated fertilizers for each farm. In the initial phase, ‘ n ’ crops are filtered for each farmland ‘ F_j ’ from the pool of ‘ i ’ different crops. This phase involves assessing the compatibility of available crops with the local soil and weather conditions and filtering suitable crops. Further, the filtered crops are directed to the next stage, which identifies the suitable fertilizer for each crop for the farmer’s land. Implementing fertilizer tailored to the specific site offers benefits in terms of environmental sustainability, economic efficiency, and enhanced yield [35]. Each of these phases is further elaborated in the following subsections.

3.1. Crop filtration. Figure 3.2 illustrates the initial phase that focuses on filtering ‘ n ’ suitable crops. For every farmland ‘ F_j ’, consider $\{W_1(t), W_2(t), \dots, W_k(t)\}$ as weather conditions like temperature, rainfall, etc., at a time ‘ t ’, and $\{S_1(t), S_2(t), \dots, S_l(t)\}$ as soil attributes such as N, P, K, etc. Meteorological departments or local government agencies provide regular weather updates ‘ $W_k(t)$ ’ to farmers, aiding them in making informed decisions for their farming activities. Furthermore, the government provides a soil health card containing 12 vital soil macro and micro nutrients ‘ $S_l(t)$ ’, including pH, EC, Organic Carbon (OC), Nitrogen (N), Phosphorus (P), Potassium (K), Sulphur (S), Zinc (Zn), Boron (B), Iron (Fe), Manganese (Mn), and Copper (Cu). Since crop growth is intrinsically influenced by weather and soil conditions, these critical soil parameters are retrieved from the farmer’s soil health card and government weather updates to determine the most suitable crops. A proposed deep learning model computes probabilities $\{p_1, p_2, \dots, p_x\}$ based on these input parameters to rank crops. Subsequently, the top ‘ n ’ crops are selected and passed on to the next phase for further estimation.

Figure 3.4 portrays the architecture of the proposed artificial neural network model employed in the first phase. In this feed-forward backpropagation network, elements like weights, biases, the number of hidden layers, hidden neurons, learning rate, and training epochs play a pivotal role in determining prediction accuracy. These parameters are selected for precise predictions through a trial-and-error approach. A total of 7 inputs are fed into the input layer, and along with the bias, they are propagated to the hidden layer. The activation function ReLU is implemented for the hidden layers, while the output layers utilize the softmax activation function to predict probabilities. Furthermore, each hidden layer encompasses 512 neurons, the input layer consists of 7 neurons, and the output layer comprises 22 neurons, corresponding to each crop.

3.2. Fertilizer prediction. The second phase of the framework involves predicting fertilizer for each of the ‘ n ’ filtered crops obtained from the first phase. Figure 3.3 depicts the second phase of the ML-CSFR framework that predicts fertilizer using an ML model for each filtered crop individually on the available farmer’s

Fig. 3.2: Crop Filtration phase

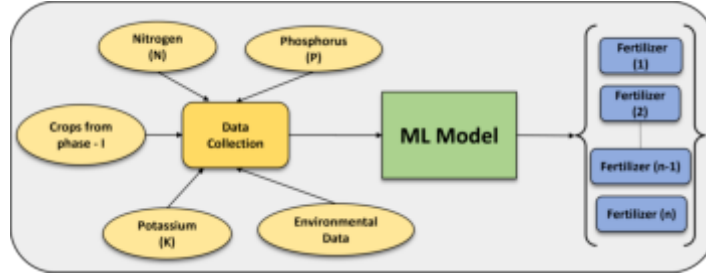

Fig. 3.3: Filter prediction phase

land. For every farmland ‘ F_j ’, filtered crops $\{C_1, C_2, \dots, C_i\}$, weather conditions $\{W_1(t), W_2(t), \dots, W_k(t)\}$, soil attributes $\{S_1(t), S_2(t), \dots, S_l(t)\}$, and $\{Fr_1, Fr_2, \dots, Fr_m\}$ be the available fertilizers.

The goal of the model is to recommend the appropriate fertilizer (y) for each filtered crop from the input set ‘ X ’, as described by Equation 3.1. The soil fertility level is determined by the quantities of nitrogen, phosphorus, and potassium in the soil. Equation 3.2 and Equation 3.3 represent the input and output feature set.

$$y = f(X) \tag{3.1}$$

$$X = \{W_k(t), S_l(t), C_m(t)\} \tag{3.2}$$

$$Y = F_n(t) \tag{3.3}$$

where, ‘ X ’ is the variables set representing weather, soil, and crop parameters; ‘ Y ’ represents the collection of commercially available fertilizers utilized as the model’s output for every combination of input variables. Each fertilizer available in the market possesses distinct compositions of essential nutrients like Nitrogen (N), Phosphorus (P), and Potassium (K), typically indicated in their names. The model inputs filtered crops, weather, and soil parameters and predicts suitable fertilizers for the land. Various models, including LR, DT, GaNB, LrSVM, XGB, and RF, are employed and compared to determine the most effective classification model for this phase.

3.3. Machine Learning models. Various machine learning models were employed and compared to determine the most effective classification model for fertilizer prediction. The models used include Logistic Regression, Decision Tree, Gaussian Naive Bayes, Support Vector Machine, Random Forest, Gradient Boosting, and XGBoost. Below is a detailed description of the setup for each model:

3.3.1. Logistic Regression. Logistic Regression is a linear model for binary classification. It models the probability that a given input point belongs to a particular class. The probability is modeled using a logistic

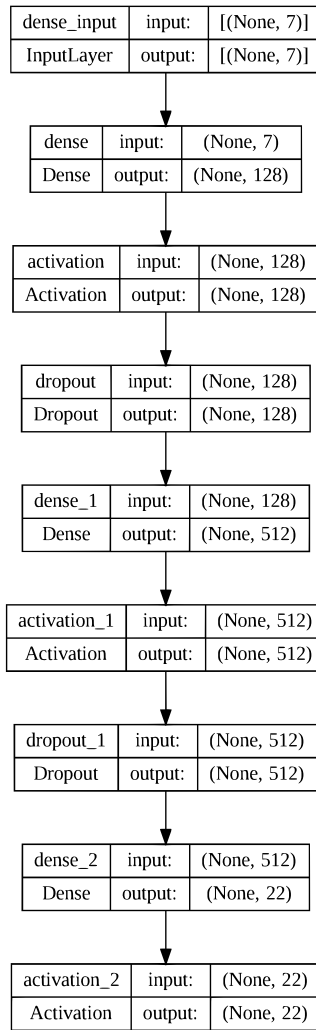

Fig. 3.4: Proposed ANN Architecture for Crop Filtration phase

function:

$$P(Y = 1|X) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p)}} \tag{3.4}$$

where $\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p$ are the parameters to be estimated.

3.3.2. Decision Tree. Decision Trees are non-parametric models that split the data based on feature values. Each internal node represents a "test" on an attribute, each branch represents the outcome of the test, and each leaf node represents a class label. The Gini impurity or information gain is often used as a criterion to split the nodes:

$$Gini(D) = 1 - \sum_{i=1}^C P_i^2 \tag{3.5}$$

where P_i is the probability of an element being classified to a particular class.

3.3.3. Gaussian Naive Bayes. Gaussian Naive Bayes is based on Bayes' theorem and assumes independence between features. For continuous features, it assumes a Gaussian distribution:

$$P(x_i|y) = \frac{1}{\sqrt{2\pi\sigma_y^2}} e^{-\frac{(x_i - \mu_y)^2}{2\sigma_y^2}} \quad (3.6)$$

where μ_y and σ_y^2 are the mean and variance of the feature x_i for class y .

3.3.4. Support Vector Machine. SVMs find the hyperplane that best separates the classes by maximizing the margin between the nearest points of the classes (support vectors). For the linear case, the decision function is:

$$f(x) = \beta_0 + \sum_{i=1}^n \beta_i x_i \quad (3.7)$$

with the optimization objective:

$$\min_{\beta} \frac{1}{2} \|\beta\|^2 \quad \text{subject to} \quad y_i(\beta_0 + \sum_{j=1}^n \beta_j x_{ij}) \geq 1 \quad \forall i \quad (3.8)$$

3.3.5. Random Forest. Random Forest is an ensemble method that constructs multiple decision trees during training and outputs the mode of the classes (classification) of the individual trees. The model's prediction is the average prediction of the individual trees. The construction process involves:

$$\hat{f}(x) = \frac{1}{B} \sum_{b=1}^B f_b(x) \quad (3.9)$$

where B is the number of trees and $f_b(x)$ is the prediction of the b_{th} tree.

3.3.6. Gradient Boosting. Gradient Boosting builds trees sequentially, with each new tree aiming to correct the errors of the previous one. The key idea is to fit a new model to the residual errors made by the previous model:

$$F_m(x) = F_{m-1}(x) + \lambda h_m(x) \quad (3.10)$$

where $F_m(x)$ is the ensemble model at stage m , $h_m(x)$ is the new tree, and λ is the learning rate.

3.3.7. XGBoost. XGBoost is an advanced implementation of gradient boosting with additional regularization terms to control overfitting. The objective function is:

$$L(\phi) = \sum_{i=1}^n l(\hat{y}_i, y_i) + \sum_{k=1}^K \Omega(f_k) \quad (3.11)$$

$$\Omega(f) = \gamma T + \frac{1}{2} \lambda \|\omega\|^2 \quad (3.12)$$

where $\Omega(f_k)$ is a regularization term, T is the number of leaves, w is the leaf weight, and γ and λ are regularization parameters.

4. Experiment. This section provides a comprehensive evaluation of the proposed architecture through empirical analysis. It begins by outlining the experimental setup, detailing the dataset source, and discussing data analysis methods. Subsequently, the execution of the suggested model is discussed, followed by a comparative assessment of the attained outcomes compared to alternative machine learning models.

Table 4.1: Feature description (Crop filtration phase)

Features	Description	Unit
Nitrogen (N)	It is responsible for photosynthesis in the plant.	kg/ha
Phosphorus (P)	It is crucial to the crop's development.	kg/ha
Potassium (K)	It is required for the reproduction of crops.	kg/ha
pH level (pH)	It determines the availability of essential plant nutrients.	pH value
Temperature	Temperature is a key factor in plant growth and development.	degree Celsius
Humidity	Humidity is important for photosynthesis in plants.	%
Rainfall	The primary source of water for agricultural production.	mm

Table 4.2: Feature description (Fertilizer prediction phase)

Feature(s)	Description
Temperature	Degree Celsius
Humidity	%
Moisture	%
Soil type	5 types
Crop type	11 types
Nitrogen	Ratio
Potassium	Ratio
Phosphorous	Ratio
Fertilizer	7 types

4.1. Experimental setup. The experimental setup involves an Intel Core i5 processor with a quad-core x64-based architecture running at 3.6 GHz and 8 GB of RAM. The programming language used is Python, and the program was executed using the Google Colab notebook. Various standard software libraries such as Keras, Tensorflow, Matplotlib, and Numpy were utilized for implementation.

4.2. Dataset. Two distinct datasets are employed to assess the efficacy of the proposed ML-CSFR framework. The initial crop filtration phase dataset is sourced from [28]. This dataset categorizes lands and crops according to various attributes, encompassing soil characteristics such as nitrogen, phosphorus, potassium, and pH, and environmental factors impacting crop growth, such as humidity and rainfall. The collected dataset comprises 2200 land samples and encompasses 22 distinct crop types. Each crop category includes 100 individual land samples for analysis. The data has been divided into the ratio of 80:10:10 for training, validation, and testing sets. Table 4.1 describes the dataset features used in the first phase of the framework.

The second phase dataset [29] contains seven fertilizer varieties and eleven crops. The attributes of the collected dataset for the fertilizer dataset are shown in Table 4.2. The fertilizer used in executing the proposed approach is represented in Equation 4.1.

$$Y = \{Fr_1, Fr_2, \dots, Fr_m\} \quad (4.1)$$

The fertilizer names are used as ' Fr_1 ' for '20-20', ' Fr_2 ' for '14-35-14', ' Fr_3 ' for '26-28' fertilizer, ' Fr_4 ' for 'DAP', ' Fr_5 ' for '10-26-26', ' Fr_6 ' for 'Urea', and ' Fr_7 ' for '17-17-17'.

4.3. Dataset analysis. This section delves into the analysis of the soil and environmental data that influence both the crop filtration and fertilizer prediction processes. Initially, each dataset undergoes data cleaning procedures, as various attributes encompass distinct measurement scales. The Min-Max Scaler uses

Fig. 4.1: Phase-1 dataset (a) Correlation matrix (b) Feature importance

the rescaled formula mentioned in Equation 4.2 for precise crop selection.

$$C = \frac{B - B_{min}}{B_{max} - B_{min}} \quad (4.2)$$

where C signifies the rescaled value, B is the feature value, B_{min} is the minimum value, and B_{max} is the maximum value. Further, the data has been apportioned into training and test sets, with an 80:10:10 split. The accuracy of these models is evaluated on both the training, validation, and test datasets.

The primary macronutrients, nitrogen, phosphorus, and potassium (N, P, and K), are pivotal in enhancing crop yield and quality. Figure 4.1(a) illustrates the correlation between the employed features, emphasizing the high correlation between potassium and phosphorous soil parameters and a moderate correlation between humidity and rainfall. On the other hand, Figure 4.1(b) provides insight into the crucial features within the crop filtration dataset, highlighting that among all the weather parameters, rainfall and humidity emerge as essential factors.

Figure 4.2 compares the nitrogen, phosphorus, and potassium values that different crops need. Among the crops, cotton, apple, and grapes exhibit the highest demand for macronutrients for optimal growth, whereas lentils, black gram, and oranges have the lowest requirements. The significance of various soil macronutrients such as N, P, and K holds a relatively uniform weightage across all crops. Notably, rainfall has the most significant importance among the considered parameters, while pH records are the least effective.

The dataset used for the study's second phase is sourced from [29]. The various commercial fertilizers used in the dataset and the distribution are classified in Figure 4.3. Many fertilizer products are labeled with the abbreviation NPK, followed by numerical values, such as NPK 10-26-26. The numbers following NPK indicate the percentage amounts of each nutrient in the fertilizer. For instance, an NPK value of 10-26-26 indicates that the fertilizer contains 10% nitrogen, 26% phosphorus, and 26% potassium [30]. The selected fertilizer and crop data type distribution in the dataset is visualized in Figure 4.4(a) and Figure 4.4(b), respectively.

Each type of soil has its unique attributes and composition. For instance, Urea is the most widely used solid nitrogen fertilizer and is usually applied as granules. Hence, its count is maximum in the dataset, as seen in Figure 4.4(a). Further, the crop has specific nutrient requirements for successful growth and enhanced production. Some crops necessitate lower nutrient levels, while others demand more. Consequently, in addition to soil type, crop type significantly influences fertilizer needs and recommendations.

The dataset distribution of the three macronutrients is categorized based on the provided classification. The application of fertilizer heavily relies on factors such as crop type, soil, and soil fertility regarding NPK nutrients. The soil nutrient level is interconnected with crops and fertilizers needed. Moreover, the relationships between crop type, soil type, and existing nutrient levels are even more intricate.

Fig. 4.2: N, P, K values required by different crops

Fig. 4.3: Fertilizer class distribution

4.4. Algorithm for ML-CSFR framework. The primary goal of this experiment is to develop a recommendation model that will advise crop filtration and crop-specific fertilizer on various factors such as soil constituents, crop traits, and climate. Algorithm 1 presents the algorithm with the detailed steps involved in crop-based fertilizer prediction using ANN-XGB.

The algorithm is divided into two parts: (1) compute each crop’s rank and filter the top-n crops; (2) predict fertilizer for each crop corresponding to the farmer’s land. It requires soil health card details and environmental values concerning each land as input.

4.5. Evaluation Metrics. This study involves two separate datasets corresponding to the two phases of the framework. In the initial phase, the framework filters crops from multiple crop categories, while in the second phase, it predicts fertilizers from a range of different classes. As a result, a multi-class classification approach is utilized, and a confusion matrix is generated to calculate classification instances, including True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN). In the context of multi-class classification, these instances can be interpreted as follows:

- True Positive (TP): The model correctly predicts the positive class.
- False Positive (FP): The model incorrectly predicts the positive class.
- True Negative (TN): The model correctly predicts the negative class.
- False Negative (FN): The model incorrectly predicts the negative class.

Algorithm 1 ML-CSFR: Crop Selection and Fertilizer Recommendation**Require:** Local input variables $X = \{x_1, x_2, \dots, x_n\}$, Soil parameters S , Weather parameters W **Ensure:** Top 3 recommended crops $C = \{c_1, c_2, c_3\}$, Recommended fertilizers F

```

1: Phase 1: Crop Selection using ANN
2: Initialize ANN parameters: number of layers  $L$ , neurons in each layer, activation functions
3: for epoch = 1 to  $N$  do

19:    end for
20:  end for
21: Output top 3 recommended crops  $C = \{c_1, c_2, c_3\}$  based on highest probabilities  $\hat{y}_i$ 
22: Phase 2: Fertilizer Recommendation using XGBoost
23: Initialize XGBoost parameters: number of trees  $T$ , learning rate  $\eta$ , maximum depth  $d$ 
24: for  $t = 1$  to  $T$  do
25:   Compute predictions  $\hat{y}_t = \sum_{i=1}^t f_i(X)$ 
26:   Compute residuals  $r_t = y - \hat{y}_t$ 
27:   Fit regression tree to residuals:  $f_t = \arg \min_f \sum_{i=1}^n L(y_i, \hat{y}_{t-1} + f(x_i))$ 
28:   Update model:  $\hat{y}_t := \hat{y}_{t-1} + \eta f_t(X)$ 
29: end for
30: For each crop  $c \in C$ , predict the suitable fertilizer  $F$  using XGBoost
31: Output: Recommended crops  $C$  and fertilizers  $F$ 

```

$$Accuracy = \frac{TP + TN}{TP + FN + FP + TN} \quad (4.3)$$

$$Precision = \frac{TP}{TP + FP} \quad (4.4)$$

$$Recall = \frac{TP}{TP + FN} \quad (4.5)$$

$$F_1 = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (4.6)$$

Equation 4.3 represents accuracy, calculating the ratio of correctly predicted observations to total observations. Equation 4.4 defines precision, which measures the ratio of the true positive predictions to the total number of positive predictions. In contrast, Equation 4.5 represents recall, which determines the number of true positive predictions divided by the total number of relevant observations. The F_1 Score, as calculated in Equation 4.6, represents the harmonic mean of precision and recall.

Fig. 4.4: Fertilizer data distribution (a) Fertilizer type (b) Crop type

Table 5.1: Comparative analysis (Crop filtration phase)

Accuracy / Models	DT	SVM	RF	KNN	XGBoost	ANN
Training Accuracy	0.985	0.985	0.992	0.988	0.992	0.992
Testing Accuracy	0.974	0.976	0.985	0.976	0.981	0.991
Validation Accuracy	0.972	0.975	0.983	0.975	0.980	0.990
Precision	0.972	0.975	0.983	0.975	0.981	0.991
Recall	0.974	0.976	0.985	0.976	0.982	0.992

Table 5.2: List of filtered crops for sample lands

Land	Top filtered crops
Land 1	Rice, Maize, Cotton
Land 2	Maize, Rice, Jute
Land 3	Maize, Chickpea, Lentil

5. Results. A series of comparative experiments were conducted to evaluate the performance of the proposed framework for crop filtration and crop-specific fertilizer recommendation. The results of these experiments are comprehensively analyzed and discussed in this section.

5.1. Result Analysis of Crop Filtration Phase. The crop filtration phase utilizes a classification model to filter crops based on their probabilities. The obtained results for the initial phase under different environmental conditions are summarized in Table 5.1.

The evaluation outcomes demonstrate that the proposed Artificial Neural Network (ANN) model achieves a validation accuracy of 99.07%, testing accuracy of 99.10%, precision of 99.13%, and recall of 99.24%. These results are the highest among all the studied models. Additionally, the Random Forest (RF) and XGBoost (XGB) models also performed well, with testing accuracies, precision, and recall all above 98%. Conversely, the Decision Tree (DT) recorded the lowest validation and testing accuracies of 97.20% and 98.50%, respectively. This lower accuracy could be attributed to variations in the dataset, as DT is very sensitive to small perturbations in the data.

Table 5.2 provides an overview of the crops the ANN model filtered for three distinct farmlands. While the present study filters only three crops, the number of crops can be customized according to the user's preferences.

Fig. 5.1: ANN result (a) accuracy vs epoch (b) loss vs epoch

Table 5.3: Performance Comparison (Fertilizer Prediction Phase)

Model	Training Accuracy	Testing Accuracy	Precision	Recall	F1-Score	AUC
LR	0.92	0.70	0.71	0.70	0.70	0.75
DT	0.99	0.94	0.94	0.94	0.94	0.96
GaNB	0.96	0.50	0.52	0.50	0.49	0.55
LrSVM	0.94	0.85	0.86	0.85	0.85	0.88
XGB	0.99	0.97	0.97	0.97	0.97	0.98
RF	0.99	0.95	0.95	0.95	0.95	0.97

Figures 5.1(a) and (b) illustrate the graphs depicting accuracy versus epoch and loss versus epoch for the proposed Artificial Neural Network (ANN) model. Examining the loss curve reveals that the global optimal minimum is attained in the initial stages of iterations. The results justify the selection of ANN as the proposed model for crop filtration as its performance consistently improves and error reduces over time.

5.2. Result Analysis of Fertilizer Prediction Phase. In the fertilizer prediction phase, the performance of various machine learning models is evaluated, and the most effective model is selected for this phase. The most appropriate model is chosen by considering the performance metrics such as accuracy, precision, recall, and F1-score. The models, including LR, DT, GaNB, LrSVM, XGB, and RF, were applied to the preprocessed dataset for fertilizer prediction. The performance assessment of these models is detailed in Table 5.3.

The analysis revealed that tree-based models like RF, XGB, and DT exhibited more exceptional performance stability than other models. This stability arises from the fact that these models establish decision boundaries that are more consistent and accurate by aggregating the outcomes of multiple trees and utilizing majority voting to arrive at a precise prediction.

Notably, the XGB performs exceptionally well in recommending suitable fertilizers, achieving an accuracy of 99.23% and 97.66% on the training and test datasets, respectively. The classification report and confusion matrix for the best-performing model XGB are shown in Table 5.4 and Figure 5.2, respectively. The table indicates that all the fertilizers achieved 1.00 precision except 17-17-17, which achieved a precision of 0.67. Further, fertilizer 10-26-26 achieves a low recall of 0.67, indicating that the proposed model misclassifies 33 out of 100 classes. The low recall value can be attributed to the imbalance dataset, as depicted in Figure 4.3, where class 10-26-26 only accounts for 7.07% of the data.

Conversely, the GaNB model is the worst-performing, primarily due to its unsuitability for dealing with imbalanced class problems. When dealing with imbalanced datasets, where certain classes have much larger instances than others, GaNB can encounter difficulties delivering accurate outcomes. This problem may lead to biased predictions favoring the majority class and suboptimal performance for the minority class.

In summary, XGB performed better than other models in testing accuracy, precision, recall, F1-score, and AUC values. Table 5.4 present the classification report of the XGB model. The table depict a consistent performance in model's accuracy, with a reduced error over time, thereby justifying the selection of XGB as

Table 5.4: Classification report (XGB)

Classes	Code	Precision (%)	Recall (%)	F1-Score
10-26-26	0	1.00	0.67	0.80
14-35-14	1	1.00	1.00	1.00
17-17-17	2	0.67	1.00	0.80
20-20	3	1.00	1.00	1.00
28-28	4	1.00	1.00	1.00
DAP	5	1.00	1.00	1.00
Urea	6	1.00	1.00	1.00
Accuracy				0.97

Fig. 5.2: Confusion matrix (XGB)

the proposed fertilizer recommendation model.

The fertilizer recommendations for each of the filtered crops for Land 1 are outlined in Table 5.5. The proposed model suggested DAP, 20-20, and 14-35-14 as the appropriate fertilizers for the predicted crops: Rice, Maize, and Cotton, respectively. These recommendations are substantiated by the references provided in the table. For example, the prediction of DAP or Urea fertilizer for the Rice crop aligns with established practices [31]. Moreover, the 28-28 fertilizer, a complex blend rich in Nitrogen and Phosphorus, is suitable for crops like Paddy, Cotton, Chillies, Sugarcane, and Vegetables, offering immediate and sustained greenness [32]. Similarly, the 14-35-14 fertilizer is optimal for Rice, Cotton, Groundnut, Chillies, Soya bean, and Potato crops, particularly those demanding high initial Phosphate [33]. Thus, the proposed framework is validated by its ability to suggest fitting crop-specific fertilizers, providing farmers with insights to enhance yields.

5.3. Discussion. The development of the proposed two-phase framework for crop filtration and fertilizer recommendation represents a significant advancement in precision agriculture. The experimental results underscore the framework's effectiveness, showcasing its ability to make accurate and reliable recommendations tailored to specific agricultural conditions.

In the crop filtration phase, the Artificial Neural Network (ANN) model demonstrated superior performance compared to other classification models, achieving a remarkable testing accuracy of 99.10%, precision of 99.13%, and recall of 99.24%. These metrics indicate the model's robustness in correctly identifying suitable crops under varying environmental conditions. The high precision and recall values further affirm the model's ability to make precise and consistent predictions, minimizing false positives and negatives.

The fertilizer prediction phase involved evaluating various machine learning models, where XGBoost (XGB) emerged as the best-performing model. It achieved training and testing accuracies of 99.23% and 97.66%, respec-

tively, along with a high F1-score and AUC, indicating its exceptional ability to distinguish between different classes of fertilizers. The classification report for XGB showed that most fertilizers achieved precision and recall of 1.00, except for fertilizer 17-17-17 and 10-26-26, which had a lower precision and recall. This discrepancy can be primarily attributed to class imbalance, as evidenced by the confusion matrix and distribution of the dataset.

Further, the framework iteratively follows a dynamic update mechanism, continuously updating its recommendations based on the latest soil and weather data. After each planting season, soil health is reassessed using an updated Soil Health Card or periodic soil testing. This updated soil data and ongoing weather information are fed back into the framework, which reruns the crop and fertilizer recommendation process. This dynamic feedback loop ensures that the recommendations remain relevant and accurate over time, adapting to changes in soil nutrient levels resulting from fertilizer applications and other environmental factors.

5.3.1. Error-Analysis. The error analysis from the first phase revealed that the Decision Tree (DT) model recorded the lowest validation and testing accuracies of 97.20% and 98.5%, respectively. This lower performance can be attributed to the model's sensitivity to small perturbations in the dataset, highlighting its limitations in handling imbalance data. Conversely, the Random Forest (RF) and XGBoost (XGB) models also performed well, with testing accuracies above 98%, but were slightly outperformed by the ANN model, suggesting that the latter's deeper architecture and non-linear learning capabilities offer significant advantages in this application.

Further, from the second phase error analysis is the model's occasional misclassification of minority class fertilizers, such as 10-26-26, which had a recall of 0.67. This misclassification suggests further data balancing techniques or augmenting the minority class samples to improve the model's performance on underrepresented classes.

5.3.2. Contributions. The significant contributions of this work include:

- *High Accuracy and Reliability:* The ANN model achieved exceptional accuracy in the crop filtration phase, and the XGB model demonstrated superior performance in the fertilizer prediction phase. These results highlight the models' effectiveness in handling complex agricultural data and making accurate recommendations.
- *Robustness to Environmental Variations:* The high precision and recall values across different models indicate the framework's robustness and adaptability to varying environmental conditions, ensuring reliable performance in diverse agricultural settings.
- *Scalability and Practicality:* The framework's architecture is designed to be scalable and capable of processing extensive agricultural data inputs in a cloud-based environment. This scalability ensures its applicability to small-scale farms and large agricultural enterprises.
- *Real-world Applicability:* The proposed framework's ability to provide farm-specific recommendations and its potential integration with real-time sensor data make it a practical tool for enhancing decision-making in agriculture. The accurate predictions of crop selection and fertilizer recommendations can lead to improved crop yields and optimized resource use.

Further, the proposed ML-CSFR framework is highly relevant to scalable computing due to its inherent ability to handle real-life problems. Using machine learning models such as ANN and XGBoost allows the framework to process extensive agricultural data inputs, including soil characteristics and weather conditions, in a scalable manner. This scalability ensures that the framework can be applied to diverse agricultural settings, from small-scale farms to large agricultural enterprises, that can be a versatile solution for improving crop selection and fertilizer recommendation processes. Additionally, the framework's architecture is designed to be deployable on cloud-based platforms, leveraging the power of distributed computing further to enhance its scalability and applicability in different agricultural scenarios.

Finally, the significant observation drawn from the results is the remarkable effectiveness of the proposed model in scenarios demanding farm-specific recommendations. These findings further confirm the practicality of the proposed framework, particularly in situations characterized by limited resources and constraints. Moreover, besides its simple architecture, the framework serves a dual role of crop selection and associated fertilizer recommendation, eliminating the requirement for separate applications for these tasks. This reduction in

Table 5.5: Recommended Fertilizer

Crop	Recommended Fertilizer	Ref.
Rice	DAP	[31]
Maize	28-28	[32]
Cotton	14-35-14	[33]

overhead enhances the model's efficiency and practicality. These findings underscore the adaptability of the proposed framework, positioning it as a valuable tool ready for implementation in real-world scenarios.

6. Conclusions and Future Works. The exponential growth of the world's population has boosted demand for both quantity and quality of food. Consequently, the agricultural sector is required to undergo a modern transformation to address this demand adequately. The integration of modern technologies with intelligent algorithms holds the potential to benefit the farming community significantly. This paper proposes ML-CSFR, a two-phase Crop Selection and Fertilizer Recommendation framework designed to provide better returns for the agricultural sector. The framework is a machine-learning tool that provides crop selection and fertilizer recommendations by leveraging local input variables. It harnesses various weather and soil data sources to deliver precise recommendations. The initial phase of crop filtration is executed using Artificial Neural Networks. The result justifies that ANN outperforms other ML models with an accuracy of 99.10%. In the second phase of fertilizer prediction, the results indicate that XGBoost is the most accurate machine learning model, achieving an accuracy of 99.23% for the training dataset and 97.66% for the test dataset. The proposed work contributes to increased accuracy in crop prediction, improved soil health with proper fertilization, and enhanced decision-making.

Additionally, potential areas for future exploration involve enlarging the datasets used and extending the application's utility to gain more comprehensive insights into crop and soil management. In terms of practical implications, the simple and lightweight design of the suggested framework offers potential for future integration with handheld devices. This integration could help farmers conveniently forecast crops and their corresponding fertilizers. Moreover, enhancing recommendations could involve integrating real-time sensor data collected from crop fields. This approach would enable precise determination of the exact quantities of macro and micro nutrients required, tailored to the specific demands of each crop.

A NEW MULTI-ROBOTS SEARCH AND RESCUE STRATEGY BASED ON PENGUIN OPTIMIZATION ALGORITHM

OUARDA ZEDADRA ^{*}, AMINA ZEDADRA [†], ANTONIO GUERRIERI [‡], HAMID SERIDI [§] AND DOUAA GHELIS [¶]

Abstract. In response to the challenging conditions that arise after natural disasters, multi-robot systems are utilized as alternatives to humans for searching and rescuing victims. Exploring unknown environments is crucial in mobile robotics, serving as a foundational stage for applications such as search and rescue, cleaning tasks, and foraging. In our study, we introduced a novel search strategy for multi-robot search and rescue operations. This strategy draws inspiration from the hunting behavior of penguins and combines the Penguin Search Optimization Algorithm with the Random Walk Algorithm to regulate the global and local search behaviors of the robots. To assess the strategy's effectiveness, we implemented it in the ARGoS multi-robot simulator and conducted a series of experiments. The results clearly demonstrate the efficiency and effectiveness of our proposed search strategy.

Key words: Swarm Intelligence, Swarm Robotics, Search and Rescue Problem, Penguin Search Optimization Algorithm, Random Walk Algorithm.

1. Introduction. Exploring unknown environments is a fundamental concern in mobile robotics, crucial for applications like cleaning, search and rescue, and foraging. Search and rescue operations play a critical role in disaster management, aiming to ensure the safety of individuals and minimize rescue time. While these operations can be challenging for human rescuers, mobile robots are utilized to navigate and explore disaster-stricken areas, locate victims, and perform various tasks that enhance the effectiveness and efficiency of rescue operations. They can access hazardous or inaccessible areas, gather information, and provide assistance to humans.

In search and rescue operations, the effectiveness of multi-robot systems lies in their capacity to cover extensive areas, gather more data, and improve operational efficiency, particularly in tasks deemed perilous, time-consuming, or beyond human capabilities. Despite these advantages, coordinating and communicating among robots present significant challenges. Effective collaboration and information sharing are crucial for comprehensive search area coverage. Designing systems that facilitate seamless coordination and communication is essential to maximize the multi-robot team's effectiveness. Additionally, the ability of these systems to operate in environments with limited communication and navigation capabilities is crucial, considering that search and rescue scenarios often occur in areas where communication infrastructure may be damaged or nonexistent. Therefore, multi-robot systems need robust communication and adaptable search methods for such challenging environments.

Swarm intelligence has been a source of inspiration for various applications of mobile robotics. For example, some animals' exploration, return, and communication strategies have shown great effectiveness, especially in mobile robot exploration. In this work, we proposed a new search and rescue strategy based on swarm intelligence algorithms to achieve the following objectives:

1. Increase the explored areas.

2. Disperse robots widely in their environment to increase the number of found victims.
3. Reduce search time.
4. Decrease the visits to already explored areas.

The majority of research in the search and rescue field predominantly relies on old SI algorithms (mature algorithms such as Ant Colony Optimization, i.e., ACO, Particle Swarm Optimization, i.e., PSO, Artificial Bee Colony, i.e., ABC). The Penguin Optimization Algorithm (POA) is an optimization technique inspired by the cooperative hunting strategies of penguins, specifically their ability to work together to locate and capture fish in harsh and dynamic environments. POA simulates this behavior by modeling the search process as a collaborative effort among multiple agents, each representing a penguin, to explore the solution space and converge on optimal solutions. To the best of our knowledge, the Penguin Search Optimization Algorithm (PeSOA) was used to optimize mathematical benchmark functions and has not yet been used in multi-robot-related problems. That is why we adapted and used the PeSOA in search and rescue problems. The POA is particularly well-suited for the problem of multi-robot search and rescue for several reasons:

- *Cooperative Behavior*: Similar to how penguins coordinate their movements to find food efficiently, POA enables multiple robots to collaborate, share information, and optimize their search patterns in a coordinated manner, enhancing the overall efficiency of search and rescue operations.
- *Adaptability*: The dynamic nature of the POA allows it to adapt to changing environmental conditions and obstacles, which is critical in unpredictable search and rescue scenarios where obstacles and conditions can vary widely.
- *Robustness*: The algorithm's robustness in dealing with complex and dynamic environments ensures that the robots can effectively navigate and perform their tasks despite uncertainties.

The paper is organized as follows: in Section 2, we introduce the Penguin Optimization Algorithm and summarize some recent related works. In Section 3, we present the finite state machine and the pseudo-code of the proposed algorithm. In Section 4, we present and discuss the obtained results. Finally, in Section 5, we conclude the work and present some perspectives.

2. State of the art. In this Section, we first present a description of the Penguin Optimization Algorithm (PeSOA). Then, we summarize some relevant and recent works related to the search and rescue problem and present a qualitative comparison of the reviewed works based on some relevant characteristics.

2.1. Description of the Penguin Optimization Algorithm (PeSOA). The Penguin Optimization Algorithm is a meta-heuristic algorithm inspired by the collaborative hunting strategies of penguins. This bio-inspired algorithm mimics the way penguins hunt for fish in groups, optimizing their energy expenditure and maximizing their food intake.

Hunting Strategy of Penguins. Penguins hunt in groups and use a strategy that involves synchronized dives and communication to locate and capture fish. Each penguin searches for food individually and then communicates its findings to the group. This collaboration allows the group to identify the areas with the highest concentration of food and optimize their foraging efforts. The key behaviors modeled in PeSOA include [1]:

- **Group Hunting**: Penguins hunt in groups, coordinating their efforts to maximize efficiency.
- **Communication**: Penguins communicate their positions and the amount of food found to the group, enabling collective decision-making.
- **Synchronized Dives**: Penguins synchronize their dives to systematically search different depths and areas.

Algorithm Structure. PeSOA simulates these behaviors to solve optimization problems by following these steps [1]:

1. **Initialization**: Generate an initial population of solutions (penguins) grouped into several groups.
2. **Random Search**: Each penguin performs a random search within a defined range (hole and level) until its oxygen reserves are depleted.
3. **Communication**: After the search, penguins return to the surface and share their findings (location and amount of food) with their group.
4. **Update Positions**: Penguins update their positions and probabilities of finding food in different locations based on the shared information.

5. Iteration: The process repeats for a number of generations, with the group collectively moving towards the areas with the highest food concentration (optimal solutions).

Key Components. The algorithm is composed of the components below [2]:

- Population Groups: Penguins are divided into groups, and each group searches specific areas.
- Intra-Group Communication: Penguins within the same group share their findings to refine their search strategy.
- Inter-Group Communication: Groups with less success may follow the more successful groups to improve their chances of finding food.
- Probabilistic Search: The search process is guided by the probability of food presence, which is updated based on the findings.

Mathematical Formulation. The position of each penguin is updated using the following equation:

$$D_{new} = D_{last} + rand() \times |X_{localbest} - X_{last}| \quad (2.1)$$

where D_{new} is the new position, D_{last} is the last position, $rand()$ is a random number for distribution, $X_{localbest}$ is the best local solution, X_{last} is the last solution.

PeSOA has been validated against several benchmark functions, such as the Rastrigin and Schwefel functions, and compared with other optimization algorithms like Particle Swarm Optimization (PSO) and Genetic Algorithm (GA). The results showed that PeSOA is robust and efficient, particularly in avoiding local optima and finding global solutions.

2.2. Related works. In the literature, Firthous and Kumar [10] introduced a new search and rescue algorithm called *Artificial Bee Colony with Modified Evolutionary Programming (ABCMEP)*, combining ABC and Modified Evolutionary Programming (MEP). ABC is used for obstacle avoidance, while MEP optimizes the path for efficiency. Simulated in MATLAB, the algorithm was tested in various environments, comparing it with ABC and ABCEP (Artificial Bee Colony with Evolutionary Programming). The ABCMEP algorithm demonstrated superior performance, providing efficient target localization in unknown areas by avoiding obstacles. The study presents the best cost values for each algorithm in different environments, highlighting the effectiveness of ABCMEP.

Garg et al. [7] introduce the Velocity-inspired Robotic Fruit Fly Algorithm (VRFA) as a search strategy for efficient victim search and real-time assessment in search and rescue operations. VRFA combines the Fruit Fly Optimization algorithm (FOA) for target search and tracking and the PSO algorithm for updating positions and velocities. The independent robot in the system performs activities such as local data processing, data sharing, movement plan formulation, and timeline generation. The study compares VRFA with other techniques using centralized and decentralized cooperation strategies for both static and dynamic targets. Results indicate that VRFA outperforms other algorithms, particularly in decentralized cooperation, demonstrating reduced search and rescue time and superior performance in dynamic scenarios.

Huang et al. [9] propose a novel algorithm for task allocation in a multi-robot cooperative rescue system, integrating the Ant Colony Contract Net Protocol (ACCNP). The algorithm uses the ACO algorithm to determine the initial allocation results and the CNP algorithm for dynamic adjustments in changing environments. Notable features include parallel computation, time efficiency, and adaptability to environmental changes. Simulated experiments in a fire rescue scenario reveal the CNP algorithm's superiority over ACO in terms of computation time, average task completion cost, and average task completion time. The results emphasize the effectiveness of CNP in solving multi-robot task assignment challenges within dynamic environments.

In their paper [12], the authors introduce a novel strategy called Distributed Particle Swarm Optimization (DPSO) for multi-robot exploration in search and rescue operations. The focus is on guiding a robot swarm to navigate the search space, avoid obstacles, and locate victims. Key concepts include robots avoiding static and dynamic obstacles, victims scattered randomly, robots sensing local environments, and sharing positions. DPSO addresses the drawbacks of classical PSO by incorporating an artificial potential function to attract forces toward unknown areas and victims, along with a repulsion forces function for collision avoidance, divided into intra and inter-repulsion forces. Experiments were conducted using Python and VRep for multi-agent model implementation and environmental simulation. Four experiments demonstrated that the DPSO algorithm

enables robots to escape local minima, find alternative paths, and navigate through disaster scenarios effectively, leading to optimal solutions.

Dah-Achinanon et al. [5] present a search and rescue algorithm utilizing ad-hoc networks with sporadic connectivity. The algorithm aims to bridge the gap between theoretical concepts and practical applications, emphasizing autonomy, decentralization, and effective research strategy. It facilitates communication among swarm members to share information about target findings and locations, enabling a base station to coordinate rescue efforts. The search method employs belief space exploration, incorporating key information from authorities, such as the last known locations of targets. The algorithm's principles include individual drones conducting searches based on available belief information, updating and distributing belief maps to prevent redundant searches, and using virtual stigmergy for belief map distribution. Validation of the algorithm involves tests in the ARGOS simulator platform and real-world experiments, assessing the time required for target discovery and relay chain establishment. Results from simulations and real-world tests confirm the feasibility and effectiveness of the proposed approach, demonstrating superiority over a random walk strategy.

In [13], authors describe an adverse search and rescue Multi-Agent Reinforcement Learning (MARL) approach to learning efficient coordination and collaboration strategies to achieve search and rescue mission objectives in the presence of adverse search and rescue communications. A Centralized Training approach with Decentralized Execution is used in this training approach. The aim is to coordinate the search to avoid visiting the same location multiple times and reduce the overall target exploration time by cooperative agents in the presence of adverse search and rescue. To investigate how adverse search and rescue interference can derail the performance of cooperative agents in a search and rescue mission and to what extent the proposed training algorithm can mitigate adverse search and rescue actions, the authors conducted four case studies to evaluate the proposed model. According to each case's results, the agents could locate the targets more successfully in the case with the modified reward structure.

The difficulties of search and rescue operations when the space is difficult to cover by human rescuers and ground robots have led to the emergence of a new technology for use, namely Unmanned Aerial Vehicles (UAVs). Authors in [14] proposed a Self-Organizing Mesh Network that is optimized for area coverage by maximizing the search area and maintaining wireless communication. This new system lays the groundwork for the behavior of more than two unmanned aerial vehicles. Whenever a UAV is connected to more than one other UAV, it will attempt to remain within the range of all of them. Additionally, this system prevents UAVs belonging to the same swarm from colliding with one another. Rather than having a leading coordinator UAV, all of the UAVs adjust based on each other. The authors proposed a mesh reliance architecture, which works by assigning the swarm a connectivity matrix, with each UAV connection being a rep and a swarm controller based on a Genetic Algorithm (GA) and Neural Network (NN). Based on the simulation results, the proposed methods are valid for organizing swarms. However, they are not as effective for swarm travel, and adding each drone did increase computation time. GA runs very slowly, making it a poor choice in emergencies.

In order to solve the problems of full-coverage path planning in search and rescue operations, which strive to completely cover the area of interest in a limited time and avoid obstacles autonomously in unknown areas, the authors in [16] proposed a new Neural Network Algorithm through the ABC algorithm. The Neural Network takes as input information about obstacles and coverage in the five directions and gives as output the speed of the left and right wheels. In the initial situation, the parameters are randomly generated, giving the path the neural network planned a lower score. According to the advantages of the ABC algorithm, such as the increased probability of finding the optimal solution and the robustness of the system, the authors used this method to optimize the parameters of the Neural Network and improve the training efficiency and effects of the entire system. To analyze the algorithm's performance, the authors define an evaluation function, which is divided into three parts: the coverage rate, the path repetition rate, and the failure rate. Based on experimental results, the ABC method, combined with a Neural Network path planning algorithm, can effectively control rescue robots to plan complete coverage paths and can be migrated to various environments with high robustness.

Naval operations such as marine search and rescue operations require a higher performance and efficient control to rescue survivors. The authors [15] presented a new method for visual navigation and Unmanned Surface Vehicle (USV) control named Conventional Convolutional Neural Network Spatial Softmax (CNN-SS). The authors divided their work into two main parts, summarized as follows:

- Deep learning-based visual navigation architecture for USV and floating object positioning in USV-UAV operations. This approach improves visual positioning accuracy and computational efficiency by introducing a soft-max spatial layer and a two-stage structure.
- Reinforcement Learning (RL)based USV control strategy approaches and encircles a floating object. The trained control policy can improve the control system's performance under wave disturbances by adding observable wave features to the state space.

The proposed visual navigation architecture consists of two stages: the first consists of estimating the position of the USV and the floating object, and the second stage consists of estimating the heading angle of the USV. This two-stage architecture is built based on CNN and the network structure. A USV controller based on RL has been developed to avoid collisions with floating objects. The basic principle of RL is to maximize the accumulated reward at every step by iteratively optimizing a policy. The authors conducted several experiments to evaluate the performance of the visual navigation model and the USV controller model. They evaluated four network models (CNN-SS, Conventional Convolutional Neural Network (CNN), Fully Convolutional Network (FCN), YOLOv5) for the first proposed algorithm and designed three tasks to evaluate the second algorithm. Therefore, the proposed visual navigation architecture can provide high-accuracy position, velocity, and heading angle estimations under most weather conditions. However, this latter still has some limitations in heavy foggy weather. Finally, after the simulation, the authors demonstrated the effectiveness and superiority of the proposed algorithms.

Authors in [11] developed a new algorithm called the Ant Search Path with Visibility algorithm (ASPV) for the NP-hard optimal search path problem with visibility. This algorithm draws inspiration from ACO principles, which define 96 variants based on four key components of traditional ACO: pheromone initialization, pheromone update, restart, and boosting. The authors conducted several experiments to identify the best variant of the proposed ACO algorithm variants. In these experiments, three phases were conducted:

- Configuration phase, which determines the optimal parameter pairs for each variant.
- multi-run evaluation phase allows for determining how the performance of an ACO varies between runs on a given instance.
- The across-instance evaluation phase provides a better understanding of an ACO's performance in a variety of instances.

The authors compared the performance of the best ASPV algorithm variants with that obtained through a Mixed-Integer Linear Program (MILP) and with a simple greedy heuristic. Results indicated that the proposed algorithm produced search paths with higher success probabilities in a shorter period.

In the study by AI et al. [3], a novel autonomous coverage planning model for maritime search and rescue operations is introduced, leveraging reinforcement learning. The key contributions include (1) complex environment modeling, and (2) introducing a reinforcement learning algorithm with a multi-objective reward function. This function considers avoiding obstacles, preventing repeated paths, and favoring high-probability areas. The algorithm effectively addresses issues like sparse rewards, sub-goal conflicts, and reduces overlapping paths during learning, (3) developing an action selection policy that balances exploitation and exploration to determine the global-optimal solution. Experiments in a simulation area demonstrate the model's validity. Comparisons with various trajectory planning algorithms, including Boustrophedon Motion (BM), Boustrophedon Cellular Decomposition (BCD), and Boustrophedon Motions with the A* search (BA*), show that the proposed algorithm generates search paths covering the entire search and rescue area safely, with low repetition rates and prioritization of high-probability areas for searching.

Authors in [6] proposed a new extension of the A* algorithm for the 3D search and rescue environment. This algorithm is based on the A* and Task Allocation algorithms to obtain a faster and more efficient path-planning method. The objectives achieved by the author are summarized below:

- General 2D and 3D trajectory planning of UAVs.
- Granting UAVs the ability to avoid obstacles when performing tasks.
- Identifying the shortest path for all UAVs in a minimum of time.

In this paper, the task allocation algorithm provides advantages to the system, such as a parallel search of the environment, allowing the drones to complete the entire task by distributing the assignments to each drone, helping to reduce the total route planning time and memory space of each drone. Moreover, the A* algorithm

is generally used for the path planning optimization problem. To evaluate the performance of the proposed algorithm, the author created 2D and 3D simulation scenarios to test the functionality of the task allocation algorithm and performed experiments in a 3D environment to verify and evaluate the performance of the improved A* algorithm compared to the classical A* algorithm. According to the results obtained from the simulation, it can be observed that the improved algorithm has better running time, speed, and efficiency than the classical algorithm and has higher efficiency in the coverage environment, and reduces the amount of storage required.

Because of the increase in the number of casualties in the maritime sector, maritime authorities and operation centers are trying to develop a quick search for survivors at sea using different technologies such as USV, Unmanned Underwater Vehicle (UUV), and UAV. [4] introduced a new contribution by using a UAV swarm. This latter was divided into a two-phase method to solve the (CPP) problem. The first phase presents a methodology for transforming the search area into a graph consisting of vertices and edges using grid-based area decomposition. Hence, the proposed method takes into account the angle at which the area is decomposed to minimize the size of the coverage area. The second phase focuses on determining the optimal path for multiple UAVs based on the results of the first phase to reduce the completion time. The authors developed a Mixed-Integer Linear Programming (MILP) model that minimizes the time required to cover the search area. As a constraint, the region (position of nodes, the angle between nodes, etc.) and the dynamics of the robot covering the nodes are considered. The researchers in this paper observed that the proposed MILP model was time-consuming for large-scale real-world problems. To solve this problem, a new algorithm called Randomness Search Heuristic (RSH) was developed. This approach consists of three phases in each iteration:

1. Random construction: constructs the coverage path of UAVs by sequentially selecting the adjacent nodes.
2. Repair: repairs the generated roads if all nodes are uncovered to recover the feasibility.
3. Local search: improves the constructed path for each UAV to obtain high-quality solutions that are close to the optimal road.

This paper considered numerical experiments to validate the efficiency and effectiveness of the proposed approach and real-world experiments with two UAVs to verify the validity of the proposed algorithm in the real world. According to the results of the numerical experiments, the RSH algorithm can produce near-optimal solutions in a much shorter computational time than a commercial solver. In contrast to the real-world experiments, the mission execution time was longer due to the influence of wind or network communication uncertainty.

After summarizing the different related works, we conclude some important points:

1. Based on Table 2.1, we can group the research according to the scenarios used in the different search and rescue operations (based-ground search and rescue, maritime search and rescue, and aerial search and rescue).
2. Some works used a single sink with a fixed position, the others did not specify the number of sinks and their positions.
3. Most of the works have used static targets with a random position.
4. The majority of the works used multiple robots with a random position.
5. All research done in the based-ground search and rescue focuses on homogeneous robots and is based on decentralized control.
6. Most research focuses on cooperation between robots using direct communication.
7. The majority of studies take into account the lack of redundancy in space exploration, and all of these studies use different search methods.
8. In the search and rescue based-ground, all research experiments were conducted by simulation using different simulators.
9. As for all the works, the use of swarm intelligence-based algorithms is very weak and needs to be investigated since these algorithms provide scalable, flexible, and robust solutions to systems like search and rescue ones.

3. Proposed Algorithm: Modified Penguin Search Optimization Algorithm (MPeSOA). In this Section, we present the proposed search and rescue algorithm named: The Modified Penguin Search Optimization Algorithm (MPeSOA). During its life cycle, the robot can be in one of the four behaviors: **Global**

Search, Local Search, Migration, and Obstacle Avoidance. The robots start all from the central depot and change their behaviors according to input data gathered by their sensors. The state machine representing the behavior of the robots is given by Figure 3.1.

We also present in this section a pseudo code of the **proposed MPeSOA algorithm** (Algorithm 1), and the pseudo-codes of the four key states: **Global search** (Algorithm 2), **Local search** (Algorithm 3), **Obstacle avoidance** (Algorithm 5), and **Migration** (Algorithm 4).

Below, we explain the different behaviors of the state machine. Throughout the subsequent rules, the oxygen reserve $O(t)$ will be treated as a constant value set to 1.

Global search. During this phase, each group of robots undergoes a relocation process to a new position, guided by the LocalBest solution obtained from the previous dive. This relocation is executed by employing the penguin search position equation as depicted in Equation 3.1. Individual robots may encounter obstacles or victims throughout the search process, prompting distinct decision-making. For instance, when faced with

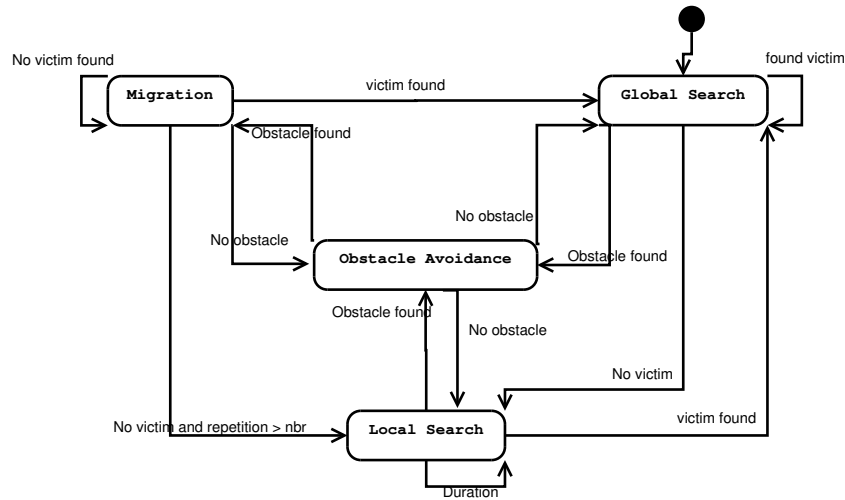

Fig. 3.1: MPeSOA's State Machine.

```

1 Initialize the number of groups;
2 Initialize the total number of robots;
3 Generate a random local best for each group;
4 Distribute randomly the robots in groups;
5 while (stopping criteria is not reached) do
6   for each group i do
7     Goto Global Search (Algorithm 2);
8     Update the food abundance degree for this group using Equation 3.4;
9   Update the total eating food;
10  Update the global best solution;
11  Update membership function values for each group by Equation 3.3;

```

Algorithm 1: Pseudo code of the MPeSOA Algorithm.

obstacles, a robot must avoid them using the *obstacle avoidance state*. Conversely, the robot must prioritize its rescue and subsequent safety upon discovering victims. Once the group reaches a new position, all group members must shift their state to the Local Search state. Algorithm 2 presents the pseudo-code of the Global search state.

$$x_j^i(t+1) = x_j^i(t) + rand() \times |x_{Localbest}^i - x_j^i(t)| \quad (3.1)$$

where: $x_j^i(t)$ is the position of penguin j allocated to the i^{th} group at t^{th} instant. $x_{localbest}^i$ is the best solution found by i^{th} group. $rand(a, b)$ is a random number drawing from $(0, 1)$

Local Search. Before starting the local search, the robots must await the arrival of all group members, ensuring the collective initiation of the search procedure employing the Random Walk Algorithm (RWA) (Equation 3.2). As in the Global search, the robots have to get around obstacles and effectively rescue victims encountered along the way. However, the key distinction lies in the search duration. In this case, the robots apply the RWA for a predefined period and subsequently repeat this process in the absence of victim discoveries, thereby providing additional opportunities to locate victims. In instances where no victims are detected, the robots must undergo migration by reverting to the Migration state. Conversely, upon successful victim detection, the group updates their local best and transitions to the Global search state. The pseudo-code of this state is

```

1 calculate new position using Equation 3.1;
2 while the group does not reach the new position do
3   if  $\exists$  obstacle then
4     Goto Obstacle Avoidance (Algorithm 5);
5   else
6     if  $\exists$  victim then
7       get the victim;
8       update the number of victims rescued;
9       wait a few time before updating localbest for this group;
10      if the time is expired then
11        update localbest for this group;
12        update the quantity of eating fish for this group;
13        Goto Global Search (Algorithm 2);
14 if the group reached the new position then
15   Goto local Search (Algorithm 3);

```

Algorithm 2: Pseudo code of the global search Algorithm.

represented by Algorithm 3.

$$sl_i = rand(a, b) \quad (3.2)$$

where: sl_i is the step length for the i^{th} , and $rand(a, b)$ is a random number drawing from (a, b)

```

1 while repetition process > 0 do
2   while the duration has not expired do
3     while  $\nexists$  obstacle or victim or pheromone do
4       Random walk using Equation 3.2;
5     if ( $\exists$  obstacle) then
6       Goto Obstacle Avoidance (Algorithm 5);
7     else
8       if ( $\exists$  victim) then
9         Get the victim;
10        Update the number of victims rescued;
11        Update the quantity of eaten fish for this group;
12        Update duration for this group;
13    Update LocalBest for this group;
14    if new localbest=the last localbest then
15      decrease repetition process;
16      if repetition process =0 then
17        Goto Migration (Algorithm 4);
18    else
19      Goto Global Search (Algorithm 2);

```

Algorithm 3: Pseudo code of the Local Search Algorithm.

Migration State. If victims remain undetected, the group will initiate migration and merge with another group. Before the migration process, it is necessary to search and rescue to compute the probabilities of the existence of fish for all groups using Equation 3.3. However, if all computed probabilities are found to be less than 0.5, the current group will refrain from migrating and take a random localbest. Conversely, if at least one probability exceeds or equals 0.5, the group will initiate migration based on the aforementioned approach

outlined in the Migration State. The equation governing the update of the Quantity of Eating Fish is equation 3.4:

$$P_j(t+1) = \frac{QEF^i(t)}{\sum_{i=1}^k QEF^j(t)} \quad (3.3)$$

$$QEF^i(t) = \sum_{j=1}^{di} E_j^i(t) \quad (3.4)$$

where: $E_j^i(t)$ represents the quantity of eaten fish of the j^{th} robot of i^{th} group at t^{th} instance.

```

1 Return to the best position;
2 calculate Pi using Equation 3.3;
3 if all probabilities < 0.5 then
4   set a random localbest;
5   Goto Global Search (Algorithm 2);
6 else
7   divide the group into two subgroups;
8   give the subgroups opposite directions;
9   while  $\nexists$  obstacle or victim or pheromone do
10    use the same random step for all members within the same group until they reach the hunting group;
11   if  $\exists$  obstacle then
12    Goto Obstacle Avoidance (Algorithm 5);
13   else
14     if  $\exists$  victim then
15       get the victim;
16       update the number of victims rescued;
17       update localbest for this group;
18       update the quantity of eating fish for this group;
19       Goto Global Search (Algorithm 2);

```

Algorithm 4: Pseudo code of the Migration Algorithm.

Obstacle avoidance. Our explorer robot is equipped with 24 IR proximity sensors positioned strategically around its structure. These sensors possess detect obstacles within a proximity range of 30 cm. In accordance with the readings obtained from these sensors, if the robot identifies the presence of an obstacle, it retrieves the angle information and adjusts its movement accordingly. When encountering a negative angle, the robot executes a right turn, whereas a positive angle prompts a left turn.

```

1 Get readings from all proximity sensors;
2 Accumulate all readings and get the accumulated value and the angle;
3 if accumulated value > 0 then
4   if accumulated angle > 0 then
5     Turn left;
6   else
7     Turn right;

```

Algorithm 5: Pseudo code of the obstacle avoidance Algorithm.

Table 4.1: The proposed simulation scenarios

Scenario 1: the influence of robot's number	Scenario 2: the influence of group's number
number of robots = 30, 40, 50, 60 victim distribution: clusters number of groups: 6 number of clusters: 12 number of victims: 910 obstacle density: 10% environment size: 120m X 120m	number of robots = 50 victim distribution: clusters number of groups: 3, 5, 6, 8 number of clusters: 12 number of victims: 910 obstacle density: 10% environment size: 120m X 120m
Scenario 3: the influence of cluster's number	Scenario 4: the influence of environment size
number of robots = 50 victim distribution: clusters number of groups: 6 number of clusters: 2, 4, 8, 16 number of victims: 1000 obstacle density: 10% environment size: 120m X 120m	number of robots = 50 victim distribution: clusters number of groups: 6 number of clusters: 12 number of victims: 910 obstacle density: 10% environment size: 80m X 80m, 100m X 100m, 150m X 150m, 190m X 190m

4. Results and Discussions. In order to validate the proposed algorithm (PeSOA), we implemented it by using the ARGoS mobile robotics simulator. Finding the right parameters for the algorithm will certainly increase its efficiency. We conducted various simulations to test the influence of the different parameters on the performance of the proposed algorithm. The considered parameters comprehend (i) the number of robots, (ii) the number of groups, (iii) the number of clusters, and (iv) the environment size. Moreover, we used as a performance criterion the number of collected victims in a fixed time (20 minutes).

4.1. Simulation scenarios. We provide in this section an overview of four simulation scenarios. We test the influence of robot numbers, group numbers, cluster numbers, and environment sizes on the performance of the proposed strategy by using these scenarios. Table 4.1 shows the different proposed scenarios:

4.2. Results and discussions. We introduce and analyze in this section the results obtained by applying this algorithm using scenarios presented in Table 4.1. It is important to note that the reported results represent the average outcome from five simulations.

Results of scenario 1. As the number of robots increases, the total number of found victims also increases. Increasing the number of robots positively impacts search and rescue operations. However, the rate of increase in the number of found victims is non-linear with the increase in the number of robots. The rate of increase diminishes as the number of robots increases. When the number of robots increases from 30 to 40 robots, the number of found victims is increased by 27, while going from 50 to 60 robots, it is increased by 156. After 60 robots, the performances did not significantly improve. Table 4.2 and Figure 4.1.a show the results obtained in this scenario.

Table 4.2: Results of scenario 1

Number of robots	30	40	50	60
MPeSOA	40%	43%	48%	65%

Results of scenario 2. With a smaller number of groups, there might be fewer opportunities for efficient coverage of the search area. Increasing the number of groups leads to a notable improvement in the number of found victims. This indicates that the algorithm benefits from finer granularity in dividing the search area into smaller sections, enabling more thorough exploration and detection of victims. However, the rate of improvement starts to diminish compared to the previous increase from 3 to 5 groups. The results indicate that

there's an optimal number of groups for maximizing the effectiveness of the search and rescue operation. Also, increasing the number of groups allows for better coverage of the search area but also introduces challenges in coordination among the groups. Table 4.3 and Figure 4.1.b show the results obtained in this scenario.

Table 4.3: Results of scenario 2

Number of groups	3	5	6	8
MPeSOA	38%	48%	64%	72%

Results of scenario 3. The algorithm achieves the maximum possible number of found victims when all clusters are thoroughly searched. This suggests that having a smaller number of clusters simplifies the search process and maximizes coverage within each cluster. Further increasing the number of clusters leads to a significant decrease in the total number of found victims. With eight clusters, the search area becomes more fragmented, making it challenging for the robots to cover each cluster thoroughly. Additionally, coordinating movements and managing resources across more clusters might introduce inefficiencies or delays in the search and rescue process. Table 4.4 and Figure 4.1.c show the results obtained in this scenario.

Table 4.4: Results of scenario 3

Number of clusters	2	4	8	16
MPeSOA	100%	75%	60%	57%

Results of scenario 4. The results indicate that the environment size has a significant impact on the algorithm's performance in terms of finding victims. As the environment size increases, the total number of found victims decreases consistently. When the environment size increases from 80x80 to 100x100, there's a noticeable decrease in the number of found victims. This reduction suggests that expanding the search space slightly beyond a certain threshold can lead to decreased search efficiency. The trend continues as the environment size increases to 150x150 and 190x190, with a corresponding decrease in the number of found victims. The rate of decrease appears to accelerate as the environment size grows larger. This indicates diminishing returns in search efficiency with further expansion of the search area. Table 4.4 and Figure 4.1.d show the results obtained in this scenario.

Table 4.5: Results of scenario 4

Environment size	80X80	100X100	150X150	190X190
MPeSOA	84%	81%	70%	39%

4.3. Recommendations for parameters settings. Based on the analysis of the results from the experiments detailed in the document, here are some extended recommendations on how to set the studied parameters to enhance the effectiveness of the search and rescue strategy using the Penguin Optimization Algorithm (PeSOA):

1. *Number of Robots:* Deploy a fleet of around 50-60 robots for optimal performance without unnecessary redundancy. This range maximizes the number of found victims while maintaining efficiency.
2. *Number of Groups:* Use 6-8 groups to balance the coverage area and coordination complexity. This setting ensures thorough exploration and effective victim detection while managing inter-group communication efficiently.
3. *Number of Clusters:* Keep the number of clusters low (2-4 clusters). This approach simplifies the search process, allows more thorough coverage of each cluster, and enhances the efficiency of the overall search and rescue operation.

(a) Results of scenario 1

(b) Results of scenario 2

(c) Results of scenario 3

(d) Results of scenario 4

Fig. 4.1: Simulation results

4. *Environment Size*: For environments larger than 100x100 meters, consider deploying additional robots or segmenting the environment into smaller manageable areas. For optimal performance, environments around 100x100 meters provide a good balance between search efficiency and area coverage.
5. *Enhanced Local Search*: Develop a more efficient local search strategy beyond the Random Walk Algorithm (RWA) to improve detection rates within local clusters. This can involve using heuristic or machine learning-based approaches to optimize the search paths dynamically.
6. *Redundancy Reduction*: Implement mechanisms to prevent redundant exploration of already searched areas. Techniques such as virtual stigmergy or communication protocols that share explored regions among robots can significantly reduce overall search time and increase efficiency.
7. *Obstacle Avoidance*: Ensure robust obstacle avoidance mechanisms are in place. The use of multiple proximity sensors and adaptive movement strategies based on sensor input can enhance the robots' ability to navigate complex environments effectively.

5. Conclusion and future work. Our focus in this study lies in the dispersion of robot groups achieved through an implicit division of the environment based on the positions of each group. To address this, we proposed a multi-robot search and rescue algorithm, PeSOA (Penguin-inspired Search Optimization Algorithm). The algorithm has been successfully implemented within the ARGoS simulation platform, and the obtained results are promising.

Future perspectives may include: (1) Further analysis is needed to evaluate the robustness of the proposed algorithm under different scenarios, such as varying cluster densities, uneven distribution of victims, or obstacles in the search area, (2) developing a more efficient local search strategy that surpasses the randomness of the current approach, (3) preventing redundant exploration of previously explored areas and consequently reducing the overall search time.

FEDERATED LEARNING FOR INTERNET OF MEDICAL HEALTHCARE: ISSUES AND CHALLENGES

NIKITA CHELANI*, SHIVAM TRIPATHY†, MALARAM KUMHAR‡, JITENDRA BHATIA§, VARUN SAXENA¶, SUDEEP TANWAR|| AND ANAND NAYYAR**

Abstract. Federated Learning is a decentralized machine learning method that allows collaborative model training across several devices or institutions while maintaining the privacy and localization of data. Since the raw data is used locally, this collaborative method enables the development of a strong and precise global model without jeopardizing the privacy and security of sensitive data. The healthcare sector is an important one that focuses on preserving and enhancing people's health through medical services, diagnoses, treatments, and preventative measures. Efficient evaluation of Federated Learning in the Internet of Medical Things (IoMT) enables breakthroughs in medical image analysis, electronic health record analysis, personalized treatment planning, and drug development by enabling institutions to train models locally on sensitive patient information without sharing raw data. This paper presents the role of Federated Learning in healthcare and current trends in Federated Learning-based healthcare. A case study is presented on deep Federated Learning for privacy-preserving in healthcare. Finally, challenges and future research directions are discussed in the paper.

Key words: Federated Learning, Healthcare, Data Privacy, Machine Learning, Medical Image Analysis, Electronic Health Records, Data Security.

1. Introduction. A powerful machine learning-based health protection system utilizes the doctor's clinical judgment and the computer's massive processing power. Machine learning is crucial in healthcare, especially in areas such as computer-aided diagnosis, image annotation, image-guided medical help, image database retrieval, multimodal image fusion, and medical image segmentation, where inadequacies may be fatal. There are more options to create a system for patient recovery thanks to the improvement of health-related information. In the healthcare sector, machine learning has had limited social impact. Machine learning is the key to decreasing healthcare costs and encouraging improved patient-clinician communication. Multiple health-related uses of ML solutions include assisting physicians in locating multiple patient-specific drugs and therapies and assisting patients in deciding when and if to arrange follow-up visits [2]. Various ML algorithms have been used in healthcare environment. It vary in their implementation in terms of their methodology, the nature of input and output data [37]. The authors in [38] reviewed IoT frameworks and ML algorithms in healthcare sector, specifically on voice pathology. It also covers the impact of ML in various healthcare applications such as blood pressure and oxygen saturation monitoring using smartphones. ML technologies continue to go deeper into the healthcare environment, which also places higher demands on intelligent healthcare [36]. Figure 1.1 shows the various applications of ML in healthcare.

Federated Learning is an innovative approach for training a global machine learning model using data scattered across many data groups, removing the necessity for raw data exchange. Once a global model is shared

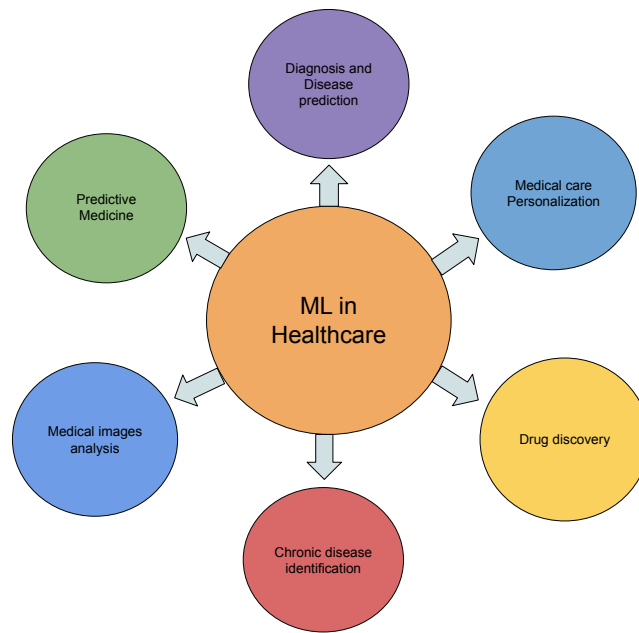

Fig. 1.1: Machine Learning applications in Healthcare

between different locations, the model is trained at each site using local data. The local models' parameter changes are then transmitted to an aggregation server and integrated into the final model. This is repeated until the global model's convergence requirement is met. Figure 1.2 presents the basic federated learning architecture. The benefits of Federated Learning have lately been proven in many practical applications, such as language modeling and picture classification. It is particularly pertinent in healthcare applications where data is replete with sensitive, personally identifiable information, and data analysis techniques must adhere to legal and regulatory standards [1].

1.1. Motivation. The potential for the Federated Learning technique to change the area of healthcare is what led to choosing it for research. The study aims to explore the intersection between cutting-edge machine learning methods and the complexity of healthcare data administration. The primary problem of protecting patient privacy and data security in healthcare research is addressed by Federated Learning's capability to support collaborative model training across diverse data sources. This compatibility between decentralized data analysis and the need for data secrecy provides a strong justification for this research work. The anticipated results, like improved diagnosis accuracy, customized treatment plans, and expedited medical research, highlight the profound change that Federated Learning might bring to the healthcare industry. Through the examination of Federated Learning applications, the research is conducted in hopes of assisting in the development of a healthcare environment that is more secure, effective, and patient-centered. Figure 1.3 shows various key technologies used for implementing Federated Learning in healthcare. Today's biggest difficulty for AI researchers and practitioners is how to legally address the issue of data fragmentation and isolation [3]. By developing a global model without distributing raw data among sites, Federated Learning offers a first degree of privacy protection. Federated Learning, however, may occasionally be exposed to inference attacks.

1.2. Scope of the paper. The importance of data privacy and security has emerged as a major global problem as huge organizations compromise user privacy and data security. Public media and governments are very concerned about reports of data leaks. Federated Learning aims to enable ML from non-located data, hence addressing privacy and data governance issues. Each data controller in an Federated Learning context establishes its governance procedures and privacy guidelines, managing data access and having the authority to withdraw it. It covers both the validation phase and the training phase. Federated Learning might provide new

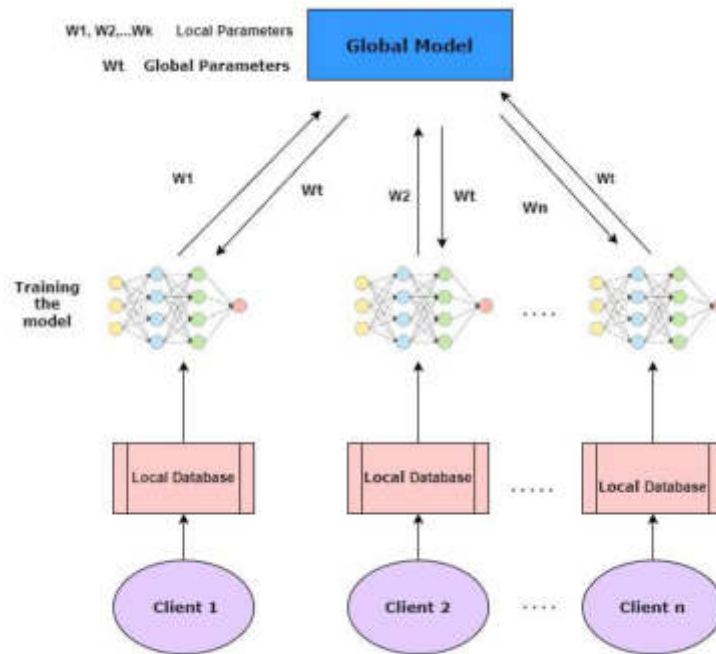

Fig. 1.2: Basic Federated Learning Architecture

opportunities in this way [4]. In this paper, the authors explore the role of Federated Learning in healthcare and review the current trends.

1.3. Organization of the paper. This section discusses the organization of the survey. The rest of the paper is organized as follows: Section 3 examines earlier research on collaborative machine learning that protects privacy with an emphasis on medical applications. Section 2 gives a brief introduction about the topic and its various use cases in medical field. Section 4 discusses the RPDFL method for digital healthcare applications. It deals with problems with conventional Federated Learning, such as gradient leaking and data silos in healthcare companies. Section 5 outlines machine learning’s potential to benefit healthcare and its transformational role in clinical decision-making, healthcare research, and tailored therapy while maintaining data security and privacy.

2. Background. Technological breakthroughs have revolutionised the healthcare business over the last several decades, ushering in a new era of customised, efficient, and data-driven medical services. At the centre of this transformation are several interconnected technologies, including IoT, SDN, Fog Computing, IoMT, and Machine Learning. Each of these technologies is critical to the transformation of healthcare, the improvement of patient outcomes, and the simplification of administrative operations.

2.1. Healthcare. Healthcare is one of the industries that is connected to everyone’s life. It is a necessary part of people’s life, encompassing physical, emotional, and mental aspects. It entails detecting, treating, and dispensing vaccinations. The healthcare business has incorporated technological advancements to make it more efficient and effective. There are various stages in the evolution of healthcare that might be labelled as “Healthcare X.0.” These stages represent significant developments and advancements in healthcare practices, techniques, and delivery systems. Figure 2.1 depicts the evolution of healthcare from 1.0 to 5.0, and the

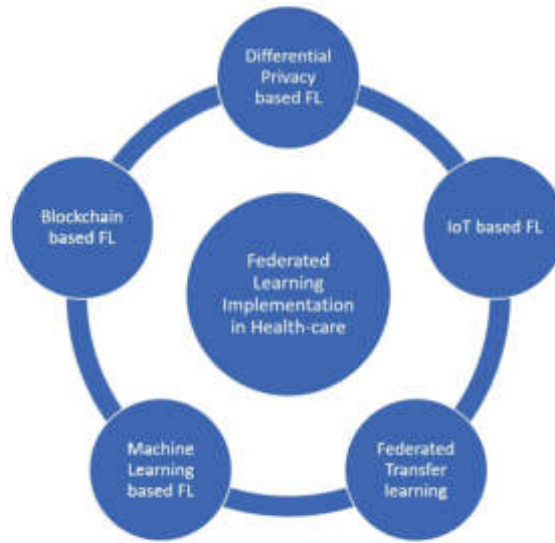

Fig. 1.3: Federated Learning Implementation in Healthcare

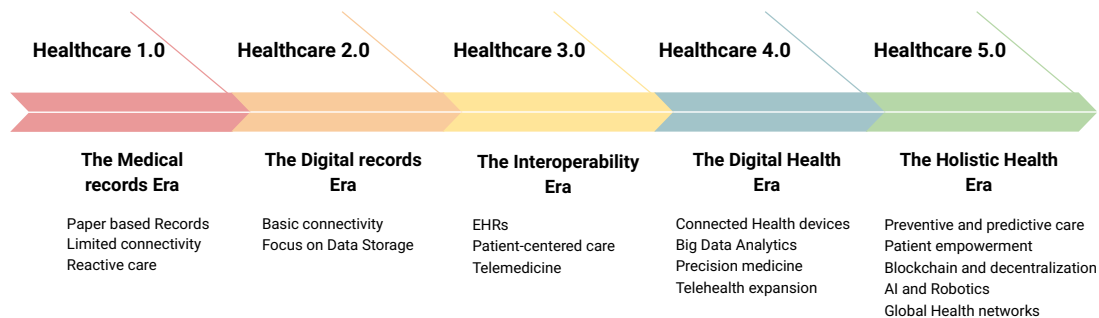

Fig. 2.1: Healthcare Domain Transformation [19]

significant advancements in healthcare are highlighted in this section.

- Healthcare 1.0: Healthcare was first focused on home medicines, traditional healing practices, and a lack of medical expertise. Medical treatments were not standardized, and healthcare was frequently given by local healers and herbal experts.
- Healthcare 2.0: This period saw improvements in medical knowledge, technology, and hospital development. During this time, the standardization of medical education and practices began. The doctor-patient connection was formalized.
- Healthcare 3.0: The digitization of healthcare records and the implementation of electronic health records (EHRs) occurred during this period. The emphasis has shifted to data-driven decision making and evidence-based medicine. Technologies for telemedicine and remote monitoring began to emerge.
- Healthcare 4.0: During this stage, big data, artificial intelligence, and machine learning are being integrated into medical practises. These technologies provide predictive and preventative treatment,

allowing for more personalised and accurate therapy. Because of the growth of wearable technology and sensors, patients may now measure their wellbeing and physical activity.

- **Healthcare 5.0:** Healthcare 5.0 is at the forefront of healthcare change. It focuses on personalized medicine, which involves adapting therapies to individuals' genetic, genomic, and lifestyle characteristics [21]. Advances in genomics, artificial intelligence, and big data analytics are critical in more precisely identifying and treating illnesses. Patient empowerment and active involvement in healthcare decision-making remain critical.

2.2. Federated Learning. Federated Learning, a revolutionary machine learning paradigm, has emerged as a possible answer to these problems in the healthcare industry. In contrast to traditional data aggregation methods, Federated Learning allows for the cooperative training of machine learning models across several institutions or devices while preserving the localization of raw data [24]. Data privacy is met by this dispersed strategy, which also protects patient data and complies with strict legal requirements like HIPAA. Federated Learning offers several benefits, including privacy preservation, reduced communication costs, and improved scalability [25].

- **Privacy preservation:** Since the data remains on the device, it is unnecessary to send it to a central server for processing, ensuring the data's privacy.
- **Reduced communication costs:** Since only model updates are sent to the central server, the communication costs are significantly lower than the traditional machine learning approach.
- **Improved scalability:** Since the computation is distributed among multiple devices, Federated Learning can handle multiple devices without needing extra resources.

The way people control their diabetes has been transformed by Continuous Glucose Monitoring (CGM) technology. For the treatment of diabetes, CGM systems continually assess glucose levels in real time. However, the volume and complexity of CGM data produced by these devices provide major hurdles, particularly in making accurate forecasts and enhancing patient outcomes. An original solution to these problems is the decentralized fusion of CGM data via Federated Learning, which combines the power of CGM data from many sources while maintaining individual privacy and security.

With the help of Federated Learning, CGM data owners may build a global glucose prediction model without disclosing their raw data, protecting their privacy [26]. Local updates from participating CGM devices are combined to train a global model. Diverse data sources are advantageous for this model aggregation. The global model can offer particular people specific insights and suggestions for managing diabetes. The decentralized method improves data security by lowering the possibility of data breaches or illegal access. The use of decentralized CGM data fusion and Federated Learning shows great potential for overcoming the difficulties in adequately maintaining and exploiting CGM data. It makes it possible to create precise, privacy-preserving models that provide people with diabetes the ability to take care of their health while advancing study and treatment in diabetes management. This technology has the potential to fundamentally alter how we perceive and manage diabetes as it develops. Figure 2.2 shows the process of implementing Federated Learning in healthcare.

2.3. Internet of Medical Things (IoMT). The Internet of Medical Things (IoMT) integrates medical devices with the Internet of Things (IoT). IoMT represents the future of modern healthcare systems, where all medical devices will be interconnected and monitored online by healthcare professionals [22]. This development promises to enhance the speed and reduce the costs of healthcare services as it progresses. IoMT enhances the volume of health data accessible to caregivers, diversifies its sources, and accelerates the processes of collection, transmission, and analysis. The increased flow of data aids in improving decision-making for both patients and healthcare providers. This network of interconnected technology allows for the constant collection, analysis, and transmission of health data, enabling real-time monitoring and management of patients' health. IoMT devices encompass wearable fitness trackers, smart implants, remote patient monitoring systems, and connected diagnostic instruments [20]. IoMT streamlines data flow and automates routine tasks, alleviating administrative burdens and enabling medical staff to concentrate more on patient care, thus boosting operational efficiency. It helps lower healthcare costs by decreasing hospital readmissions, reducing the need for in-person visits through remote monitoring, and optimizing resource allocation. IoMT also enhances personalized healthcare through comprehensive data, increases patient engagement with intuitive interfaces, and supports telemedicine, thereby

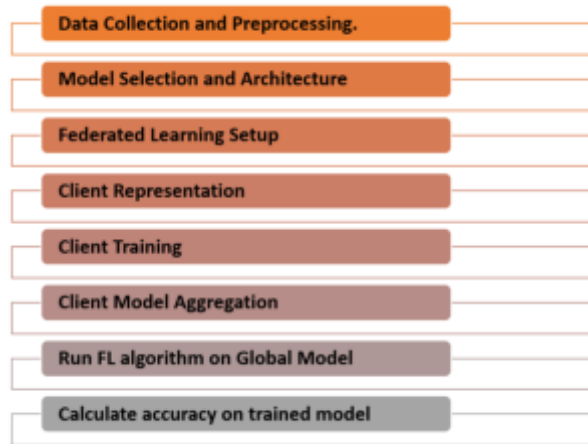

Fig. 2.2: General Implementation Process

improving healthcare accessibility, particularly in underserved regions [23]. Furthermore, IoMT ensures patient safety and adherence to prescribed treatments through reminders and alerts and enhances data analytics, propelling medical research and innovation.

3. Related Work. In the realm of Federated Learning, numerous studies have delved into the healthcare domain. This section reviews prior research on Federated Learning in healthcare, including new frameworks and architectures in this area and existing surveys.

Choudhury et al. [16] applied three classification algorithms—the perceptron, support vector machine (SVM), and logistic regression—that are amenable to distributed solutions using gradient descent for ADR and mortality prediction tasks. The models’ usefulness is assessed using the F1 score before and after applying a privacy-preserving technique. It is demonstrated that FL, even without differential privacy, may deliver model performance near the theoretical scenario of total data centralization. The performance of the developed global FL model for a specific level of privacy is next examined with differential privacy. Contrasting the outcomes with baseline techniques demonstrates how the adaptive contribution weighting strategy enhances learning accuracy and convergence. The tests also validate the privacy-preserving techniques and show the framework’s potential for usage in real-world smart healthcare applications.

Gupta et al. [8] examine using digital twins and hierarchical Federated Learning for anomaly detection in smart healthcare. It emphasizes the value of anomaly detection in healthcare and the difficulties with centralized, conventional methods. To enable data sharing and collaborative model training while preserving privacy, the authors suggest a hierarchical Federated Learning architecture that uses digital twins and virtual representations of actual items. The review gives a general description of the framework, goes through its benefits, and shows experimental findings to show how well it works at spotting abnormalities in healthcare data. The authors also examine possible uses for digital twins and hierarchical Federated Learning and potential future studies in smart healthcare.

Xu et al. [9] thoroughly investigate Federated Learning’s use in healthcare informatics. It discusses Federated Learning’s ideas, architectures, algorithms, and privacy-preserving techniques, among other topics. To illustrate the efficacy and promise of Federated Learning in various fields, the authors look at various healthcare informatics applications, including population health analysis, illness detection, therapy suggestion, and predictive modeling. The paper also emphasizes the significance of model aggregation approaches, data heterogeneity, and data quality in Federated Learning for healthcare. Overall, the literature analysis highlights research gaps, offers insightful information about the current status of Federated Learning in healthcare informatics, and makes recommendations for future developments.

Stripelis et al. [10] emphasize using Federated Learning to scale neuroscience research. Due to privacy issues and restricted access to massive datasets, they discuss the difficulties traditional centralized systems in neuroscience research confront. The paper demonstrates how Federated Learning might facilitate group analysis of dispersed neuroimaging data while protecting individual privacy. The authors also discuss the advantages of Federated Learning, including better data sharing, bigger sample sizes, and greater study reproducibility. Additionally, they give examples of Federated Learning applications in neuroscience, such as cognitive modeling, brain imaging processing, and research into neurodegenerative diseases.

Liu et al. [12] used a traditional method to assess the contributions of members inside a coalition accurately Shapley Value (SV). Furthermore, the coalition's overall utility is to be calculated because FL may use it as a fair contribution evaluation principle. The average of all marginal contributions a participant makes over all coalitional permutations is that individual's SV. To investigate CAREFL's suitability for further intelligent healthcare application situations. Adding contribution-based data pricing mechanisms to the CAREFL framework would help the development of a market for FL-based healthcare data sharing. The ultimate objective is to include these capabilities in the free and open-source FATE framework so that they may be used by more programmers, scholars, and practitioners.

Le Sun and Jin Wu [13] proposed a model that comprises a parameter protection method to prevent catastrophic forgetting, a lightweight 1-D CNN-based feature extractor, and a PCC mechanism to facilitate class scaling. To increase the effectiveness of training models for new tasks, SCALT also implements two significant model transfer methods. The trained SCALT models' mean parameter values from previous tasks are utilized as model initialization for a new task. To eliminate fuzzy boundaries between various classes, a KL-divergence-based sharing knowledge removal technique is used in the transferring process.

Patel et al. [14] suggested FL in healthcare for improved privacy and security of user data. A centralized intelligence system must cope with many constraints, including resource constraints, data update delays, a lack of high precision and accuracy, and privacy and security issues. The suggested FL-EHR case study incorporates differential privacy, which guarantees learning data privacy, which is advantageous in real-world settings. It also eliminates data bias throughout the training phase, increasing the model's accuracy. As a result, the suggested study enhances model validation, the foundation for efficient analytics setups in diverse medical ecosystems compared to present healthcare systems. The FL training scheme calculates the local slopes. Then, using techniques like FedAvg, Fed-Prox, and FedSGD, all local gradients are combined at the aggregation level. Here, a 6G network is being used for communication. Effective optical wireless communication channels in 6G networks can be used to establish direct, close connectivity with healthcare infrastructure. The prediction model is then sent to numerous clients via the aggregation layer using a HE to FL training strategy.

Wu et al. [15] proposed FedHome, a cloud-edge FL system. FedHome employs a novel generative convolutional autoencoder architecture. To compensate for the loss in prediction performance caused by an unbalanced and non-IID distribution of user data, GCAE synthesizes minority class samples and retrains the user's local model using the resultant class-balanced dataset. The Federated Learning framework safeguards data privacy by keeping user data local and learning a common global model in the cloud from several network edge homes. To deal with the unbalanced and non-IID distribution inherent in user monitoring data, a generative convolutional autoencoder (GCAE) is created with the goal of achieving accurate and personalised health monitoring by refining the model with a generated class-balanced dataset from user-specific data.

Lu et al. [16] use a FedAP as a weighted, tailored, batch-normalized federated transfer learning technique for the healthcare industry. FedAP combines data from several companies while maintaining privacy and security, and by taking into account similarities and maintaining local batch normalization, it provides reasonably customized model learning. The statistical mean of the relevant layer's inputs and the running mean of the BN layer are positively correlated. As a result, the researchers may run many rounds of FedBN while maintaining local batch normalization and use the parameters of BN layers to substitute the statistics when a pre-trained model is unavailable. This variety is known as f-FedAP. The authors suggest FedAP, a personalized Federated Learning method for healthcare that uses adaptive batch normalization to collect data from several clients without sacrificing security and privacy and develop customized models for each client.

Islam et al. [17] gave a system for universal data sharing for Federated Learning that uses differentiated privacy to forecast specific heart failure conditions. The system minimizes the total data dimension through

feature selection, lowering the noise addition for differential privacy while keeping effective scores. The authors propose a feature selection strategy based on the correlation value of the data to reduce dimension and boost the utility of the ML models. The authors employ Federated Learning infrastructure to enable private data sharing among collaborating parties in a differentially private manner. The basic structure of this Federated Learning model is comprised of two components. A model manager with whom all data owners communicate and the owner(s) of the raw data used to train the model. Furthermore, the model is protected by a second privacy layer that employs differential privacy, and the authors assume that the aggregator server is truthful yet interested in recovering the raw data of a data owner from it. The same training data was utilized in both Naive Bayes and Random Forest in a two-party configuration where the data is divided into two groups. The data's correlation value serves as the foundation for feature selection. The authors then added noise using Laplace transformation to the statistics they had generated using Differential Privacy (DP) techniques. The generated noisy data are finally sent to the aggregator server in place of the raw data. The central aggregator server feeds the machine learning framework to create a global model that is used to forecast the likelihood of cardiac failure.

Li et al. [5] focus on developing a smart healthcare system that preserves privacy using Federated Learning techniques. The proposed approach aims to solve concerns about the privacy and security of sensitive patient data while utilizing the benefits of machine learning in healthcare. Patient data must frequently be centralized in traditional healthcare systems, raising privacy concerns and the possibility of data breaches. However, Federated Learning allows training models collaboratively without transferring raw data. Multiple edge devices, including wearables and smartphones, are included in the system to gather patient data.

Yang et al. [3] introduced the concept of federated machine learning (FML), and its different applications are explored. A distributed approach to machine learning called FML enables numerous parties to jointly train a single model without disclosing their personal information. The authors outline the FML systems' structure, consisting of a dispersed client base and a central coordination server. The study discusses methods and strategies to handle technological difficulties such as communication effectiveness, privacy protection, and system robustness. In addition, practical uses in healthcare, finance, and smart cities are investigated, demonstrating how FML promotes collaborative learning while protecting data privacy. Overall, the paper illustrates the importance of FML in dealing with privacy issues and thoroughly discusses its idea, design, difficulties, and practical applications.

Abdulrahman et al. [6] provides an in-depth overview of Federated Learning, tracing its development from centralized to distributed on-site learning and exploring its advancements. It covers various aspects of Federated Learning, including architectures, communication protocols, optimization algorithms, privacy-preserving mechanisms, and model aggregation methods. The survey discusses applications in healthcare, IoT, edge computing, and autonomous vehicles, highlighting challenges and open research areas. Additionally, it explores recent advancements such as federated transfer learning and reinforcement learning and emerging trends like edge intelligence and blockchain-based Federated Learning. The paper serves as a comprehensive resource for researchers and practitioners interested in understanding the current state and future directions of Federated Learning.

Prayitno and Shyu [7] thoroughly assess the literature on Federated Learning in the healthcare industry, emphasizing data characteristics and applications. To illustrate the usefulness and promise of Federated Learning in tackling healthcare issues, the authors look at various healthcare applications, including illness prediction, medical picture analysis, electronic health record analysis, and wearable device data analysis. The study intends to present insightful analyses of current research, identify knowledge gaps, and suggest future research avenues in Federated Learning in healthcare.

Table 3.1 summarizes the existing research work on Federated Learning in healthcare. This literature review on Federated Learning in healthcare finds an emerging area with a strong emphasis on protecting patient privacy and exploiting decentralized data for model training. To handle the variety of healthcare data, researchers are building specialized Federated Learning strategies focusing on multiple data types and matching machine learning models. Key use cases like illness prediction, medical picture analysis, and personalized therapy recommendations highlight the potential to improve patient outcomes and healthcare efficiency. However, issues such as communication overhead, model convergence, data quality, scalability, and regulation compliance

Table 3.1: Survey of Existing Research Works

Author	Year	Key Contributions	Evaluation Parameters	Limitations and Future Scope
Dai <i>et al.</i> [31]	2020	Presented a blockchain-enabled framework to address the security and privacy issues with IoMT systems	Security and Privacy	Improving the performance by implementing more scalable consensus algorithms is not easy. Deep learning can be used to enhance the performance
Choudhury <i>et al.</i> [11]	2020	Federated Learning framework with two levels of privacy protection that can learn a global model from dispersed health data.	The global Federated Learning model's performance is then evaluated with respect to differential privacy at a specific privacy level.	Differential privacy hampers Federated Learning's prediction capacity due to excessive noise.
Gupta <i>et al.</i> [8]	2021	A threat model for centralized anomaly detection with particular threat scenarios and suggested a privacy-preserving model.	Accuracy, sensitivity, and efficiency of the anomaly detection system.	Scalability, Data Quality and Algorithmic Challenges.
Xu <i>et al.</i> [9]	2021	Privacy-Preserving Techniques in Healthcare Informatics and Model Aggregation Approaches	Accuracy, privacy preservation, model performance, scalability, and Computational efficiency.	Real-world Deployments and Interoperability
Stripelis <i>et al.</i> [10]	2021	A brain age prediction model based on structural MRI scans from several locations with varying quantities of data and subject (age) distributions.	Elapsed time and a Mean Absolute Error (MAE)	The proposed technique demonstrates distinct relative performance of the multiple training approaches and, in the future, federated transfer learning in neuroimaging might be investigated.
Ali <i>et al.</i> [34]	2022	Presented the role of FL in IoMT for detecting privacy threats	Privacy and Accuracy	Need robust and universal FL architecture from privacy perspective.
Arya <i>et al.</i> [35]	2022	Proposed an ensemble FL approach for training a DL model to classify decentralized data streams in IoMT	Accuracy, Precision, Recall and F1-score	Since ensemble learning is carried out on a server, so there can be a threat for data privacy.
Liu <i>et al.</i> [12]	2022	Adaptive contribution weighting mechanism, privacy-preserving methods, contribution-aware Federated Learning framework.	Accuracy and balance between performance and privacy.	CAREFL's potential for other healthcare applications
Le Sun and Jin Wu [13]	2022	A scalable and transferable classification framework, SCALT to protect privacy of patients data	Measured accuracy of ECG, EEG, and PPG data	SCALT's space complexity can be reduced by minimizing the feature extractor's volume. Sophisticated model transfer methods will enhance new model training.
Patel <i>et al.</i> [14]	2022	FL in HI for enhanced privacy and security and a centralized intelligence systems to overcome resource constraints, data delays, and privacy issues.	The FL-EHR case study incorporates differential privacy for data privacy and reduces bias during training, enhancing model accuracy and validation.	The framework examines FL performance on healthcare datasets with different sensitivity levels. It introduces a DP model for FL-HI, ensuring high secrecy and accurate diagnosis.
Wu <i>et al.</i> [15]	2022	Developed a Generative Convolutional Autoencoder (GCAE) to provide accurate and personalized health monitoring by improving the model using a newly constructed class-balanced dataset.	Local minibatch size, training passes on each client's data; and number of participating clients per communication round.	GCAE's few parameters reduce communication overhead during model transfer.
Lu <i>et al.</i> [16]	2022	FedAP is a weighted, batch-normalized federated transfer learning for healthcare.	BN layer parameters to replace statistics, enabling multiple rounds of FedBN with local batch normalization when a pre-trained model is not available.	Consider implementing more accurate methods for calculating and updating client similarity.
Islam <i>et al.</i> [17]	2022	Feature selection based on correlation values minimizes data dimension, preserving model effectiveness.	Model manager and data owner(s), with no direct message exchange between providers. Naive Bayes and Random Forest were trained.	Data anonymization and differential privacy should be included, and the score should be further enhanced using a better feature selection technique.
Li <i>et al.</i> [5]	2022	A convenient and privacy-preserving system named ADDETECTOR to detect Alzheimer's disease (AD)	Accuracy, Time overhead, F-score	Find additional useful features to reflect the characteristics of Alzheimer's disease and test the viability of ADDETECTOR on a bigger dataset.
Tian <i>et al.</i> [18]	2023	Ring Structure for Federated Learning, Threshold Secret Sharing Mechanism and edge-dropout handling	Accuracy and convergence pace	To boost parallelism to lower the computational cost and communication overhead of the RPDFL training scheme.
Rani <i>et al.</i> [32]	2023	An exhaustive survey on the security of FL-based IoMT applications	Data Security and Privacy	Real world health data analytics with integrity of the data.
Alamleh <i>et al.</i> [33]	2023	Developed an multicriteria decision-making (MCDM) framework for standardising and benchmarking the ML-based IDSs for FL architecture of IoMT applications	Systematic ranking and Computational cost	More investigation on MCDM methods that consider the experts' importance is needed.

Fig. 4.1: Data sharing procedure of Ring AllReduce

prompt continuous research. Interdisciplinary research, the creation of Federated Learning frameworks, and an increasing interest in scalable and efficient methodologies are all exciting futures for Federated Learning's revolutionary role in healthcare.

4. Case Study. The potential to improve patient care and medical research has been demonstrated by using deep neural networks in digital healthcare applications. Deep learning in healthcare, however, has a set of issues, the main among them is patient data protection. Because healthcare companies are spread, and patient information is sensitive, traditional machine learning algorithms sometimes ask for the centralization of data, which poses challenges. Federated Learning has become recognized as a viable response to these issues. Federated Learning allows training machine learning models without exchanging and centralizing raw data.

In this case study, we have examined a unique strategy called Robust Privacy-Preserving Decentralized Federated Learning (RPDFL) proposed by Tian et al. [18] in the context of digital healthcare. "Data silos," where healthcare institutions keep patient data in separate databases, frequently plague digital healthcare systems. Given that the data is scattered around several institutions, developing comprehensive and efficient machine-learning models is difficult due to these data silos. Data interoperability and cooperation are hampered by this fragmentation, making it challenging to fully utilize deep learning, which benefits from extensive and varied training datasets. Traditional centralized Federated Learning approaches also have their problems. These include communication bottlenecks between clients, the possibility of malicious servers attempting to deduce gradients, and single points of failure in the central server.

By grouping Federated Learning clients into a logical ring structure, RPDFL presents a novel strategy motivated by the widely utilized distributed computing Ring-AllReduce technique. This structure gives Each client a left and a right neighbor node. The fundamental idea is that each client should only communicate information with the proper neighbors to ensure synchronized global model updates and reduce vulnerability to malicious servers.

The strong privacy protection system of RPDFL is one of its key characteristics. It uses a threshold secret sharing mechanism, a cryptographic method to protect gradient privacy. This method maintains data security even if healthcare edge nodes gracefully leave during Federated Learning training. Clients exchange gradients from their local models. This sharing mechanism must preserve the privacy of each client's gradients. The remaining clients can complete the program uninterrupted if a client withdraws or disconnects, providing continual instruction. This privacy protection measure is essential to guarantee that sensitive patient data is kept private throughout the Federated Learning procedure.

Using their local datasets, RPDFL edge nodes in the healthcare industry produce local models across a number of training rounds. Stochastic Gradient Descent (SGD) is used to update these local models under the direction of the acquired global model. The Ring-Allreduce technique is used to broadcast gradients, which

stand in for the updates needed to the model parameters. Because of the threshold secret sharing technique, privacy is maintained during the whole procedure. Gradient averaging is used to produce new global models once gradients have been compiled and global model modifications have been made. For the upcoming training cycle, these upgraded global models will take the place of the local models. Up till the target level of model performance is attained, this iterative procedure is continued. Gradient averaging is used to generate new global models once gradients have been accumulated and global models have been modified. These improved global models will replace the local models in the future training cycle. This iterative method is repeated until the desired level of model performance is achieved.

For the performance evaluation of RPDFL on healthcare data, the UCI-HAR dataset from UCI was used, which captures daily human activities via smartphones and was evaluated using a fully connected network architecture. This capability enables RPDFL to effectively overcome information barriers between healthcare organizations, facilitating highly efficient decision-making in complex scenarios.

Thus, a new data-sharing scheme was implemented by updating the execution processes of the CRT in the threshold secret sharing scheme, allowing healthcare edges to drop out during training without causing data leakage and ensuring the robustness of the RPDFL training. The RPDFL scheme also supports edge dropout during the training process while preserving local gradient privacy. Security analysis demonstrates that RPDFL is highly secure under the HbC security model.

RPDFL exhibits promising performance in terms of privacy protection and accuracy. RPDFL obtains an accuracy level of around 98% by the fifth training round, which is an impressive accomplishment given its emphasis on privacy protection. Despite slower convergence after this first phase, RPDFL's accuracy is nevertheless on par with the conventional federated averaging (FedAvg) method. It demonstrates how RPDFL can maintain good performance while guarding against gradient privacy leaks. RPDFL has had a thorough security evaluation and has been shown to be extremely secure. According to security studies, RPDFL is resilient against harmful attacks and data breaches, protecting patient information's privacy and confidentiality.

RPDFL is a revolutionary technique for addressing the critical concerns of privacy and scalability in digital healthcare systems. RPDFL integrates a novel ring Federated Learning structure, a Ring-AllReduce-based data sharing mechanism, and a robust threshold secret sharing mechanism to provide a secure and effective solution for Federated Learning in the healthcare business. Figure 4.1 shows the data sharing process of Ring-AllReduce. Because of its extensive security features and promising performance, it is an excellent choice for healthcare organizations wishing to utilize the potential of deep learning while preserving patient privacy. As digital healthcare evolves, RPDFL is a valuable tool for harnessing the potential of machine learning in improving patient care and promoting medical research.

Then the performance of RPDFL in comparison to FedAvg and Gossip Learning is evaluated. Based on available information, Gossip Learning is the first implementation of decentralized learning. However, it is important to note that neither FedAvg nor Gossip Learning consider the privacy of gradients.

The training loss and testing accuracy for RPDFL, FedAvg, and Gossip Learning were recorded. Since FedAvg and Gossip Learning do not support edge dropout during the training process, RPDFL was also evaluated without edge dropout for comparison. It was observed that the accuracy of the RPDFL training model significantly surpasses that of Gossip Learning and is comparable to that of FedAvg. Additionally, RPDFL utilizes an enhanced CRT-based threshold secret sharing protocol to ensure gradient privacy. This protocol involves a truncation process, which results in some accuracy loss and a slower convergence speed. For instance, RPDFL converges slightly slower than FedAvg, but achieves an accuracy of 98% by the fifth round and maintains similar accuracy levels thereafter. Consequently, RPDFL offers excellent efficiency while safeguarding gradient privacy. This ensures that RPDFL can prevent malicious users from inferring the privacy of others in practical applications.

5. Open Research Challenges and Future Research Directions. In the rapidly evolving world of healthcare technology, data holds the key to ground-breaking advancements. This paper explores the dynamic world of Federated Learning in the healthcare domain, revealing the unique challenges posed by the distributed nature of medical data.

5.1. Non-IID Data Management. Data's inherent non-IID (Non-Independent and Identically Distributed) nature across various healthcare organizations presents substantial hurdles for Federated Learning in

the healthcare industry. Healthcare data is frequently gathered from several sources with variances in patient demographics, illness incidence, and treatment procedures, unlike typical centralized machine learning, where data is homogeneous and evenly disseminated. Using common Federated Learning techniques is challenging due to this heterogeneity directly. Innovative approaches like federated transfer learning and domain adaptation are being explored to tackle this issue [27]. These methods seek to account for the differences in data distributions while adapting and transferring information gained from one institution's data to another. Federated transfer learning makes it possible to share knowledge effectively by utilizing pre-trained models and fine-tuning them using data relevant to the institution.

5.2. Privacy-Preservation. The delicate nature of patient data needs sophisticated privacy-preserving strategies in Federated Learning since privacy is of the utmost significance in the healthcare industry. Traditional Federated Learning guarantees that data stays local to the institutions and is decentralized, but more developments are needed to improve privacy [28]. Differential privacy, a potential method, adds controlled noise to the model updates to secure patient information while allowing for useful learning. Homomorphic encryption is one of the most sophisticated encryption methods that can contribute to the protection of data throughout transmission and aggregation procedures. By implementing these privacy-enhancing strategies, Federated Learning may preserve patient confidentiality and adhere to stringent data protection laws.

5.3. Cross-Modal Data Fusion. The integration of multi-modal data develops as a crucial endeavor in the scene of healthcare improvement. It requires integrating many data types, from electronic health records to complex medical images, while respecting the fundamental principles of privacy protection. Modern approaches like federated transfer learning and meta-learning are simultaneously integrated, taking center stage [29]. By utilizing these methods to their full potential, the healthcare industry benefits from quick and seamless knowledge transfer, effective information translation and application across various contexts and activities, and strategic sharing of insights and expertise across institutions.

5.4. Interoperability and Data Harmonization. Integrating interoperability and data harmonization techniques is a crucial requirement in the healthcare field. These methods are essential for reducing inequities from disparate data formats and semantic details used by various healthcare facilities. Addressing the requirements for explainability and interpretability in the context of Federated Learning simultaneously becomes crucial. It requires developing models that produce reliable outcomes and foster mutual understanding and trust between patients and medical professionals. Model interpretability is a goal that has increased importance since it facilitates a broader understanding and acceptance of the results of Federated Learning projects.

5.5. Resource Management and Communication Efficiency. The successful deployment of Federated Learning in the healthcare sector depends on the effective allocation and use of resources. Notably, the need for effective communication is emphasized. It calls for developing novel strategies like decentralized aggregation and compressed model updates, which are key to reducing bandwidth requirements and boosting communication effectiveness. Healthcare systems can balance resource conservation and the seamless flow of vital information by carefully improving these strategies, eventually paving the way for a strong and effective Federated Learning framework.

The advancement of Federated Learning in healthcare, overcoming difficulties and supporting its effective application for improved patient care and medical insights [30]. By focusing on these future research routes, Federated Learning in healthcare may evolve further and contribute to better patient outcomes, customized treatment, and collaborative medical research as long as privacy, security, and ethical considerations are addressed.

6. Conclusion. Federated Learning in the healthcare industry has enormous potential to improve clinical decision-making, medical research, and customized treatment. Federated Learning makes it possible to use machine learning on decentralized healthcare data while protecting patient privacy by utilizing the strength of distributed computing and safe data sharing. This article has offered a comprehensive review of the current trends and issues facing the field of Federated Learning in healthcare. We explored how Federated Learning has emerged as a potential method for leveraging decentralized healthcare data while maintaining privacy and security. A case study on privacy preservation is presented in the context of digital healthcare. We have

also covered the key challenges that must be overcome, such as non-IID data management, interoperability, communication efficiency, and multi-model data integration. Federated Learning has a promising future in the medical field. Medical professionals and researchers should keep working collectively to create novel approaches, improve current techniques, and solve the legal and ethical challenges involving the sharing of medical data. To guarantee that Federated Learning helps the healthcare business and the persons it serves, it is critical to prioritize its appropriate and ethical deployment.

AIMS AND SCOPE

The area of scalable computing has matured and reached a point where new issues and trends require a professional forum. SCPE will provide this avenue by publishing original refereed papers that address the present as well as the future of parallel and distributed computing. The journal will focus on algorithm development, implementation and execution on real-world parallel architectures, and application of parallel and distributed computing to the solution of real-life problems. Of particular interest are:

Expressiveness:

- high level languages,
- object oriented techniques,
- compiler technology for parallel computing,
- implementation techniques and their efficiency.

System engineering:

- programming environments,
- debugging tools,
- software libraries.

Performance:

- performance measurement: metrics, evaluation, visualization,
- performance improvement: resource allocation and scheduling, I/O, network throughput.

Applications:

- database,
- control systems,
- embedded systems,
- fault tolerance,
- industrial and business,
- real-time,
- scientific computing,
- visualization.

Future:

- limitations of current approaches,
- engineering trends and their consequences,
- novel parallel architectures.

Taking into account the extremely rapid pace of changes in the field SCPE is committed to fast turnaround of papers and a short publication time of accepted papers.

INSTRUCTIONS FOR CONTRIBUTORS

Proposals of Special Issues should be submitted to the editor-in-chief.

The language of the journal is English. SCPE publishes three categories of papers: overview papers, research papers and short communications. Electronic submissions are preferred. Overview papers and short communications should be submitted to the editor-in-chief. Research papers should be submitted to the editor whose research interests match the subject of the paper most closely. The list of editors' research interests can be found at the journal WWW site (<http://www.scpe.org>). Each paper appropriate to the journal will be refereed by a minimum of two referees.

There is no a priori limit on the length of overview papers. Research papers should be limited to approximately 20 pages, while short communications should not exceed 5 pages. A 50–100 word abstract should be included.

Upon acceptance the authors will be asked to transfer copyright of the article to the publisher. The authors will be required to prepare the text in $\text{\LaTeX} 2_{\epsilon}$ using the journal document class file (based on the SIAM's `siamltex.clo` document class, available at the journal WWW site). Figures must be prepared in encapsulated PostScript and appropriately incorporated into the text. The bibliography should be formatted using the SIAM convention. Detailed instructions for the Authors are available on the SCPE WWW site at <http://www.scpe.org>.

Contributions are accepted for review on the understanding that the same work has not been published and that it is not being considered for publication elsewhere. Technical reports can be submitted. Substantially revised versions of papers published in not easily accessible conference proceedings can also be submitted. The editor-in-chief should be notified at the time of submission and the author is responsible for obtaining the necessary copyright releases for all copyrighted material.
