THE TRAJECTORY DATA MINING MODEL FOR COLLEGE STUDENTS IN CAMPUS LIFE AND ACADEMIC MANAGEMENT

WUGANG LIU*

Abstract. The main objective of the study is to address the lack of comprehensive management technology in student campus life in universities. Starting from the life trajectory data of students in campus life, a trajectory mining model combining data mining technology and university information system is designed. In addition, an applied clustering algorithm is designed to classify different trajectory feature types. The research results show that in actual trajectory analysis, the categories of action trajectories from dormitories to canteens, from 0 to 4, are 87.64%, 87.86%, 86.97%, 88.63%, and 88.71%, respectively, which are the most matched effective action trajectories. It can be seen that the trajectory analysis model designed in the study is effective and can provide assistance for the comprehensive academic management of college students.

Key words: Data mining, Clustering, Academic management, Trajectory features

1. Introduction. With the increasing attention of the state to social talent cultivation in recent years, college students, an important source of national talent reserve, have gradually received extensive attention from all sectors of society. The traditional talent cultivation system lacks adaptability to personalized and practical talent cultivation, and it is difficult to meet the talent demand of today's society, and it has become a new way of talent cultivation to update the talent cultivation system by using the current wave of social informationization and data development [1-3]. The new practical talent cultivation system not only involves the application of information technology in college talent cultivation, but also involves the definition of modern talent cultivation in college. In the traditional education concept, academic achievement is the most important evaluation index for college students and the ultimate value of students' learning career. However, with the gradual convergence of university talent education and social talent demand, academic performance can no longer form a more comprehensive assessment of students. Students will also develop various campus learning activities such as school-enterprise joint practice, campus activities, part-time entrepreneurship, campus exchanges, etc. Meanwhile, students' learning habits in the process of efficient learning have also become one of the important factors to assess students' comprehensive quality [4-6]. It is difficult to assess the daily learning life of students because they are influenced by social networks and learning life landscape, and they are characterized by both group and diversity. Data mining technology provides a technical grip for this problem. By integrating data mining technology with the information record system of college students, it can track and manage students' campus life and study in a trajectory way, and then achieve adaptive management and efficient management [7-9]. Therefore, this study designs a trajectory mining model combining data mining technology and college information system from the perspective of students' academic trajectory, and achieves academic tracking and analysis by analyzing students' trajectories.

The innovation of this study is to extend data-driven student management from learning management to comprehensive management of campus life, and apply trajectory mining models to information systems. By comprehensively analyzing the life trajectory of students, targeted management is implemented.

2. Related Works. Lee S M's team conducted a follow-up study on the adjustment of dental hygiene students to campus life and proposed appropriate management strategies. The study analyzed students' adjustment to campus activities in terms of their club participation, personality, professional adaptation, and interpersonal relationships. The results of the study showed that the campus life management strategy developed by the study can effectively improve the students' adaptability to campus life [10]. Li W's team developed

*School of Arts and Science, Nanning College of Technology, Nanning, 530100, China (wuganglw@163.com)

an intelligent campus management system based on IoT technology from the perspective of smart campus, which uses IoT face recognition technology as long as the data collector and realizes the tracking of students' campus life trajectory and campus life through standardized data analysis. management. The results of the study showed that the system is practical [11]. Kim Y's team analyzed the satisfaction of college students with campus life and analyzed the mediating role between students' social network consistency and satisfaction in campus life based on the survey data. The results of the study showed that the satisfaction of college students with campus life must be reflected in their self-efficacy through participation in campus social life [12]. Purnama S's team proposed a support system for college students' digital weaknesses in the learning process, which is based on the perspective of students' learning life and combines electronic devices and student-centered blockchain to enhance the digital capabilities of cooperative education while meeting the needs of university students' learning lives [13]. Way conducted a study on the important factors influencing students' learning behaviors in their daily learning lives in higher education, which is a combination of qualitative and quantitative analysis from the perspective of students' daily learning lives, emotional content, and temporal dimensions. The results of the study showed that online teaching and learning can fully complement offline teaching and learning and contribute to student outcomes [14].

In the development of data mining technology, its specific application in various fields is its main development situation. Haoxiang team applied data mining technology to online privacy data protection and used a perturbation algorithm to solve similar problems. There is also a significant improvement in the efficiency of the model, compared to other privacy-preserving algorithms [15]. Kuma applied data mining to finance and marketing and designed a data mining-based decision system for financial market information. This system analyzed organizational performance from a practical point of view and determined how the decision solution can be used to help companies balance competitive pressures under external environmental factors such as tax pressure and industrial costs. The results of the study showed the feasibility of this solution [16]. Edastama P's team proposed a data mining tool-based student data analysis system, which is a comprehensive data warehouse in the form of web information reports, and mined the characteristics and patterns of student data through basic data to finally achieve the effect of assessing the status of students' academic and campus life [1,7]. Ageed addressed the issue of combining data mining technology with cloud computing notation. The results of the study showed that the technique designed in the study effectively solves the cloud compatibility problems that arise when data mining is applied in parallel with cloud computing [18]. Mengash designed a data mining model for predicting the performance of college applicants in colleges and universities. Data mining model, which is combined with a reliable standardized admissions system, enables the prediction of possible post-admission learning outcomes of cohort students before they are admitted to colleges and universities. Over two thousand students were selected as the dataset to validate the model proposed in the study, and the predictive accuracy of the model was analyzed by tracking the actual academic performance of students after admission. The results of the study showed that the model designed in the study is able to predict the academic performance of students after enrollment, and such performance prediction can be used as a basis for student admission judgment [1,9].

Garg et al. proposed a decentralized evaluation system to address the issue of tampering in online education evaluation systems, to ensure the integrity of online education evaluation and further achieve the review of online education content. The research results showed that the system is practical [20]. Dutt et al. applied fuzzy set technology to learning neural network classification technology and proposed a digital learning assistance system for people with learning disabilities, achieving intelligent and personalized learning guidance. The research results showed that this method has a more efficient guidance function [21]. Choudhary et al. applied deep learning algorithms to personalized learning recommendation systems based on the extraction and analysis of user preference information, thereby improving the accuracy and personalization of recommendations for different users. The results showed that the system can effectively improve recommendation accuracy and personalization level [22].

It can be seen that data mining technology has unique advantages in the analysis of group data, and it can be better integrated with other systems. There have been some research examples of data mining technology applied in the university system so far. However, it can be found that the current data analysis of students in universities mainly focuses on the analysis of students' academic performance and learning status, but not

from the perspective of students' comprehensive campus life, which is relatively one-sided. Therefore, this study starts from students' life trajectory data in campus life, combines data mining technology with university information system, and designs a trajectory mining model to provide new ideas for students' data analysis.

This study designs a trajectory mining model that can manage students' comprehensive campus life by combining campus life trajectory data and big data mining strategies. The model collects information using different information endpoints of integrated information systems and processes trajectory characteristics based on this. This is a novel perspective and effective information tool for managing students' campus life. This study further designs an applied clustering algorithm and uses it to classify different trajectory feature types. The application of this method greatly enhances the accuracy and effectiveness of research and implementation of management strategies. This study can predict students whose behavior patterns may change through models, and predict the direction of changes, which has important practical significance for early warning and prevention of student behavior problems. Meanwhile, the applied clustering algorithm in this study is better at clustering data into groups with features. Compared to other clustering algorithms, it processes and classifies data more meticulously and accurately. Overall, this study provides a new perspective and effective means to assist universities in comprehensively managing students' academic lives by designing and implementing a model that excavates their daily academic life trajectories, combined with big data mining technology and existing university information systems.

3. Data Mining Model Design for College Students' Trajectories. These feature points include campus consumption records, campus network usage records, campus access control records, scholarship information, and student information. Through these data, it can roughly depict the campus image of students. When analyzing the characteristics of students' campus life trajectory, it needs to label the campus and its internal functional areas, as universities may have multiple campuses and multiple functional areas with similar functions within the same campus. Therefore, it labels the campus and differentiates its functions into twelve different categories. On this basis, the semantic trajectories of students will be further segmented, and the segmentation operation can appropriately divide the long-term trajectories of students. The main trajectory segmentation method used is time-threshold trajectory segmentation. After extracting the required student activity trajectory feature information, an academic management model based on clustering algorithm is proposed. The model is mainly divided into three modules, namely data clustering analysis, trajectory frequent pattern analysis, and trajectory deviation analysis. The model first uses the k-means algorithm for clustering analysis, and then uses the PrefixSpan strategy to perform frequent pattern analysis on the student trajectories within the cluster based on the clustering results. Finally, based on the output results of frequent trajectory patterns, it calculates the degree of deviation between the trajectories of individual students within the cluster and the trajectories of the cluster center, and provides academic warnings based on the degree of deviation to achieve previous academic management. Overall, this model extracts valuable information by analyzing students' behavioral trajectories, and then identifies common and abnormal patterns of student behavior through clustering and pattern analysis, thereby achieving early warning and management of students' academic performance.

3.1. Design of Campus Life Information Collection Model for College Students. In the campus life of college students, the factors that affect students' academic achievement are mainly divided into two categories, which are personal and impersonal factors. The personal factors include students' cognitive ability, creative ability and other inherent abilities, while the impersonal factors are based on the view of academic life and social network in which students live [23]. In the student trajectory feature analysis model part, the trajectory feature analysis model construction is shown in Fig 3.1.

From Fig 3.1, the trajectory feature analysis model converts and analyzes information feature points of students in campus life and academic management information feature points, respectively. The campus life information feature points include campus consumption records, campus network usage records, and campus access control records. The academic management information feature points include scholarship information and student information, etc. The dimension of information features is shown in Figure 3.2.

From this, three types of data collection contacts are derived. One is the campus information system, i.e., the system containing dormitory access control information, student campus network information, and student consumption information. The second is the basic student information and dormitory assignment information. The third is student academic performance and scholarship data. Starting from these three data

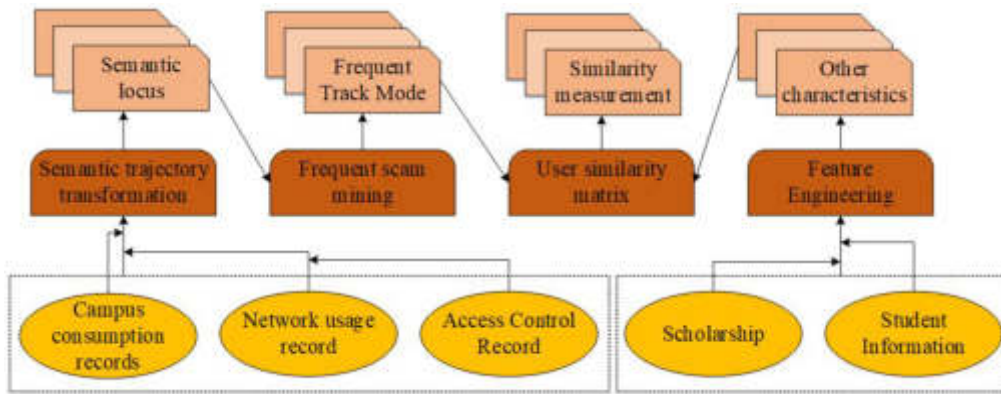

Fig. 3.1: Trajectory feature analysis model

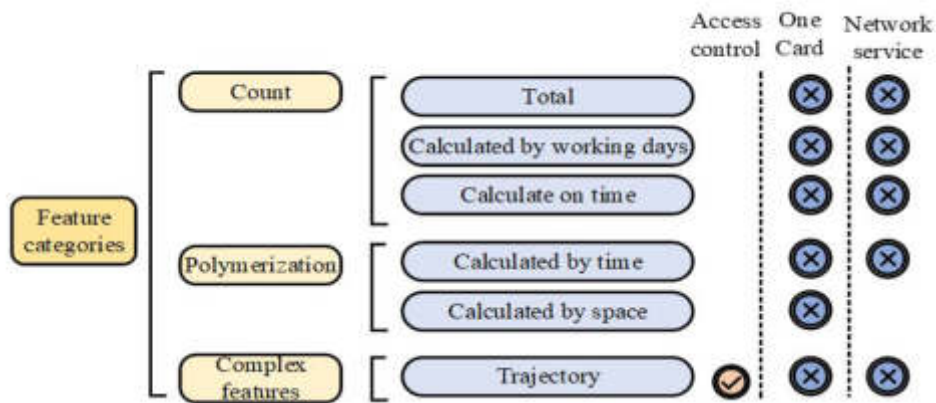

Fig. 3.2: Information feature dimension

dimensions, the model can basically outline the campus image of students when conducting data collection. The data collection process is based on quantitative behavior statistics, time statistics and frequency statistics as the main quantitative measures, and different quantitative statistics are used depending on the nature of the behavior. Quantitative behavior statistics refers to the quantitative count of a behavior or behavior results. Time statistics is used to measure the duration of a student’s behavior, while the frequency statistics is used to measure the number of times a student performs a particular behavior. The model quantitation values are collected in the manner shown in Fig 3.3.

In analyzing the trajectory characteristics of students’ campus life, it is necessary to mark the campus and the functional areas within the campus repeatedly, because the university may have more than one campus, and there may be several functional areas with similar functions within the same campus for diverting student traffic. Therefore, the campus is labeled as C_γ and the functional areas are classified into twelve different categories according to the functions they perform: classroom, dormitory, cafeteria, library, courtyard building, bathroom, office, hospital, supermarket, water room, multimedia area, and other areas, denoted by F_η . For the first λ location within the campus, it can be expressed by $p_{(\gamma,\lambda)}$, which can be defined by the location and spatial position in the form of equation (3.1).

$$P = (p.loc, p.fun) \tag{3.1}$$

Fig. 3.3: Model quantization value acquisition method

In equation (??), $p.loc$ denotes the actual spatial location and $p.fun$ denotes the functional area. Based on this, the study defines student activity as a vector dependent on activity behavior, represented by $a.attr$. The student activity sequence is also defined as a spatio-temporal sequence around the individual student, as shown in equation (3.2).

$$Aseq = \{(t_1, p_1), \dots, (t_k, p_k)\} \quad (3.2)$$

In equation (3.2), t denotes the timestamp, $t_i < t_j$ ($i < j$), assuming the existence of a given active sequence with sequence parameters. p_1 and p_k are different spatio-temporal point locations. When both spatio-temporal point locations satisfy the constraints of Equation (3.3) at the same time, the two point locations can be judged as the same point location.

$$\begin{cases} p_i = p_{i+1} \\ |t_i - t_{i+1}| < \xi \end{cases} \quad (3.3)$$

In equation (3.3), ξ denotes the sequence parameters, t_i denotes the time, and p_i denotes the location. The model performs dwell point detection on the activity sequence, and then uses the dwell point data as the basis for trajectory compression, and finally outputs the semantic trajectory. In the semantic trajectory representation, the activity sequence of individual student and individual is fixed, and the relationship between trajectory Tra and activity sequence is shown in equation (3.4).

$$Tra \subseteq Aseq \quad (3.4)$$

3.2. Analysis Model of Campus Life Information Trajectory for College Students. . Due to the different daily routines of different students, there are periodic differences in their life trajectory information. Therefore, the system needs to effectively distinguish this differential information [24]. On this basis, the model will further segment the semantic trajectories of the students, and the segmentation operation can divide the trajectories of the students for a long time appropriately. The main trajectory segmentation methods can be divided into three types: time-threshold trajectory segmentation, set topology trajectory segmentation, and trajectory semantic trajectory segmentation. Since the student trajectories are based on the campus teaching and activity time as the main axis, the study adopts the time-threshold trajectory segmentation method. According to the time-threshold trajectory segmentation method, students' action trajectories are divided into day-based daily trajectories, and each segment of daily trajectories represents a day's travel of students. When dividing the daily trajectory, a day is not a day divided by a specific time point in physical time, but a complete activity of students in a basic time unit of a day is used as the basis for dividing the trajectory. If a student's activity trajectory exceeds the physical time boundary of a day, but is still within the complete activity of the day, then this part of the trajectory is still slid into the daily trajectory. An example of this classification is shown in Fig 3.4.

Fig. 3.4: Division example

The daily trajectory can be expressed in the form of equation (3.5).

$$DTra = \{(t_1, p_1), \dots, (t_s, p_s)\}, DTra \in Tra \tag{3.5}$$

In Tra , there exists one and only (t_j, p_j) , such that $(t_1, p_1) = (t_j, p_j), (t_{1+n}, p_{1+n}) = (t_{j+n}, p_{j+n})$. The imputation pattern is then shown in equation (3.6).

$$TraP = P'_1 \xrightarrow{\Delta t'_1} P'_2 \xrightarrow{\Delta t'_2} \dots \xrightarrow{\Delta t'_{u-1}} P'_u \tag{3.6}$$

Where $p'_i \in \{p_j\}$. If p'_i corresponds to (t_i, p_i) , and p'_{i+1} corresponds to (t_j, p_j) , then $\Delta t'_i = t_j - t_i$.

3.3.3 Academic Management Model Design. . After extracting the required student activity trajectory feature information, the study proposes an academic management model based on clustering algorithm. The model is divided into three main modules, which are data clustering analysis, trajectory frequent pattern analysis and trajectory deviation analysis. K-means can classify student trajectory data information based on data features [25]. The model first uses the k-means algorithm for clustering analysis, based on which the frequent pattern analysis of student trajectories within the clustered clusters is performed using the PrefixSpan strategy based on the clustering results. The PrefixSpan method flow is shown in Figure 3.5.

Finally, based on the output results of frequent trajectory patterns, it calculates the degree of deviation between the trajectories of individual students in the clusters and the trajectories of the cluster centers, and carries out academic warning according to the degree of deviation to achieve prior academic management. The specific structure is shown in Fig 3.6.

When the model performs the clustering operation, it assumes that there exists a base data set X and each data has a M dimensional feature vector X_n , then x_{nm} represents the feature value of the m feature of the n data. The clustering approach is shown in Fig 3.7.

The model divides the data instances into clusters as shown in equation (3.7).

$$C = \{C_1, C_2, \dots, C_k\} \tag{3.7}$$

There is no intersection between clusters, while each cluster has a cluster center, and the similarity between different clusters is relatively low, but the data instances inside the clusters are more similar. The sum of the distance between the data inside the cluster and the cluster center is the objective function, as shown in equation (3.8).

$$P(U, c) = \sum_{k=1}^K \sum_{n=1}^N u_{nk} \sum_{m=1}^M d(x_{nm}, c_{km}) \tag{3.8}$$

In equation (3.8), U denotes the matrix describing the affiliation status of the clusters, and u_{nk} denotes the affiliation status of the data instance with the ordinal number n for the ordinal number k . $d(x_{nm}, c_{km})$ denotes the distance between the center of the clustering cluster and the data instance. Since this distance

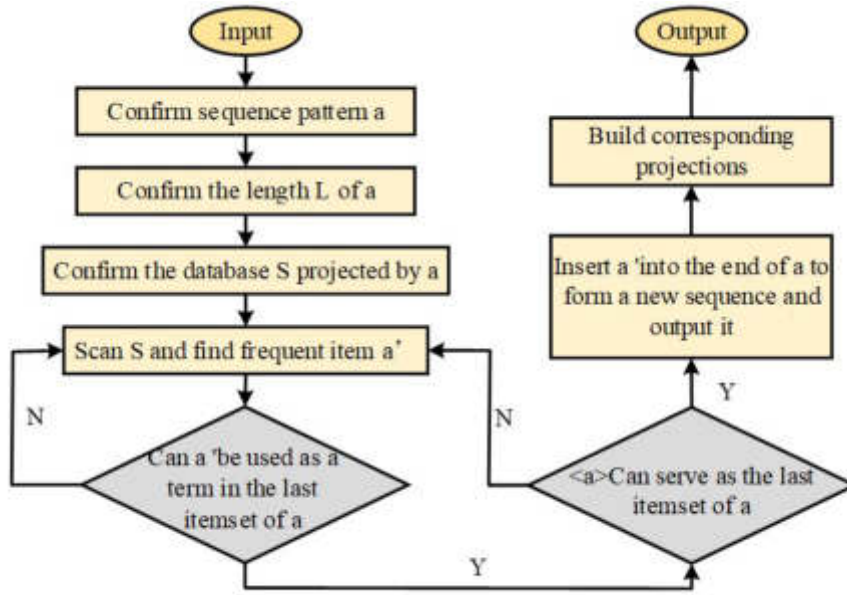

Fig. 3.5: The PrefixSpan method flow

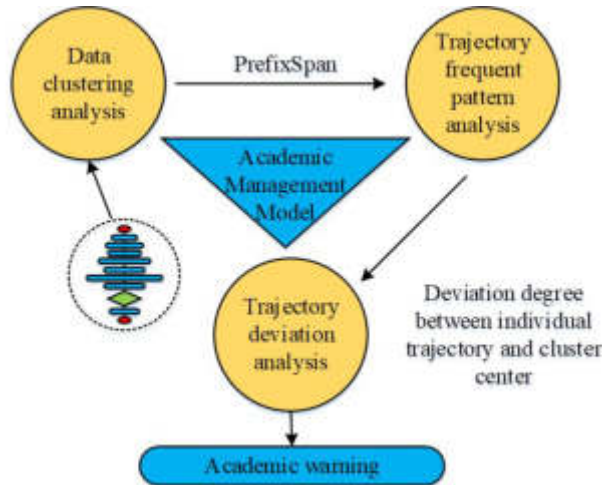

Fig. 3.6: Academic management model structure

yields different results with different metrics, the study requires a choice of metric for the model. The model mainly uses the Euclidean metric as the main metric, as shown in equation (3.9).

$$P(U, c) = \sum_{k=1}^K \sum_{n=1}^N u_{nk} \sum_{m=1}^M d(x_{nm} - c_{km})^2 \tag{3.9}$$

As can be seen from equation (3.9), the metric treats all data features equally, and differences in data feature differences lead to different clustering results, so a weighting mechanism needs to be added to the

Fig. 3.7: Clustering method

model, as shown in equation (3.10).

$$P(U, c) = \sum_{k=1}^K \sum_{n=1}^N u_{nk} \sum_{m=1}^M w_m^\beta (x_{nm} - c_{km})^2 \quad (3.10)$$

In equation (3.9), w_m denotes the data feature weights with the number m and β denotes the custom parameter. Equation (3.10) can be transformed into equation (3.11) since the weights are subject to the naturalness condition of data sum equal to 1.

$$w_m = \frac{1}{\sum_{t \in F} [D_m / D_t]^{1/(\beta-1)}} \quad (3.11)$$

In equation (3.11), D_m denotes the sum of variances of all features within the clustered clusters. After designing the weighting mechanism, the study introduces the objective and subjective combining weighted k-means (Wosk-means) algorithm to assign values to each data feature, and the assignments are made in two ways: subjective weight assignment and objective weight assignment, and the integrated weights are shown in equation (3.12).

$$a_m = \frac{w_m v_m}{\sum_{i=1}^M w_m v_m} \quad (3.12)$$

In equation (3.12), w denotes the subjective weights, v denotes the objective weights, and m denotes the data feature numbers within the data clusters. The flow of the Wosk-means algorithm is shown in Fig 3.8.

In Fig 3.8, the model first standardizes the initial data, after which the data feature weights are initialized to make all data feature weights consistent. After processing the weights, the cluster centers need to be confirmed, and in the face of the given cluster centers and weights, the distance metric of the weights needs to be used to update the division of clusters. Based on this, the mean values of all features within the clusters are divided according to the existing weights and clusters, and the clustering centers are calculated and updated. Finally, the feature weights are updated according to the new clustering centers and clusters, and whether the algorithm converges or not is observed. At present, there are two main algorithms in the field of trajectory frequent pattern analysis, namely, Apriori algorithm and tree algorithm. The study uses the PrefixSpan algorithm which integrates the two algorithms for analysis, and the method can effectively reduce the cost of data mining. In the PrefixSpan algorithm, all sequences are arranged in an ordered manner, while all sequences are composed of item sets, which can be further split into different items. First, the database is input to the model and the minimum support minSup is defined. The length of the sequence pattern α is set to L and the projected database is $S|_\alpha$. A word scan is performed on $S|_\alpha$ and frequent items are found that satisfy the qualification.

On top of the trajectory pattern, the study transforms the trajectory data in a certain way and thus forms the distance between the trajectory features. The distance is expressed in the form of similarity. Similarity is essentially a comparison of the percentage of similar nodes with similar matches. Since there may be reading trajectory matches with different lengths between two trajectories, it is necessary to first find the frequent match

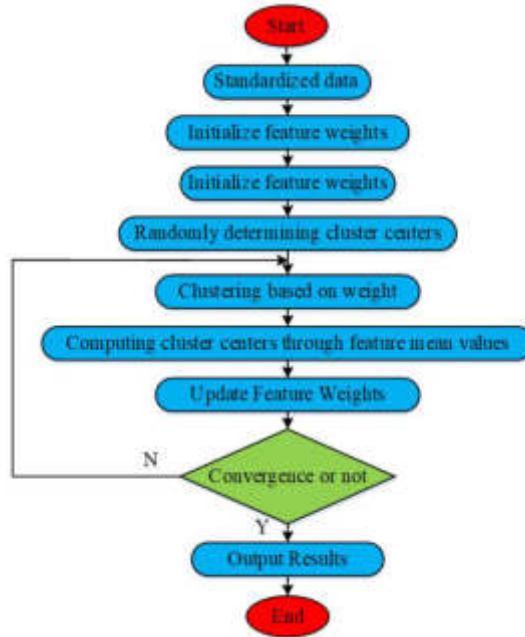

Fig. 3.8: Wosk-means algorithm flow

pattern, and then calculate the different match lengths to finally obtain the combined similarity of different length trajectory matches. It supposes that there exists a trajectory pattern $TraP_1$, as shown in equation (3.13).

$$TraP_1 = p'_{11} \xrightarrow{\Delta t'_{11}} p'_{12} \xrightarrow{\Delta t'_{12}} \dots \xrightarrow{\Delta t'_{1[u-1]}} p'_{1u} \tag{3.13}$$

In equation (3.14), t indicates the time and p indicates the location. A trajectory pattern $TraP_2$ is also presented.

$$TraP_2 = p'_{21} \xrightarrow{\Delta t'_{21}} p'_{22} \xrightarrow{\Delta t'_{22}} \dots \xrightarrow{\Delta t'_{2[u-1]}} p'_{2v} \tag{3.14}$$

Then the similarity of the two trajectories is shown in equation (3.15).

$$S(TraP_1, TraP_2) = \sum_{k=1}^K f_w(k) Sl(FT_1^k, FT_2^k) \tag{3.15}$$

In equation (3.15), k represents the trajectory matching length, $f_w()$ is the weight ratio representation, l is the trajectory matching pattern representation, and FT_1^k and FT_2^k represent the pattern matching subset, respectively.

4. College Student Trajectory Data Mining Model Trajectory Analysis Results.

4.1. Elbow Method Test . In the study of trajectory analysis of college students' trajectory data mining model, student information was first collected from various information segments within the university. The main information collection ends were five types of campus student information system, all-in-one card consumption record, network service record, access control record and action trajectory record. The dataset settings used in the experiment are shown in Table 4.1.

The experimental setup is shown in Table 4.2.

Table 4.1: Data type and data scale

Data source	Data properties	Data size
Campus student information system	Number of students	6714
	Location type and quantity	23
	Time interval	2021.12.01-2022.12.01
All-in-one card consumption record	Number of data records	185298
Network service record	Number of data records	187592
Access control record	Number of data records	167817
Action trajectory record	Maximum action trajectory length	181

Table 4.2: The experimental setup

Simulation settings	Detailed description
Experimental software	Use Python programming language for algorithm development and data processing.
	The applied clustering algorithm was implemented using the Scikit learn library.
	Use Jupyter Notebook for interactive calculations.
Experimental hardware	Desktop computer with Intel Core i7 processor and 16GB of memory.
	Using solid-state drives as storage devices.
Experimental condition	Experimental data collection period: December 1, 2021 to December 1, 2022.
	Use internal data sources within universities for analysis.
	Use elbow analysis and homogeneity analysis to evaluate performance.

Based on Table 4.1 and 4.2, the study first tested the performance of the applied clustering algorithm designed for the study, in which the elbow analysis method and the homogeneity analysis method were used to analyze the data, as shown in Fig 4.1.

In Fig 4.1, in the elbow method test, the overall error sum of squares of the applied clustering algorithm designed in the study showed a significant decreasing trend when the number of clusters rose. The decrease shrank significantly after the number of clusters was greater than 5, while the decrease almost disappeared when the number of clusters reached about 8, which shows that the number of clusters in the interval of 5 to 8 is the optimal setting range. The homogeneity test showed that the homogeneity of the algorithm was significantly improved at the number of clusters 5 and 8. In the comparison test, the clustering of data features in the traditional k-mean algorithm was more evenly distributed and did not provide effective information. In contrast, the applied clustering algorithm designed in the study first clustered the data into two large clusters of 0 and 1, where the feature distribution was still balanced. Then the algorithm further divided the two large clusters into five small clusters, where the feature differences between the clusters were already obvious.

4.2. Trajectory Feature Analysis. The results of trajectory features for different student types are shown in Table 4.3.

From Table 4.3, the model can classify trajectories in more detail for different disciplines and genders, from which the trajectory classification can reveal the characteristic patterns of action trajectories of different types of students in campus actions. The matching statistics of action trajectories between two two locations are shown in Fig 4.2.

In Fig 4.2, the action trajectory category from dormitory to dormitory received the highest number of matches within each cluster, with 98.92%, 98.98%, 96.15%, 98.37%, and 97.61% from category 1 to category 4, respectively. This was followed by the category from dormitory to canteen, with 87.64%, 87.86%, 86.97%, 88.63%, and 88.71% from category 1 to category 4, respectively. However, the category from dormitory to dormitory was somewhat invalid, so a trajectory similarity analysis was also needed, as shown in Fig 4.3.

Figure 4.3 illustrates the discrepancy in similarity between students' behavioral trajectories and the centroid trajectories of the cluster category to which they belong. A lower similarity indicates a greater divergence in students' behavioral trajectories from those of other students within the same cluster category. Moreover, a

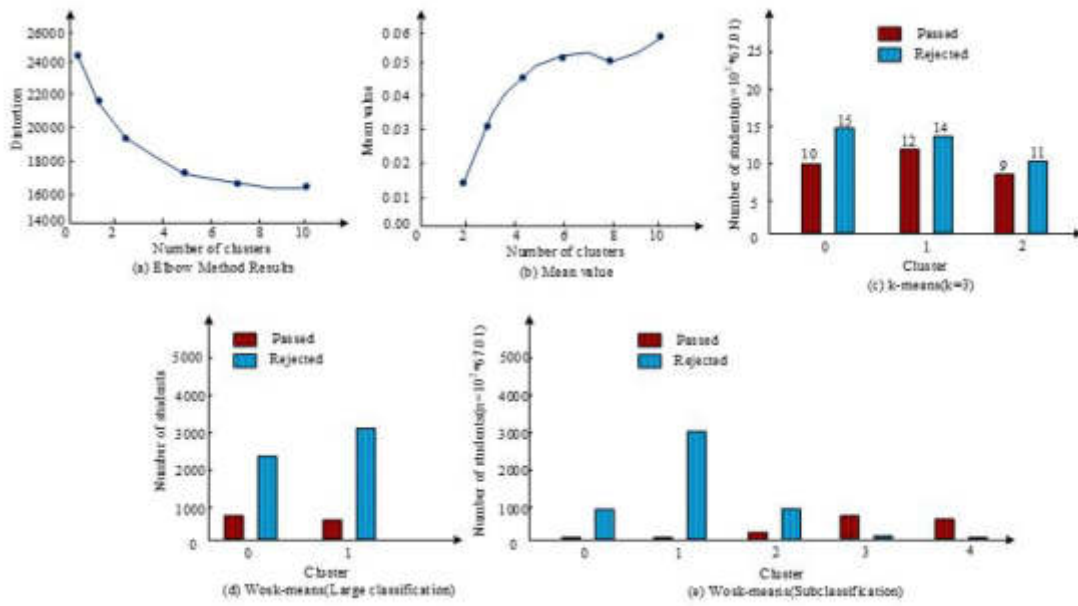

Fig. 4.1: Elbow analysis and homogeneity analysis

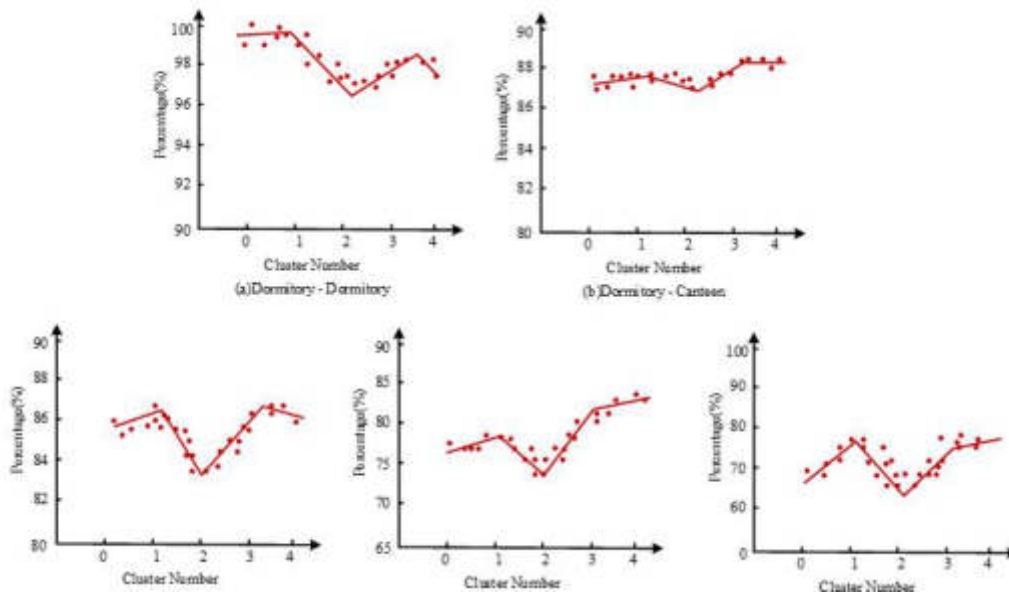

Fig. 4.2: Matching of action trajectories between two locations

higher percentage of this group of students indicates a greater number of students within that cluster category whose action patterns have changed. In this study, the similarity threshold was set at 10%, where the percentages of students with less than 10% similarity in categories 0, 1, 2, 3, and 4 were 1.18%, 1.17%, 0.66%, 0.42%, and 1.45%, respectively. The behavior patterns of this group of students were likely to change dramatically. The deviation directions of students whose trajectories deviated from the centroid cluster category are shown

Table 4.3: Trajectory features results for different student types

Table 4.4: Deviation direction

Percentage (%)	0	1	2	3	4
0	\	41.64	33.34	8.37	16.65
1	25.12	\	58.35	13.82	2.72
2	12.61	37.53	\	50.00	0.00
3	0.00	33.34	66.68	\	0.00
4	10.01	20.00	40.00	30.00	\

in Table 4.4.

In Table 4.4, the vertical direction represents the cluster in which the student is located, and the horizontal direction represents the cluster that the student is deviating towards. The bias of category 0 toward category 1 was higher, with a bias value of 25.12%. The bias of category 1 toward category 0 was higher, with a bias value of 41.64%. The bias of category 2 toward category 3 was higher, with a bias value of 66.68%. The bias of category 3 toward category 2 was higher, with a bias value of 50.00%. The bias of category 4 toward category 1 was higher, with a bias value of 16.65%. This showed that the model designed in the study can not only characterize the trajectory of students' campus actions, but also predict the possible changes of students' action patterns, providing new ideas for the management of students' campus life and academics.

In the benchmark comparison, the total sum of squared errors of the trajectory analysis clustering algorithm designed in the study was slightly lower than that of the benchmark K-means clustering algorithm. From the

Fig. 4.3: Trajectory similarity analysis

Table 4.5: Benchmark comparison of different dataset sizes

Dataset size	Algorithm	Number of clusters	Total sum of squared errors	Cluster homogeneity
Sample size: 100 cases	Benchmark K-means	5	10251	0.83
		8	7562	0.88
	Applied clustering algorithm	5	8674	0.83
		8	7346	0.89
Sample size: 1000 cases	Benchmark K-means	5	102302	0.77
		8	75525	0.83
	Applied clustering algorithm	5	86007	0.82
		8	73220	0.89

perspective of clustering homogeneity, the total sum of squared errors of the trajectory analysis clustering algorithm was higher. Therefore, the trajectory analysis clustering algorithm designed in the study had more advantages in data feature extraction and analysis.

By increasing the size of the dataset by 10 times, the trajectory analysis clustering algorithm designed in the study still had advantages in the total sum of squared errors, indicating that the designed algorithm had stronger processing power when facing large-scale datasets. In the comparison of clustering homogeneity, the trajectory analysis clustering algorithm had higher clustering homogeneity, indicating that as the dataset size increased, the designed algorithm had more performance advantages.

With the increasing emphasis on talent cultivation in society, college students, as an important source of national talent reserves, are gradually receiving widespread attention from all sectors of society. The traditional talent cultivation system lacks adaptability to personalized and practical talent cultivation, making it difficult to meet the talent needs of today's society. Therefore, utilizing the current wave of social informatization and data development to update the talent cultivation system has become a new way of talent cultivation [26-27]. However, how to effectively utilize data mining technology to track and manage students' campus

life and learning, in order to achieve adaptive and efficient management, is an urgent problem to be solved [28]. In the research results, it can be seen that the model first collected student information from various sub sources within the university. After clustering analysis of these data, the applied clustering algorithms demonstrated significant performance in effectively distinguishing students' behavioral characteristics, while traditional K-means clustering algorithms could not provide this effective information. In addition, the applied clustering algorithm designed in the study had the optimal setting range within the range of 5 to 8 clusters. After analyzing the trajectory characteristics of different types of students, it can be found that the model could classify trajectories in more detail for students of different disciplines and genders. This indicated that through trajectory classification, characteristic patterns of different types of students' school behavior can be discovered. At the same time, it can be observed that the matching rate of behavior trajectories from dormitories to canteens was relatively high, but further trajectory similarity analysis is needed to confirm. In trajectory similarity analysis, there were significant differences between the behavior trajectories of most students and the centroid trajectories of their clustering categories. This difference may indicate a change in students' behavioral patterns.

By analyzing the similarity of trajectories, it was found that the similarity between students' action trajectories and the centroid trajectories of their cluster category was low, indicating that their behavior trajectories were different from those of other students within the cluster category. The more students in this situation, the greater the likelihood of changes in student behavior patterns within the cluster category. Finally, the study also found that students' action trajectories deviate from the direction of centroid clustering categories to a certain extent. For example, the deviation degree from category 0 to category 1 was relatively high, with a deviation value of 25.12%. The deviation degree from category 1 to category 0 was relatively high, with a deviation value of 41.64%. The deviation degree from category 2 to category 3 was relatively high, with a deviation value of 66.68%. The deviation degree from category 3 to category 2 was relatively high, with a deviation value of 50.00%. The deviation from category 4 to category 1 was relatively high, with a deviation value of 16.65%. These results indicated that the model designed in this study can not only describe students' campus action trajectories, but also predict possible changes in student behavior patterns, providing new ideas for students' campus life and academic management. Meanwhile, in the research, it is also possible to predict the possible changes in student behavior patterns, providing new ideas for students' campus life and academic management. Overall, through data mining technology, it is possible to gain a deeper understanding and analysis of the learning behavior and life trajectory of college students, thereby providing more effective support and methods for personalized education of students and talent cultivation in universities. So far, data mining technology has provided people with a novel and efficient method for student management and educational reform.

5. Conclusion. The research addressed the problem that the academic management of students in universities lacks daily campus life management, and proposed a model for mining students' daily academic life trajectories that combines the existing university information system and data mining technology. The model extracted and analyzed the information of students' daily activity, and designed an applied clustering algorithm to classify different trajectory types on this basis. The research results showed that in the elbow test and the homogeneity test, the applied clustering algorithm had obvious variation characteristics at the cluster number 5-8, and this interval was the best cluster number interval. The applied clustering algorithm in the comparison test was better at clustering the data into clusters with features than the ordinary clustering algorithm. In the trajectory analysis, the model could classify trajectories in more detail for different disciplines and genders, in which the categories of action trajectories from dormitory to canteen were 87.64%, 87.86%, 86.97%, 88.63%, 88.71% from category 0 to 4 respectively, which were the most effective action trajectories with the highest number of matches. The percentage of people with similarity less than 10% in categories 0 to 4 were 1.18%, 1.17%, 0.66%, 0.42%, and 1.45%. The behavior patterns of this group of students were likely to change dramatically. In addition, the model was able to predict the direction of trajectory change, with the main directions being category 0 to category 1, category 1 to category 0, category 2 to category 3, category 3 to category 2, and category 4 to category 1. This showed that the model designed in the study can effectively analyze student estimation and provide assistance for comprehensive academic life management in universities.

However, the drawback is that this study mainly relied on data from university information systems, but students' daily life trajectories may be influenced by more elements, such as social media activities, health,

and psychological conditions. At the same time, this study mainly focused on the analysis of student behavior trajectories, but did not involve how to effectively intervene based on these analysis results. Therefore, in future research, it is possible to explore how to use these analysis results to design and implement effective student life management strategies. At the same time, future research can consider integrating more types of data sources to provide a more comprehensive trajectory of student life.

MULTI CHANNEL ELECTRONIC COMMUNICATION SIGNAL PARAMETERS BASED ON NONLINEAR PHASE PRINCIPLE MODULATION AND DEEP LEARNING

XIAOQING YAN*

Abstract. In order to solve the problem of high sampling rate and large number of sampling points required by current phase modulation signal parameter estimation methods, a parameter modulation method for multi-channel electronic communication signals based on nonlinear phase principle and deep learning is proposed. Firstly, classify and introduce the modulation methods, and propose a new algorithm for identifying instantaneous feature parameters. The author conducted nonlinear phase principle modulation recognition on seven typical digital signals: 2ASK, 4ASK, 2FSK, 4FSK, 2PSK, 4PSK, and 16QAM. Using the author's algorithm, experiments were conducted on the recognition of seven digital nonlinear phase modulation signals under different signal-to-noise ratios. As can be seen from the results, when the signal-to-noise ratio is greater than or equal to 10dB, the recognition accuracy of the seven digital nonlinear phase modulation signals can reach 100%, verifying that the new algorithm proposed by the author improves the recognition accuracy.

Key words: Nonlinearity, Phase principle modulation, Communication signal, characteristic parameter

1. Introduction. Automatic modulation recognition technology is a very important topic in the field of non cooperative communication signal processing research. The task of modulation recognition for communication signals is to identify signals without sufficient or complete prior knowledge, by performing various processing on the received signal, the modulation method and related modulation parameters used in the signal can be accurately determined[1]. For the signal receiving end, determining the modulation method of the received signal and correctly demodulating the signal is a necessary prerequisite for restoring the original signal. The study of automatic modulation recognition technology for signals has significant practical value in both military and civilian fields. The practical value of modulation recognition technology is mainly reflected in: In the military field, successfully determining the modulation mode of the signal is a prerequisite for achieving reconnaissance and interference of enemy communication. Knowing the modulation method of enemy signals can estimate some useful parameters, in order to conduct targeted reconnaissance and electronic interference on enemy communication; In the civilian field, the task of radio management work in the communication management department is to monitor whether legitimate radio stations comply with the working parameters assigned by the management department during the communication process, while listening for interference from illegal radio stations to ensure the normal communication of legitimate radio stations. The most crucial technology to achieve these non cooperative communication tasks is modulation recognition technology. There are two methods for modulation recognition of wireless communication signals: One is manual judgment, and the other is machine automatic recognition. Early modulation recognition methods used a set of demodulators with different modulation methods, the received signal is downconverted and input into each demodulator to obtain an observable signal, which is then judged by the operator based on information such as time-domain waveform, signal spectrum, instantaneous amplitude, instantaneous frequency, and instantaneous phase [2,3]. The recognition method of manual judgment requires experienced operators. Due to the subjective factors involved in the judgment process, the judgment results will vary from person to person, and the modulation types that can be recognized by manual judgment will be very limited. And automatic modulation recognition technology can solve the above problems.

The ultimate goal of automatic modulation recognition technology is to develop a machine that can recognize as many modulation modes as possible without any prior knowledge and low signal-to-noise ratio. We hope that the less prior knowledge there is in modulation recognition, the better, or the more "blind" the

*College of Education, Jiangxi University of Engineering, Xinyu Jiangxi, 338000, China (XiaoqingYan78@126.com)

modulation recognition algorithm is [4,5]. However, in the actual research process of modulation recognition technology, researchers will more or less add some prior knowledge, such as only studying digital modulation recognition, which means that they already know that the received signal is a digital signal, not an analog signal.

2. Literature Review. Radar signal recognition is an important aspect of electronic reconnaissance, which refers to the process of matching the features of the received signal emitted by the radar signal source with the pre accumulated signal features to confirm the signal modulation method. Radar signal recognition usually includes: Intentional modulation recognition and unintentional modulation recognition of radar signals, target recognition of radar signal source platforms, and estimation of recognition credibility [6]. At present, Western countries led by the United States are in a leading position in radar signal recognition technology, but due to their military confidentiality, they have limited access to information. As far as we know, the main algorithms for radar signal recognition include time-frequency analysis, spectral correlation, time-domain autocorrelation, wavelet transform, digital intermediate frequency, and time-domain cepstrum. The time-domain cepstrum method extracts modulation features and related modulation parameters by calculating the cepstrum of the signal. This method requires various transformations, requires a large amount of computation, is difficult to implement in hardware, and has low accuracy, so its practical application value is not significant. The digital intermediate frequency method can comprehensively recognize radar signals, with the increasing processing speed of DSP chips, it is a promising technology, however, the relevant technology is not yet very mature and requires a lot of research. The advantage of spectral correlation method is that it has good resolution, but the actual environment is complex and the received signal length is limited, resulting in low recognition accuracy. The time-frequency analysis method and wavelet transform method are newly developed and highly effective tools for processing non-stationary signals in recent years [7]. The time-frequency analysis method is a two-dimensional joint analysis of the time-domain and frequency-domain characteristics of a signal, the real-time frequency analysis method can simultaneously describe the energy density of a signal at different times and frequencies, and can effectively describe the local characteristics of the signal, in recent years, it has received increasing attention. The wavelet transform method is also a time-frequency analysis method, which has the characteristics of multi resolution analysis and can characterize the local characteristics of the signal. The signal has high frequency resolution and low time resolution in the low frequency range, while it has low frequency resolution and high time resolution in the high frequency range, therefore, applying wavelet transform to the signal can obtain different details. And different radar signals have different detailed features, which can be used to identify radar signals [8]. Researchers have been striving to find fast and efficient automatic recognition technologies, and have achieved considerable success. However, the research on automatic modulation recognition technology has not yet matured and finalized, due to: One reason is that new modulation methods are constantly emerging, and the modulation types of communication signals are becoming more diverse, while previous modulation recognition algorithms only worked on specific types of modulation signals. Secondly, the complexity of wireless communication environments poses challenges to non cooperative communication. Compared to wired communication, wireless communication has its own characteristics: Firstly, the wireless channel of wireless communication is open and susceptible to interference from other signals and various noises; Second, radio propagation has a variety of ways, including diffraction, reflection and refraction. The signal received by the receiver will cause signal fading due to multi-path effects; Thirdly, there is also the Doppler effect in mobile communication, which can cause signal items to change at times. The multipath and Doppler effects seriously affect the reception quality of signals. In the process of non cooperative communication, the receiver cannot obtain the signal parameters of the sender like in cooperative communication. The diversified wireless communication technology requires non cooperative communication receiving systems to have characteristics such as wide coverage, strong adaptability, and anti fading. Thirdly, the signal environment is becoming increasingly dense, and at the same time, multiple signals with different modulation methods will enter the receiver. This puts forward new requirements for signal modulation recognition, that is, how to achieve recognition of multiple modulation signals at the same time. These situations all determine that there are many new research works to be carried out in the field of automatic modulation and recognition of communication signals [9].

This article briefly introduces a digital nonlinear phase modulation recognition algorithm proposed by E.E. Azzouz and A.K. Nandi to address these issues, because the features extracted by the nonlinear phase modula-

tion recognition algorithm based on instantaneous features are all derived from the operation of instantaneous amplitude, instantaneous phase, and instantaneous frequency, the algorithm proposed by the author is used to identify, simulate, and analyze seven types of digital nonlinear phase modulation signals, and the decision process and selected decision threshold are provided.

3. Methods.

3.1. Classification of modulation methods .

From the perspective of modulation recognition, communication signals can be classified using various methods. The first classification is based on the information content contained in the signal, and any communication signal can be classified into one of the following four categories:

1. If a signal only contains amplitude information but not phase information, it is called an amplitude signal [10,11]. The so-called amplitude information here refers to the instantaneous amplitude of the signal not being constant; Phase information refers to the instantaneous phase of a signal that is not constant. Correspondingly, without amplitude information, the instantaneous amplitude of the signal is constant; No phase information refers to the instantaneous phase of a signal being constant. Amplitude signals such as MASK (M-scale amplitude keying) signals.
2. If a signal only contains phase information but not amplitude information, it is called a phase signal. For example, MFSK (M-ary Frequency Shift Keying) signal and MPSK (M-ary Phase Shift Keying) signal.
3. If a signal has both amplitude and phase information, it is called a composite signal. For example, MQAM (M-ary Orthogonal Amplitude Modulation) signal [12].
4. If a signal has neither amplitude nor phase information, it is called a carrier wave (CW) signal. Such as sine and cosine signals.

The second classification is based on the symmetry of the signal spectrum with respect to the carrier frequency. Usually, the spectrum of a signal consists of one carrier component and two sideband components, but in some modulation methods, the carrier component and two sideband components may not be all preserved. According to the presence of sidebands, communication signals can be divided into two categories: symmetric signals and asymmetric signals.

The third classification is divided into analog modulation signals and digital modulation signals based on the properties of modulation signals.

The fourth classification is divided into two categories based on the types of carriers: sine wave modulation and pulse modulation [13].

This project studies the sine wave modulation methods of digital signals, including the following modulation methods: 2ASK (binary amplitude keying), 4ASK (quaternary amplitude keying), 2FSK (binary frequency shift keying), 4FSK (quaternary frequency shift keying), 2PSK (binary phase shift keying), 4PSK (quaternary phase shift keying), and 16QAM (hexadecimal orthogonal amplitude modulation). Other modulation methods are not discussed here.

3.2. Recognition algorithm based on new instantaneous feature parameters . Parameter extraction and threshold selection: The author conducted nonlinear phase principle modulation recognition on 7 typical digital signals, including 2ASK, 4ASK, 2FSK, 4FSK, 2PSK, 4PSK, and 16QAM. After comprehensive consideration of various aspects, the following 5 instantaneous feature parameters were extracted for signal classification.

(1) *The mean M_a^2 of the normalized instantaneous amplitude square at zero center.* The mean M_a^2 of the normalized instantaneous amplitude square at zero center is obtained by the following equation:

$$M_a^2 = \frac{1}{N} \sum_{i=1}^{N_s} |a_{cn}(i)|^2 \quad (3.1)$$

In Equation 3.1, N_s is the total number of sampling points; $a_{cn}(i)$ is the zero center normalized instantaneous amplitude, and $a_{cn}(i)$ is calculated from Equation 3.2:

$$a_{cn}(i) = a_n(i) - 1 \quad (3.2)$$

Fig. 3.1: The variation of parameter M_a^2 of modulated signals with different phase principles with signal-to-noise ratio

In Equation 3.2, the normalized instantaneous amplitude $a_n(i) = \frac{a(i)}{m_s}$, while $m_s = \frac{1}{N_s} \sum_{i=1}^{N_s} a(i)$ is the average of the instantaneous amplitude $a(i)$, and the characteristic parameter M_a^2 . Seven types of digital nonlinear phase modulation signals can be divided into three categories: MASK signals are classified into one category, 16QAM signals are classified into one category, and MFSK and MPSK signals are classified into another category. The instantaneous amplitude of MASK and 16QAM signals varies [14]; The instantaneous amplitude of the MPSK signal only undergoes a sudden change in amplitude at the moment of phase change, so its characteristic parameters are relatively small; The instantaneous amplitude of the MFSK signal is constant, the envelope is constant, and its characteristic parameter is zero. The actual simulation results are shown in Figure 1. From the figure, we can observe that at low signal-to-noise ratios, the characteristic parameters of signals modulated by different nonlinear phase principles are not significantly different due to the influence of noise[15]. However, as the signal-to-noise ratio increases, the characteristic parameters of signals modulated by different nonlinear phase principles begin to approach the theoretical calculated values, therefore, by selecting appropriate thresholds, MASK, 16QAM, and MFSK, MPSK signals can be separated. Based on multiple simulation attempts and weighing the impact on global decisions, the threshold $t1(M_a^2)$ of the mean M_a^2 of the normalized instantaneous amplitude squared at the zero center was selected as 0.12, and the threshold $t2(M_a^2)$ was selected as 0.08. When the threshold is $t2(M_a^2) < t(M_a^2) < t1(M_a^2)$, it is determined as a 16QAM signal; When the threshold is $t(M_a^2) > t1(M_a^2)$, it is judged as a MASK signal; When the threshold is $t(M_a^2) < t2(M_a^2)$, it is determined as an MFSK signal or an MPSK signal [16,17].

(2) Recursive Zero Center Normalized Instantaneous Amplitude Square Mean RM_a^2 .

$$RM_a^2 = \frac{1}{N} \sum_{i=1}^{N_s} |ra_{cn}(i)|^2 \tag{3.3}$$

In Equation 3.3, N_s is the total number of sampling points, $ra_{cn}(i)$ is the recursive zero center normalization instantaneous amplitude, that is, after normalizing the zero center, the instantaneous amplitude $a_{cn}(i)$ is calculated, and then the zero center normalization instantaneous amplitude $ra_{cn}(i)$ is calculated by the following equation:

$$ra_{cn}(i) = \frac{a_{cn}(i)}{\frac{1}{N} \sum_{i=1}^{N_s} a_{cn}(i)} - 1 \tag{3.4}$$

Fig. 3.2: Changes in parameter AA of modulated signals with different phase principles as a function of signal-to-noise ratio

The feature parameter RM_a^2 is used to distinguish between 2ASK signals and 4ASK signals. According to the time-domain characteristics of these two types of signals, their instantaneous amplitudes are 2 and 4, respectively, indicating that the RM_a^2 corresponding to the 4ASK signal is greater than the RM_a^2 corresponding to the 2ASK signal. Therefore, by setting an appropriate threshold value $t(RM_a^2)$, 2ASK and 4ASK signals can be identified. Based on multiple simulation attempts and weighing the impact on global decisions, finally, the threshold $t(RM_a^2)$ of the mean RM_a^2 of the normalized instantaneous amplitude square of the zero center is selected as 0.17. The variation of the mean RM_a^2 of the recursive zero center normalized instantaneous amplitude square of modulated signals with different digital nonlinear phase principles with signal-to-noise ratio is shown in Figure 3.2.

(3) The mean M_f^2 of the square of the normalized instantaneous frequency at zero center.

$$M_f^2 = \frac{1}{N_s} \sum_{i=1}^{N_s} |f_{cn}(i)|^2 \quad (3.5)$$

In Equation 3.5, N_s is the total number of sampling points: $f_{cn}(i)$ is the zero center normalized instantaneous frequency. According to the time-domain characteristics of the signal, the MFSK signal has at least 2 instantaneous frequency values, while the MPSK signal only has 1 instantaneous frequency value, meaning that the M_f^2 corresponding to the MFSK signal is greater than the M_f^2 corresponding to the MPSK signal. Therefore, this feature parameter can be used to distinguish between MFSK signals and MPSK signals. Based on multiple simulation attempts and weighing the impact on global decisions, finally, the threshold $t(M_f^2)$ of the mean M_f^2 of the zero center normalized instantaneous frequency squared is selected as 0.075. The variation of the mean M_f^2 of the zero center normalized instantaneous frequency square of modulated signals with different digital nonlinear phase principles with signal-to-noise ratio is shown in Figure 3.3 [18].

(4) Recursive Zero Center Normalized Instantaneous Frequency Square Mean. RM_f^2

$$RM_f^2 = \frac{1}{N_s} |rf_{cn}(i)|^2 \quad (3.6)$$

In Equation 3.6, N_s is the number of sampling points, and $rf_{cn}(i)$ is the recursive zero center normalized instantaneous frequency, namely, normalize the instantaneous frequency of the zero center and then calculate

Fig. 3.3: The variation of parameter M_f^2 of modulated signals with different phase principles with signal-to-noise ratio

the normalized instantaneous frequency $f_{cn}(i)$ of the zero center using the following formula:

$$f_{cn}(i) = \frac{f_{cn}(i)}{\frac{1}{N_s} \sum_{i=1}^{N_s} f_{cn}(i)} - 1 \tag{3.7}$$

In Equation 3.7, $f_{cn}(i)$ is the zero center normalized instantaneous frequency. According to the time-domain characteristics, the number of instantaneous frequency values of the 2FSK signal is 2, which is significantly smaller than the number of instantaneous frequency values of the 4FSK signal, therefore, the RM_f^2 value corresponding to 2FSK is smaller than the RM_f^2 value of 4FSK, so this feature parameter RM_f^2 can distinguish between 2FSK and 4FSK signals. Based on multiple simulation attempts and weighing the impact on global decisions, the threshold $t(RM_f^2)$ of the mean RM_f^2 of the normalized instantaneous frequency square of the recursive zero center was ultimately selected as 0.225 [19]. The variation of the mean RM_f^2 of the recursive zero center normalized instantaneous frequency square of modulated signals with different digital nonlinear phase principles with signal-to-noise ratio is shown in Figure 3.4.

(5) Mean M_p^2 of normalized instantaneous phase squared at zero center.

$$M_p^2 = \frac{1}{N} \sum_{i=1}^{N_s} |p_{cn}(i)|^2 \tag{3.8}$$

In Equation 3.8, N_s is the number of sampling points, $p_{cn}(i)$ is the zero center normalized instantaneous phase, calculated by the following equation:

$$p_{cn}(i) = p_n(i) - 1 \tag{3.9}$$

In Equation 3.9, $p_n(i) = \frac{p(i)}{m_s}$, while $m_s = \frac{1}{N_s} \sum_{i=1}^{N_s} p(i)$ is the average of the instantaneous phase $p(i)$. The instantaneous phase number of 4PSK is greater than that of 2PSK, and the characteristic parameter M_p^2 can distinguish between 4PSK and 2PSK signals. Based on multiple simulation attempts and weighing the impact on global decisions, the threshold $t(M_p^2)$ of the mean M_p^2 of the normalized instantaneous amplitude squared at the zero center was ultimately selected as 0.2. The variation of the mean M_p^2 of the zero center normalized instantaneous phase square of modulated signals with different digital nonlinear phase principles with signal-to-noise ratio is shown in Figure 3.5.

Fig. 3.4: The variation of parameter RM_f^2 of modulated signals with different phase principles with signal-to-noise ratio

Fig. 3.5: The variation of parameter M_p^2 of modulated signals with different phase principles as a function of signal-to-noise ratio

4. Results and Analysis. Figure 4.1 is the non-linear phase principle modulation recognition flowchart of the algorithm in this paper. In the recognition algorithm proposed by the author, only 5 feature parameters can identify 7 types of digital nonlinear phase principle modulation signals. However, the five features proposed by scholars E.E. Azzouz and A.K. Nandi can only recognize six types of digital nonlinear phase modulation signals [20,21].

Firstly, in order to ensure that when the signal sender uses symbol 0 to modulate the MASK signal using the nonlinear phase principle, the MASK can be recognized, we can only use the feature M_a^2 related to instantaneous amplitude to distinguish MASK signals from other signals, and RM_a^2 to distinguish 2ASK signals from 4ASK signals.

Secondly, from the instantaneous characteristic maps of MFSK and MPSK, it can be seen that the instantaneous frequency of MFSK has only a finite number of discrete values, while the instantaneous frequency of

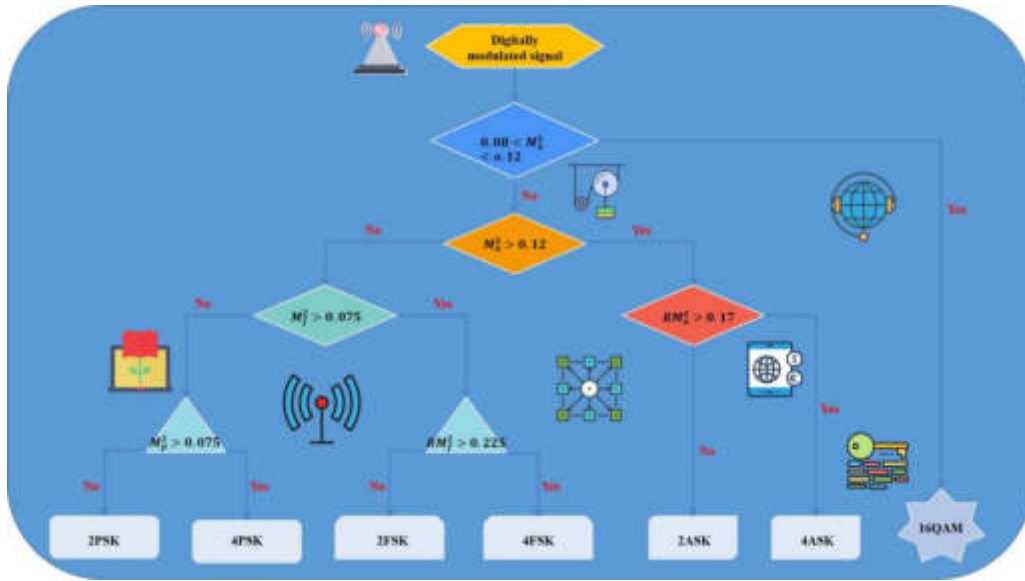

Fig. 4.1: Nonlinear Phase Principle Modulation Recognition Flowchart of the Author's Algorithm

MPSK is constant, the use of feature M_f^2 can effectively distinguish between MFSK signals and MPSK signals. It is not appropriate to use feature M_p^2 to distinguish between MFSK signals and MPSK signals, because the instantaneous phase of the MFSK signal is not constant, but time-varying.

Finally, feature RM_f^2 is used to distinguish between 2FSK and 4FSK signals, and feature M_p^2 is used to distinguish between 2PSK and 4PSK signals. At this point, all seven types of digital nonlinear phase modulation signals have been distinguished [22].

Figure 4.2 shows the recognition results of seven digital nonlinear phase modulation signals using the author's algorithm under different signal-to-noise ratios. As can be seen from Figure 4.2, when the signal-to-noise ratio is greater than or equal to 10dB, the recognition accuracy of all seven digital nonlinear phase modulation signals can reach 100%.

E. Azzouz and A.K. Nandi, two scholars, did not provide a simulation diagram similar to Figure 4.2 showing the variation of digital nonlinear phase principle modulation signal recognition results with signal-to-noise ratio. Instead, they only provided the recognition accuracy under three conditions of signal-to-noise ratio: 10dB, 15dB, and 20dB[23]. Table 1 is a comparison table of the correct recognition rates of the author's algorithm and classical algorithm under three different signal-to-noise ratios of 10dB, 15dB, and 20dB, respectively. By comparison, it can be seen that, compared with the classic algorithms of E.E. Azzouz and A.K. Nandi, the new algorithm proposed by the author achieves better recognition results at low signal-to-noise ratios by adding a 16QAM nonlinear phase principle modulation method .

5. Conclusion. The features extracted by the nonlinear phase modulation recognition algorithm based on instantaneous information are all derived from the operation of instantaneous amplitude, instantaneous phase, and instantaneous frequency, the author analyzed how to extract these three instantaneous feature parameters. Simulation and analysis were conducted on the recognition of seven types of digital nonlinear phase modulation signals using the feature parameters proposed by the author, the decision process and selected decision threshold were provided, and the results showed that the author's algorithm improved the recognition success rate. In recent years, the research methods and directions of automatic nonlinear phase modulation recognition algorithms have been continuously expanded, and progress has been made to some extent, however, there are still many key issues that have not been well resolved. The author's research on nonlinear phase principle modulation recognition algorithms still has many shortcomings. All research on nonlinear phase principle modulation recognition focuses on certain types of modulation signals, the author only studied seven

APPLICATION OF ARTIFICIAL INTELLIGENCE TECHNOLOGY AND DEEP LEARNING IN LABORATORY INTELLIGENT MANAGEMENT PLATFORM

XING LU*

Abstract. In order to effectively utilize data for laboratory management, a laboratory management model was studied, the author proposed a data-driven intelligent laboratory management process and logical architecture. For actual management work, there are mainly two types of operations: "Selection" and "action", the author proposes a data-driven laboratory intelligent management process and logical architecture; Based on the idea of big data, label systems are used to classify and store laboratory related data and laboratory evaluation GBDT and other algorithmic models; Building an intelligent laboratory management platform based on the label system has realized laboratory management functions, which are widely used and highly scalable. This data-driven laboratory intelligent management platform plays a role in the entire life cycle of laboratories, including laboratory demonstration construction, construction process management, experimental teaching and open use, operation management and maintenance, and experimental effect evaluation, and can promote the maximum effectiveness of laboratories, provide strong support for later construction project approval.

Key words: Artificial intelligence technology, Intelligent laboratory management, Application, Laboratory Evaluation GBDT Algorithm

1. Introduction. The term "artificial intelligence" was coined by McCartney, Minsky, Rochester and Shenon First proposed by a group of young scientists, it marks the emerging science of "artificial intelligence" Generation of family. Artificial intelligence has many advantages, including the following points: First, artificial intelligence can greatly save human cost. Second, artificial intelligence can greatly improve resource utilization. Third, AI can greatly improve work efficiency. Fourth, artificial intelligence has high commercial value. Fifth, artificial intelligence can free people's hands to focus on a better life. Sixth, artificial intelligence can promote social development and human progress. With the development of global economic integration, information technology has made great progress, Artificial intelligence technology has been widely used, such as car autonomous driving, robots Automatic sweeping, robot automatic cooking, robot waiter, rescue and disaster relief robot, Underwater robots and dance performance robots.

With the development of science, technology, and information technology, artificial intelligence theory has attracted more and more attention in recent years, not only because artificial intelligence technology can improve the efficiency of production and work, but also because of the emergence and application of artificial intelligence technology, it has greatly liberated human hands and is an important symbol of humanity's progress towards a new stage. It is conducive to understanding artificial intelligence technology [1]. Studying the theory of artificial intelligence, especially the transformation results of representative artificial intelligence technologies, is conducive to the widespread application of artificial intelligence technology, thereby reducing production costs, improving work efficiency, and benefiting the economic development of enterprises, contribute to China's economic and social development. It is conducive to the development of relevant industries and disciplines. Studying representative AI technologies is not only conducive to guiding the development of AI technology in the industry, but also conducive to the integration of other disciplines with AI, achieving the effect of one plus one greater than two, and promoting the development of relevant industries and disciplines. Third, it is conducive to stimulating the enthusiasm of the whole society for innovation. Through the popularization of artificial intelligence technology, people can realize that artificial intelligence technology is a discipline closely related to our daily life, through the transformation of theoretical achievements in artificial intelligence, it is possible to cultivate the enthusiasm of the whole society for creation and invention, thereby increasing the

*State-owned Assets Management Office, Jilin Agricultural University, Changchun, Jilin, 130118, China (XingLu167@163.com)

vitality of the development of artificial intelligence technology [2]. With the deepening of educational reform and the increasing demand for innovative, skilled, and talented people in society, investment in the construction scale, equipment, and practical teaching arrangements of university laboratories continues to increase, it has played an important role in cultivating socially applicable talents in colleges and universities. While meeting the needs of teaching practice, university laboratories also undertake heavy scientific research tasks, so the traditional manual management model is well suited to the new management requirements. Factors such as the increase in laboratory operation time and instrument usage frequency, as well as insufficient management personnel, not only reduce management efficiency, but also bring various safety hazards. Establishing innovative, open, and resource sharing central laboratories and adopting artificial intelligence technology for scientific management have become an inevitable trend in the development of university laboratories [3,4]. What is the significance of studying artificial intelligence: First, it is conducive to understanding artificial intelligence technology. Research artificial intelligence theory In particular, the main research on the transformation of representative artificial intelligence technologies, It is conducive to the wide application of artificial intelligence technology, thus reducing production costs and improving production Work efficiency, is conducive to the economic development of enterprises, for China's economic and social development Make a contribution. Second, it is conducive to the development of related industries and disciplines. Research is representative Is not only conducive to guiding the development of artificial intelligence technology in the industry Exhibition, but also conducive to the combination of other disciplines and artificial intelligence, to achieve one plus one greater than The effect of two, promote the development of related industries and disciplines. Artificial intelligence technology has It is widely used in all aspects of society. In the current background of rapid economic development and Under the reforming and opening environment, only artificial intelligence technology that suits our national conditions is long For a long time, it will promote the sustainable development of science and technology, sustainable development, sound and rapid development Exhibition. Based on the current situation of laboratory management, this paper mainly studies the application of artificial intelligence technology In the laboratory management of advantages, the main technology, in order to improve and develop artificial intelligence The application of technology in laboratory management is even popularized in the whole society.

2. Methods.

2.1. Laboratory management model based on management process . With the development of the Internet, the information collected in the Internet is timely Feedback to the lab's network platform, through cloud computing and analytics technology, the information Processing, compare the camera data and cloud computing database, handle Cloud computing results, realize the automation of laboratory management, intelligent. The laboratory serves teaching and research work, and its management objects include people, events, materials, information, funds, etc. It involves all activities of laboratory application, construction, and experimental teaching, mainly including: Laboratory construction planning and setup, laboratory management mode and operating mechanism, configuration and use of laboratory instruments and equipment, management of experimental materials and low value consumables, basic laboratory information management and archive management, construction and training of experimental teaching teams, management of experimental teaching and scientific research, and use and inspection of laboratory funds. It can be seen that laboratory management is relatively complex and involves many aspects, but these tasks can be subdivided into specific tasks, from a specific project perspective, the basic model of management work is shown in Figure 2.1 [5].

As can be seen from Figure 2.1, no matter how much management content there is, for a specific project management work, it can be summarized into two steps: "selection" and "action"; "Select" refers to selecting management content, and "Action" refers to generating management results such as reports and emails after appropriate processing. "The operation of selecting management content is actually to limit the content to meet certain requirements, such as when an experimental teacher conducts experimental course management, according to the selected experiment 1 score of 80 or more, moreover, with a theoretical course score of 80 or above and not being a make-up or re major student, the designated students are selected and selected for elective experimental courses. This process is limited to specific experimental objects and can include multiple conditions, the subdivision model is shown in Figure 2.2 [6].

As can be seen from Figure 2.2, through the logical combination of multiple conditions, you can select a management object and then perform corresponding "actions" on the object, "selection" is the basis, and

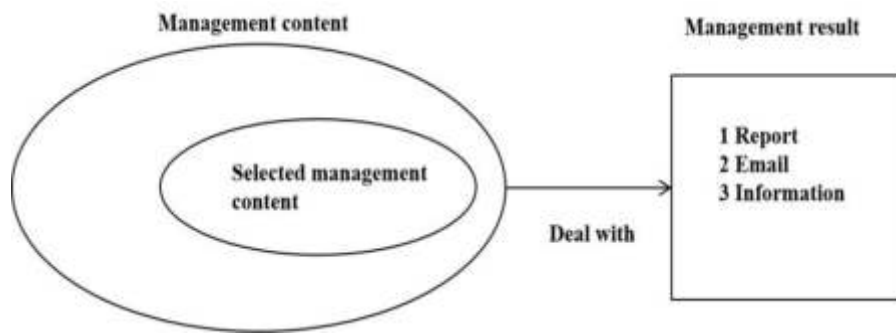

Fig. 2.1: Basic model of laboratory management

Fig. 2.2: Selection Management Content Segmentation Model

”Action” is the operation based on actual needs. ”Selection” is mainly based on various data sources [7].

2.2. Data-driven laboratory intelligent management platform framework . The project function of laboratory management system based on artificial intelligence technology It mainly includes the following: (1) Facial recognition personnel ID and automatic registration information. (2) Intelligent power distribution function. (3) Remote communication.

Facial recognition personnel ID through the facial features collection and recognition function of electronic eye technology, can identify every A person enters the lab, the electronic eye recognizes facial information and sends a message Information processing and existing database for information comparison, record visitor information, to achieve paperless facial registration.

The power distribution function of intelligent system refers to the use of mature solar energy, wind energy and so on Electric technology, to achieve the continuous circulation of laboratory electricity, will not accidentally cut off the movie The development of laboratory work, when the power supply is insufficient, the intelligent system will automatically lift At the same time, through solar and wind power generation technology to achieve the laboratory electricity reserves,

To achieve continuous uninterrupted laboratory power supply effect. Another way of telecommunication That is, the manager of the laboratory can observe the reality through the intelligent monitoring camera Laboratory conditions, improve the observation times, increase the observation duration, in order to timely understand the laboratory The latest internal dynamics, flexible handling of various laboratory situations.

According to the laboratory management model, in order to implement the ”select” action, it is necessary to make reasonable use of data to formulate rules, but the specific requirements for each management role may vary, rule making is also different, for experimental teachers, experimental technology, and system managers, their management processes are shown in Figure 2.3 [8,9].

The laboratory management platform is divided into a front-end and a back-end, the front-end uses Web pages for user operations, and the back-end uses logical computing for front-end display. Logic and data support. For a data-driven laboratory management platform, the front-end is used by business personnel in business

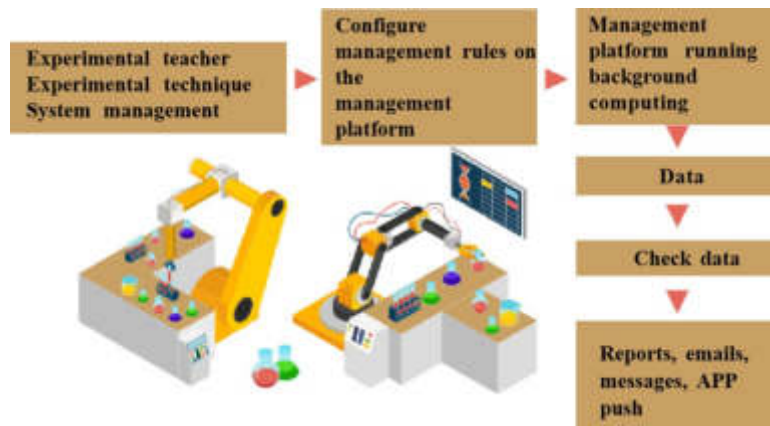

Fig. 2.3: Data-driven laboratory intelligent management process

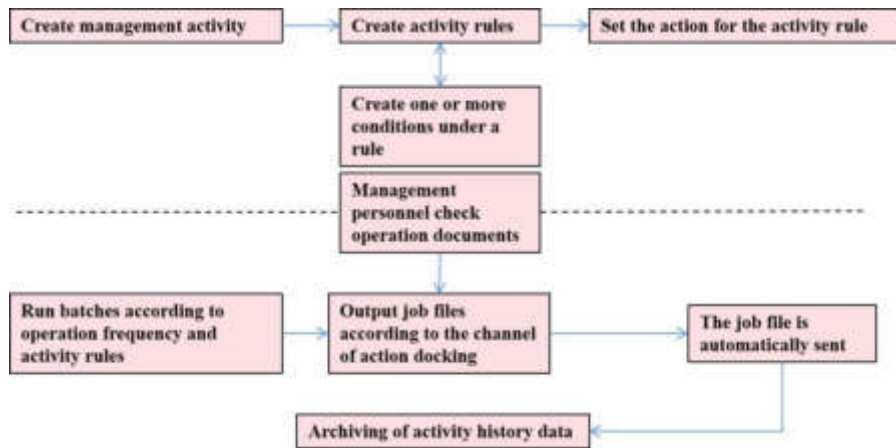

Fig. 2.4: Logical architecture of data-driven laboratory intelligent management platform

departments, such as laboratory teachers and laboratory technicians; The responsible person for the backend is the data engineer and system development engineer in the IT department. According to the laboratory management model, the logical framework of a data-driven laboratory intelligent management platform is shown in Figure 2.4 [10].

Managers log on to the management platform, first create a new laboratory management, set information such as the management name, responsible person, time range, and running frequency, and then create one or more rules under this laboratory management, create different combinations of conditions under each rule, and finally set an action for the created rule. This completes a basic data-driven laboratory management configuration [11].

2.3. Implementation of Lab Intelligent Management Platform Based on Label System . In order to achieve intelligent management on the above management platform, another important step is to set the conditions of activity rules, we use the label system to implement labels, which refer to data labels, which describe entity attributes, the value of the label marks a piece of information about the entity, for example, for a student, "gender" is a label, and "male" is the value of this label, which marks the gender information of the student. The label system is a collection of labels that are calculated and stored according to certain rules, it performs class management on labels according to established logic, and calculates and updates label values

Table 2.1: Various laboratory data labels

Label Theme	Base Label	Behavior label	Titles
Experi- -mental Courses	Name, course, type (course experiment, open experiment, online experiment), experiment content, goal, first opening time, responsible person	Last Opening Time, Last Opening Number, Hours Opened this Month, Hours Opened this Month, Hours Opened this Semester, number of Users this Semester	The number of days since the first opening, cumulative open class hours, cumulative number of open students, and cumulative extracurricular open class hours
Experimental equipment	Name, manufacturer, production date, price, first use time, storage location, responsible person	Last usage time, last usage time, usage time of this month, usage time of this semester, last maintenance time, performance status	Cumulative usage time, cumulative usage times, open usage times, loan times
Experimental site	Site name and size. Number of work stations, first use time, number of storage equipment, responsible person	Last usage time, last usage time, usage time of this month, usage time of this semester, power consumption data, monitoring access control	Cumulative usage time, cumulative usage times, open usage times
student	Name, date of birth, class, mobile phone number, email address, start date of experiment	Last experiment time, last experiment content, last experiment result, number of experiments this month, content of experiments this semester	Cumulative number of experiments, cumulative experimental hours, in class experimental hours, open experimental hours
teacher	Name, unit, personnel type (full-time teacher, part-time technician), mobile phone number, email address, start of experimental course, time of first course opening	Last experiment time, last experiment content, last number of experiments this month, content of experiments this month, number of experiments this semester	Cumulative number of experiments, cumulative experimental hours, in class experimental hours, open experimental hours

according to rules, data access issues are resolved through pre calculated tags, reducing the threshold for data usage [12,13].

(1) *Laboratory Data Label System*. The label system is a collection of a series of labels, which can be divided into experimental courses, experimental equipment, venues, students, teachers, administrators, and other topics, these topics are divided into basic tags, behavior tags, and derived tags by data update method, as shown in Table 2.1 [14].

As can be seen from Table 2.1, label topics are divided into basic labels, behavior labels, and derived class labels. The value of the base tag is generally fixed or has a long update cycle, incremental updates are used

Table 2.2: Mapping Table of Label System Hierarchy and Data Backend

Hierarchical structure	Relational database	HBase
Label Theme	Schema	Table Name
Label Type	Table Name	Clan name
label	Column Name	Column Name

to refresh the tag value, updating only tags with changed values each time or inserting newly added customer base tags; The behavior tag is used to describe historical behavior, which is always in change, and adopts periodic full volume updates or real-time (message queue+stream processing) fixed point updates; Derived class tags are logical combinations between other tags, they do not store tag values themselves, but rather store computational logic between tags, the tag value is calculated in real time only when called, which is a special dynamic tag. In this way, experimental data can be converted into label data, and the label system, like the management system, should also be divided into two parts: The front end and the back end [15].

The label administrator uses the front end (management) page of the label system, configure the mapping relationship between the label and the data background, the configuration information is stored in the label mapping Table, after the label user enters query criteria on the front-end (query) page of the label system, the system first locates the physical location of the label through the label mapping Table, then, the corresponding label value is read from the label data background and returned to the page side for display, the label mapping Table is associated with the front-end and back-end of the label system, it stores all attributes in the label system except for the label value, including all description information about the label hierarchy, the backend of the system stores the values of all labels, which are stored through relational database tables or HBase Tables, the label mapping table is shown in Table 2.2, the values of the corresponding labels can be intelligently located based on the information sequence stored in the label mapping Table [16].

(2) *Labelled Laboratory Evaluation GBDT Model.* In the actual management processes such as laboratory construction demonstration, course effectiveness evaluation, and laboratory benefit evaluation, how to effectively use data pairs for scoring and evaluation is a matter of great concern to all parties, the author adopts GBDT (GradientBoosting Decision Tree) regression algorithm to model the previous experimental data. However, in the GBDT modeling phase, a large amount of computation is required, so the modeling process is completed in the back-end through offline computation, and the established GBDT model is converted into tags for online use. Taking the benefit evaluation of a new laboratory as an example, in the GBDT modeling stage, based on the previously stored student experimental data, performance, equipment purchase prices and updates, equipment usage data, laboratory electricity, access control, and other data, models such as in-class experiment scores, open experiment scores, equipment usage benefit scores, equipment sharing scores, equipment depreciation rate scores, and site operation efficiency scores are established on the server backend, store these models as label data. When evaluating the benefits of a new laboratory, call these models on the Web side and input the application data for the new laboratory, the corresponding score can be quickly obtained for reference by the evaluation experts. The laboratory evaluation is implemented using the GBDT algorithm, with historical experimental data as training data, after training using the GBDT algorithm, the model functions are stored as tags for online invocation [17].

3. Management process example based on label system. The laboratory intelligent management platform implements laboratory management through configuration management rules. The following is an example of pushing selected experiments to outstanding students to illustrate the management process based on the label system, the corresponding table of conditions and labels for this management activity is shown in Table 3.1.

In order to configure this rule, managers need to add the three tags in Table 3.1: iEX_Score iTH_Score BRE_EXA sets the corresponding conditions and connects with AND, you can manually edit logical relationships to make adjustments, Table 4 and Table 5 show the key page for rule settings. It can be seen that the label system needs to provide as many public labels as possible to meet as many rule (condition) setting requirements as possible. Once a label user discovers that a label required by the condition does not exist, they

Table 3.1: Condition and Label Correspondence Table

Condition	Corresponding label name	Conditions after converting to labels
Experiment 1 with a score of 80 or above	Experiment 1 Score (EX_Score)	iEX_Score>=80
Theoretical course score above 80 points	Theoretical Course Score (iTH_Score)	iTH_Score>=80
Not a retake student	Makeup Exam (bRE_EXA)	bRE_EXA("TRUE")

Table 3.2: Label Settings

Label Name	Tag ID	Label Value Type	Subject	Label Type
Experiment 1 Score	35	Integer	student	Behavior label
Theoretical Course Score	36	Integer	student	Base label
A make-up exam	37	BOOL	student	Base label

Table 3.3: Selected Conditions for Management Platform Rules

Condition 1	Experiment 1 Score	>=	80	Delete this condition
Condition 2	Theoretica Course Score	>=	80	Delete this condition
Condition 3	A make-up exam	==	TRUE	Delete this condition

need to submit a new label request to the label manager, after the label manager adds the new label to the label system, the label user can see and use the label on the above page of the management platform [18].

When the rule setting page is submitted, the logical relationship corresponding to the rule is saved to the background database, the tag is stored in the form of a tag ID, which allows you to further find the fact Table where the tag is located and obtain the corresponding tag value. If the final logical relationship value is true, it indicates that the student meets the rule; If the result is false, it indicates that the customer does not meet the rule, so the optional experiment is not recommended. The Run Frequency option in the interface is "Every day", which refers to the logical combination of the rules converted into conditions through the page, parse the conditions into SQL statements, perform batch processing in the background, and store the results in a result Table, the subsequent management action stage will produce different formats of job files, or production reports or email job files based on the result Table. In addition to batch processing, you can also choose scenario based management, and management activities can be processed in real-time based on scenarios, for example, after a student has completed Experiment 1 and received a system evaluation score of 80 or more, they can be directly recommended for the experiment. This requires changing batch processing to "real-time processing", the management process is actually consistent, and only technically requires the introduction of "message queues" to complete management based on these messages [19,20].

4. Conclusion. The development of intelligent technology has for the development of our society It plays an important role in applying artificial intelligence technology to laboratory management Now the trend of intelligent and automatic laboratory management. Artificial intelligence technology should Used in laboratory management work, such as facial recognition personnel ID, automatic registration letter The intelligent power distribution function ensures sufficient power supply to the laboratory and prevents accidental breaks The uncontrollable loss caused by electrical accidents can be realized by the remote communication technology of artificial intelligence Laboratory management personnel remotely monitor the internal conditions of the laboratory to find laboratory differences in time Often, take timely measures to nip in the bud. Applying artificial intelligence technology to the real world The development process of laboratory management is not smooth sailing, nor can it be accomplished overnight Need us to give full play to their own subjective initiative, actively contribute to daily life From quantity to quality, the innovation in our science and technology development

and social progress Make contributions and strive to realize the great Chinese Dream. Structured data brings value, and data brings new ideas, with the application of new devices and the Internet of Things in laboratories, there are more and more sources of experimental related data, and more and more management bases are available. Based on the reality of laboratory management, the author studied a laboratory management model. Using a label system to classify and store laboratory data and laboratory evaluation GBDT and other algorithmic models, an intelligent laboratory management platform based on the label system is constructed, realizing batch processing and scenario based laboratory management, the intelligent management platform has strong scalability and can play a role in the entire life cycle of the laboratory.

A MACHINE INTELLIGENCE EVALUATION SYSTEM BASED ON INTERNET AUTOMATION TECHNOLOGY AND DEEP LEARNING

HONGCHUAN LIU*

Abstract. To realize the machine intelligence evaluation system, a method based on Internet automation technology is proposed. Firstly, then extracted and optimized, and finally combined with each other. A BP neural machine evaluation system is designed to compare the results of machine evaluation with the average value of teachers' independent evaluation by selecting 20 students' test paper translation samples from a class randomly. The test results show that by selecting a random class of 20 students, the comparison of machine evaluation results and teacher independent evaluation shows that the error range of the evaluation results of 20 samples is -5.6% -6.7%, which is within the allowable range of translation evaluation and meets the requirements of teaching evaluation. It is proved that the Chinese-English machine translation evaluation system based on Internet automation technology has excellent performance, which can improve the reliability and accuracy of the evaluation and reduce the degree of human intervention and misjudgment rate of the Chinese translation evaluation.

Key words: Internet, automation, evaluation system, translation, misjudgment rate, Intelligent evaluation system

1. Introduction. Intelligent characteristics are one of the important characteristics of intelligent systems. Qualitative evaluation of the intelligent characteristics of intelligent systems is a challenge and a new issue. Because, firstly, people's definition of the concept of intelligent characteristics itself is not clear enough. Secondly, the evaluation of intelligent characteristics is related to the environment, era, and conditions. Therefore, this evaluation has relativity, correlation, and time effects. In addition, there is very little specialized research and communication on this evaluation. And the theory and application of intelligent control continue to develop. It is necessary to conduct specialized research on the evaluation of intelligent characteristics in a timely manner, as various products and systems with the term "intelligent" are constantly entering the market. This is not only an academic need, but also an application need. Intelligent system is a system with anthropomorphic intelligence. anthropomorphic intelligence is the intelligent characteristic of simulating, extending and expanding human. Such as: self-learning, self-adaptation, self-organization, self-optimization, self-stabilization, self-identification, white planning, self-coordination, self-repair, self-reproduction, etc. Because the intelligence of human body control system is multi-level and multi-faceted, the intelligence of anthropomorphic system is also divided into different levels and different aspects such as high level, middle level and basic level. In order to realize the intelligent characteristics in the system, the commonly used intelligent methods include expert system, artificial neural network, fuzzy control and so on. With the development of the Internet and the advent of the era of economic globalization, the need to overcome language barriers and realize free communication across languages has become increasingly prominent [1]. The language barrier severely restricts the breadth, depth and speed that most users can obtain information from the Internet [2]. However, the development of advanced machine translation technology and the realization of large-scale application of machine translation products pose new challenges to the machine translation technology.

With the increasing progress and development of modern science and technology such as "Internet +" and artificial intelligence, people's work, study and life have been closely related to the modern information technology, and people rely on intelligent technology and tools increasingly [3]. Computer-aided translation means that translators can improve translation efficiency and control translation costs effectively by scientifically selecting language translation tools based on Internet, artificial intelligence and big data technologies. The computer translation technology emerged at the end of the 20th century, providing a technical support for

*School of cultural communication, Institute of disaster prevention, Langfang, Hebei, 065201, China (HongchuanLiu5@163.com)

people's scientific research activities, work and life, and promoting the cross-language communication [4,5].

In foreign countries, the research on this technique can only provide some reference for translators. Due to the limitation of the algorithm level, early computer translation is difficult to form a smooth and reasonable translation text. In the context of the rapid development of the Internet, big data and artificial intelligence provide strong support for the development of this technology and promote CAT technology to achieve great progress. Many translation websites and platforms based on CAT technology provide convenience for translators and relieve the pressure of translation work. CAT technology has been further developed with the help of translation memory libraries. Based on a brief review of the history of machine translation, the research discusses the existing methods of machine translation, and then discusses the challenges and technical routes of Internet machine translation.

2. Literature Review. Broadly speaking, machine translation involves all aspects of natural language processing technology, and almost all the research results of natural language processing can be directly or indirectly applied to machine translation. In a narrow sense, machine translation methods can generally be divided into three categories: rule-based machine translation, case-based machine translation and statistical machine translation, of which the latter two methods can be collectively referred to as corp-based methods [6]. The rule-based translation approach, which holds that the process of translation needs to analyze the source language and express the meaning of the source language, and then regenerate into an equivalent target language, has been dominant in the field of machine translation from the mid-1970s to the late 1980s. A large-scale rule-based commercial machine translation system should not only solve the problem of machine translation methodology, but also organize the system from the perspective of knowledge engineering and software engineering, in which the rules are often multi-level and fine-grained. The refinement of rule level and knowledge granularity can control the interaction and conflict between rules effectively, and make the rule system have good expansibility.

The essence of case-based machine translation is "machine translation based on translation instance and similarity principle". Translation instances can be stored in their natural form without any processing, or they can be represented in a completely structured form. Recent researches show that semi-structured translation instance representation approaches strike a good balance between the difficulty of preprocessing translation instances, the temporal and spatial efficiency of translation and the quality of translation. Another on the principle is very similar with case-based machine translation technology is translation memory, which is a computer-aided. It is a kind of auxiliary translation in essence. It retrieves similar translation instances from the instance library and submits them to users in a friendly form, thus achieving the purpose of assisting users in translation [7]. In recent years, translation memory technology is increasingly integrating various automatic translation technologies [8]. Statistical machine translation is also based on bilingual corpus, but unlike the case-based method, which directly uses translation examples in the translation process. Statistical method abstracts the translation knowledge implied in bilingual corpus into statistical model through prior training process. The translation process is usually a decoding process based on these statistical models. Statistical models used in statistical machine translation usually include translation model and language model [9]. Compared with language model and decoding, translation model is currently the most involved content in statistical machine translation research [10]. Generally, translation models can be divided into three types: word-based model, phrase-based model and grammar-based model. At present, phrase-based and grammar-based models have significantly better performance than word-based models. Although statistical methods are valued for their good mathematical model, unguided learning ability and robustness, rule methods are also valuable for their good generalization and description of language rules and instance methods for the accurate translation of similar sentences. In fact, the combination of multiple methods is becoming an important direction in the development of machine translation, such as the combination of rules and statistical methods, case-based methods and statistical methods, phrase-based and syntactic statistical translation methods.

On the basis of the current research, a machine translation evaluation system for TCSL based on Internet automation technology is proposed in the research. Firstly, then extracted and optimized, and finally combined with each other. A BP neural machine evaluation system is designed to compare the results of machine evaluation with the average value of teachers' independent evaluation by selecting 20 students' test paper translation samples from a class randomly. The test results show that by selecting a random class of 20 students,

Table 3.1: Description of statement set information

The statement text	Number of translation	Number of statement text	Scores range	Number of sentence patterns
1	1650	10	0-3	8
2	1825	10	0-3	8
3	1756	6	0-3	4
4	1622	6	0-3	4

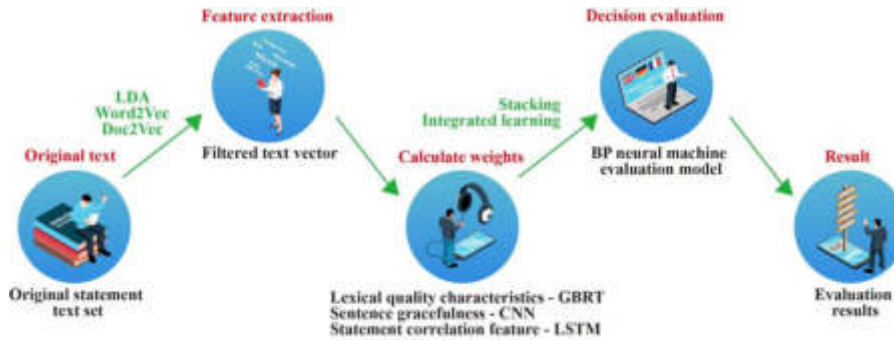

Fig. 3.1: Basic framework of ETSS system (high-end)

the comparison of machine evaluation results and teacher independent evaluation shows that the error range of the evaluation results of 20 samples is -5.6% -6.7%, which is within the allowable range of translation evaluation and meets the requirements of teaching evaluation.

3. Research Methods.

3.1. The development and design of ETSS system. In the research, the Chinese translation texts of the university Chinese (1-4) courses of a university in 2019 are selected. The sentence translation texts include the sub-texts of the four courses, with a corresponding number of translation sentences [10, 10, 6, 6]. More than one thousand students answer the translation sentences under each sub-text, and the score of each sentence ranges from 0 to 3. The details are shown in Table 3.1.

3.1.1. Basic system framework. The basic framework of ETSS(English Translation Scoring System) is shown in Figure 3.1. The main functions of the system are divided into three core modules: text feature extraction, weight calculation and decision evaluation [11]. System uses the annotated corpus, i.e., nearly 8 years of text translation for libraries of a university, as well as Chinese corpus, structures, vocabulary quality evaluation model, the beautiful statement and statement relevance evaluation model, evaluation model. Then the input text sets are evaluated separately, and then integrated with BP neural machine model for comprehensive evaluation [12].

3.1.2. Extraction of ETSS feature vectors. Figure 3.1 shows the ETSS feature text library [13]. As can be seen from the system structure diagram in Figure 3.1, the text library W of ETSS system needs to establish the text library h [T] for vocabulary quality evaluation, the text library g [T] for sentence elegance evaluation and the text library l [T] for sentence relevance evaluation. According to the comprehensive summary, the basic characteristics of sentence text judgment include 11 items, such as word accuracy, average word length, number of high-frequency words, number of advanced words, proportion of nouns, adjectives or verbs, number of connectives, number of word blocks, advanced sentence patterns, specialty of key words, word granularity and sentence granularity, etc [14]. There is a progressive relationship between different levels of the system, so the system database design first needs to analyze and integrate different types of text data, and obtain the text feature vector. In order to extract feature vectors quickly, the extraction standards and numbers are

Table 3.2: The feature text database W [i] of ETSS system

The text library	Number	Features	Feature description	Specificity	Weight
h [T] for vocabulary quality evaluation	T_1	Word accuracy	The proportion of words that are spelled correctly	0% ~ 100%	X_1
	T_2	Average word length	Obtained by median or standard deviation	2-20	X_2
	T_3	Number of high-frequency words	Commonly used unmarked words	1 ~ 8	X_3
	T_4	Number of advanced words	Commonly used marker words	1 ~ 5	X_4
	T_5	The proportion of nouns, adjectives and verbs	Average the proportion of the number of words in different parts of speech	0 ~ 100%	X_5
g [T] for sentence elegance evaluation	T_6	Number of connectives cause and effect	Including phrases such as turning point, juxtaposition, choice,	1 ~ 3	X_6
	T_7	Number of word blocks	Including phrasal verbs, prepositional phrases, adverb phrases, adjective phrases and so on	1 ~ 5	X_7
	T_8	Advanced sentence patterns	Including emphasis sentences, clauses, inversion sentences, hypothetical sentences and so on	Y/N	X_8
	T_9	Specialty of key words	The rank of key words in the reference answer	1 ~ 5	X_9
l [T] for sentence relevance evaluation	T_{10}	Word granularity	Describe the relatedness characteristics of words	0 ~ 100%	X_{10}
	T_{11}	Specialty Sentence granularity	Describe the semantic dispersion characteristics of statements	0 ~ 100%	X_{11}

formulated specially, as shown in Table 3.2. In order to ensure that the system data query, modification and update can be saved in advance, it is necessary to adjust the text library system, which is not only conducive to data management, but also convenient for the system to modify the stored procedure of the required data according to the actual demand, and improve the portability of the system source code [15].

After the establishment of ETSS system feature text database W [i], the filtering extraction method of

selected text features is studied. Word2Vec tool model and K-means clustering method are used to filter and extract the word quality features (T1-T5). According to the text library h [T], the text is mapped from the statement text to the feature vector of fixed dimensions, and the text words are encoded. The feature degree and feature base weight are obtained according to the feature description of the text base [16,17]. The feature base weights obtained through experiments (X1~ X5) can be adjusted by modifying the feature degree in practical application to actively adapt to Chinese translated texts of different stages and difficulties. The research is also applicable to the calculation of other weights or weight coefficients later [18,19].

Extraction of feature vectors of sentence elegance is as follows [20]. Elegant Chinese sentences need to integrate advanced lexical blocks, sentence patterns and ingenious rhetorical devices. The identification of elegant Chinese sentences can also be treated as a text classification problem. Doc2Vec tool is used to filter and obtain the text feature information, and then the feature of sentence elegance (T6-T7) is filtered and extracted. According to the text library g [T], the feature base weight (x6-x8) is obtained from the given text label classification training. Due to the influence of language features, cultural background, oral expression and other factors, the feature and degree of sentence elegance are difficult to grasp. Convolutional neural network CNN can be used for modeling feature extraction, and its advantage lies in automatic feature selection and combination, which is used in the subsequent text elegance evaluation in the research [21].

Extraction of sentence relevance feature vectors is as follows. The judgment of sentence relevance is subjective and difficult to be judged by machine, which requires the integration of meaning, sentence meaning and vocabulary. Therefore, the judgment of Chinese sentence relevance needs to combine the above extraction features to comprehensively analyze word granularity, sentence granularity and sentence theme. Here, LDA model is used to read text feature information, and then sentence relevance features (T9-T11) are extracted. According to the text library L [T], subject probability distribution of text is obtained through Bayesian network learning and training, and then feature base weight (x9-x11) is obtained [22].

3.1.3. Feature extraction algorithm. The symbol used to identify or distinguish text is feature. In the research, VSM method of vector space model is used to filter and extract feature information in text. A feature vector is used to represent a Chinese sentence text, which consists of feature terms and weights. The feature vector extracted from the text directly represents the original text, and the extracted optimized feature vector is one of the key factors affecting the results of system evaluation [23]. In VSM model, Chinese text uses space vector $(T_1, X_1; T_2, X_2; \dots; T_j, X_j)$. T_j is the feature item, and X_j is the corresponding basic weight of the feature item, which is used to define the importance of the feature item in the description statement text. In order to improve the accuracy and speed of feature item acquisition, Doc2Vec method, NLTK and StanfordParser toolkit are used for text filtering and extraction processing (including counting, part of speech tagging, average, local maximum and minimum, word frequency weighting, position weighting, syntax analysis, etc.). The text encoding and text feature degree are obtained [24].

Feature vector filtering and extraction methods: Text vector features are obtained through Doc2Vec text parsing. Feature details are obtained through NLTK and Stanford Parser tool package sampling. The second level decomposition is the same, with more detailed space division. It can not only rely on one filtering to extract degree of text feature. And filtering should be continuously repeated several times in order to avoid misoperation accident conditions. By using the wavelet transform and short time Fourier analysis mathematical tools, sentence text features are processed again. Equation 3.1 is used to obtain the square mean root value of the feature degree in the i th time window at the j node, which can achieve better feature discrimination effect [25].

$$X_{j,i} = \left(\frac{1}{N} \sum_{n=1}^N K_{j,n}^2 \right)^{\frac{1}{2}} \quad (3.1)$$

In Equation 3.1, $X_{j,i}$ is the square mean root value of the feature degree in the i th time window at the j node. $K_{j,n}$ is the n th coefficient at the j node. N is the total number of coefficients of j node.

In order to judge the weight of feature degree, the basic assignment table corresponding to feature degree of Chinese sentences is first established, as shown in Table 3.3. Then, based on Chinese sentence rules and translation characteristics, a simulation model of feature weight assignment is established, as shown in Equation

Table 3.3: Chinese sentence feature assignment

Feature	Assignment x				
	1	1.5	2	2.5	3
T_j	1	1.5	2	2.5	3
T_1	10%~20%	21%~40%	41%~60%	61%~80%	81%~100%
T_2	2~5	17~20	6~8	14~16	9~13
T_3	1	2	3~4	7~8	5~6
T_4	1	2	3	5	4
T_5	1%~10% or 91%~100%	11%~30%	31%~50%	51%~70%	71%~90%
T_6	1	-	2	-	3
T_7	1	2	3	4	5
T_8	N	-	-	-	Y
T_9	5	4	3	2	1
T_{10}	10%~20%	21%~40%	41%~60%	61%~80%	81%~100%
T_{11}	10%~20%	21%~40%	41%~60%	61%~80%	81%~100%

3.2. The maximum and minimum values of feature weights are obtained by using reference answers and random answers of translation sentences, and the coefficient changes after wavelet transform are used as the basis of the model. Taking the 5-layer wavelet packet decomposition method as an example, the node importance ratio λ is used, and the ratio of importance between 2 to 5 nodes and the importance of 1 node in Equation 3.3 is taken as the effective weight of feature quantity. The threshold value is set as 0.025, and 11 feature degrees are calculated continuously. In a preset period, the weight of feature quantity is obtained through this simulation model.

$$\frac{1}{g} \frac{dg}{dt} = \frac{1}{\tau} \left(\frac{x_j^2}{x_c^2} - 1 \right) \quad (3.2)$$

$$\lambda_{j,i} = \frac{E}{E_1} = \frac{\sum_{r=2}^{r=j} \sum |u_r(n)|^2}{\sum |u_1(n)|^2} \quad (3.3)$$

In Equation 3.2 and 3.3, g is the derivative value of the characteristic quantity. τ is a time constant; x_j is base weight assignment. x_c is weight assignment coefficient. $\lambda_{j,i}$ is the weight of feature quantity. E is the sum of importance between node 2 and node 5. E_1 is the importance of 1 node. $u_1(n)$ is the reconstruction coefficient of 1 node. $u_r(n)$ is reconstruction coefficient of r node.

3.2. Application of ETSS system.

3.2.1. Comprehensive evaluation of sentence text. The previously extracted sentence text feature vectors are then input into the trained BP neural machine evaluation model for interactive fusion promotion regression verification after stacking learning by sentence vocabulary quality evaluation model GBRT, sentence elegance evaluation model CNN and sentence relevance evaluation model LSTM, respectively. The final score of the sentence text is obtained, and the process of comprehensive evaluation is shown in Figure 3.2.

3.2.2. BP neural machine evaluation method. The proposed ETSS system is based on BP neural network algorithm and machine learning to automatically judge the results of Chinese sentence translation. This evaluation method can consider the language factors of Chinese sentences and judge the correctness of sentence translation relatively accurately. ETSS system introduces the translation result evaluation into BP neural machine algorithm to ensure that input vector and output vector meet nonlinear mapping, which can greatly improve the accuracy of system evaluation results. Based on the above simulation model of feature weight assignment, the weight of feature quantity and the weight coefficient, which affect the translation quality, are regarded as the input layer of BP neural machine, and the output layer of BP neural machine is the judgment value of the system after the decomposition of 5-layer wavelet packet and the calculation of 312 subdivision consecutively within one period.

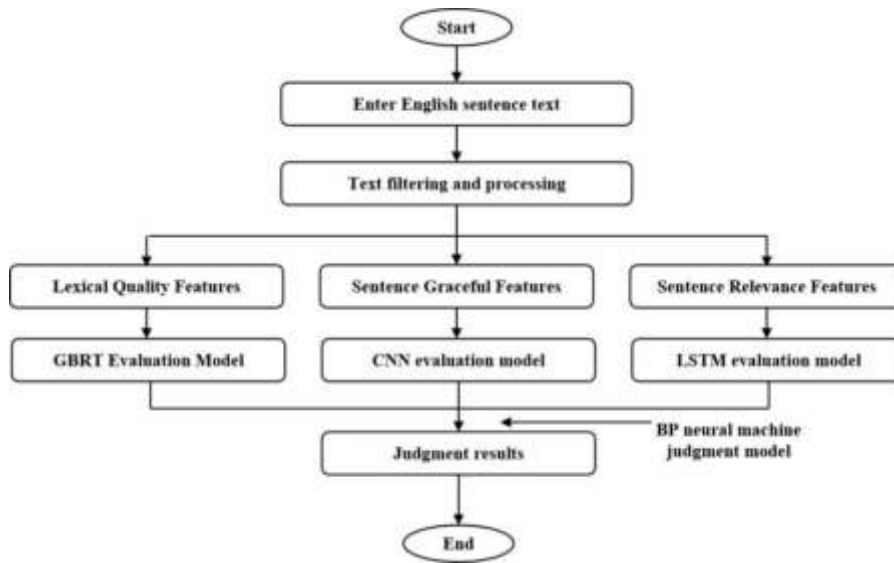

Fig. 3.2: Flow chart of comprehensive evaluation

4. Result Analysis. In the research, the English-Chinese translation questions of the final examination of College Chinese courses in a certain university are selected as the evaluation sample, and the score features, feature degree and feature assignment of English-Chinese translation questions are integrated and provided to the examination evaluation team members for understanding and familiarity. Experts in the field of Chinese translation and linguistics are invited to form an evaluation team, and the feature base assignment x is given according to the text features and feature degree, as shown in Table 4.1. And the feature assignment coefficient xc is given according to the features and difficulty of the actual translation topics. Through MAT-LAB software input Equation 3.1-3.3 and text feature weight, machine learning is carried out in a preset period to obtain the evaluation score ix . BP neural machine algorithm can carry out self-diagnosis and detection, and finally modify machine learning according to the evaluation results and manual correction, so as to meet the needs of teaching effect evaluation. If the error of the output result is less than the set , or the number of training learning exceeds the set maximum, the algorithm ends and starts the next text automatically. If the criteria are not met, the retraining is required from Equation 3.1. The software operation rules are as follows:

Output001: IF(results fit well);
 THEN(go to the next text to learn);
 Output002: IF(result coincidence is general);
 THEN(adjust the weight assignment coefficient);
 Output003: IF(the result is relatively poor);
 THEN(returns to the previous stage to adjust the feature degree and base weight assignment).

The operation of the BP neural machine learning rules mentioned above should also be based on the classification of Chinese course translation. With the help of this system, translation evaluation teachers set evaluation criteria of different levels according to the difficulty of Chinese translation at different stages of university, so as to meet the ultimate goal of examination scoring. Figure 4.1 shows the results of a specific example. By selecting test paper translation samples of 20 students in a class randomly, the comparison between the machine evaluation results and the average value of teachers' independent evaluation shows that the error range of the evaluation results of the 20 samples is -5.6%-6.7%, which is within the allowed range of translation evaluation and meets the requirements of teaching evaluation.

5. Conclusion. In the research, an automatic judgment algorithm for Chinese sentence text was proposed. The algorithm first splits and filters sentences, then extracts and optimizes them, and finally combines them

Fig. 4.1: Comparison of evaluation results

with each other. The recognition and extraction of text feature vectors, as well as the fusion and interaction of feature weights, play a crucial role in determining the correctness of the results. A basic framework for evaluating Chinese sentence translation has been designed. By comparing the results of machine validation and manual evaluation, the ETSS system has excellent performance and high evaluation reliability and accuracy. Developed a BP neural machine evaluation model, completed automatic processing of natural language and evaluation of Chinese translated sentences. By selecting test paper translation samples of 20 students in a class randomly, the comparison between the machine evaluation results and the average value of teachers' independent evaluation shows that the error range of the evaluation results of the 20 samples is -5.6%-6.7%, which is within the allowed range of translation evaluation and meets the requirements of teaching evaluation. Artificial intelligence and computer technology have promoted the development of intelligent assisted teaching methods, reducing human intervention in Chinese translation evaluation.

This article has achieved certain results in the above aspects, but there are still many shortcomings. The main problem is the quantity and quality of user feedback. It is difficult to collect large-scale user feedback in laboratory environments. At the same time, there is a large amount of noise in user feedback. This article uses corresponding quality control strategies to remove some of the noise. However, overall, larger scale user feedback experiments are needed to further confirm the experimental conclusions of this article. At the same time, there are still shortcomings in the noise processing work of this article.

In future research work, we should explore using large-scale user feedback data to confirm the conclusions of this article. The work of this article reveals the contribution of several user behavior features to automatic translation evaluation, and the processing and utilization of overall user feedback information is still quite limited. Therefore, future work should explore more diverse user behavior features and other feature selection and fusion methods on this basis for automatic translation evaluation.

RESEARCH ON INTELLIGENT BUILDING INTEGRATED CABLING SYSTEM BASED ON INTERNET OF THINGS AND DEEP LEARNING

RONG ZHOU*

Abstract. In order to solve the problem that the traditional integrated wiring system has many inconveniences in management, which affects the stability and efficient operation of the entire system, an intelligent building energy management control system in the Internet of Things era is proposed. In terms of hardware, design intelligent building switches, and in terms of software, plan the IP address of intelligent building wiring based on the Internet of Things, formulate comprehensive backbone wiring layout structure of intelligent building, set up auxiliary power distribution horizontal lines, and connect intelligent building wiring data, so as to realize intelligent building integrated wiring. On this basis, the architecture design of the wiring assistant design system is carried out, and the artificial intelligence building integrated wiring assistant system is realized with the help of the Net platform, and the system test is carried out. The experimental results show that the PM10 concentration parameters and the energy consumption simulation curve are highly consistent with the actual value curve. According to the calculation of the data volume points, the coincidence degrees can reach 96.4% and 98.9%, respectively. The experimental results show that the designed wiring system is superior to the traditional wiring system in terms of energy saving, and has certain reference value.

Key words: IoT technology, intelligent building, system integration, artificial intelligence, general wiring

1. Introduction. Cabling system refers to the network transmission, design time Attention should be paid to the connection of various devices, including voice, data processing equipment. Adopt An integrated wiring system, which connects equipment to the interior and exterior of the same building, is The general idea of the current design. The Internet of Things and digital technologies are developing rapidly in the current environment. In the good state of the momentum of the Internet of things, the modern construction industry is also gradually inclined to intelligent development. Simply put, intelligent building is a combination of information technology and modern building technology, with a new way of display to provide a service platform, so that people become more comfortable in the use of the process, instead of the traditional method, so that the display is more comprehensive. Following the emergence of computer, Internet and mobile communication network information control technology, the rise and development of Internet of Things technology has promoted the third scientific and technological revolution, which is also an important part of information technology under the new situation [1]. One after another, all parts of the world have taken the lead in launching research plans for the strategic development of the Internet of Things. Under the influence of the global Internet of Things trend, the Internet of Things was written into the Chinese government work report for the first time in 2010, and it was officially listed as one of the five emerging development strategies of the country, and was given a high degree of attention and policy support [2,3]. In recent years, the Internet of Things technology has gradually become a new hot spot for development, and it also presents a huge development prospect, penetrating into all aspects of people's lives. Traditional wiring techniques often lack reliability and energy saving in terms of transmission Also not satisfactory, can not meet the current needs of smart buildings, can not replace the end equipment, and has high maintenance and renewal costs, the overall is also very ugly.

In the field of construction, usually shallow geothermal energy needs to be collected and exchanged by ground source heat pump system before it can be utilized. After years of research and practice, ground source heat pump technology has proved that this technology is suitable for the requirements of sustainable development, and has the advantages of high efficiency, energy saving and environmental protection.

Traditional intelligent buildings are based on integrated wiring and use computer networks as bridges. Most of them use an extensive three-layer structure, which is the field control layer, the automatic control layer and

*Shaanxi vocational and Technical College, Xi'an, Shaanxi 710038, China (RongZhou56@163.com)

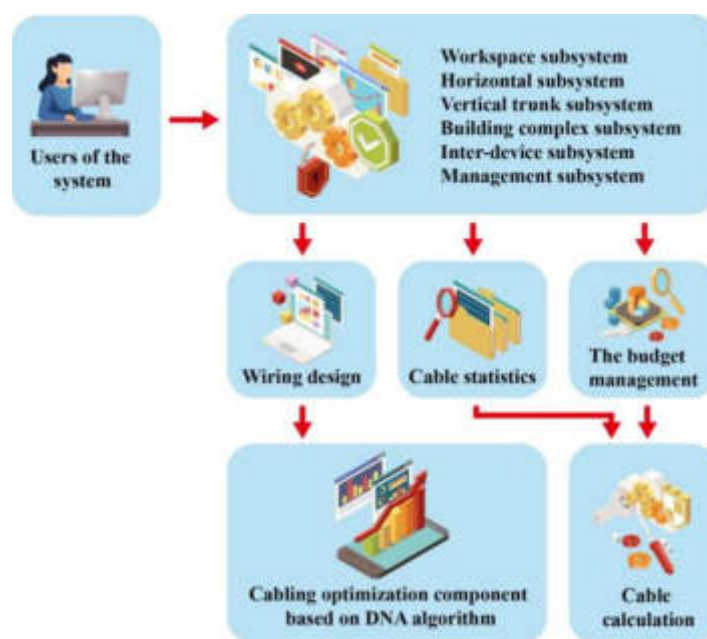

Fig. 1.1: System integration architecture diagram of integrated wiring of intelligent building

the top management layer. Various subsystems in the building (elevator, water supply and drainage, HVAC, power distribution, intelligent lighting, security, etc.) are configured through various communication protocols, and the system integration method of a unified protocol is often used to realize the integration of various systems in the building. Comprehensive management and centralized monitoring of various equipment and subsystems. The traditional integration method is easy to cause problems such as difficult coordination and operation between subsystems, heavy configuration workload, poor openness, and poor flexibility [4-5], so it is not conducive to the development of building intelligence. The object in the Internet of Things is the basic unit. If this concept is applied to the building, the electrical equipment can be regarded as a basic information unit and is endowed with "wisdom", then the network is connected to the Internet of Things system according to the unified communication protocol. All information perceived by the underlying device can be received. Therefore, the Internet of Things technology solves the existing drawbacks from the bottom device side, and the information exchange and information communication based on the Internet of Things technology become much easier. Therefore, to realize system integration of intelligent buildings, the overall structure will change, and the emergence of a new integrated system architecture based on the Internet of Things is an inevitable trend. Figure 1.1 is a system integration architecture diagram of integrated wiring of intelligent buildings. The traditional cabling method makes the reliability of each line is poor, and the cost is high Design of intelligent building cabling system based on Internet of Things. In terms of hardware, I designed intelligent building switches; in terms of software, I planned intelligent building wiring IP address based on the Internet of Things. Formulate the intelligent building comprehensive trunk wiring layout structure, set the auxiliary distribution horizontal line, connect the intelligent building wiring data, so as to realize the intelligent building comprehensive wiring.

2. Literature review. Qian, H. et al. proposed that in recent years, the application field of the Internet of Things has become more and more extensive, and it has been widely used in fields such as smart home, smart transportation, agriculture, environmental protection, industry, medical and health, etc., and has achieved good results. Demonstration effect [6]. According to the research report by Zhu, Z. M. et al., during the 12th and 13th Five-Year Plan period, the Internet of Things technology has developed rapidly, has received strong support from national policies, and has become the driving force for the economic development of China's key industries. Under the influence of the global trend of smart earth and smart city, China has also put forward

the slogans of "perceive China" and "smart city" based on the Internet of Things [7]. Xiao, B. et al. proposed that, as the most basic unit of a smart city, smart buildings can effectively promote the development of smart cities with the help of the Internet of Things [8]. Liu, Z. and others believe that the Internet of Things makes the various subsystems of intelligent buildings "smart", and each system can freely increase or decrease the corresponding functions and services according to the needs of users, turning "intelligent buildings" into "Smart building" realizes the integration of "management, control and operation" to build a smart city [9].

X, He. et al. pointed out that a large number of sensors are installed in various subsystems in the building, such as lighting, HVAC, and security systems, and the data measured by the sensors constitute the information basis. The Internet of Things technology can realize the collection and transmission of data., computing processing, and the structure of the Internet of Things system is shown in Figure 2.1 [10]. According to the research of Qin, N. et al., on the one hand, the comprehensive perception and intelligent analysis of Internet of Things technology provide technical support for intelligent buildings. New intelligent buildings should be open, equipment can self-organize, and the system should be flat to meet the needs of different manufacturers[11]. On the other hand, with the continuous maturity of the Internet of Things, big data, and artificial intelligence technologies, the intelligent era of the Internet of Everything and the integration of the human-machine-object ternary world have become inevitable, "connection + big data intelligence + personalization" "Service" will become the basic paradigm of building intelligence. Tong, Y. U. et al. proposed that the application of the Internet of Things in the field of intelligent buildings is very limited, and generally there are only four aspects: intelligent monitoring, intelligent security, smart home and energy saving and emission reduction. For example, various sensors are installed in home equipment, information is transmitted through the network, and users are monitored through B/S access mode [12]. Therefore, Ren, L. et al. pointed out that through the perception layer device, the building can fully perceive the data information generated by people/environment, and store, analyze and learn, and can think independently [13]. Abdurraheem, AS et al. believe that people-oriented, in addition to the standards of building equipment itself, pay more attention to people's needs; at the same time, it solves the problems existing in traditional intelligent buildings, and a new type of intelligent building architecture that adapts to the Internet of Things era emerges as the times require [14]. Guo, L. et al. proposed that IoT buildings apply IoT technology to realize comprehensive perception of various physical parameters in buildings. Through heterogeneous network fusion, information aggregation, decision-making diagnosis, online control, big data analysis and other means, Form an integrated service management system from the bottom equipment to the upper application, and realize the comprehensive optimization management of energy saving, comfort, safety, health and other objectives in the whole life process of the building [15].

3. Research method.

3.1. Design and implementation of artificial intelligence DNA algorithm based on Internet of Things. The design idea of integrated wiring system is mainly structure and modularization, and adopt Hierarchical star topology is used for integrated wiring of the whole building. From the machine room to The structure of each floor adopts the star topology, the wiring cabinet of each floor and each work Regional information points are no exception. The data communication and signal transmission of the 3A system of a smart building requires a complex wiring system to provide transmission support. The signal cables are routed from the trenches. Interleaving can negatively affect network performance and signaling [16]. The solution to cable crossover is to perform layered wiring: if crossover cables occur, route them to different layers of the trunking, while ensuring that cables on the same layer do not cross. In order to reduce the amount of wiring construction, it is required to control the number of wiring layers to a minimum. The hierarchical problem can be mapped to the vertex coloring problem of the graph. Vertices of the same color can be routed to the same layer, and vertices of different colors need to be routed to different layers. Compared with the traditional computing mode, the artificial intelligence DNA sorting algorithm based on the Internet of Things has the advantages of fast computing speed, low power consumption, high storage capacity and high degree of parallelism. At present, the fastest supercomputer operates at an order of magnitude of 10¹² operations per second, while the speed of DNA computers can reach 10¹⁴ operations; the biggest problem of traditional computers is power consumption, and the power consumption of DNA computers is only one billionth of that of traditional computers; the information stored in one gram of DNA is equivalent to 2.5 million optical discs; traditional computers have the characteristics of seriality, while DNA has native support for parallel

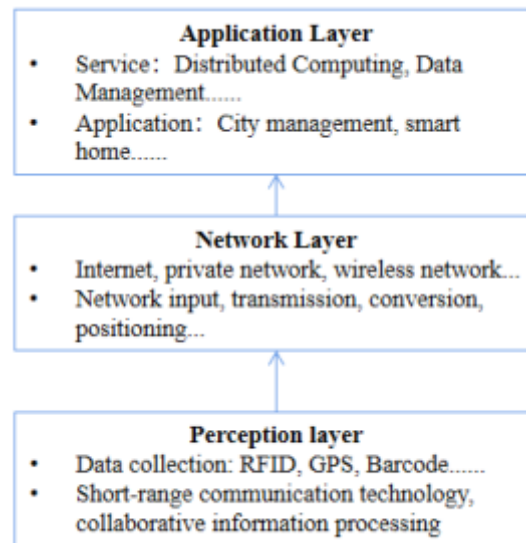

Fig. 2.1: IoT Architecture

computing [17].

Firstly, the basic model composition of artificial intelligence DNA algorithm is described. The first problem that needs to be solved is the coding problem. The coding in the artificial intelligence DNA model is realized by single-stranded or double-stranded DNA molecules. DNA molecular strand is a storage complex, which consists of storage strand and sticking strand. A storage chain can be formed by concatenating n heterogeneous sub-chains, each sub-chain contains m bases, and each pasting chain also contains m bases. Firstly, the basic model composition of artificial intelligence DNA algorithm is described. According to the principle of base complementarity, it can be determined that there is a complementary relationship between the pasted chain and a certain sub-chain in the storage chain. Therefore, it can be agreed that when a single chain exists in the storage complex, it means 0, and if it is a double chain, then Represents 1[18]. On this basis, four basic operations of the storage chain are defined:

- 1) Set: Set the non-zero storage location to "1", represented by $\text{Set}(T, i)$;
- 2) Clear: change the storage location from non-zero to "0", represented by $\text{Clear}(T, i)$;
- 3) Merge: Use the ligation reaction to merge the two DNA single-stranded or double-stranded DNA, that is, merge the two storages into one, expressed as $T=T_1 \cup T_2$;
- 4) Decomposition: Decompose the storage T represented by the single-stranded or double-stranded DNA molecule into two sets $+(T, i)$ and $-(T, i)$ as needed, where $+(T, i)$ represents the storage bit A combination of bit strings of 1, similarly $-(T, i)$ represents the set of bit strings of 0 [19].

The vertex coloring algorithm for solving the graph can be expressed as the algorithm of deleting uncolored points and deleting adjacent same-color points, which are described in Table 3.1 and Table 3.2 respectively:

In the above code, r and t are the subscripts of the two vertices that make up the edge e_i , respectively, and Δ represents the deletion operation. After the above iterative operations, the DNA strand in the test tube T_0 is a feasible coloring scheme for the graph G , and the desired result is obtained after decoding[20]. The core of this computational model is to use a library of magnetic bead probes with biomarkers to implement continuous separation of non-solutions in the initial solution space, and finally find the target solution, where the initial solution space is composed of library chains (that is, DNA representing all possible coloring schemes) sequence) and probe library strands representing the structural information of the graph.

    abando+(T1,(t-1)*k+j)
  End
End

```

3.2. Design of intelligent building integrated wiring system based on IoT artificial intelligence DNA algorithm. When all kinds of new energy are introduced into intelligent buildings to be used, the automatic operation and management of all kinds of application systems will naturally be included in the intelligent building equipment management system. This not only increases the content of building equipment monitoring system, but also expands the scope of energy management services. The intelligent building work area system consists of information sockets, adapters, and cables connecting the user terminal equipment to the sockets. The terminal office environment of the intelligent building is provided directly to the end user, and its design is relatively simple. When the user's network usage requirements are not accurate, an independent work area can be estimated based on the area of 5-10 square meters. The second core problem of workspace design is to count the number of information points. A work area in an ordinary office area is usually equipped with 2-3 information points. For work points with special needs (such as setting up services such as server, fax, video, network printing, etc.), 3-5 dedicated information points can be added. In terms of transmission cable requirements, conventional office areas can lay 10-100M twisted pair cables, while for business or technology development office areas with high bandwidth requirements, fiber optic information points that support more than 100M can be laid. In terms of socket design, the information points are mainly composed of standard RJ45 sockets, and the selection of other sockets must comply with EIA/TIA standards. In scenarios with special requirements, various types of adapters can be selected for connection according to needs [21]. The workflow of the workspace subsystem design is as follows:

- 1) Determination of design level and work area information points: Determine the number of information

points in the work area according to the design level selected by the user. The design of the number of information points N must consider the future development needs, and the number of information sockets corresponding to different design levels can refer to the national standards for integrated wiring and related manuals [22];

2) Calculation of working area: Calculate the area of each working area according to the building plan, and count the total area S of the working area of the building [23];

3) Calibration of the number of sockets and their positions: First determine the area P of the work area. If there is no special requirement, it is usually calculated according to $P = 5 \sim 10m^2$, then the number of sockets is $M = (S \div P) \times N$, where S is the total work area, P is the area of a single workspace, and N is the number of information points in a single workspace [24];

4) Calculation of socket type and the number of associated devices: the type of socket can be surface-mounted or embedded[25]. New buildings usually use the embedded method; the sockets installed on the floor have two types: fixed type and movable type. User needs and costs to choose. Associated equipment includes bottom boxes, covers, panels, etc. The type and quantity of sockets and related connectors can be determined according to user needs and architectural drawings.

4. Result analysis.

4.1. Realization of intelligent building integrated wiring system based on IoT. In order to realize the integrated wiring of intelligent building, it is necessary to distribute the integrated wiring system To the various parts of the smart building. Design cabling for various types of hardware Standard information sockets for equipment need to be provided by capital engineering and open systems. Practical design of integrated wiring system and The installation will be on the building , structure and other industries make many requirements when designing The comprehensiveness of the cabling system must be considered to meet the needs of modern intelligent buildings Demand. Thus, the information transmission between various automatic systems is stable. The system is implemented according to the three-layer structure. The presentation layer, in the form of a local client, provides users with a visual cable routing auxiliary interface. This section focuses on the implementation of the business logic layer. The business logic layer includes core parts such as cable routing optimization design module and database access module, which are encapsulated in the form of reusable components. The database access component provides the encapsulation of the database Create, Retrieve, Update and Delete operations. In terms of coding implementation, the database access operation is divided into three steps: first, create and obtain a business logic object; then create a persistent object related to database access and a business class for storing data through the business object; finally, the business object Call the methods of the persistent object to perform operations such as searching, inserting, deleting, and updating the database. On the .Net platform, database access operations are designed to database-driven loading, connecting to the database, and database operations.

4.2. Test results of integrated wiring system of intelligent building based on Internet of Things. In order to ensure the correctness, reliability and safety of the system, a scientific test strategy must be formulated in the test link. For the test of this system, the project team has formulated the following test links and test strategies:

(1) Functionality and robustness testing: Whether the software system meets user requirements is the primary indicator that needs to be confirmed during software delivery. The functional test is carried out according to the software requirements analysis specification, and the method of black-box testing is used to assess whether the system functional modules meet the requirements of the requirements specification, and whether they can be expected under the given input; Robustness test: robustness test Used to ensure the robustness and stability of the system. During the test, illegal values are entered manually to judge the response of the system. The system should provide feedback for wrong input, and it will not crash; (2) User interface test and performance test: In order to facilitate the use of users and improve work efficiency, the system should have a friendly human-machine interface, which is convenient, intuitive and beautiful and concise; performance test: this system belongs to a typical C/S mode application, the client side involves editing the building structure diagram, and is used to realize the wiring and routing design; the server side mainly involves database operation. This system does not have large server-side load and pressure requirements, and the client

Fig. 4.1: Contrast curve of PM10 concentration in experimental room of passive experimental building

hardware configuration can currently meet the requirements. Therefore, this system can theoretically meet the performance test requirements in most environmental scenarios. The test results for system functionality and robustness are shown in Figure 4.1. In the experiment, the actual PM10 concentration curve was obtained through traditional measurement methods, and the measurement curve was transmitted back to the system in this paper through the artificial intelligence building wiring system based on the Internet of Things. It can be seen from Figure 4.1 that the PM10 concentration parameters obtained by the experimental measurement are highly consistent with the actual value curve, and the degree of agreement can reach 96.4% according to the calculation of the data volume points, indicating that the system has the conditions for measuring various parameters and verifies its functionality; the actual saturation value The difference from the measured saturation value of the system is 6.4%, which verifies that the system has good robustness.

For the user interface and its performance, the energy consumption prediction interface is called to test the prediction accuracy and performance of the system. The obtained prediction model curve and the actual energy consumption curve are compared as shown in Figure 4.2. It can be seen from Figure 4.2 that the energy consumption prediction interface The predicted energy consumption simulation curve coincides with the actual energy consumption curve measured in the experiment at multiple sampling points. The calculated curve fitting degree is as high as 98.9%, which verifies the accuracy and efficiency of the interface of the artificial intelligence building wiring system.

By analyzing the comparison curve between the above prediction model and the measured value, the following conclusions can be drawn: In the module testing process, the project team conducted a black-box test on the remaining functional modules of the integrated wiring auxiliary system. Description of functional requirements. Before functional testing, the system conducts unit testing by means of code walk-through to avoid coding errors. In addition, user interface testing was carried out to ensure that the user interface is friendly, straightforward view. In order to ensure the good compatibility of the client, a platform compatibility test is also carried out, and the test results show that, thanks to .Net The platform naturally supports the Windows platform, and the system can run stably on the Windows series operating system platform. At present, the integrated wiring auxiliary system has been in trial operation in the laboratory, showing good performance and effectively improving the efficiency of design work. A character is designed Integrated environment of intelligent building wiring system, after design, the system experiment, According to the experimental results, the intelligent building wiring system designed in this paper is based on the Internet of Things The system is superior to the traditional wiring method in energy saving and has been popularized to some extent Meaning.

5. Conclusion. Up to now, the concept of the Internet of Things and the idea of "smart energy" have made clear the future development direction of intelligent buildings, especially in the aspect of energy management. It

Fig. 4.2: Comparison of the predicted model curve and the actual energy consumption curve of the energy consumption prediction interface

will break through the shackles of single buildings or independent parks, and stride forward to the broader and more integrated field of "smart city" energy management. Aiming at the problems existing in the traditional intelligent building system architecture and the development of the Internet of Things technology in intelligent buildings, this paper improves the system architecture of the traditional intelligent building, and proposes an artificial intelligence building control system based on the Internet of Things technology. Comprehensive perception of various physical parameters in the system, information fusion and aggregation of heterogeneous data, through service decision-making, system diagnosis, online monitoring, big data analysis and other means, to form an integrated service management system from the bottom equipment to the upper application., to achieve multi-objective optimization and comprehensive optimization management of energy saving, comfort, safety and health in the whole life process of the building.

This paper has completed the design and implementation of the IoT artificial intelligence building system, and has achieved certain results by applying it to the passive experimental building, but the research on the energy saving of the IoT in buildings needs to be further deepened. In the following work, the factors affecting building energy consumption, such as the environment, building envelope, building shading, indoor heat gain, etc., should be analyzed first; then the energy consumption correlation model should be established, and the energy consumption data of building monitoring should be analyzed by regression analysis. Or neural network technology can establish energy consumption model, and use big data analysis technology to predict the energy consumption of the entire building. Finally, the system is optimized considering the comfort requirements of green buildings. Under the background of advocating rational use of traditional energy and active exploitation of green renewable energy, intelligent buildings have added new contents: introducing new energy application systems such as solar energy, geothermal energy and wind energy into intelligent buildings to reduce the consumption of traditional energy in buildings; At the same time, it is integrated into the construction equipment management system to make the application of new energy more transparent and reasonable.

THE APPLICATION OF INTELLIGENT ROBOTS AND DEEP LEARNING IN THE CONSTRUCTION MANAGEMENT PLATFORM SYSTEM OF CONSTRUCTION ENGINEERING

YANDONG ZHOU*

Abstract. In order to solve the problem of duplicate data entry between construction management platform systems in construction engineering, the author proposes to apply RPA intelligent process robots to replace manual data collection, operation, entry, and verification. The design of the system is divided into overall architecture, instruction program loading process, human-machine interaction system level services, and other levels. An end-to-end procedural instruction transmission control method is adopted, establish a low-level control command output module for the online calibration system of the flight path, using a basic service architecture system, implement human-machine interactive control of the online calibration system for flight paths on the B/S architecture system. Build a record controller module for the inspection trajectory correction of RPA intelligent process robots, and perform feedback control during the trajectory correction process in LOG-CONTROL-BLOCK, using the RPA feedback correction algorithm, achieve adaptive correction and error feedback tracking of the inspection trajectory of RPA intelligent process robots. Implement calibration system development and design in an integrated DSP (Digital Signal Processing) information processing platform. The experimental results show that good economic benefits have been achieved through application, and the problem of duplicate data entry between the employer's IFS system and the ENPOWER document management system has been solved, greatly reducing error rates and personnel costs. It can replace manual data collection, entry, verification, and business operations; It has the characteristics of low error rate, low cost, high accuracy, compliance, and 24/7 standby; In 2021, 108000 yuan was saved, in 2022, 432000 yuan was saved, and in 2023, 432000 yuan was saved, demonstrating the labor hour cost savings achieved by utilizing RPA intelligent process robots.

Key words: Intelligent robots, Construction engineering, Construction management platform

1. Introduction. Traditional project management work is greatly influenced by the professional qualities and abilities of management personnel. If the management knowledge reserve of management personnel is not rich and lacks project management experience, it may be difficult to implement job responsibilities in engineering practice, increase the quality and safety risks of construction projects, and threaten the life safety of construction personnel. In addition, the construction site environment is relatively complex and diverse, and the cultural level of construction personnel is generally low, they usually lack awareness of safe and civilized construction, do not pay attention to the standardization of operations, and fail to use safety protection facilities reasonably, when a sudden unexpected event occurs, one is at a loss and loses the best opportunity to escape, not only will construction be delayed, but once casualties occur, their families will be in a state of disaster[1]. There are numerous high-rise buildings in the city, and the amount of construction work is larger and the complexity is higher. Traditional project management models are no longer applicable, in order to avoid safety accidents, strengthen the construction process and site management, and use intelligent technology is imperative[2].

With the advent of the information age, the application of information technology in the construction industry has become more and more common, with the help of the Internet of Things, BIM, cloud computing, Big data, artificial intelligence and other technologies, smart site systems are built, develop safety management strategies based on the characteristics of construction projects and the specific situation of the construction site, and make timely adjustments based on the relevant information obtained, storing information in the cloud breaks the limitations of outdated and outdated management, and aligns with the full lifecycle management of buildings, the smart construction site system consists of multiple layers, including perception layer, transmission layer, processing layer, etc., it can process and analyze the collected project information at corresponding levels, providing project management personnel with strong data support for decision-making[3]. Relying on the smart

Fig. 1.1: Intelligent construction site personnel management system

construction site system, we implement smart supervision, coordination, and training to ensure the organic coordination of progress, quality, safety, and environmental management. By practicing the concept of safe and civilized construction, the project management system has been comprehensively reformed.

At present, the smart construction site system has become an important auxiliary tool for construction project management. During the construction phase of the project, the smart construction site system has played a significant role. The application process is to use sensors and video monitoring devices to monitor the operation of construction machinery, transfer the attendance information of construction personnel to the smart construction site system, and the personnel located in the management and command center will combine the video and image information to order the quality and safety responsible person to promptly rectify the hidden dangers and reduce the probability of safety accidents[4]. Ensuring the personal safety and vital interests of construction personnel is the fundamental goal of construction project management, given the low professional quality and poor safety protection awareness of some construction personnel, utilize the smart construction site system for training, assessment, salary management, and other aspects, reflecting the concept of smart management. One is to specially build a database to store the basic information of all construction personnel, and issue smart cards to construction personnel, smart cards must be used for entering and exiting the construction site, as well as for construction and consumption activities within the site, it is strictly prohibited to use others' smart cards under false names[5]. The second is for construction personnel to enter the safety education and training section of the smart construction site system to learn safety knowledge, learn about the causes of safety accidents and their own job responsibilities, participate in safety knowledge assessments online, and obtain certificates to participate in construction after passing the assessment. The third is to distribute exclusive safety helmets to construction personnel, which can automatically locate the positions of construction personnel and record the operation time as a basis for attendance, when construction personnel take off their safety helmets for a period of time or suffer severe impacts, the safety helmets will emit an alarm signal. The fourth is that the smart construction site system can calculate the wages payable based on the attendance status and salary standards of construction personnel, ensuring that the interests of construction personnel are not infringed, as shown in Figure 1.1.

With the development of artificial intelligence control technology, the types and complexity of robots have increased, and robots have been applied in various fields. In auditing, artificial intelligence robots are used to process bills and reports during the auditing process, improving the intelligence level of auditing. In the process of auditing robot operations, due to factors such as the irregularity and uncertainty of the robot's job interface, the robot's trajectory tracking and control ability is not good. Therefore, it is necessary to conduct online calibration of the audit robot's inspection trajectory, combined with environmental parameter recognition and obstacle avoidance processing, to improve the robot's inspection and control performance. Studying the optimization design method of online calibration system for audit robot inspection trajectory is of great significance in improving the inspection ability of audit robots.

2. Literature Review. At present, there are multiple separate information systems in the project, such as NC (financial shared software), OA (office automation), ENPOWER (nuclear power multi project management

system), IFS3. o (construction management information system), and other heterogeneous databases. To develop various API interfaces, WCF (Windows communication development platform), Web Service (remote call technology across programming languages and operating systems) to rebuild and achieve automation processing, it is not only costly, but also costly, And the development cycle is long. At this point, RPA technology has a powerful advantage in connecting these system interfaces. When using RPA intelligent process robots to simulate manual operations, they do not need to modify the original system, but directly imitate human behavior for operation, with good confidentiality. Especially in the processes of data extraction, input, filling out forms, and extracting structured and semi-structured data from various systems, RPA robots can be developed to achieve automation operations without making any program changes to the original system. At this time, RPA technology has powerful advantages in connecting these system interfaces. The RPA intelligent process robot does not transform the original system when simulating the manual operation, but directly imitates human behavior, with good confidentiality. In particular, RPA robots can be developed to extract data, input, filling in forms, and extracting structured and semi-structured data from various systems, and automatic operation can be realized without any program changes to the original system.

The construction industry is one of the pillar industries in China, playing a very important role in the development of the national economy and the employment of the people. In 2016, the national construction industry enterprises (referring to qualified general contracting and professional contracting construction enterprises, excluding labor subcontracting construction enterprises) had a total output value of over 19 trillion yuan, an increase of 7.09% compared to last year, the proportion of its increment to the national GDP is 6.66%, and the number of people employed in the entire construction industry exceeds 50 million, accounting for 6.68% of the total number of employed people in society. However, China's construction industry still has outdated technology and extensive management, resulting in serious waste of resources, building an ordinary residential building can result in up to 40 in 2016, the profit margin of China's construction industry is still very low. At present, the industrialization level of China's construction industry is very low, and many construction methods, processes, and skills in the construction process heavily rely on the on-site construction operations of construction workers, which are greatly influenced by human factors and the environment, this is an important factor contributing to the unfavorable situation of low quality and low profits in China's construction industry. In current construction, although a large number of mechanical equipment have been involved, more processes still rely on manual work, which is inefficient and time-consuming. On the other hand, the issue of worker health and safety is also an important obstacle to the development of China's construction industry. Construction workers are always exposed to dangerous and deadly external environments. In 2015, 43 construction workers in the UK died at work, accounting for 30% of the total number of deaths in various industries throughout the year. In the same year, 937 construction workers in the United States were fatally injured during construction, accounting for 19.37% of the total number of fatal work-related injuries in the country. In China, from 1997 to 2014, there were an average of over 2500 fatal accidents occurring at construction sites every year. Based on global statistical data, the average casualty rate of the construction industry is 2-3 times that of other industries. Despite improvements in recent years, the casualty rate of construction workers is still very high. Moreover, the working environment of construction workers is extremely harsh, with dust and loud noise, which seriously affect the physical and mental health of on-site personnel in engineering projects, bringing health hazards to them. The large number of workers and imperfect management systems on the construction site have also brought many safety hazards, seriously restricting the healthy development of the construction industry.

Zhou.L believe that intelligent manufacturing is the theme and main direction of the development strategy of "Made in China 2025", and the application of industrial robots is an important direction of intelligent manufacturing. In the coming years, industrial robots will be widely used in various enterprises, which will inevitably require a large number of high-tech industries. Industrial robots are high-tech products in modern society, playing an important role in the process of economic development, especially in the manufacturing industry. Industrial robot technology is widely used in automated production lines, greatly improving industrial production efficiency. Replacing manual labor for various complex production operations to achieve industrial production automation. Analyze the current application of industrial robots in automated production lines, explore their future development direction, in order to better serve the manufacturing industry [6]. Wei, H. H conducted a bibliometric analysis of publications related to the application of social network analysis in the field

of engineering construction management to describe existing research activities and determine future directions in this research field. These publications were retrieved from the China National Knowledge Infrastructure Database. There has been a significant increase in the knowledge system of using social network analysis in the field of engineering construction management. Out of 513 retrieved literature, 98 relevant literature related to the application of social network analysis in the field of engineering construction management was selected for research and analysis through reading abstracts. Through a comprehensive analysis of keywords and relevant literature, it can be found that the application of social network analysis in the field of engineering construction management is mainly studied from the perspectives of stakeholders, construction projects, and workers [7].

In order to solve the problem of duplicate data entry between construction management platform systems in construction engineering, the author proposes to apply RPA intelligent process robots to replace manual data collection, operation, entry, and verification. The design of the system is divided into overall architecture, instruction program loading process, human-machine interaction system level services, and other levels. An end-to-end procedural instruction transmission control method is adopted, establish a low-level control command output module for the online calibration system of the flight path, using a basic service architecture system, implement human-machine interactive control of the online calibration system for flight paths on the B/S architecture system. Build a record controller module for the inspection trajectory correction of RPA intelligent process robots, and perform feedback control during the trajectory correction process in LOG-CONTROL-BLOCK, using the RPA feedback correction algorithm, achieve adaptive correction and error feedback tracking of the inspection trajectory of RPA intelligent process robots. Implement calibration system development and design in an integrated DSP (Digital Signal Processing) information processing platform.

3. Intelligent Process Robot Based on RPA Technology.

3.1. Research Content and Objectives.

(1) *Research content.* After research and analysis, the nuclear power project takes the construction of "smart nuclear power" as an opportunity to research new generation information technologies such as RPA technology, OCR, artificial intelligence, etc. on the basis of the existing nuclear power multi-project management system, ultimately, a set of intelligent process management platforms with nuclear power project management characteristics will be formed, achieving intelligent control of project document management, budget data, item warehousing, and other processes, replacing personnel automation for process operations.

(2) *Business pain points.* The project of China Nuclear Power Fifth Company has deployed a nuclear power multi-project construction management system, which can basically cover all businesses during the construction phase of nuclear power projects, however, there is no data interface between the nuclear power multi-project management archive management system (EN-POWER) and the employer's construction management system (IFS3.0), there is a large amount of data re recording work, which not only increases labor costs and low work efficiency, but also cannot guarantee accuracy[8]. At the same time, there is a significant amount of data guidance work in the areas of construction budget data, financial reimbursement, and construction task sheet data backfill. Therefore, there is an urgent need to use more intelligent methods to solve this problem.

(3) *Research objectives.* Based on the analysis of the above issues, nuclear power projects take the construction of "smart nuclear power" as an opportunity to investigate and research new generation information technologies such as RPA technology, OCR, artificial intelligence, etc. on the basis of the existing nuclear power multi-project management system, ultimately, a set of intelligent process management platforms with nuclear power project management characteristics will be formed, achieving intelligent control of project archive management, budget data entry, item management, and construction process management processes, this will replace personnel in automatic file merging, naming, authorization, entry, uploading attachments, distribution, and archiving of the entire process automation management, and replace manual automatic operation and data entry business[9].

1. Having the characteristics of low cost, low error rate, high accuracy, compliance, and 24/7 work III;
2. Implement cross platform automated operation between ENPOWER and IFS3.0 systems;
3. Implement automated input of ENPower budget data and item arrival data;
4. Replacing personnel to automatically execute repetitive business processes, saving labor costs;
5. Automated execution of procedural operations to improve work efficiency; Reduce the workload of technical personnel, enable technical personnel to focus more on creative work;

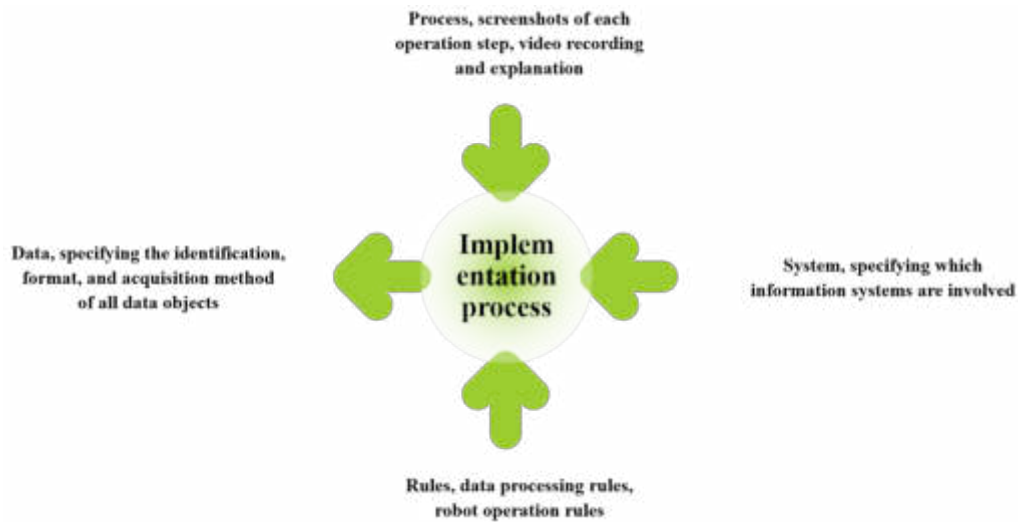

Fig. 3.1: RPA study technical route

6. Seamless connection with ENPOWER for data integration; Assist in Digital transformation of the project [10].

3.2. Technical Proposal and Application.

(1) *Design Platform and Research Methods.* The nuclear power project uses UiBot as the design platform for intelligent process robots; The main research Technology roadmap is shown in Figure 3.2:

1. Sort out and analyze the workflow of various existing information systems, and mine application points; Transform highly repetitive and relatively fixed processes into "intelligent process robots" to achieve automation;
2. By designing a platform, we can develop and implement "intelligent process robots" from a technical perspective, by simulating mouse, keyboard operations, and data interaction during human-computer interaction in specific scenarios, computers can independently operate and complete work tasks[11];
3. Deploying the developed "intelligent process robot" into the actual working environment, computer users can start the intelligent process robot automatically with just one click, and monitor the robot's operation status, if problems occur, they need to handle them in a timely manner.

(2) *Introduction to the functional modules of the R&D platform.* The research and development platform for intelligent process robots based on RPA technology consists of designers, runners, AI integration platforms, and intelligent process robots. The process robot equipment and management platform are shown in Figure 3.3:

1. Designer: Mainly used for developing "intelligent process robots", and can also run and debug RPA robots; Mainly designed to meet the needs of users in developing and designing process robots for different scenarios, helping users easily complete the design work of machine process automation;
2. Runner or controller: After RPA development is completed, users use the runtime platform to run the built robot; When it is necessary to run "intelligent process robots" on multiple computers, these "software robots" can be centrally controlled, such as unified distribution and setting of startup conditions[12];
3. AI integration platform: Providing intelligent process robots with various AI capabilities required for executing process automation; Through OCR character recognition, Natural language processing, image recognition and other AI technologies, the process processing capability and efficiency are further improved.

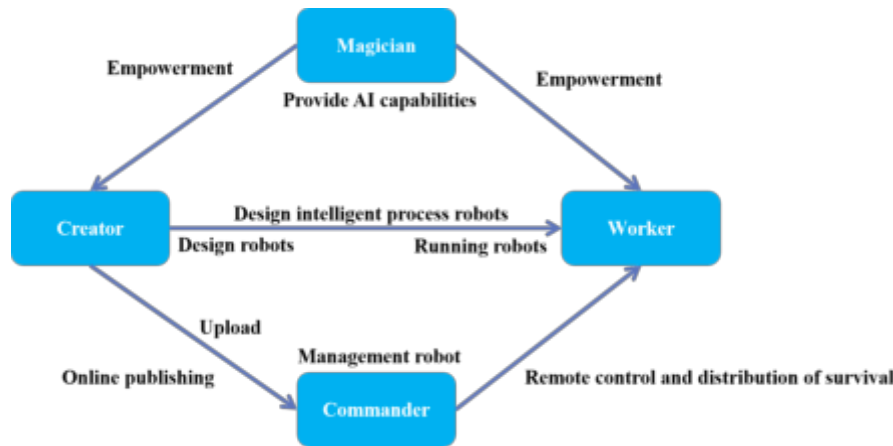

Fig. 3.2: Intelligent process robot design and management platform

3.3. Technological innovation and progressiveness . In order to solve the duplicate data entry work between the IFS and ENPower systems, the Nuclear Power Project Department of CNNC No.5 Company, by researching and developing RPA technology, we greatly reduce the error rate of personnel entering data and reduce project personnel costs. Instead of technical personnel, we automatically perform the entire process of file merging, naming, authorization, input, uploading attachments, distribution, and archiving, saving labor costs[13]; Solved the problem of duplicate entry of design file data in the document management system of the contracting party (IFS3.0) and the nuclear power multi-project management system (ENPOWER). Its main innovation points are as follows:

(1) *Management Innovation.*

1. Implement cross platform automated operation between ENPOWER and IFS3.0 systems;
2. Implement automated input of ENPower budget data and item arrival data;
3. Replacing personnel to automatically execute repetitive business processes, saving labor costs;
4. Automated execution of procedural operations to improve work efficiency;
Reduce the workload of technical personnel and make them more focused on doing creative work;
5. Seamless integration of ENPOWER data; Use AI technologies such as OCR and image recognition to help Digital transformation of nuclear power projects.

(2) *Technological innovation.*

① Visual programming technology

The original visual programming and source code programming can be switched at any time, making it simple and easy to use. Designers do not need advanced programming skills, by visualizing process views and rich source code command library views, the presentation of processes and process blocks can be achieved, effectively improving the efficiency of RPA process development[14].

② Business processing and software process intelligence

In RPA intelligent process design and daily office processes, it is often necessary to automate commonly used software such as Excel, Word, and browser, the use of RPA technology can achieve intelligent operation of these software. Meanwhile, RPA can perform repetitive and mechanical operations based on pre written scripts, replacing manual task processing with automated processing to improve work efficiency.

③ Simulate human-computer interaction

The RPA intelligent process machine mainly simulates the manual operation of users, such as data entry, character copying, pasting, mouse clicking, keyboard input, etc., and automatically processes the data conversion between tables, automatically adjusts the document format and article layout, automatically sends and receives emails, automatically opens the links of inspection web pages, Document retrieval,

Fig. 3.3: The comparison of traditional working mode and RPA robot

collects data and other repeated operations. The comparison between its traditional work and RPA robots is shown in Figure 3.4.

④ Strong scalability and compatibility

Support custom plugins written in multiple programming languages such as Python, C/C++, C #, JAVA, etc., support custom commands, and support a multi-level developer ecosystem. At the same time, it has cross platform advantages, and the engine supports platforms such as Windows/Mac/Android. It is compatible with multiple PC and mobile devices, and supports various UI automation such as browsers, desktops, and SAP[15].

3.4. Design of online calibration algorithm for robot inspection trajectory. In order to achieve the design and research of the online calibration system for the audit robot’s inspection trajectory, combined with the algorithm design and bus transmission design for the online calibration of the audit robot’s inspection trajectory, a bus development design method is adopted, and the integrated DSP control is used to perform the online calibration and trajectory path tracking control of the audit robot’s inspection trajectory from the input end to the output end. The overall structural model of the audit robot’s inspection trajectory online calibration system is constructed, combining the hardware module design of the online calibration system for the audit robot’s inspection trajectory with the MicroChannel expansion bus, the overall control of the audit robot’s inspection trajectory online calibration system is carried out. Based on the audit robot’s inspection control unit, a component functional modular development method is adopted to establish a human-machine interaction control module for the audit robot’s inspection trajectory online calibration system, which is controlled by dynamic units, Implement the output unit conversion and overall structural design of the online calibration system for the audit robot’s inspection trajectory.

$${}^4T_5^{-1}(q_i) = {}^4T_7 \prod_{i=6}^7 {}^{i-1}T_i(q_i) \tag{3.1}$$

Among them, 4T_7 is the 4th order equilibrium moment, and $T_i(q_i)$ is the average degree of freedom of the RPA intelligent process robot, q_i is the balance parameter of the robot’s end pose, and the robot’s end pose constraint control is used to establish an adaptive planning model for the inspection trajectory of the RPA intelligent process robot, combined with the center of gravity offset planning, the feedback constraint parameters for the

inspection trajectory center adjustment of the RPA intelligent process robot are obtained as follows:

$$q_0 = [\alpha_0, \beta_0, \gamma_0]^T \equiv [\theta_1, \theta_2, \theta_3]^T \tag{3.2}$$

Among them, $\alpha_0, \beta_0, \gamma_0$ represents the coordinates of RPA intelligent process robot in the patrol Polar coordinate system, $\theta_1, \theta_2, \theta_3$ is the phase parameter of the RPA intelligent process robot's inspection trajectory space. When measuring distance and pose, the offset correction is performed based on the calibration method of the plane template, resulting in a pose offset of $q_1 = [q_1, \dots, q_7]^T = [\theta_4, \dots, \theta_{10}]^T$; By homogeneous transformation, the pose is transformed into the robot base coordinate system, and the fuzzy information parameters of the inspection trajectory of the RPA intelligent process robot are composed of n omnidirectional motion parameters, the dynamic distribution function of the calibration trajectory is:

$$\begin{aligned} \min F(x) &= (f_1(x), f_2(x), \dots, f_m(x))^T \\ \text{s.t. } g_i &\leq 0, i = 1, 2, \dots, q \\ h_j &= 0, j = 1, 2, \dots, p \end{aligned} \tag{3.3}$$

Among them, $f_1(x), f_2(x), \dots, f_m(x)$ represents the contour sensing output parameters for the inspection trajectory inspection of RPA intelligent process robots, respectively, is the dynamic torque of the robot's end pose, h_j is the calibration feature parameter for path correction, and q and p respectively represent the calibration object positions of the inspection trajectory of the RPA intelligent process robot, based on this, a center of gravity offset planning model for online calibration of RPA intelligent process robot inspection trajectory is constructed, represented as:

$$H(s) = \frac{e^{-\tau s}}{1 + G_c(s)G_0(s)} \tag{3.4}$$

Among them, $G_c(s)$ represents the main control parameter for the center of gravity shift of the inspection trajectory of the RPA intelligent process robot; $G_0(s)$ represents the expected pose parameters of the inspection trajectory of the RPA intelligent process robot, $e^{-\tau s}$ represents the dynamic error of the inspection trajectory of the RPA intelligent process robot, for solving constrained nonlinear optimization problems, based on the correction method of center of gravity shift, the calibrated dynamic parameter distribution model in the robot's base coordinate system is obtained as follows:

$$L = J(w, e) - \sum_{i=1}^N \alpha_i \int_{i=1}^M H(r) \{w^T \phi(x_i) + b + e_i - y_i\} \tag{3.5}$$

Among them, $J(w, e)$ is the inertia function of motion along the expected path, α_i is the distribution along the edge of the expected path, is the adjustment function of the path edge, and w is the dynamic feature point for angle symmetry adjustment, $\phi(x_i)$ is the compensation torque, b is the alternating feature point in the path edge, e_i is the path offset error, y_i is the motion direction adjusted by the robot according to the path, and a discrete spatial planning method L is used to construct the inspection trajectory control model of the RPA intelligent process robot, the output is:

$$\begin{cases} K_i(d) = \sum_{r=1}^t \sum_{q=1}^{k_2} (x_{ir} - x_{irq})(x_{ir} - x_{irq})^T B_{irq} \\ F_1 = W_i^T H_2 W + f_i(d) \times \log(\frac{N}{n_i} + 0.01) \\ C_{oconst} = \sqrt{\sum_{i=1}^n \sum_{r=1}^t \sum_{p=1}^{k_1} [(x_{ir} - x'_{irp})(x_{ir} - x'_{irp})^T A_{irp}]^2} \end{cases} \tag{3.6}$$

Among them, t is the time sampling point, x_{ir} is the head torque, x_{irq} is the width required for the robot to swing, and B_{irq} is the extension direction of the path determined by the target point, A_{irp} is the directional

Fig. 4.1: Comparison of online correction error of intelligent robot inspection track

control parameter, W_i is the intersection point of the expected effective edge of the path, H_2 is the modeled parameter moving along the centerline of the path, and W is the alternating parameter between path edges, $f_i(d)$ is the mass of a single module, N is the target point selection parameter, n_i is the initial pose. Based on the above analysis, the RPA feedback correction algorithm is used to achieve adaptive correction of the inspection trajectory and error feedback tracking of the RPA intelligent process robot.

4. Application Achievements and Benefit Analysis. Feedback control during the trajectory correction process is carried out in LOG-CONTROL-BLOCK, using position sensors such as accelerometers and Doppler velocimeters (DVL) for data acquisition, the calibration system development and design were implemented in an integrated DSP information processing platform, and the results are shown in Figure 4.1. Analysis of Figure 4.1 shows that the error feedback performance of using this method for online calibration of RPA intelligent process robot inspection tracks is good, improving the accuracy of robot inspection[16].

The nuclear power project has been applied based on the conventional islands of Unit 1 and Unit 2 of the nuclear power plant, as well as some BOP engineering projects, with document, budget data, and item management as the entry points; Good economic benefits have been achieved through application, and the problem of duplicate data entry between the employer's IFS system and the ENPOWER document management system has been solved, greatly reducing error rates and personnel costs. It can replace manual data collection, entry, verification, and business operations; It has the characteristics of low error rate, low cost, high accuracy, compliance, and 24/7 standby; At present, the project has been applied in fields such as budget data and material management, with good application value and prospects[17,18]; It provides reference and guidance for the digital transformation work of similar nuclear power projects in the future, and its benefits in the construction of conventional nuclear power island projects are as follows:

RPA intelligent process robot, as a new software automation technology, is currently applied in nuclear power project documents, budget data, and item management; The application effect is good; through research and application, proved that RPA intelligent process robots can replace manual collection, input, verification of document data, and operation of business; Table 1 shows the labor cost savings after using RPA intelligent process robots.

5. Conclusion. Conduct online calibration of audit robot inspection trajectory, combine environmental

Table 4.1: The saved labor costs

Serial number	Year	New output value/10000 yuan	Cost savings /10000 yuan
1	2021	0	10.8
2	2022	0	43.3
3	2023	0	43.2
Three years of conservative calculation of the economic benefits generated			97.2

Note: After the above analysis, after the RPA intelligent process machine is put into use, it is expected to save 8 data or losers in the fields of budget data, item management and document management; cost (54 000 yuan / year 8 people) for 2 years + RMB 108,000 = RMB 0972,000.

parameter identification and obstacle avoidance processing to improve the robot's inspection control performance, and propose a design method for an RPA based audit robot inspection trajectory online calibration system. Establish an adaptive planning model of the audit robot's patrol path, use the Discretization space planning method to build the control model of the audit robot's patrol path, and use the RPA feedback correction algorithm to realize the adaptive correction and error feedback tracking of the audit robot's patrol path. The experimental results show that it has achieved good economic benefits through the application, solved the problem of repeated data entry between the employer's IFS system and the authorized document management system, and greatly reduced the error rate and personnel cost. It can replace manual data collection, input, verification and business operation; low error rate, low cost, high accuracy, compliance and 24 / 7 reserve; 108,000 in 2021, 432,000 in 2022, and 432,000 in 2023. Through the application research of RPA intelligent process robot technology, we have promoted the transformation and functional improvement of nuclear power project information processes, and explored a path of information management with nuclear power characteristics; Making the information management of nuclear power projects increasingly "intelligent", while improving work efficiency and reducing management costs, it also breaks the data silos with the contracting party's system, exploring a new approach and method for subsequent digital transformation and intelligent project management; In the future, it will be promoted and applied in fields such as construction task orders, financial accounting, smart warehousing, and invoice verification, which has good application value and market prospects. It is hoped that the research on the application of intelligent site system can play a reference role in practical work and make a contribution to the innovation and development of the construction industry.

I hope to do better or make breakthroughs in the following areas in the future, so that the intelligent search robot system can better serve everyone and create a new situation for us to use the Internet.

The stability and real-time performance of the system. As the number of users continues to grow and the load on the system continues to increase, the system can still maintain its stable and fast characteristics.

The expansion of business seeks businesses with more business opportunities, linking actual business with virtual internet.

OBSTACLE AVOIDANCE PATH PLANNING FOR POWER INSPECTION ROBOTS BASED ON DEEP LEARNING ALGORITHMS

YUXIN LIU^{*}, XIAOXI GE[†], HAOWEI JIA[‡], LIN YUAN[§] AND MIN ZHOU[¶]

Abstract. The current research on obstacle avoidance path planning methods for power inspection robots has problems such as poor obstacle avoidance ability and poor inspection effectiveness. Therefore, a planning method for obstacle avoidance path of power inspection robots is proposed. By utilizing motion relationships and the potential field theorem of robot motion, a three-dimensional model of the power inspection robot's route is established to determine the direction of the robot's route when obtaining action tasks. The fuzzy support vector algorithm is used to plan obstacle avoidance paths for the initialized walking path, making the inspection robot intelligent. The experimental results show that the average success rates for avoiding static and dynamic obstacles are 98.37% and 96.12%, respectively. The average time for obstacle avoidance path planning is 1.56 seconds, and it has fast, efficient, and accurate obstacle avoidance and path planning capabilities, which can improve the robot's obstacle avoidance ability and path planning efficiency for dynamic and static obstacles.

Key words: path planning, Inspection robot, three-dimensional model

1. Introduction. Entering the 21st century, with the continuous development of economies and cultures in various countries, the level of technology is also constantly improving. Among them, robotics is one of the most eye-catching development disciplines. The development of robotics has made an important contribution to the progress of social civilization and the development of market economy, and has played an important role in human's food, clothing, housing and transportation. Robots can complete various high-load, difficult, and high-precision tasks that are difficult for humans to complete, such as medical, military, agricultural, and other aspects [1]. This has greatly liberated productivity, improved human labor efficiency, and also improved the efficiency of human technological development, making significant contributions to the technological development of various countries and regions.

Nowadays, automation reform has emerged in many labor-intensive industries. The emergence of automated robots has saved human resources and greatly reduced labor costs. At the same time, labor efficiency in various industries such as manufacturing assembly lines has been greatly improved. Robots have been widely used in many fields, such as medical robots, transportation robots, etc [2]. With the continuous innovation of high-precision sensors and advanced artificial intelligence algorithms, it is not only possible to use robots in large-scale industrial production workshops, but also to complete related tasks in crowded indoor spaces and even within the human body. Some service robots, such as outdoor cleaning robots, robot nurses, and smart home assistants, have greatly improved people's quality of life. The research and development of wheeled inspection robots applied to various industries, such as warehousing and logistics, and electrical equipment inspection work, began as early as the beginning of this century. With the continuous development of modern power systems, both industrial and residential electricity consumption is significantly increasing, and the requirements for the long-term stable operation of substations in the power grid are also constantly increasing [3]. Therefore, how to complete inspection work more efficiently and accurately, the proposal of this issue further promoted the research

and development process of power inspection robots. In addition, the country has also invested a large amount of financial support in the use of industrial site inspection robots. Currently, China is undergoing a process of developing from traditional manufacturing to modern manufacturing. Revitalizing the manufacturing industry and realizing its industrialization are of great significance for the vigorous development of the economy. In the process of industrial development, mechanical automation is a necessary stage to achieve industrialization. It is not difficult to see from the industrialization development process of developed countries in the past that the improvement of production efficiency and the continuous expansion of industrial productivity must go through the process of mechanization, automation, intelligence, and information transformation [4]. With the rapid development of the national economy, the continuous improvement of industrial production efficiency, and the continuous increase in human resource costs, the use of automated robots instead of manual inspection has gradually become an inevitable direction for industrial equipment inspection and maintenance. The traditional manual inspection method has many shortcomings, such as large workload and low detection efficiency; The detection effect is not satisfactory, and the detection method mainly relies on visual inspection, resulting in significant errors; In some extreme meteorological environments, such as thunderstorm days, traditional manual detection methods pose safety hazards for detection personnel and cannot complete troubleshooting in a timely manner; The traditional inspection method, which mainly involves installing cameras at designated locations, has a large blind spot due to the limitations of the camera's shooting range, making it difficult to truly meet the requirements of comprehensive fault screening within the station. At the same time, due to the cumbersome design of the control system, the large number of equipment installations, and poor economic efficiency, this inspection method has a high false detection rate for faults and poses great difficulties in maintaining monitoring equipment.

2. Literature Review. The increasing amount of data in the power system greatly increases the task of power transmission, and traditional manual power grid inspections face greater risks. Adopting robots instead of manual power grid inspections can not only ensure the health of workers, but also improve inspection efficiency and create higher value economic benefits. The inspection robot must carry out path planning, that is, in an unknown environment with obstacles, plan the best running path that can avoid all obstacles, which is of great significance [5].

Abdallaoui, S conducted a comprehensive and up-to-date overview analysis and rigorous review of the safety and best path of autonomous vehicle. The focus is on sampling algorithms, node based optimization algorithms, mathematical model based algorithms, bioheuristic algorithms including neural network algorithms, and multi fusion based algorithms, which combine different methods to overcome their respective shortcomings. All of these methods consider different conditions and are used in multiple fields [6]. Xu, T proposed an improved artificial potential field method, in which the object can leave the local minimum point trapped by the algorithm while avoiding obstacles and following a shorter feasible path along the repulsive equipotential surface of local optimization. The entire obstacle avoidance process is based on an improved artificial potential field method, which is applied to the path planning action of the robotic arm, along the motion from the starting point to the target point. The simulation results of the research results show that compared with the improved artificial potential field method based on fast exploration random trees, the algorithm proposed in this paper can effectively perceive the shape of obstacles in all selected situations, and can effectively shorten the distance of the planned path by 13%-41%, significantly improving the planning efficiency [7]. Cheng, J proposed an intelligent robot food runner suitable for restaurants with lower prices but better performance. Among them, this article mainly analyzes how to use LiDAR SLAM to establish restaurant maps, positioning, and navigation, as well as how to establish obstacle avoidance and path planning. Through the ROS platform, the entire process of the intelligent robot vegetable runner is simulated and verified, which can meet the needs of restaurants [8].

Traditional power inspection robots, due to their immature technology, may collide with power equipment during the inspection process, resulting in power inspection accidents and causing losses to both the power inspection robots and the power system, therefore, the author proposes a machine learning based obstacle avoidance path planning method for power inspection robots, achieving the goal of safe inspection for inspection robots.

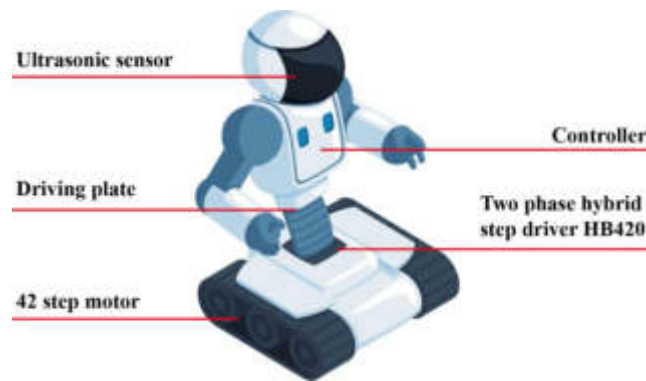

Fig. 3.1: 3D Model of Electric Power Inspection Robot

Fig. 3.2: Coordinate System of the 3D Model of the Electric Power Inspection Robot

3. Application of machine learning in obstacle avoidance path planning for power inspection robots.

3.1. Establishment of a three-dimensional model for the route of the power inspection robot

. The goal of the author's design of a three-dimensional model for the route of the power inspection robot is to ensure stable inspection, and to enable the power inspection robot to have the ability to recognize and perceive the direction of the inspection path, and to complete the inspection path planning of the inspection task in all aspects [9].

In order to improve the stability of the inspection robot, four intersecting driving wheels are designed at the bottom of the power inspection robot based on physical principles, the motion direction and period of the driving wheels are the same, the specific 3D model of the physical power inspection robot is shown in Figure 3.1.

The perception of direction is very important for power inspection robots. Once the robot's directional perception ability decreases, it will cause the inspection route of the power inspection robot to deviate from the normal inspection route, and may collide with other electronic system inspection obstacles or equipment, resulting in power inspection errors [10]. In order to solve the above problems, the author uses motion models and terrain strength to establish a three-dimensional model of the route of the power inspection robot, so as to optimize the perception angle of the center of gravity of the power robot, therefore, the author chooses the center of mass of the power robot as the center origin of the model, and the two-dimensional coordinate system diagram of the power inspection robot is shown in Figure 3.2.

Simulate the motion behavior of the power inspection machine, firstly, set the direction vector of the four driving wheels of the inspection robot as P , and then combine it with real-time environmental conditions, firstly,

Fig. 3.3: Schematic diagram of the rotation route of the power inspection robot

calculate the relative position of the robot within the inspection range, and the calculation formula is as follows:

$$P_B = \left| \frac{x(t)}{LW}, \frac{y(t)}{LW} \right| \sum \frac{1}{L} \left[\frac{Q}{\prod} \right] P_n \quad (3.1)$$

Among them, P_B represents the starting position of robot inspection; $X(t)$ represents the directional guidance coefficient of the X-axis of the inspection robot; $Y(t)$ represents the directional guidance coefficient of the Y-axis of the inspection robot; L represents the radius of the driving wheel of the inspection robot; P_n represents the motion direction vector of the driving wheel of the inspection robot. W_x and W_y represent the weight matrices of the X-axis and Y-axis of the 3D model of the power inspection robot route, respectively [11].

The power inspection robot will perform basic inspection behavior operations during the inspection process, such as walking straight, turning, reversing, translating, and rotating, in order to improve the smoothness of the operation of the power inspection robot, the author uses the theorem of resultant force balance to constrain the robot's inspection motion behavior during the robot inspection process. The schematic diagram of the circular motion path planning for the power inspection robot is shown in Figure 3, and the formula is as follows:

$$F = \frac{f_7}{\varepsilon} \sqrt{Fx^2 + Fy^2} \quad (3.2)$$

Among them, f_7 represents the repulsive force of the motion of the electric inspection robot; F represents the combined force of the motion of the electric inspection robot; Fx^2, Fy^2 represents the motion components of the electric inspection robot on the X-axis and Y-axis, respectively; ε represents the robot's motion balance coefficient [12].

3.2. Robot obstacle avoidance path planning. Machine learning technology is widely used in various fields such as home services, industrial guidance, and military operations. Machine learning is divided into two types: Single machine machine learning technology and multi machine machine learning technology, select the best machine learning method based on the difficulty of object-oriented machine learning. The application range of single machine learning technology is relatively limited compared to multi machine machine learning technology, based on the obstacle avoidance path planning method designed by the author for power inspection robots, multi machine machine learning technology is selected, this technology can complete the planning of static and dynamic paths through learning the environment, and has a self verification process during the path planning process to avoid redundant planning paths [13].

The power inspection robot determines its own location and plans the specific path that the power inspection robot needs to inspect based on the inspection tasks sent by the control center. During the planning process, the repulsion function is used to determine the effective range of the inspection, and obstacles within the inspection range are marked using an artificial potential field method. The principle of obstacle marking is that

the artificial potential field at the location of the obstacle, combined with the field strength of the real-time environment, will emit a repulsive force outward, which affects the gravitational force of the inspection target on the inspection robot's route. The electric inspection robot determines the specific position of the inspection obstacle based on the magnitude of the gravitational force. The repulsion function is as follows:

$$U_t = \frac{k_1}{O} \quad (3.3)$$

Among them, U_t represents the repulsion function; O indicates the relative distance between the inspection robot and the obstacle; k_1 represents the coefficient [14].

After identifying the effective range and obstacles for inspection, the power inspection robot can complete the planning of obstacle avoidance routes for the first time, this route plan will eliminate the accessible routes with obstacles, but if all routes have obstacles, the obstacle avoidance function of the power inspection robot needs to be activated. The author uses the DWA sliding window method to drive the power inspection robot to avoid obstacles during operation and stably complete the inspection work, the formula for generating obstacle avoidance motion behavior is as follows:

$$y(h) = V_s \times \frac{V_a}{V_b} + \frac{ad_{path} + \beta d_{good} + \gamma d_{obstacle}}{\Delta t} \quad (3.4)$$

Among them, $y(h)$ represents the obstacle avoidance command of the power inspection robot; V_b represents the angular velocity of the power inspection robot; V_s represents the linear velocity of the motion of the power inspection robot; V_a represents the acceleration of the motion of the power inspection robot; Δt represents the inspection cycle of the inspection robot; ad_{path} represents the shortest distance between the inspection robot and the obstacle; βd_{good} represents the distance from the endpoint of the trajectory to the local target; $\gamma d_{obstacle}$ represents the maximum obstacle cost for the operation trajectory of the power inspection robot [15].

Using a fuzzy support vector model to set path planning constraints, according to the author's research objectives, setting path planning constraints to maximize the inspection range and minimize the inspection path can improve the efficiency of obstacle avoidance path planning for power inspection robots. The formula for the constraint conditions is as follows:

$$D = \sum_{i=1}^n a_i \times \frac{f(k)}{2} + \frac{y(h)}{\min_L \frac{c_1+c_2}{2}} \quad (3.5)$$

Among them, D represents the constraint condition model; c_1, c_2 represents the mean of the decision functions for the upper and lower bounds of the fuzzy support vector machine model; a_i represents the membership degree of the fuzzy control algorithm; \min_L represents the minimum path for inspection; $f(k)$ represents the kernel function of the inspection probability of the power inspection robot, and the meaning of other unknowns is the same as above. Finally, machine learning technology is used to plan the path constraints and obstacle avoidance behavior instructions for the inspection of the power robot, and the planning formula is as follows:

$$s(t) = f(x, y, z) + \omega \times maxr - Q(x, y, z) \times \mu \quad (3.6)$$

Among them, $s(t)$ represents the inspection path of the power inspection robot; $Q(x, y, z)$ represents the feature vector of inspection behavior classification; μ represents the path planning coefficient; ω represents the inner product of high-dimensional feature space vectors; $F(x, y, z)$ represents the loss function of path optimization.

4. Experimental Results and Analysis. Through the above analysis and design, the design of a machine learning based obstacle avoidance path planning method for power inspection robots has been completed, in order to verify the working performance of this method, the author utilized the obstacle avoidance path planning method for power inspection robots based on GPS navigation technology (traditional method 1) and the obstacle avoidance path planning method for power inspection robots based on carrier free communication technology (traditional method 2) to jointly complete comparative experimental testing, ensuring the scientific nature of the testing [16]. In order to improve the reliability and analyzability of the test results, the inspection

Fig. 4.1: Statistics of Robot Obstacle Avoidance Quantity

robots tested in the article are all HKD09 series inspection robots, the functions of the drivers, motors, and other accessories of this series of inspection robots are optimal and will not result in the experiment being terminated due to the inspection robot. Set at 12 meters \times The 12 meter area is a simulation environment, where 20 rectangular obstacles are unevenly distributed. The starting position and target point coordinates of the inspection robot are $[0,0]$ and $[11,11]$, respectively, with a robot step size of 0.50. 12 repeated obstacle avoidance tests were conducted based on the planned path trajectory, and the obstacle avoidance results are shown in Figure 4.1 [17].

As shown in Figure 4.1, during the obstacle avoidance test of the inspection robot in the established path, among them, the accuracy of obstacle avoidance for 9 times reached 100%, with an average obstacle avoidance rate of 97.92%, proving that the author's method has good obstacle avoidance effect [18].

Comparative experiments were conducted using the author's method to compare the effectiveness of obstacle avoidance with traditional methods 1 and 2, respectively, under the same workspace and number of obstacles, static and dynamic obstacle avoidance experiments were conducted, and the experimental results are shown in Figure 4.2.

From Figure 4.2(a), it can be seen that the author's method outperforms traditional method 1 and traditional method 2 in avoiding static obstacles, in the case of the initial two obstacles, the success rates of obstacle avoidance for the three methods are almost the same, reaching over 99.90%. However, as the number of obstacles increases, the success rates of obstacle avoidance for all three methods show a downward trend, the author's method has an average obstacle avoidance success rate of 98.37% for static obstacles, which is 8.37% and 3.49% higher than the comparison methods of traditional method 1 and traditional method 2, respectively [19]. From Figure 5b, it can be seen that when facing dynamic obstacles, the difference in obstacle avoidance success rates among the three comparison methods gradually widens as the number of obstacles increases. As the number of dynamic obstacles increases, all show significant fluctuations, the author's method has an average obstacle avoidance success rate of 96.12% for dynamic obstacles, which is 15.03% and 9.10% higher than the comparison method of traditional method 1 and traditional method 2, respectively. The results indicate that, the author's method has good obstacle avoidance ability in both static and dynamic obstacles. Under the same conditions, three methods were used to conduct multiple obstacle avoidance path planning experiments for inspection robots, and the data of 8 path planning times is shown in Figure 4.3.

From Figure 4.3, it can be seen that the author's method takes the highest time of 1.80 seconds and the lowest time of 1.40 seconds in obstacle avoidance path planning, with an average time of 1.56 seconds, the traditional method 1 takes the highest time of 3.10 seconds, while the traditional method 2 takes the highest time of 2.10 seconds, with an average time of 1.12 seconds and 0.20 seconds, respectively [20].

Fig. 4.2: Comparison Test Results for Obstacle Avoidance

Fig. 4.3: Statistics of robot obstacle avoidance path planning time consumption

5. Conclusion. Based on fuzzy control algorithms, the directional recognition and perception ability of obstacle avoidance paths for power inspection robots has been fundamentally improved, and the robot is controlled to minimize rotation errors during turning behavior. Utilizing motion models and potential field theorems to improve the reasonable path planning ability of inspection robots, resulting in the output of the planned route with minimal obstacle avoidance and the widest effective range of inspection. Machine learning algorithms have improved the self-learning habits and intelligence of power inspection robots for inspection path planning, enabling them to achieve the goal of safe inspection. Obstacle avoidance methods based on machine learning, on the one hand, it can effectively avoid conflicts between algorithm time and accuracy in planning.

On the other hand, by adjusting the repulsive potential function, gravitational potential function, and the calculation of the resultant force, it can enhance the adaptability of the inspection robot to the environment, thereby improving the robot's obstacle avoidance ability and inspection efficiency.

ANALYSIS OF FROZEN DATA ANOMALY AND UPDATE METHOD OF ELECTROMECHANICAL ENERGY METER TERMINAL BASED ON DEEP LEARNING

FANG YAO* AND LIBIN TAN†

Abstract. In view of the lack of advanced and mature substation fault detection and facility detection technology, combined with the characteristics of the actual application environment of substation, a substation operating equipment autonomous monitoring and fault diagnosis detection system based on deep learning intelligent detection robot is proposed. That is, the deep learning algorithm, Big data analysis technology and patrol robot with HD camera are organically combined. The image information collected by the high-definition camera is fused with the data information collected by a variety of sensors, and then the fault tree and Big data analysis algorithm are used to carry out real-time intelligent detection and analysis of all equipment in the substation, and the early warning can be sent to the relevant equipment maintenance personnel in a timely manner. The experimental results indicate that, the number of input nodes in the fault tree is 7, the number of output nodes is 2, the number of center vectors is 14, the number of nodes in the basis function layer is 7, and the threshold of the basis function is set to 0.8257. In actual training, after 31 iterations, the training results can quickly converge to the target value, the training error meets the requirements, and the fault diagnosis accuracy reaches over 90%. It has been proven that the diagnostic performance of the system is good, achieving the expected design effect.

Key words: Substation, Inspection robot, Fault diagnosis, Intelligent algorithms

1. Introduction. Ensuring operation and maintenance production, as well as maintaining the safety of the power grid, is the top priority in power production work. Equipment inspection is an important part of operation and maintenance production. Conducting regular equipment inspections and inspections of substations, mastering equipment status, and promptly identifying and eliminating equipment hazards are important tasks for achieving safe, stable, and fault free operation of substations [1]. In recent years, intelligent inspection robots for substations have been widely installed in ultra-high voltage and intelligent stations. Robots are used to cooperate with or even replace operation and maintenance personnel in daily inspection work, constantly detecting the status of substation equipment. Taking ultra-high voltage substations as an example, two outdoor mobile intelligent inspection robots are equipped, responsible for the inspection of 1000kV GIS, main transformers, and high impedance equipment, as well as the inspection of 500kV GIS and 110kV equipment [2]. They can perform daily work such as red ginseng 'I-N temperature, meter reading, oil level, etc, and through preset threshold comparison, timely indicate the general, serious, and critical defects of the equipment. However, the current intelligent inspection robot system cannot automatically search for and analyze the types of faults in hidden equipment, and can only generate reports on devices whose data has exceeded the threshold. Moreover, it is currently difficult for robots to identify equipment appearance defects, in the process of equipment status evaluation, many equipment appearance damage, oil leakage and other defect information can only be obtained through manual inspection and entered into the production system [3]. In order to make greater use of intelligent inspection robots as a powerful tool, deepen the application of robot backend, and improve the efficiency of intelligent inspection robots in substation operation and maintenance work, a data processing and feedback system is designed, integrating data from the production system, online monitoring, and robot control backend, and analyzing and processing the data, automatically evaluating the status of equipment, determining the type and location of fault hazards, searching for inspection points related to faults, developing the best inspection strategy, and achieving intelligent inspection robots to independently strengthen special inspections of hidden equipment, is very challenging and feasible [4].

2. References. At present, the development of power equipment towards high power, high reliability, and high intelligence has increased the difficulty of daily operation, maintenance, and testing. In the trend of unmanned substations, traditional inspection methods and fault diagnosis technologies are increasingly difficult to meet the needs of complex equipment diagnosis. The traditional inspection work of substation equipment mainly relies on regular inspections by operation and maintenance personnel and infrared temperature measurement. However, due to the influence of the experience and technical level of the inspection personnel, there is often a phenomenon of missed testing [5]. At the same time, using existing testing instruments makes it difficult for testing personnel to centrally manage data, resulting in low efficiency in deep mining of historical data, which greatly restricts the development of live detection technology. The research and application of intelligent inspection robots in substations have brought new solutions to the above-mentioned problems, providing a foundation for timely, effective, comprehensive, and intelligent diagnosis and maintenance of power equipment. Many scholars at home and abroad have conducted research on intelligent inspection robots for substations [6,7].

Liao, X will use OCR technology to improve the anomaly recognition system for detecting robot equipment. Based on the collection of video information, DSP comprehensive information processing is carried out, and the detection information is analyzed using frequency domain filtering methods through the human-computer interaction interface. At the same time, pattern recognition methods were used to extract the main component features of substation detection components, and a resolution model for similar features in video surveillance images was constructed [8]. Traditional cage inspections require divers to complete, which is inefficient and dangerous. Underwater robot detection is a method to solve this problem. When the robot is in motion, the camera captures the mesh cage, replacing manual inspection. Wei, Y proposed a hybrid control strategy based on neural networks (NN) and proportional integral differential (PID) for underwater three-dimensional path tracking, overcoming the drawback of traditional feedback regulation that can only work after deviations occur [9]. The purpose of Jiang, C is to demonstrate a multi-purpose detection robot that can walk on the ground and climb on power poles. The structure design, size optimization, Kinematics analysis, experiment and algorithm of the robot are introduced. The robot consists of three adjustable modules and a series connected two degree of freedom parallel mechanism. The wheel finger mechanism of each module can open and close the wheel finger to achieve rapid movement and obstacle crossing [10].

From the above analysis, it can be seen that the current research on intelligent inspection robots for substations has certain advantages compared to traditional manual inspection methods, but they still cannot meet the requirements of automatic removal of faulty parts and foreign object removal of equipment. Their performance in autonomous tracking and intelligent diagnosis analysis also needs to be improved. In addition, most of the intelligent inspection robots mentioned above use a single grid charging method, which is not conducive to the long-term inspection work of the intelligent inspection robots, especially when monitoring key equipment point-to-point for a long time, it cannot ensure sufficient electricity.

3. Application of Robot Intelligent Inspection Technology in Fault and Defect Detection of Substation.

3.1. Intelligent inspection robot. Robot technology is a strategic technology industry in China, related to a series of cutting-edge technologies such as automatic control, image recognition, and intelligent learning. According to the "Made in China 2025" plan, industrial robots will be selected as one of the ten key fields to promote epoch-making development, promote robot standardization and modularization, expand market applications, and effectively promote the growth of the emerging robot market [11]. With the development of the times, the lack of human resources and the requirements of refined operation and maintenance of electrical equipment, intelligent inspection robots in substations are increasingly valued. This will be widely used for intelligent inspection of transmission equipment, real-time evaluation and auxiliary decision-making of power grid operation status, informatization, automation, and the establishment of interactive intelligent networks.

The intelligent intelligent inspection robot is equipped with intelligent detection equipment such as high-quality visual light cameras, infrared imaging devices, high-definition photography heads, environmental monitoring sensors, and intelligent analysis algorithm software [12]. It completes the management and control circuit of fast data collection and real-time information transmission, intelligent analysis and early warning decision feedback, replacing manual detection, achieving automatic detection and intelligent analysis of the

status of power equipment, and improving the quality of power equipment, research on the reliability of power grid and power equipment operation, and the use of power intelligent inspection robots is an important means of realizing the intelligence of power grid, and also an important direction for the development of future smart grids.

3.2. Intelligent algorithms. With the rapid development of the era of artificial intelligence and Big data, many industries are also following the development form of "machines replacing people". It is mainly divided into two application fields: Machine vision intelligent algorithm for fault tree and Big data analysis algorithm for multidimensional heterogeneous data [13].

(1) *Intelligent Algorithm for Machine Vision.* In recent years, with the deepening of industrial restructuring and the structural transformation and upgrading of modern manufacturing, more and more enterprises have implemented the "robot strategy". The application of robots in fields such as automobiles, logistics, aerospace, and even food has become increasingly widespread, driving the development of related industries.

Machine vision is a system that automatically obtains target images, analyzes and processes image features, analyzes results, obtains target knowledge, and makes decisions. Moving object testing technology is one of the functions of machine vision systems, this is the process of serializing image change regions and extracting moving targets from background images. The main purpose of machine vision research is to provide convincing data sources for subsequent object extraction and tracking in image arrangement compared to camera moving targets. Machine vision algorithms generally target specific application scenarios, there is currently no universal algorithm applicable to any situation. That is to say, all machine vision algorithms have their own applicability [14].

(2) *Big data analysis and processing intelligence.* The field of algorithm Big data involves a wide range. It deepens the Big data that occurs in the industrial field. With the deep integration of informatization and industrialization, information technology has penetrated into all parts of the industrial chain of various industries. For example, bar codes, two-dimensional codes, communication and identification, industrial sensors, industrial automatic control systems, industrial networks, etc., enterprise resource planning, Computer-aided design, Computer-aided manufacturing, Computer-aided engineering, etc. are widely used in enterprises. The application of next-generation information technologies such as the Internet, mobile Internet, and Internet of Things in the industrial field has brought enterprises into a new stage of development, and data is becoming increasingly abundant, especially in manufacturing enterprises where production lines are running at high speeds and a large amount of data is generated in industrial equipment. Models and algorithms are the two core issues of Big data analysis. The research on Big data analysis models can be divided into three levels [15]. Descriptive analysis, predictive analysis, and normative analysis. Descriptive analysis is the analysis and exploration of historical data, explaining what has happened. This stage includes discovering a set of data rules, mining related rules, describing model discovery, and visual analysis of data rules. Predictive analysis is used to predict future probabilities and trends.

3.3. Intelligent inspection fault diagnosis system. The intelligent patrol fault detection system uses fault tree vision algorithm, Big data analysis technology and intelligent patrol robot with high-definition camera. Through the fault tree, the image information collected by the HD camera carried by the intelligent patrol robot is fused with the data information collected by various sensors, and then through the Big data analysis algorithm, the real-time intelligent fault detection and analysis of all equipment in the substation is carried out. The overall diagram of the intelligent inspection fault detection system is shown in Figure 3.1.

(1) *Using Fault Tree Machine Vision Algorithm to Determine Fault Information.* Machine vision involves related technologies such as optical imaging, visual information processing, artificial intelligence, and mechatronics. It is a necessary technology for many highly automated industries to achieve intelligence. Machine vision technology has a series of advantages such as high accuracy and strong real-time efficiency, and is one of the important driving forces for intelligent robots. With the continuous improvement of various technologies and the increasing demand for high-quality products in the manufacturing industry, image processing has been mainly used for industrial electronic assembly error detection and is gradually applied in manufacturing, monitoring, visual navigation, communication and other applications. Therefore, studying imaging technology is of great significance for promoting the industrial development of intelligent industrial robots [16].

Fig. 3.1: Block diagram of fault detection system of intelligent inspection robot

Fig. 3.2: Schematic diagram of fault position determination by intelligent inspection system

The organic combination of fault tree machine vision algorithm and intelligent inspection robot can enable the intelligent inspection robot to flexibly and intelligently locate the key positions of all equipment faults during substation inspection, ensuring that maintenance personnel can timely maintain and handle the key positions where faults occur (Figure 3.2).

(2) *Use Big data to analyze fault information.* With the rapid development of the era of Big data and artificial intelligence, the organic integration of industrial automation and Big data and other technologies can promote the industry to move towards digitalization, intelligent transformation and integration with the era of Big data. The power generation system of all equipment in the substation is complex and highly centralized [17].

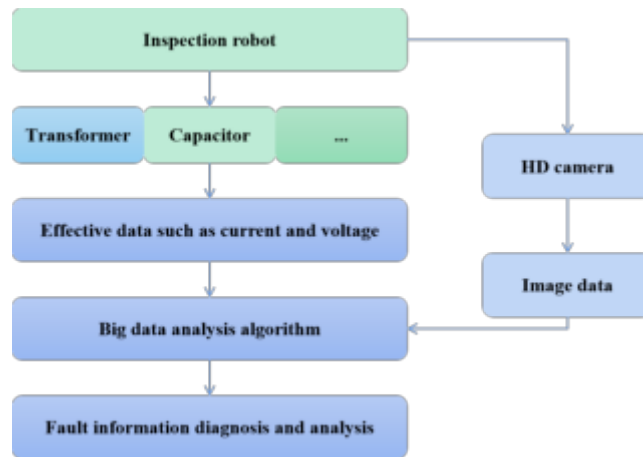

Fig. 3.3: Schematic diagram of fault information diagnosis of intelligent inspection system

Collect data transmitted by sensors on devices through intelligent inspection robots, and combine the results processed by machine vision. Through Big data analysis technology, targeted algorithms are adopted to establish various data mining models and equipment analysis models for substations, and real-time early warning and diagnosis of substation equipment faults and operation modes (Figure 3.3). The intelligent patrol robot combines the image data collected by machine vision technology with the operation data (such as real-time current and voltage data) of transformers, high-voltage circuit breakers, disconnectors, capacitors, reactors and other equipment in the substation to generate a large number of real-time effective data. After Big data analysis algorithm, it can accurately analyze whether there is fault information of the equipment at the moment. If there is any fault information, relevant equipment maintenance personnel can be notified in a timely manner through the early warning system of the intelligent inspection robot [18].

3.4. Fault Tree Diagnosis Principle. The model consists of three layers: input layer, intermediate layer, and output layer. During fault diagnosis, the data decision table is first trained as the training sample of the fault tree to obtain their respective connection weights and thresholds, and then the corresponding connection weights are stored to form a knowledge base. Finally, the trained fault Tree model model is used for fault location and diagnosis. Before working on the fault tree, the first step is to establish a fault knowledge base based on experimental data and expert experience. In order to obtain initial data, the system uses hardware circuits to obtain radar detection signals, and then uses fault trees for shallow empirical reasoning [19]. Then, fault diagnosis is carried out by combining fault trees with expert systems. The network inputs the fault phenomena of the diagnosed object, and the network outputs the probability of the diagnosed object's failure. When constructing the model, the number of nodes in each layer of the fault tree is mainly set based on the empirical formula of previous radar faults, and adjusted based on the training results.

The input layer implements nonlinear mapping from $x \rightarrow \phi_i(x)$, and the output layer implements Linear map from $\phi_i(x) \rightarrow y_k$, namely:

$$y_k = \sum_j^k \omega_{kj} \phi_j(X) + \theta \quad (3.1)$$

$$j = 1, 2, \dots, h$$

In the formula, k is the number of output nodes; ω_{kj} is the output weight value; θ is the threshold value; $(x_1, x_2, \dots, x_n)^T$. The kernel function of the hidden layer node will produce a certain response to the input signal locally. When the input signal is close to the central range of the kernel function, the hidden layer node will produce a larger output. The kernel function often used is the Gaussian function. Fault tree analysis (FTA)

is a method to describe the causal relationship. It qualitatively describes the causal relationship between the layers of fault propagation. It can use the Minimum cut set to find possible fault sources, and is effectively applied to various complex analysis and diagnosis situations. This method applies certain decision conditions to conduct in-depth analysis of specific conditional states, revealing the relationship and correlation between conditions and events, and expressing them through graphical means. The fault tree graph can clearly list the association and logical relationship between the major faults and specific Glitch of the system [20].

The fault tree is established through the following steps:

1. Determine the top event. In the backend analysis system, it generally refers to the type of fault, which can be a large category of faults or specific faults.
2. Analyze the top event, screen the various reasons that trigger the top event, and associate these identified reasons with the top event through logical gates, forming the upper input of the top event.
3. Analyze the causes of the top events, decompose these events again, and identify their input events.
4. Repeat the calculation layer by layer until it can not progress again, that is, get the bottom event, and build and complete the fault Tree model.

Fault tree is a powerful tool for establishing correlations between data and mining causal relationships, but it is difficult to automatically search for relevant knowledge through a large and complex substation operation and maintenance database, the workload of building fault trees through manual experience is too huge. So it is necessary to introduce rough set technology to obtain knowledge of data classification and attribute association for constructing fault trees, which can be used to conveniently construct fault trees.

If there is a bottom event $B_i(i = 1, 2, \dots, n)$ and its state is $x_i(t)$ at a certain time, then:

$$x_i = \begin{cases} 1, \text{The bottom event occurs at time } t \\ 0, \text{The bottom event did not occur at time } t \end{cases} \quad (3.2)$$

The probability of triggering the bottom event at this time is:

$$p_i(t) = E[x_i(t)] = p[x_i(t) = 1] \quad (3.3)$$

If the top event in the fault tree is triggered as M, and its state is M [X (t)] at a certain time, then

$$M[X(t)]_i \begin{cases} 1, \text{The bottom event occurs at time } t \\ 0, \text{The bottom event did not occur at time } t \end{cases} \quad (3.4)$$

And the probability of M at t is

$$p_1 = E\{M[X(T)]\} = p\{M[X(T)] = 1\} \quad (3.5)$$

Converting the fault tree into a structural function can facilitate data calculation and correlation analysis. If the gates and the three OR gates in the fault tree are T1T2T3T4, respectively,then

$$T_4 = B_5 + B_6 \quad (3.6)$$

$$T_3 = B_3 + B_4 \quad (3.7)$$

$$T_2 = B_1 + B_2 \quad (3.8)$$

$$T_1 = T_2T_3T_4 \quad (3.9)$$

Indicates the likelihood of an event occurring, including:

$$p_{and} = \prod_{i=1}^n p_i \quad (3.10)$$

Table 4.1: Typical Fault State Model of P100 Unit

State model	Sample number
P101 board fault	001001
P102 board fault	010010
P103 board fault	101101
Azimuth drive fault	011011
High and low drive failure	110110
15 MHz clock failure	001011
PRF signal failure	100011
Equipment is normal	000000

Table 4.2: Typical fault state model of the P 200 unit

State model	Sample number
24 V power failure	000011
P201 board fault	000110
P202 board fault	001101
P203 board fault	011010
High voltage power supply 200 V fault	000111
Serial communication failure	100111
Equipment is normal	000000

$$p_{or} = 1 - \prod_{i=1}^n (1 - p_i) \quad (3.11)$$

In summary, the event probability can be conveniently calculated through the structure of the fault tree. The system can determine the probability of each bottom event based on the obtained event probability, and make fault judgments and equipment evaluation and maintenance strategies for the most likely bottom events. However, some faults have high importance and high risk factors, and the probability of them appearing in the bottom event is often very small. Therefore, the fault coefficient is set as $F_i(u) = I_i P_i$.

4. System Experiment Results and Analysis. The radar is composed of three independent unit modules: P100, P200, and P300. In order to verify the effectiveness of fault tree for fault diagnosis, the typical faults of the radar P100 unit are taken to establish a sample training model, and the samples are initialized. The typical fault state model of the P100 unit is shown in Table 4.1.

In actual training, after 29 iterations, the training results can quickly converge to the target value, the training error meets the requirements, and the fault diagnosis accuracy reaches over 90%. In order to verify the fault diagnosis effect of the system on other units, the typical faults of the radar P200 unit are taken to establish a sample training model, and the samples are initialized. The typical fault state model of the P200 unit is shown in Table 4.2.

The number of input nodes in the fault tree is 7, the number of output nodes is 2, the number of center vectors is 14, the number of nodes in the basis function layer is 7, and the threshold of the basis function is set to 0.8257. In actual training, after 31 iterations, the training results can quickly converge to the target value, the training error meets the requirements, and the fault diagnosis accuracy reaches over 90% [21]. Each radar unit was divided into 25 sets of fault and non fault samples, with a total of 225 fault samples to test the diagnostic performance of the system. The diagnostic results are shown in Figure 4.1.

From the diagnostic results data, it can be seen that the fault diagnosis accuracy of all three units is above 90%, indicating that the diagnostic performance of the system is good and meets the expected design effect [22].

5. Conclusion. This article is based on the fact that current technologies such as fault detection and diagnosis for substation equipment have not yet entered full intelligence. By combining the practical application

Fig. 4.1: Troubleshooting results

environment characteristics of substations, an intelligent intelligent inspection robot autonomous monitoring and fault diagnosis detection system is proposed. The fault tree, Big data information analysis technology and carrying high-definition camera are organically combined, the fault tree model model is used to diagnose the fault, and a large amount of simulation data is used to provide experimental samples for the fault tree.

THE APPLICATION OF DEEP LEARNING INTELLIGENT ROBOTS IN THE DESIGN AND IMPLEMENTATION OF INFORMATION RETRIEVAL SYSTEMS

YUQI MIAO*

Abstract. Traditional information retrieval algorithms ignore user needs and are unable to obtain user gaze coordinates and gaze times, resulting in low retrieval accuracy. The author proposes a new interactive information retrieval algorithm for this purpose. Divide eye tracking technology evaluation indicators, visually process eye movement information, obtain user gaze coordinates and gaze time, and calculate the influence coefficients of each gaze area and each point in the area. Weighted visual words are accumulated to get a visual word list with the weight of the associated area, and visual word list and Rocchio algorithm are combined to build a hidden Relevance feedback retrieval model in semantic space to judge information retrieval preferences. Intelligent robot is introduced, and Jensen Shannon divergence is used to calculate the Kullback–Leibler divergence distance between the probability distributions of document sets, calculate the similarity matching, and complete the interactive information retrieval. The simulation results prove that, due to the introduction of intelligent robot strategy in this method, the amount of irrelevant retrieval information is reduced by matching user needs and retrieval results. Therefore, the amount of messages generated by information retrieval is significantly lower than that of the two literature methods, without adding additional network load. The network system is in a stable operation state, and users can quickly grasp their own required information, and the retrieval speed is also improved to a certain extent. It is proved that the proposed algorithm has high retrieval accuracy, can effectively reduce network load and achieve high-quality human-computer interactive information retrieval.

Key words: Intelligent robots, Information retrieval, System design and implementation, eye tracking

1. Introduction. Big data is actually a multi information fusion, through sorting and summarizing effective information, a large amount of effective data information is further processed and analyzed, and application information in the data is extracted, through extensive data processing, effective analysis can be conducted on various issues [1]. Big data has the following four characteristics: Firstly, there is a trend of diversification in data types, with uncertain data sources and a wide range of data types; Second, the storage space of Big data is very large, and the capacity often exceeds 10000GB; Third, Big data has high requirements for the authenticity of data, and it also needs data with a certain degree of real-time [2]. Fourth, the data structure of Big data is very complex, and a single storage mode cannot meet the needs of Big data. Gradually increasing and becoming more complex, artificial intelligence, as an emerging development discipline, cannot develop without the support of internet technology and communication devices [3]. Moreover, artificial intelligence can process information quickly and accurately, which humans cannot achieve. Artificial intelligence technology is also an extension and expansion of internet technology, especially in the application of artificial intelligence in information retrieval, which further increases the connection with the internet. However, there is also a certain mutual restriction relationship between artificial intelligence systems and the internet. In short, on the basis of Internet technology, AI technology can be effectively applied to information retrieval in the context of Big data [4].

After hundreds of years of research and exploration, artificial intelligence has also gained new characteristics and significance of the times. Given the rich scientific and technological knowledge contained in artificial intelligence technology, it is a very complex technical task and also involves psychology [5]. After completing the imitation of humans, artificial intelligence efficiently and accurately completes information retrieval work, greatly increasing work efficiency and social production efficiency. However, in the context of Big data, the work of artificial intelligence is becoming more and more difficult, and the technical characteristics of artificial intelligence should also make corresponding adjustments and changes to meet the current characteristics of the times.

2. References. With the wide application of modern communication and network technologies such as network communication, Internet of Things technology and cloud computing technology, various structured and unstructured data resources have shown explosive growth, marking a new stage of the Big data era. And text data dominates all forms of information resources, with a large amount of data presented in the form of text [6]. As the main manifestation of internet information, massive amounts of text information have become a key research object in the fields of computer science and intelligence. Therefore, text processing technology is the key way to use information in the era of Big data, in which Text retrieval is an important foundation and premise of text processing technology. How to accurately and comprehensively retrieve the information required by readers in massive text information is the key issue and research hotspot of Text retrieval technology development [7].

Xu, Y provide a method for manufacturing magnetic nanorobots, which is an intelligent robot system updated from traditional autonomous experimental platforms. Nanorobots synthesized by robots have uniformly sized samples, which can significantly reduce time costs [8]. Rahimi, T introduced a new topology structure of the proposed converter, which has the following advantages: (i) the topology structure of the converter is based on traditional boost and buck boost converters, which leads to its simplicity; (ii) The voltage gain of the converter provides a higher value through the lower value of the duty cycle; (iii) Due to the use of efficient traditional topology in its structure, the efficiency of the converter remains high for a large duty cycle interval; (iv) In addition to the increase in voltage gain, the current/voltage stress of semiconductors remains at a relatively low level; (v) The continuous input current of the converter reduces the current stress of the capacitor in the input filter [9]. Zeinoddini Meymand, H designed and implemented a speed control controller for permanent magnet synchronous motors based on an intelligent neural network. Firstly, an accurate mathematical model of permanent magnet synchronous motor was presented, and then, by designing a controller, we applied the challenge of wind turbine simulation. The designed controller was first implemented on the Arm Cortex-M microcontroller and tested on laboratory PMSM [10]. In order to solve the application problems of the traditional methods mentioned above, the author proposes an interactive information retrieval algorithm based on intelligent robots. Combining eye tracking technology, divide eye tracking technology evaluation indicators, visually process eye movement information, and obtain user gaze coordinates and gaze time. And the author first creates four eye movement evaluation indicators: gaze, scanning, pupil dilation, and scanning path.

3. Interactive Information Retrieval. Incorporating user behavior into the retrieval system can effectively achieve human-machine interaction for information retrieval. At present, Relevance feedback has two modes: explicit Relevance feedback and implicit Relevance feedback. Displaying Relevance feedback requires users to make a lot of preparations and inform users of the impact of their behavior on information retrieval in advance; In the implicit Relevance feedback mode, users do not need to consider the impact of their own behavior on the search results, but only need to pay attention to whether the search behavior meets their own needs, which can greatly reduce the workload of users, and the accuracy of the search results is also high [11].

3.1. Classification of eye tracking feature indicators. Eye trackers are tools for implementing eye tracking technology, which can be classified into three types: Helmet mounted eye trackers, desktop eye trackers, and eyeglass eye trackers. Eye tracking is divided into four categories: Gaze, scanning, pupil dilation, and scanning path. Gazing indicates the length of time the eyes stay at a fixed point; Scanning refers to the rapid movement or delay of the eyes between fixation points; Pupil dilation is used to describe the level of interest of users when browsing information; The scanning path is a trajectory formed by the rapid movement of both eyes between fixation points [12].

3.2. Implicit Relevance feedback of search page. Use multiple circles to describe the range of fixation points, with the diameter of the circle indicating the fixation time and the connecting line indicating the fixation trajectory. For each user's interest region, the region's fixation time is represented as

$$FD(i) = \sum_{e \in AOI(i)} T(e) \quad (3.1)$$

In the formula, e represents a fixation event, $T(e)$ is the user's fixation time for event e , and i is the index of the region of interest (AOI). The corresponding coordinates of the fixation point in the region of interest are

$$\begin{aligned} FiA_x(j) &= F_x(j) - AOI_{x1}(i), F(j) \in AOI(i) \\ FiA_y(j) &= F_y(j) - AOI_{y1}(i), F(j) \in AOI(i) \end{aligned} \tag{3.2}$$

In the formula, $AOI_{x1}(i)$ represents the x-coordinate of the upper left corner of the region of interest, and $AOI_{y1}(i)$ represents the y-coordinate of the upper left corner of the region of interest. The influence area of each user's fixation point is

$$\begin{cases} FiA_x(j) - r \leq IA_x(j) \leq FiA_x(j) + r \\ FiA_y(j) - r \leq IA_y(j) \leq FiA_y(j) + r \end{cases} \tag{3.3}$$

In the equation, r is the radius of influence. The calculation process is as follows

$$r = p \cdot F_{time}(j) \tag{3.4}$$

In the formula, p represents the regulatory factor, and $F_{time}(j)$ represents the fixation time of the fixation point.

Set a fixation threshold t , if the fixation time of a user's interest area is higher than t , the information relative to this area is considered as related information, and vice versa is considered as unrelated images. Express the measurement criteria for evaluating user interest as

$$M(i) = \begin{cases} 1, if FD(i) \geq t \\ 0, if FD(i) < t \end{cases} \tag{3.5}$$

According to the user's fixation time for different information, if the information correlation degree $h(i)$ is specified, the coupling relationship between fixation time and correlation degree is

$$k(i) = \frac{FD(i)}{\sum_{M(i)=1} FD(i)} \tag{3.6}$$

Based on the above information, a fixation point influence area can be obtained, and the size of this influence area is proportional to the fixation time. Record the influence coefficients of each point in the affected area as

$$IF(x, y) = e^{-\frac{((x - F_x)^2 + (y - F_y)^2)}{2\delta^2}} \tag{3.7}$$

Based on the initial search results viewed by the user, calculate the influence coefficients of each fixation point's influence area and each point in the area. Extracting visual words from each region, weighting and accumulating visual words, can obtain a visual word list that covers all associated regions and includes weights. The visual word list is the expression form of semantic space

$$word = \sum_{i \in FiA} word(i) \cdot IF \tag{3.8}$$

In order to obtain more accurate user retrieval preferences, relevant information is reordered, and the reordering process can be seen as the process of forming a visual word list of user retrieval intentions, as shown in Figure 3.1. If there are M related regions, the initial visual word list for each related region is

$$G(i) = (w_1, w_2, \dots, w_c) \tag{3.9}$$

In the equation, $G(j)$ represents the visual vocabulary, and w_n represents the vocabulary in the vocabulary [13]. The weight $WA(i)$ of each region of interest is

$$WA(i) = \frac{FD(i)}{\sum_i FD(i)} \tag{3.10}$$

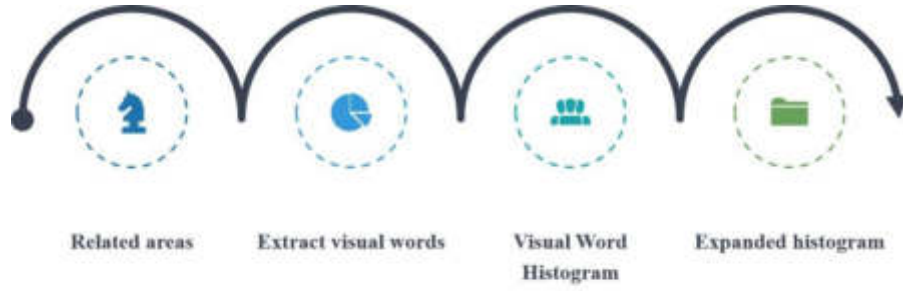

Fig. 3.1: Step of the implicit correlation feedback algorithm on the retrieval page

The improved visual word list for the relevant areas is

$$G^e(i) = (w_1^e, w_2^e, \dots, w_i^e, \dots, w_c^e) \quad (3.11)$$

where

$$w_i^e = WA(n) \cdot F_{time}(m) \cdot IF \quad (3.12)$$

In the formula, $WA(n)$ represents the range of interest of the relevant region, and $F_{time}(m)$ represents the corresponding fixation time of the relevant region. The expanded search visual word histogram H_i^e is

$$H_i^e = \sum_{j=0}^{M-1} G^e(j) \quad (3.13)$$

After using the above process to obtain new visual words, the Rocchio algorithm is integrated, and the implicit Relevance feedback retrieval model in semantic space is recorded as

$$\vec{q} = \alpha \vec{q}_0 + \beta \frac{1}{|D_r|} \sum_{\vec{d}_j \in |D_r|} \vec{d}_j - \gamma \frac{1}{|D_{nr}|} \sum_{\vec{d}_j \in |D_{nr}|} \vec{d}_j \quad (3.14)$$

In the formula, \vec{q}_0 represents the user's initial search vector, D_r , D_{nr} represent the set of known related and unrelated search contents, and α, β, γ is the corresponding weight [14]. During information retrieval, the system needs to interact with users for many times, that is, it has multiple pages of implicit Relevance feedback, each feedback will generate a corresponding retrieval strategy, introduce new information vectors into the original retrieval vector, and eliminate+irrelevant vectors, thus improving Equation 3.14 to

$$\vec{q}_{m+1} = \alpha \vec{q}_m + \beta \frac{1}{|D_r|} \sum_{\vec{d}_j \in |D_r|} \vec{d}_j - \gamma \frac{1}{|D_{nr}|} \sum_{\vec{d}_j \in |D_{nr}|} \vec{d}_j \quad (3.15)$$

The search vector \vec{q}_{m+1} in Equation 3.15 is determined by the search vector \vec{q}_m during the m-th search and the related and unrelated search content vectors fed back in the macro results of this search.

3.3. Interactive Information Retrieval Algorithm Based on Requirements Mining . It can be seen from the implicit Relevance feedback model of equation (15) that each improvement of retrieval method is obtained on the premise of Relevance feedback of the previous retrieval results [15]. Requirement mining refers to starting from the real needs of users, the system judges their needs, and obtains the information they need. From content structure - spatial navigation construction - information content presentation, this series is expressed in an interactive logical form, as shown in Figure 3.2.

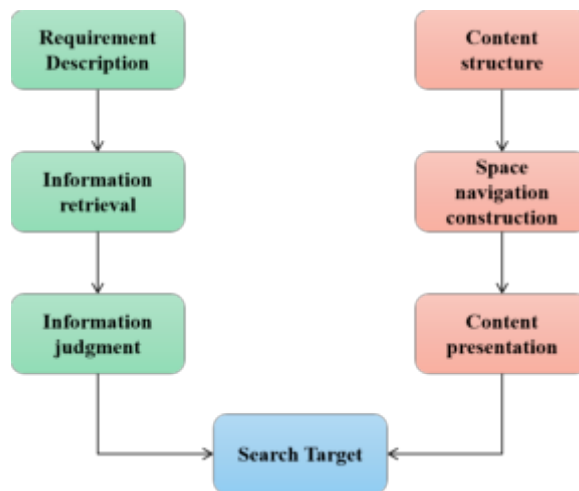

Fig. 3.2: Interactive information retrieval logical relationship

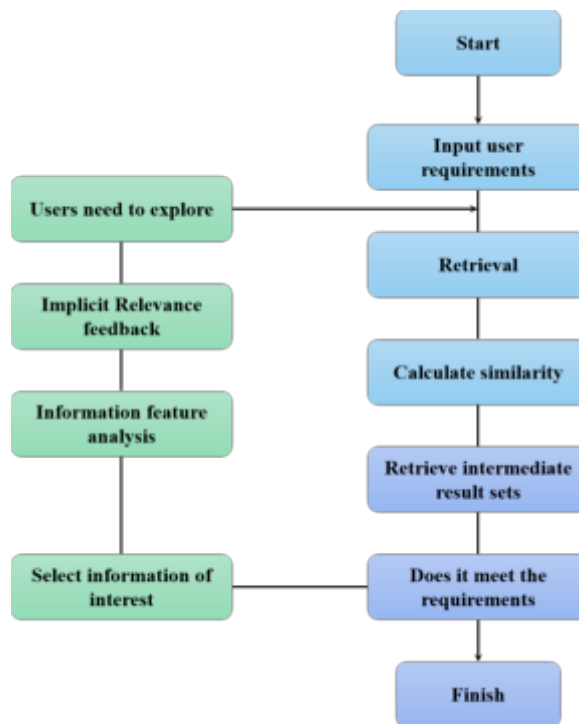

Fig. 3.3: Interactive information retrieval process based on demand mining

We introduce requirements mining conditions and design an interactive information retrieval process as shown in Figure 3.3.

In interactive retrieval systems, information retrieval refers to the similarity matching between retrieval vectors that describe information requirements and different document vectors within the system.

Currently, the cosine of the vector angle is widely used. The calculation formula for measuring the similarity

between two documents using this method is:

$$\cos(P, Q) = \frac{P \times Q}{|P| \times |Q|} = \frac{\sum_{i=1}^n \text{freq}(w_i|P)\text{freq}(w_i|Q)}{\sqrt{\sum_{i=1}^n \text{freq}(w_i|P)^2} \times \sqrt{\sum_{i=1}^n \text{freq}(w_i|Q)^2}} \quad (3.16)$$

In the formula, P and Q represent the vectors of two documents in sequence, $\text{freq}(w_i|P), \text{freq}(w_i|Q)$ represents the component in the vector, which is the frequency at which the user retrieves terms within this document.

However, in practical calculations, it has been found that the vector angle cosine method has a high computational complexity and cannot achieve fast retrieval targets. For this reason, the Jensen Shannon divergence method is used to compensate for its shortcomings. Calculate the Kullback–Leibler divergence distance between the probability distributions of two document sets, and determine the similarity between documents [16]. If the Kullback–Leibler divergence distance is shorter, the document similarity is greater, and vice versa. The derivation formula for Jensen Shannon divergence is

$$D_{js}(P||Q) = \frac{1}{2}D_{KL}(P||R) + \frac{1}{2}D_{KL}(Q||R) \quad (3.17)$$

$$R = \frac{1}{2}(P + Q) \quad (3.18)$$

where, D_{KL} represents the Kullback–Leibler divergence of P and Q probability distribution.

$$O = (o_1, o_2, \dots, o_n) \quad (3.19)$$

According to the Kullback–Leibler divergence theorem, design a probability vector o as in Equation 3.19, then the information entropy of the vector is

$$H(O) = - \sum_{i=1}^n o_i \cdot \lg o_i \quad (3.20)$$

Regarding the vocabulary set $W = \{w_1, w_2, \dots, w_n\}$, o_i can be used as , and the number of occurrences in the document, then

$$o_i = \frac{\text{freq}(w_i|o)}{\sum_{i=1}^n \text{freq}(w_i|o)} \quad (3.21)$$

If information entropy is used to describe Jensen Shannon divergence, Equation 3.17 can be transformed into

$$D_{js}(P||Q) = H(R) - \frac{1}{2}(H(P(w_i)) + H(Q(w_i))) \quad (3.22)$$

In the formula, H is the information entropy function, and R is the composite vector of P and Q. The author fully integrates the two strategies of implicit Relevance feedback and demand mining under eye tracking technology, calculates the matching degree of user needs and retrieval results by using Equation 3.22, and completes the intelligence and accuracy of information retrieval while effectively tracking user retrieval preferences.

3.4. Search engines. The fundamental idea of an intelligent search robot system is to combine two major internet applications, information retrieval and instant messaging. The most important and common manifestation for information retrieval is search engines, according to the intelligent search robot designed by the author, it also uses search engines to achieve the search characteristics of the system. In this section, we first provide a brief overview of search engines [17].

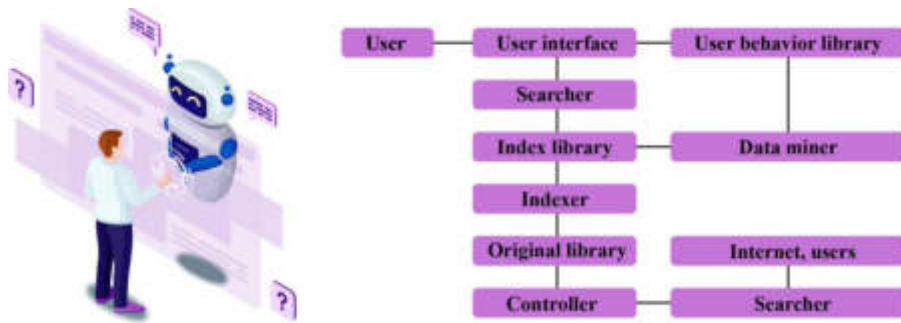

Fig. 3.4: Search engine architecture

Modern large-scale high-quality search engines generally use a three stage working mode for information collection, information processing, and query services.

Information gathering: Each independent search engine has an information gathering program, which is a web crawler for search engines. Web crawlers continuously crawl web pages along hyperlinks. In theory, starting from a certain range of web pages, they can collect the vast majority of web pages. In addition to web crawlers, users can also input information through robots for the search of this system.

Information processing: Search engines need to do a lot of processing work after collecting information in order to provide retrieval services. The most important thing is to extract keywords and establish index files. It should be pointed out that the processing of Chinese also requires the execution of Chinese word segmentation.

According to the above requirements and workflow, the architecture of the search engine is roughly shown in Figure 3.4.

4. Simulation research. In order to detect the true information retrieval performance of the proposed algorithm, simulation analysis was conducted, and traditional method 1 and traditional method 2 were compared. Using recall and precision indicators to measure the quality of a retrieval algorithm, recall represents the ratio of the number of relevant documents retrieved to the total number of relevant documents in the system document library, highlighting the comprehensiveness of the retrieval algorithm [18]. The calculation formula is

$$\text{Recall rate} = \frac{\text{Retrieved similar documents}}{\text{All detailed documents in the database}} \tag{4.1}$$

The precision ratio represents the ratio of the number of relevant documents retrieved to the total number of documents retrieved, highlighting the correctness of the retrieval algorithm. The calculation formula is

$$\text{Accuracy} = \frac{\text{Retrieved similar documents}}{\text{Retrieve all documents obtained}} \tag{4.2}$$

The comparison of recall and precision of the three methods is shown in Figure 4.1.

From Figure 4.1, it can be seen that when the recall rate is between 20% and 60%, the traditional method 1 and method 2 exhibit significant precision jitter. However, this method outperforms the other two methods in terms of precision as the recall rate gradually increases. This is because this method uses eye tracking technology to timely capture user retrieval preferences, and this interactive strategy can maximize the accuracy of information retrieval [19].

The message volume of the information retrieval process is the average message volume that meets each retrieval request. This indicator is used to verify the stability of the method’s operation, thereby reflecting the efficiency of the method’s retrieval. The comparison results of message volume simulation for the three methods of information retrieval process are shown in Figure 4.2.

Therefore, the amount of messages triggered by information retrieval is significantly lower than that of the two literature methods, without adding additional network load. The network system is in a stable operation

Fig. 4.1: Compare the recall and precision of the three methods

Fig. 4.2: Comparison of the message volume of the information retrieval process

state, and users can quickly grasp their own required information, and the retrieval speed is also improved to a certain extent [20].

5. Conclusion. In order to effectively improve the accuracy of interactive information retrieval and provide users with a better service experience, this study combines the theory of human gaze behavior and proposes a new interactive information retrieval algorithm. This method can concentrate on presenting cognitive features in the process of information retrieval, evaluate users' actual retrieval needs, and ultimately present an ideal human-machine interactive retrieval mode, bringing new exploration ideas for future research in the field of interactive information retrieval.

APPLICATION OF MEASUREMENT ROBOTS BASED ON DEEP LEARNING IN BUILDING TILT STABILITY MONITORING

WEI ZHANG* AND JUNHUA LI†

Abstract. In order to better understand the application of measuring robots in monitoring the stability of building inclination, this paper proposes a deep learning based algorithm for analyzing the trend of building inclination using measuring robots. The author first proposes a method of using measuring robots to monitor the tilting stability of buildings. Based on the principle of laser ranging, construct a robot structure and laser ranging model to achieve information exchange between different units. Secondly, based on simulation analysis, the position relationship between the laser and the building was marked with triangular coordinates, and the inclination of the building was marked with robot benchmarks. The simulation process was designed. By using the forward crossing method to evaluate the accuracy of tilt monitoring and comprehensively monitoring the three-dimensional angle of free station setting, the problem of low monitoring accuracy in traditional methods has been effectively solved. Finally, the experimental results show that using this method, the accuracy of building tilt monitoring can reach 99%, which is 7% higher than traditional measurement methods. Due to the low efficiency, high cost, and low accuracy of traditional manual monitoring work, it can no longer meet the requirements of modern engineering measurement. Therefore, high-precision measurement robots are used for tilt stability monitoring. Compared with traditional monitoring, high-precision measurement robots can achieve high-precision, high-efficiency, and low-cost monitoring with faster speed, higher efficiency, and strong automation capabilities.

Key words: Measuring robots, building tilting, stability monitoring

1. Introduction. Monitoring the tilt stability of buildings is a highly technical task that requires regular, timed, and quantitative observation of buildings. By monitoring buildings, timely detection of displacement changes in buildings can be carried out in order to take effective measures. In recent years, with the increasing scale and quantity of construction projects, slope stability monitoring has gradually become an important task in engineering surveying. Due to the low efficiency, high cost, and low accuracy of traditional manual monitoring work, it can no longer meet the requirements of modern engineering measurement. Therefore, high-precision measurement robots are used for tilt stability monitoring. Compared with manual monitoring, high-precision measurement robots can achieve high-precision, high-efficiency, and low-cost monitoring with faster speed, higher efficiency, and strong automation capabilities. The design of a measurement robot includes a motor, controller, and angle measurement system. Measurement robots can be fixed on a planar coordinate measuring machine through a machine or robotic arm installed on the ground, and then control the motion of the robot's four robotic arms on the ground to measure according to the predetermined route and orientation. Adopting a dual turntable system for fast conversion. At the same time, the measurement robot uses Total station and electronic angle measuring system to realize three-dimensional tilt measurement of buildings. The Total station can directly obtain the three-dimensional coordinates and direction information of the measured object, and the angle measuring system can collect the two-dimensional coordinates of the measured object, and then convert them into three-dimensional coordinates. Install sensors on buildings to monitor them in real-time. Sensors can be installed at different locations in buildings, and data collection and analysis can be carried out through a data acquisition software system to achieve dynamic monitoring of buildings. The terminal consists of a data acquisition module, wireless communication module, power switch module, and SD card. It can communicate wirelessly with measurement robots to achieve data collection and transmission. The terminal also has an RS485 interface, which can be connected to an industrial computer to achieve remote control of

Fig. 1.1: Robot monitoring of building tilt stability

the measurement robot. At the same time, the terminal also has the characteristics of low power consumption, strong anti-interference ability, and long service life. This terminal sets up a wireless communication link between the measuring robot and the building to collect the inclination value of the building. At the same time, two data acquisition devices are also set up, one for collecting the coordinates of control points and reference points, and the other for measuring communication between robots and buildings [1,2] (Figure 1.1).

2. Literature Review. With the development of economy and society, the height and number of buildings are gradually increasing, the construction process of new buildings will inevitably cause changes in the stability of existing high-rise buildings, therefore, it is necessary to conduct Deformation monitoring on existing high-rise buildings around the site. The tilt of buildings will pose a threat to people's life safety. Therefore, the tilt stability monitoring of Tower block is also one of the main contents of Deformation monitoring. When monitoring the tilt stability of buildings, the measurement robot should be combined with the structure and surrounding environment of the building to avoid defects such as cracks and holes in the building walls. If there are cracks, holes, and other defects on the walls of a building, traditional repair methods should be used to repair them to ensure the safety of the building. If high-precision repair methods are used to repair it, it can shorten the repair time. Especially in recent years, with the development of high-tech technologies such as sensor technology, image processing technology, and communication technology, the performance of measurement robots has become increasingly high. In addition, with the continuous development of computer equipment such as electronics and computers, measurement robots have gradually shifted from traditional measurement to intelligent measurement.

Scholars have conducted some research on this issue. Giacoppo, G. A. proposed a method for measuring the inclination of buildings in mining subsidence areas based on point cloud feature line extraction, which can measure and analyze the subsidence trajectory through point cloud features. Although this method has certain applicability in tilt measurement of settlement buildings, laser point clouds are easily affected by ground obstacles and have low accuracy in tilt measurement of urban buildings [3]. Tian, Y. M. proposed a study on the dynamic deformation laws and internal forces of ground and buildings based on numerical analysis of Metro Line 3. By constructing a numerical analysis model, the impact of ground motion on buildings is studied, deformation data is collected, and inclination degree is measured. This method achieved the estimation of inclination measurement values for transportation buildings through model numerical analysis, but did not conduct building simulation analysis, and the reliability of the measurement results needs to be verified [4]. Zhou, T. proposed the application of inclination sensor in precision detection of parallel robots. This method utilizes inclination sensor to collect monitoring data and transmit it to the parallel robot system for measurement. The above three methods rely on traditional mechanical probes for measurement. Although the mechanical probe type measuring instrument is simple to use, its range of use is limited due to limitations caused by working principles, and human factors can cause large errors, which can easily lead to low accuracy of tilt monitoring [5]. In summary, the author proposes a method for monitoring the tilt stability of buildings using measuring robots, which can obtain various spatial dimensions of the building from all directions and achieve monitoring without contact, effectively improving measurement accuracy.

3. Research methods.

3.1. Monitoring of inclination stability of measuring robots.

3.1.1. Tilt stability monitoring process. The detailed process for monitoring tilt stability is as follows:

1. Monitoring points should be set up on the platform as needed, and control points should be placed in high-rise buildings. The selection of points should be firm and not affected by mining.
2. The auxiliary observation mark of the measuring robot is set at the stable position of the building, and a cloud platform point distribution map with equal inclination is drawn based on the obtained monitoring data [6,7].
3. In the adjustment calculation of monitoring data, the Centroid coordinates of the detection layer of the building are calculated based on the measured data; According to the accuracy requirements of servo Total station, the mean square error value of horizontal observation $m_0 = \pm 0.5$ is selected.
4. Benchmarks and observation points should be set up for monitoring the inclination of buildings through coordinate positioning.
5. For the same building tilt observation object, it is necessary to set two or more reference points at different positions within the observation range of the measuring robot.

In order to ensure the accuracy and stability of building tilt monitoring, it is necessary to select stable and long-term monitoring positions for stability inspection.

3.2. Simulation of robot benchmark labeling building inclination. Because the end effector of the measuring robot is a laser sensor, the laser sensor is connected to the robotic arm through 01, and the robotic arm of the measuring robot is simplified into a planar robotic arm model. The description of the position and posture of the laser sensor using coordinate annotation is more intuitive [8].

Let X be the laser sensor, therefore, the robot base coordinate system is Equation 3.1.

$$\begin{cases} x_e = l_1 \cos \theta_1 + l_3 \cos(\theta_1 + \theta_2) \phi + l_4 \cos(\theta_1 + \theta_2 + \theta_4) \\ y_e = l_1 \sin \theta_1 + l_3 \sin(\theta_1 + \theta_2) \phi + l_4 \sin(\theta_1 + \theta_2 + \theta_4) \end{cases} \quad (3.1)$$

The Kinematics parameters obtained by simulation are basically in line with the actual situation, which can be used to describe them and verify the theoretical feasibility of the proposed method. According to the tilt simulation process (as shown in Figure 3.1), complete the tilt simulation research of the robot benchmark labeling building.

3.3. Accuracy Appraisal of Building Tilt Monitoring. The servo Total station with high precision and strong automatic tracking ability is selected, and the front crossing mode is adopted to realize the three-dimensional accurate observation of building inclination observation. This method can effectively weaken the influence of the error of conventional observation methods on the observation accuracy. The calculation formula for inclination error (2) is:

$$i = \frac{\sqrt{(x_1 - x_2)^2 - (y_1 - y_2)^2}}{|z_1 z_2|} < 0.05 \quad (3.2)$$

In Equation 3.2, x_1 , y_1 , and z_1 respectively represent the coordinate errors of the upper half of the horizontal axis of the coordinate system; x_2 , y_2 , and z_2 respectively represent the coordinate errors in the lower half of the horizontal axis of the coordinate system. Select the set of data with the highest error in the coordinate system to evaluate the accuracy of building tilt monitoring. If the monitoring error is less than 0.05, it indicates that the monitoring results of this method are relatively accurate .

3.4. Precision Analysis of Monitoring Schemes.

3.4.1. 3D free station adjustment calculation model. Before conducting long-term monitoring, analyze the accuracy of this plan based on three types of observation values and monitoring methods. When conducting accuracy analysis based on the instrument accuracy and observation method used, the mean square error in horizontal direction observation is $m_y = \pm 0.5''$, and the mean square error in horizontal distance observation is $m_s = \pm 0.5mm$, with a vertical right angle observation error of $m_g = \pm 0.7''$ [9, 10].

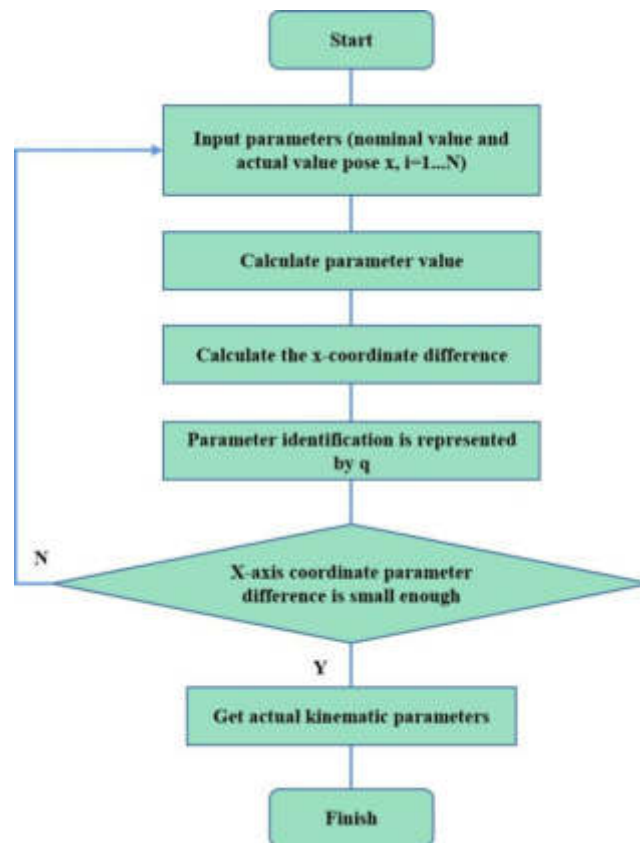

Fig. 3.1: Tilt Simulation Process

According to the principle of indirect adjustment, list the error equations for the three measurements in this scheme.

1. The error equation is shown in Equation 3.3

$$V = B\delta_x + L \quad (3.3)$$

In the equation:

- V - Correction matrix of observation values;
- B - coefficient matrix of observation error equation;
- gx - unknown number correction matrix;
- L-constant matrix of observation error equation.

2. The coefficient matrix formula of the normal Equation 3.4

$$N = B^T P B \quad (3.4)$$

3. Expected results of errors.

By writing VB program code to solve the coefficient matrix of the unknown number matrix, the expected error value is finally obtained. The expected error results are shown in Table 3.1.

From the expected results in Table 3.1, it can be seen that if the mean of two independent observations is taken as the final observation result, the measurement accuracy of the monitoring project will meet the requirement of $\leq 1\text{mm}$.

4. Actual measurement and data analysis

Table 3.1: Expected Results of Errors

Monitoring point number	Mean square error in X coordinate	Y coordinate mean square error	Mean square error of a point	Mean square error of elevation
S1	± 0.07	± 0.08	± 0.08	± 0.05
S2	± 0.07	± 0.07	± 0.09	± 0.06
1	± 0.19	± 0.39	± 0.43	± 0.16
2	± 0.19	± 0.39	± 0.42	± 0.21
3	± 0.23	± 0.23	± 0.47	± 0.15
4	± 0.34	± 0.21	± 0.45	± 0.14

Table 3.2: Results of Measured Data

1	X(m)	Y(m)	H(m)	type
2	936.25	963.45	148.36	undetermined
3	936.12	954.12	148312	undetermined
4	985.12	960.12	148.32	undetermined
S1	947.21	945.13	110.25	undetermined
S2	856.21	935.74	110.74	fixed

When observing on the actual site, the position of the measuring station remains fixed. Leica TM30 surveying robot is used to set up on S1 and s2 stations respectively for observation. Each station automatically observes 3 sets of measurements, and simultaneously observes the horizontal angle, distance and vertical angle. After collecting data from monitoring points, perform 3D adjustment model calculations, and perform overall rigorous adjustment calculations on all observation data [11,12]. The measured data is shown in Table 3.2.

3.5. Main parameters of measuring robots. The main parameters of the measuring robot include: Total station coordinate system, angle measuring accuracy, distance measuring accuracy and angle measuring speed. The coordinate system of Total station includes three coordinate systems, namely X, Y and Z direction coordinate systems, namely ground coordinate system, distance coordinate system and angle coordinate system. The distance measurement accuracy of Total station is 1 mm, and the angle measurement accuracy is 0.02° ; The ranging speed is 6-10m/s. Angle measurement accuracy refers to the ratio of the difference between the angles of Total station in two observation directions and the difference between the angles of these two observation directions, expressed in%. In practical applications, in order to ensure the accuracy of measurement, direct reading method and indirect reading method are generally used to calculate the coordinates of the measuring station. The direct reading method refers to directly reading out the coordinates of the measuring station; The indirect reading method refers to obtaining the coordinates of a given point by substituting the station coordinates into the known point coordinates, provided that the station coordinates are already known [13,14].

In the actual survey, the angle measurement accuracy needs to be corrected due to the deviation of Total station observation value. Generally, the error of station coordinates can be divided into two situations: One is the systematic error of station coordinates, which can be corrected by setting reference points; The other type is the system error of angle measurement accuracy, which mainly comes from the system error generated by the measuring robot itself, its size is related to the coordinate system error and angle measurement accuracy of the measuring station. In order to ensure the accuracy and reliability of measurement robots, the angle measurement accuracy is generally controlled within 1° . For high-precision monitoring projects, additional compensation is required.

3.5.1. Measurement method.

1. Turn on the power of the automated measurement robot and adjust the working temperature of the laser ranging sensor to $-20^\circ C \sim +40^\circ C$.

Fig. 4.1: 3D Display Results of Actual Building Inclination

2. Use a handheld computer to read the coordinates of the reference point, then place the measuring robot on the reference point and start the automatic tracking system.
3. Calculate the tilt angle and relative position of the building based on the sensor data on the measuring robot and the laser ranging sensor data.
4. Based on the laser ranging sensor data on the measuring robot and the coordinates of the measuring station, calculate the building tilt angle and relative position, and then compare the calculated building tilt angle and relative position with the reference point to calculate the error of the building tilt angle [15].

4. Experiments.

4.1. Experimental Environment. Taking a building as an example, through the method of establishing a model, the scanning angle between the coordinates of the measuring points and the light surface of each Launch pad is measured to obtain the required angle, so as to determine the relationship between the distance measurement problem functions of high-rise buildings; Utilize a large amount of random data to statistically analyze the coordinates of the measured point, and then use a three-dimensional discrete point cloud to represent the coordinates of the measured point. Through the Monte Carlo simulation of 3000 samples, the point cloud distribution is obtained, which is similar to the ellipsoidal distribution. The use of measuring robots for rapid monitoring of the inclination of buildings and the analysis of the accuracy of monitoring results using three-dimensional measurement methods have led to conclusions of universal significance.

4.2. Experimental process. The distance between the measurement target and the dual emission station will have a certain impact on the measurement results. Several monitoring points are selected within the range of 1100mm to 6000mm, with each selected point spaced at 110mm intervals, and experiments are conducted in sequence. Draw a 3D cloud spatial point map of the actual building inclination, a 3D display cloud spatial point map of building inclination under monitoring by measuring robots, and a 3D display cloud spatial electrical state of building inclination under traditional mechanical probe measurement. Compare the inclination and draw an experimental conclusion [16].

4.3. Experimental results. If the error distribution is introduced into the sensor, the direction of laser ranging can be changed. Therefore, the point cloud obtained by Monte Carlo method takes the laser ranging error into consideration, and the distribution accuracy of the point cloud obtained by laser ranging method is very high. The three-dimensional display of the actual building inclination is shown in Figure 4.1.

Using the point cloud data in Figure 4.1 as supporting data, traditional mechanical probe measurement

Table 4.1: Comparison of Monitoring Accuracy between Two Methods

	Number of monitored dimensional groups (piece)	Actual total number of groups	Detection accuracy%
Traditional mechanical probe measurement	2765	2800	92
Measurement robot mechanical probe measurement	2985	2800	99

and measurement robot monitoring methods were used to compare and analyze the monitoring of building inclination. The three-dimensional point cloud spatial distribution formed by the actual inclination of the building is used as a control group. Under traditional mechanical probe measurement, three-dimensional modeling is used to demonstrate the monitoring accuracy of building inclination, which is lower compared to measurement robots. The results of building tilt monitoring based on measuring robots are better matched with the actual situation. In order to further verify the higher monitoring accuracy of the author's research method, the monitoring accuracy of the two methods was compared and analyzed, and the comparison results are shown in Table 4.1 [17].

From Table 4.1, it can be seen that the monitoring accuracy of building inclination based on traditional mechanical probe measurement is 92%, and the monitoring accuracy based on measurement robots is 99%, which is 7% higher than the former. It can be seen that the monitoring accuracy based on measurement robots is higher.

5. Discussion. Improving the accuracy of measurement data by measuring robots

According to the actual situation of buildings, the following measures can be taken to improve the accuracy of measurement data:

1. When using high-precision measurement robots for monitoring, it is necessary to isolate the boundaries, walls, and other areas of the building from the surrounding environment to ensure the accuracy of measurement data.
2. When monitoring buildings, it is necessary to strictly follow the construction plan for monitoring, and the internal structure of the building must be the main measurement object during measurement.
3. When conducting measurements, it is necessary to ensure that the monitoring environment is dry, clean, and tidy, and to repair cracks, holes, and other defects on the building's exterior walls and walls.
4. When conducting measurements, it is necessary to ensure that the measuring robot has good stability and reliability. If there are problems in their work, they should be promptly contacted by the staff to replace them [18].
5. When monitoring buildings, it is necessary to ensure that the instruments and equipment used can meet the relevant detection requirements.

When using measurement robots for building tilt stability monitoring, it is necessary to choose appropriate measurement methods based on the actual situation to improve measurement efficiency. For example, Total station and Dumpy level can be used for slope stability monitoring. In order to ensure the safety of buildings, various parts of the building should be monitored. Due to the fact that using measurement robots can reduce the number of measurements, it can improve work efficiency.

In addition, the use of measurement robots can improve the accuracy and accuracy of monitoring, thereby reducing monitoring costs. When using high-precision measurement robots for building tilt stability monitoring, it can not only improve work efficiency but also reduce monitoring costs. In traditional building tilt stability monitoring, it is usually necessary to measure and calculate the results multiple times. Therefore, it is necessary to measure multiple monitoring points simultaneously and calculate the results [19,20].

6. Conclusion. The use of measuring robots to monitor the inclination of buildings has broken the research process of traditional building inclination observation methods, greatly improving monitoring efficiency. The use of monitoring data can quickly calculate the inclination of building materials, and the monitoring results have high accuracy and reliability. The robot measurement method can deeply measure the inclination of buildings,

and use 3D models to display the monitoring accuracy of building inclination. Compared with traditional methods, it has higher accuracy and is in line with the actual situation, resulting in better measurement results. The use of measurement robots to monitor the inclination of buildings has a significant impact on the measurement results. In the following research, heuristic search algorithms such as genetic algorithms will be used to further optimize the design and layout of monitoring points, thereby improving monitoring accuracy.

APPLICATION OF SOFTWARE ROBOTS AND DEEP LEARNING IN REAL TIME PROCESSING OF E-COMMERCE ORDERS

WENBO NIU*, YIBO HU† AND WEI ZHANG‡

Abstract. The development of e-commerce faces many problems, among which the real-time information exchange between customers and websites is the most urgent. To study the application of software robots in the real-time processing of e-commerce orders. According to the working mechanism of ALICE, JAVAPROGRAMD, AIML technology, database technology, knowledge base principle, Rule of inference, and reasoning strategies are used to design the structure, workflow, knowledge processing flow, and Inference engine supporting human-computer automatic negotiation of the software robot. Establishing a rule base is the acquisition, induction, and organization of knowledge related to order processing. It requires learning and analyzing the problems and related materials to be solved, simulating the actual process of order processing, and extracting useful processing rules and processes from it. The rules in the system are not organized in a simple list form, but have a certain hierarchical structure. This way, when using these rules for reasoning, the hierarchy is clear and it is easy to modify and add rules. The hierarchical structure of the rules referred to here is to simulate the thinking activities of the human brain in the process of order processing, and organize them in a certain way. Based on the basic rules of order processing, the process of order processing, the rational performance of the order and the possibility of necessary events, so as to realize the structure of the reasoning machine. Expands the application of Chatbot ALICE, and provides a new tool for real-time online negotiation and negotiation of e-commerce order processing. The core part of the e-commerce order processing software robot is the human-machine automatic interaction module. Database module, knowledge base module and rule base module provide the necessary data, knowledge and rule basis for its realization, while the implementation of reasoning machine provides the possibility for the intelligence and dynamic interaction of human-machine automatic interaction module.

Key words: Software robots, E-commerce, Real time processing of orders, Online negotiation, Negotiate reasoning

1. Introduction. With the development of computer technology and network technology, the development of e-commerce advances rapidly. E-commerce can reduce costs, reduce inventory, save time, and so on, but it also faces many problems, among them, the order processing transaction in the high cost, low efficiency is especially obvious. The widespread market of e-commerce has led to increasing demands and expectations from people. At present, the problems faced by e-commerce websites in order processing transactions and the resulting defects of high cost and low efficiency are becoming increasingly apparent [1]. Currently, after consumers place orders through business websites, merchants will confirm the authenticity of the order and negotiate specific matters on the order through phone or email. In the face of fierce global market competition, every merchant should respond promptly and quickly. However, in the above-mentioned order processing process, several aspects are far from meeting the needs of rapidly developing information technology and increasingly competitive online commerce [2]. Therefore, it is extremely important to design man-machine dialogue software robot based on rules and reasoning mechanism, which can free people from order processing; increase the real-time, accuracy and dynamic interaction of order processing; reduce the operating cost of merchants; realize the characteristic service of merchants and the personalized needs of buyers. The research and implementation of this real-time and online man-machine negotiation platform is one of the challenging research topics in e-commerce order processing. Firstly, when a consumer places an order, they are faced with a pre designed business website by the merchant, which includes static information such as description information of various products, prices of products, and fixed delivery times in fixed areas. Consumers have only two choices: accept or not, and cannot make personalized special requirements based on their own situation. Moreover, consumers are not aware at the time whether the order can be fulfilled in a timely manner, that is, the order is fulfilled. Secondly,

*The School of Business, Xi'an International University, Xi'an, 710077, China (Corresponding author, WenboNiu7@163.com)

†The School of Business, Xi'an International University, Xi'an, 710077, China (YiboHu9@126.com)

although online commerce based on phone and email can solve negotiation issues after placing an order, not all consumers are willing or have time to interact with merchants after placing an order. In addition, in order to improve online sales and market competitiveness, businesses need to provide online and offline services 24 hours a day, 7 days a week. This undoubtedly increases the operating costs of businesses, and due to the negligence of staff operations, timely and accurate services may not be possible. E-commerce is a further extension of human commodity buying and selling activities, which is changing the business operation mode of enterprises and people's economic lifestyle [3]. However, e-commerce, which is currently in its early stages of development, only provides functions such as information dissemination, the use of electronic currency, the sale and purchase of fixed price goods, and the fixed delivery capacity in fixed areas, lacking the intelligent negotiation part in traditional business activities. Secondly, the marketing philosophy has shifted from traditional 4P (Product, Price, Place, Promotion) to 4C (Customer, Convention, Cost, Communication), and this shift in marketing philosophy has put forward new demands for the operation of business websites [4]. The 4C theory needs to consider both consumer needs and corporate profits, so business websites should be customer-centric and constantly consider consumer needs while ensuring their own profits. Therefore, in order to solve the problems in the order processing process of e-commerce websites, providing efficient e-commerce transaction platforms with online negotiation mechanisms for merchants and customers can promote the further development of e-commerce, at the same time, it can realize personified real-time processing of orders. Therefore, it is necessary to design a human-computer dialogue software robot for e-commerce order processing based on rules and reasoning mechanism. Software robots are not fatigued and are based on a powerful real-time and dynamically updated database and rule base in the backend, enabling e-commerce websites to provide real-time, accurate, and error free online order processing services, which can promote the automation and intelligence of product buying and selling in e-commerce. Therefore, the implementation of human-machine dialogue software robots can free people from the process of order processing; Increase the real-time, accuracy, and dynamic interactivity of order processing; Reduce the operating costs of businesses: Achieve unique services for businesses and personalized customer needs, thereby increasing consumer satisfaction. The research and implementation of this real-time and online human-machine negotiation platform is one of the challenging research topics in e-commerce order processing [5,6]. At present, the research on negotiation reasoning mainly focuses on automatic negotiation model, interactive multi-objective negotiation model, negotiation support system, virtual reality technology, anthropomorphic human-computer interaction Agent, business auction system based on Agent technology, online bidding system based on XML technology, etc. The auction on Internet was so great success that some researchers believe that the auction is the only effective negotiation mechanism in e-commerce. The information integration in the real-time order processing system is also deeply concerned. The application of ALICE research is also very extensive.

This paper adopts JAVAPROGRAMD and AIML technology, using database technology, knowledge base principle, reasoning rules and reasoning strategy, and designs the structure, workflow, knowledge processing process of the software robot and the reasoning machine to support man-machine automatic negotiation. It has expanded the application of chatbot ALICE and provides a new tool for real-time online negotiation and negotiation of e-commerce order processing.

2. Literature Review. In order to solve the problems in the process of order processing of e-commerce websites, it is extremely important to provide efficient man-machine dialogue software robot with online negotiation mechanism to design man-machine dialogue software robot based on rules and reasoning mechanism.

At present, due to the research and implementation of internal and external e-commerce order processing, there is a research on the order processing process of the supply chain based on Finite-state machine. "Most of the order processing is mainly online, that is, not real-time online order processing. For example, the world's largest Chinese online book and video store, Dangdang.com, eGuo.com Mall, Gome Appliances, TOM Mall, Joyo Network, and so on, the shopping process of these websites generally includes: Logging in, selecting products, registering, logging in, filling out orders, and confirming payment methods, all these websites provide only the function of placing orders online through the network environment, without providing timely online negotiation and order confirmation when customers place orders, in this case, the so-called order processing is carried out manually offline, and the order processing personnel check the content of the order, including whether the goods ordered by the customer have sufficient supply and whether they can be delivered to the customer's

designated receiving location on time, which is the effective fulfillment of the order [7]. In this case, whether the order placed by the customer can be effectively fulfilled depends on whether the customer can provide the processing result of an order through email or phone on the order after the above processing is completed offline. At present, the real-time and online part of e-commerce online shopping includes the rationality verification of order content and the provision of online electronic payment function when placing orders. Among them, the rationality verification of order content does not refer to the verification of information that affects order fulfillment, but rather to the verification of the validity of the data by the business website according to certain rules when filling out the order, including the type of data, the number of digits of the ID number, whether the contact phone number and email address are correct, and so on. Online payment is based on financial electronic networks, using commercial electronic tools and various transaction cards as media, and using computer and communication technology as means to store electronic data in the computer system of banks, and it is a means of circulation and payment through electronic information transmission through computer network systems. Online payments circulate through electronic currency, which is a cash currency that exists in electronic digital form [8]. At present, research on online electronic payments mainly focuses on payment gateways, electronic banking, electronic wallets, electronic checks, and so on. The various online payment methods launched by the financial system are becoming increasingly perfect, which has invisibly played a role in promoting the rapid growth of online shopping. The C2it online payment service launched by Citibank in the United States can help customers establish an online account, and customers can easily complete payment procedures without entering their credit card number or bank account information each time they make a payment. Nevertheless, online electronic payment is also carried out when the order has not been confirmed to be fulfilled, adopting a mechanism of payment before delivery. The condition for its smooth execution is that both parties assume that the order will be fulfilled, but this process undoubtedly increases the uncertainty of order processing [9].

Electronic commerce order processing software robot is the core part of the man-machine automatic interaction module, database module, knowledge base module and the corresponding rule base module, provides the necessary data, knowledge and rules basis, and the implementation of the reasoning machine automatic interaction module provides the intelligence, dynamic interaction. The first step of establishing the rule base is to acquire, summarize and organize the knowledge of order processing. It is necessary to study and analyze the problems and relevant materials to be solved, simulate the actual processing process of the order, and extract useful processing rules and processes from it. The rules in the system are not organized in the form of a simple list, but in a certain way, based on the basic rules of order processing, with the process of order processing, the rational performance of orders and the possibility of necessary events as the reasoning mechanism, so as to realize the structure of the reasoning machine.

Software robots actually refer to a program that can simulate an operator's operation, and can automatically complete a certain operation without human participation, thus replacing some of the human work. The current research on software robots mainly focuses on search engine software robots (Uluka, Spider, CyBot, MetaCrawler), shopping software robots (AcseBookfinder), and chat software robots (Eliza, ALICE). The shopping software robot applied in e-commerce is particularly eye-catching, as it not only helps buyers find the most cost-effective price, but also automatically orders this product when the best performance price ratio is found. This software robot has certain advantages when ordering goods, but when customers cannot determine whether their orders can be fulfilled in a timely manner in order to ensure that they can purchase the goods, they will place the same order on multiple websites. Therefore, orders that are not processed in a timely manner can cause false demand for businesses [10,11]. The real-time order processing software robot is mainly responsible for obtaining customer ordering information, logistics and distribution arrangement results of e-commerce websites, and providing customers with negotiation information about the positioning results of supply points and the selection results of third-party logistics and distribution centers.

With the development of computer technology and network technology, the development of e-commerce has made rapid progress. E-commerce can reduce costs, reduce inventory, and save time, but it also faces many problems, among them, the high cost and low efficiency in order processing transactions are particularly evident. Currently, after consumers place orders on the website, merchants will confirm the authenticity of the order and negotiate specific matters on the order through phone calls, text messages, and emails. In the face of fierce global market competition, every merchant should make timely and rapid responses, and in the above

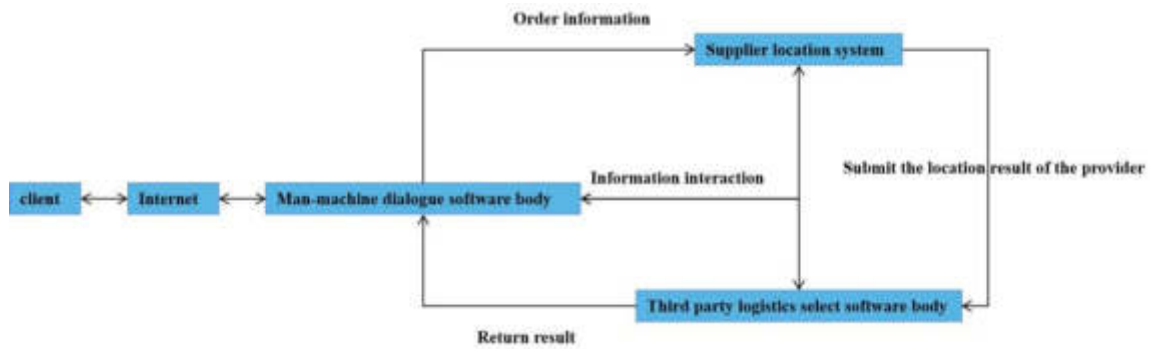

Fig. 3.1: Real time processing process of e-commerce orders

processing process, it is far from meeting the needs of online commerce. With the development of computer technology and network technology, the development of e-commerce has made rapid progress. E-commerce can reduce costs, reduce inventory, and save time, but there are also many problems, among which the high cost and low efficiency in order processing transactions are particularly evident. Currently, after consumers place orders on the website, merchants will confirm the authenticity of the order and negotiate specific matters on the order through phone calls, text messages, and emails. In the face of fierce global market competition, every merchant should make timely and rapid responses, and in the above processing process, it is far from meeting the needs of online commerce. Therefore, the structure of the human-machine dialogue software robot, inference rules and inference machines supporting human-machine automatic negotiation, have been designed, expanding the application scope of the chat robot ALICE, and providing new tools for real-time online negotiation and negotiation of e-commerce order processing [12].

3. Methods.

3.1. Determine system boundaries . Determining system boundaries means identifying what is inside and outside the system, and determining their relationships, but it is necessary to consider interface or information transfer issues within and outside the system. The location and information interaction relationship of this system in real-time processing of e-commerce orders are shown in Figure 3.1 [13].

This system is a man-machine dialogue system, in the running process of the Web application, from the customer login business website, to select goods with the server software robot after many negotiations, the system needs to remember to interact with it customers which one, what interaction behavior, namely the customer behavior, this requires business website web application ability to record and track the session. Even though the customer visits hundreds of web pages on the website and orders dozens of goods, after many negotiations with the software robot on the server side, the system can remember all the goods the customer wants to buy and the specific customers and relevant information they interact with. However, the construction and development of the website is based on HTTP protocol, and HTTP itself is a stateless protocol, namely there is no memory function, which means that it cannot each customer a request with another request, they use different ports at different times, so the server has no association about the request. In order to enable the system to remember that the customer who chose the product and the customer who negotiated with it are the same customer, and to record the relevant information in the negotiation process, the conversation tracking mechanism should be adopted to solve this problem.

Session tracking is the process of recording a customer logically associated with different access requests over a period of time. Sessions can be tracked through the customer's only-ID at each service request. Each session is identified by a unique session ID, used to track multiple requests sent from the same customer to the server, and to associate the customer with his session data.

3.2. System design of human-machine dialogue software robot. The system is divided into two parts for design and development, including web applications and EJBs. The system adopts Uml for system

Fig. 3.2: Component Relationship Diagram

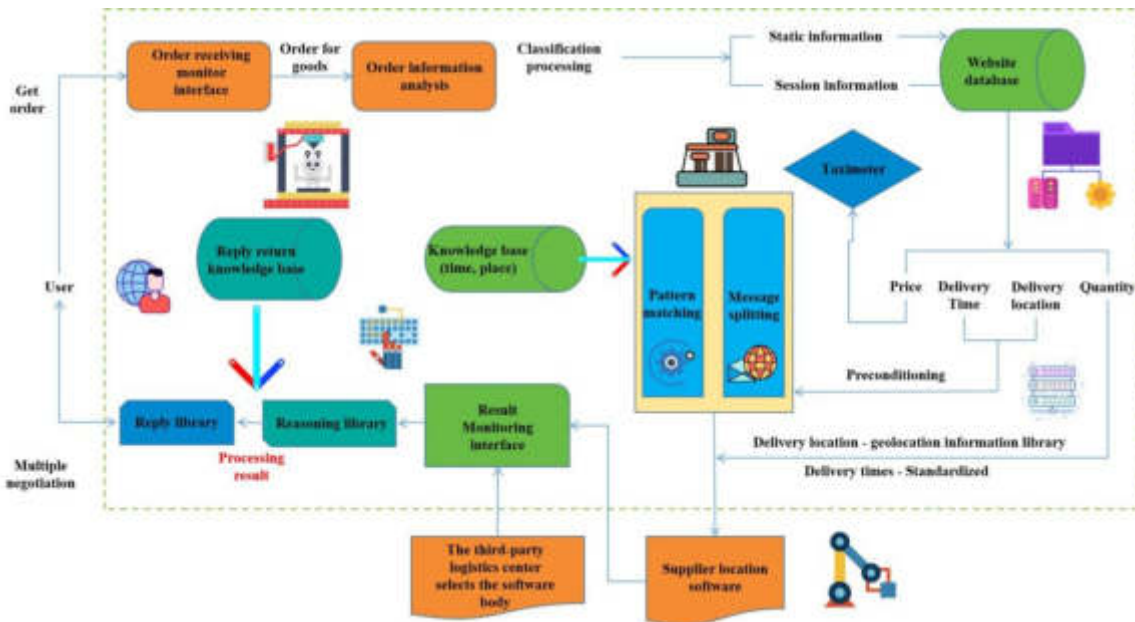

Fig. 3.3: Structure of human-machine dialogue software robot

analysis, while applying a modular design concept, and adopts Java. Jsp for system implementation [14].

(1) *Design of System EJBs Model.* The data objects involved in this system include User, Good, and Order, and three EntityBeans (UserEJBs, BookEJBs, and OrderEJBs, all of which are CMP types) were designed, each EntityBean has a table corresponding to it in the database, and each instance of EntityBean corresponds to a row of data in the Table.

The system accesses entity beans in the form of session beans. In this system, two types of session beans are used, stateful session beans representing shopping carts and stateless session beans representing evaluators. The component relationship is shown in Figure 3.2 [15].

(2) *The structure of human-machine dialogue software robot.* The main task of implementing human-machine dialogue software robots is to create a, when interested in purchasing goods, but unable to determine whether the merchant has sufficient supply of goods and can fulfill the order at the designated time and location, real-time online negotiation is conducted with the merchant to sign the order under mutually acceptable conditions. The structure of the human-machine dialogue software robot is shown in Figure 3.3 [16].

(3) *Design of Robot Analysis Mechanism for Human Machine Dialogue Software.* Information analysis is one of the most important parts of the personification real-time processing of e-commerce orders, mainly providing four functions: 1) Analyze the original information of orders received by the website, including the analysis of delivery time and location; 2) Analyze the processing results of the supply point positioning software body;

Fig. 3.4: Information Analysis Mechanism Structure of Original Orders

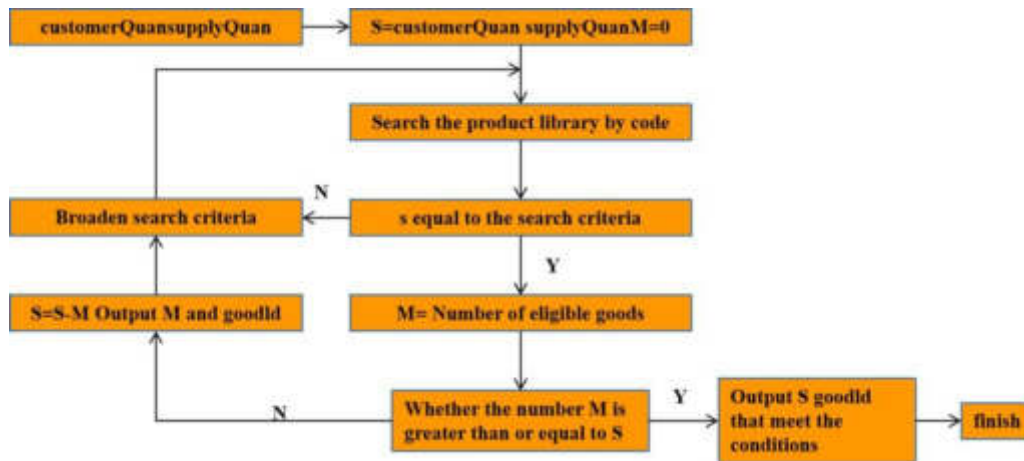

Fig. 3.5: Product Replacement Search Process

3) Analyze the processing results of selecting software entities for third-party logistics centers; 4) Combine the response and return to the knowledge base to perform secondary parsing on the processing results of 2) and 3), in order to obtain a humanized human-machine negotiation result. Therefore, in the information input interface section, it is necessary to implement the classification of received information, and input corresponding parsing rules based on the classified results for parsing, while providing the parsing results. When parsing the original order, the parsing mechanism structure is shown in Figure 3.4 [17].

(4) Reasoning Rule Design. If the user wants to buy 100<JSP Introduction and Improvement), after the first human-machine negotiation, the feedback information shows that the customerQuan (quantity of goods ordered by the user) is greater than the supplyQuan (quantity of goods available in the supply point positioning software), and the ten digit code of "JSP Introduction and Improvement" is N002C1P1W3l0, then search for books that match or approximate N002C1P1W3 in the product library, as shown in Figure 3.5 [18].

In the process of product substitution, the substitution rules used are from precise matching to approximate matching. The rule execution process is as follows: When substitution behavior occurs, first search according to the taxi system code of the book that the user wants to purchase. For example, N002C1P1W3, if the quantity requirement is met, the search will be stopped. Otherwise, the matching conditions will be relaxed and similar matching rules will be implemented. Regarding the different importance of the four types of coding rules in the ten digit system, while ensuring that the category of the ordered book remains unchanged, perform similar matching in the following order, namely N002C1P1... - N002C1... - N002... During the search process, as long as the required quantity is met, exit the search and output the product ID and quantity that meet the conditions [19].

Table 4.1: Function Table of Java Class in Inference Machine

Java class	function
resSupply. java	Call the supply point positioning software body to select the supply point, and return the quantity and time of goods provided by the supply point
judgeSupply. java	Judge the processing results of the supply point positioning software, that is, judge the quantity and time. If the quantity is not enough, replace the product. If the time cannot be met, negotiate the time and call the corresponding user negotiation interface
goodReplace. java	The product substitution module mainly performs substitution queries based on the coding rules of the product, and the query process is dynamic, from precise matching to approximate matching as needed
timeReplace. java	Time change negotiation may occur after the supplier locates the software body, or after the third-party logistics center selects the software body
resTpl. java	Call the third-party logistics center software to perform logistics delivery and return the available logistics delivery time
judgeTpl java	Judge the processing results of the third-party logistics center software body to determine whether there has been a time change negotiation. If necessary, call the corresponding negotiation interface
orderOk. java	Accept order, update order6 data table, delete temporary data table
orderEnd. java	Cancel the order, update the order6 data table, and delete the temporary data table

4. Implementation of inference engine in human-machine negotiation. The core part of the e-commerce order processing software robot is the human-machine automatic interaction module. The database module, knowledge base module, and rule base module provide necessary data, knowledge, and rule basis for its implementation, while the implementation of the inference machine provides the possibility for the intelligence and dynamic interaction of the human-machine automatic interaction module.

Establishing a rule base is the acquisition, induction, and organization of knowledge related to order processing, it requires learning and analyzing the problems and related materials to be solved, simulating the actual process of order processing, and extracting useful processing rules and processes from it. The rules in the system are not organized in a simple list form, but have a certain hierarchical structure. This way, when using these rules for reasoning, the hierarchy is clear and it is easy to modify and add rules. When modifying, you only need to modify the rules at a specific level without modifying or changing the rules at other levels. The hierarchical structure of the rules referred to here simulates the thinking activities of the human brain during the order processing process, and organized in a certain way, based on the basic rules of order processing, the inference mechanism is based on the process of order processing, the reasonable fulfillment of orders, and the possibility of necessary events, to achieve the structure of the inference machine. When designing the inference engine structure, the inference process that handles the same problem is implemented as a class, and the processing situations with the same probability of occurrence are implemented as classes at the same level. The general form of rules in this system is: (IF<state judgment>) (THEN<operation 1>ELSE<operation 2>). The inference engine of this system is written in Java language. The description of the Java classes inside the inference machine is shown in Table 4.1 [20].

5. Conclusion. With the development of computer technology and network technology, the development of e-commerce has made rapid progress. E-commerce can reduce costs, reduce inventory, and save time, but there are also many problems, among which the high cost and low efficiency in order processing transactions are particularly evident. Currently, after consumers place orders on the website, merchants will confirm the authenticity of the order and negotiate specific matters on the order through phone calls, text messages, and emails. In the face of fierce global market competition, every merchant should make timely and rapid responses, and in the above processing process, it is far from meeting the needs of online commerce. Therefore, the structure of the human-machine dialogue software robot, inference rules supporting human-machine automatic negotiation, and inference machine have been designed, expanding the application scope of the chat robot ALICE, provides new tools for real-time online negotiation and negotiation of e-commerce order processing. The core part of the e-commerce order processing software robot is the human-machine automatic interaction module. Database module, knowledge base module and rule base module provide the necessary data, knowledge and rule basis for its realization, while the implementation of reasoning machine provides the possibility for the intelligence and dynamic interaction of human-machine automatic interaction module. How to use natural

language to negotiate with human-machine dialogue software robots for order processing in e-commerce is a challenging research direction with broad application prospects, and further in-depth research is needed.

INTELLIGENT ALGORITHM OPERATION AND DATA MANAGEMENT OF ELECTROMECHANICAL ENGINEERING POWER COMMUNICATION NETWORK BASED ON THE INTERNET OF THINGS

YING LI* WENJING QU† AND ZHENQIANG ZHANG‡

Abstract. With the rapid development and gradual popularization of Internet of Things technology, it is necessary to provide necessary Operation and Maintenance (O&M) services and data control for electromechanical engineering to maintain the normal function of the power system. This paper does the following research to carry out orderly and standardized management of related communication resources in power communication networks, conduct closed-loop and process-oriented management of communication O&M work, and ensure the safe, stable, and economical operation of power grids in electromechanical engineering. Firstly, the technology selection, algorithm implementation, solutions, and other related technologies that may be used in the platform design and implementation process are introduced and selected. Secondly, the research and call logic of the design and implementation of related algorithms for intelligent O&M are introduced. It includes the design and implementation of anomaly detection algorithms to monitor equipment health status and the design and construction of fault diagnosis algorithms for abnormal analysis. Finally, the simulation experiment of the proposed processing scheme is carried out on the Mininet simulation network to prove that the proposed scheme can provide a better anonymization effect when introducing low latency. The results show that the design of the gateway system realizes the module applications of the system, such as user, data storage, O&M, and fault management. Based on the technical selection, the algorithm is implemented and optimized, and the call logic of the algorithm is implemented in the O&M module. Simulation verifies that the anonymization algorithm can complete the mapping without introducing an additional delay of more than 3%.

Key words: Internet of things, electromechanical engineering, power communication networks, intelligent operation and maintenance, data control

1. Introduction. The safety and stability control system and dispatching automation system of the power communication network and power system are important supports for maintaining the safe production of the power system. Also, it is the basis for grid dispatching automation, marketization of power grid operation, and modernization of management and provides important maintenance means to ensure the safe, stable, and economic operation of the power grid. Orderly and standardized management of relevant communication resources in power communication networks, centralized and intelligent monitoring of communication equipment and communication services, closed-loop and process-oriented management of communication Operation and Maintenance (O&M) work, and the formation of intelligent, integrated, and automated intelligent full-process management and control network of power communication network are effective means to improve work efficiency and ensure the safe operation of communication equipment [1].

This paper confirms and analyzes the O&M requirements and O&M status of electromechanical equipment and studies the implementation direction and system architecture innovation of intelligent O&M and Internet of Things (IoT) systems. Then, the overall system is designed and implemented with the idea of microservices, and the architecture pattern of microservices is formed. Platform services are provided through the architecture pattern, forming a low-coupling structure to meet the needs of convenience and scalability. Next, the box-plot, time series anomaly detection algorithm, and isolated forest algorithm are studied and presented separately. After testing and evaluating the characteristics of the three algorithms, a hierarchical intelligent detection

mechanism is designed to cope with the needs of anomaly detection in different situations. After anomalies are detected, a Decision Tree (DT) algorithm is used to troubleshoot based on anomalous data. It realizes the intelligent O&M of the system.

Data control opens up some data center interfaces. In this case, the data center of the power communication network will be significantly more likely to be attacked, and the attack methods will be very different. Data center traffic needs to be dynamically processed to prevent grid data from being improperly stolen or leaked during transmission. Through the centralized dynamic management and control capability provided by Software Defined Network (SDN), the efficient and fine-grained anonymization of data transmission is completed to achieve the purpose of security protection of power communication networks.

2. Literature Review. The IoT is a new industrial concept based on the concept of the Internet. It consists of the Internet as the core of interaction and the basis of communication. IoT involves industrial, home, medical, and logistics aspects. It is a network that interconnects the entire society. According to Muteba's research, the number of IoT devices worldwide was expected to reach 22 billion by 2025 [2]. Jalali said that the domestic output of the IoT industry was growing at a rapid rate of 20% per year, and the types and number of IoT devices were growing exponentially [3].

Algorithmic Intellectual Property Operations is an O&M with algorithms as the core. It is the latest O&M mode formed by O&M services with the continuous development of computing power, equipment, and concepts. At present, domestic and international intelligent O&M services are often integrated on large-scale platforms. For example, in the Amazon Web Services provided by Wei, the intelligent O&M function is only the overall edge function of the platform. The O&M function is relatively simple. The platform includes many functions not required by intelligent O&M services, which are prone to additional overhead [4]. You proposed a new architectural pattern that is different from traditional monolithic architecture. Its main feature is the division and treatment of system functions. The system's overall function is split, and the single function of the split is realized in a monolithic architecture pattern [5].

Network traffic control includes private information such as IP addresses and network ports of network users. If maliciously detected and analyzed by the outside world, it will cause the leakage of this information, violating user privacy and even trade secrets. Hammoudeh proposed the idea of using the programmability of SDN for anonymous services. It realized the hiding of network resources through address mapping [6]. Later, Iordache proposed some other anonymization algorithms. These algorithms achieve the purpose of shielding private information from the outside world by hashing information such as IP addresses to varying degrees. Meanwhile, some algorithms reduce the impact of anonymization operations on performance by caching [7].

Compared with foreign network management research and network management system development, China started late. After more than ten years of construction, China's network management standardization research has also achieved great results. However, the current intelligent O&M platform pays little attention to the emerging industry of the IoT. Besides, the current domestic and international intelligent O&M services are relatively simple O&M functions. The platform as a whole includes many functions that are not required by intelligent O&M services, which is prone to additional overhead. It can be seen that the intelligent O&M platforms on the market cannot meet the requirements. So, the innovation points here are as follows. First, the intelligent O&M mode is combined with the IoT industry to realize an intelligent O&M platform focusing on IoT devices' monitoring and O&M services. Second, it is very necessary and meaningful research to ensure the lightweight and scalability of the management and control platform. At present, the lack of this part of the content on the market should be filled to meet the overall development trend of the IoT. Third, anomaly detection depends on the implementation and optimization of algorithms. However, no one algorithm is suitable for all anomaly detection scenarios. Therefore, this paper selects and combines algorithms to achieve the optimal detection function.

3. Methods and materials.

3.1. Technologies related to the intelligent O&M platform of the power grid.

3.1.1. Microservices architecture. The microservice architecture realizes convenient development and flexible deployment and improves the system's scalability by redefining the separation and communication of services [8]. It is proposed that the power grid intelligent O&M platform has requirements for lightweight and

Fig. 3.1: Spring Cloud framework architecture diagram (NGINX (engine x): High-performance HTTP and reverse proxy web servers)

Fig. 3.2: Database storage structure

flexibility. The microservice architecture can realize the design of the system platform and further extend the system for this. As a result, the microservice system architecture is used to build the server-side system.

Spring Cloud is a mature framework that combines various mainstream frameworks. The implementation of individual services relies on the Spring Boot framework of the same company. Figure 1 shows the Spring Cloud framework architecture.

The Spring Cloud framework integrates with current mainstream third-party components or frameworks to provide microservices infrastructure capabilities. It encapsulates third-party components or frameworks during the integration process, shields the internal complex configuration and implementation principles, and forms a simple, reliable, and mainstream microservice system framework. There are specific requirements for lightweight deployment in the scenario of intelligent O&M for IoT devices. The non-intrusive Istio framework is not suitable for additional deployment tasks. The system studied here is designed and implemented based on the Java language, so there is no need for the Thrift system for microservice communication between multiple languages. Finally, Spring Cloud integrates many of the current mainstream components and frameworks. Additionally, it is widely used. As for stability and community considerations, Dubbo, as a recently restarted project, is far inferior to Spring Cloud.

3.1.2. Relational databases. Relational databases store data in a relational model. The data location is located by rows and columns inside the database. Several rows and columns form a table, and multiple tables form a database [9]. Figure 3.2 displays the database storage structure.

The basic data storage unit for Mongo (Humongous) is a document. Its structure uses a Binary Serialized Document Format similar to JavaScript Object Notation. As a mainstream document-based database, Mongo

Fig. 3.3: SDN three-layer network architecture

is convenient to store and read quickly. It is suitable for large-scale data storage.

3.1.3. Intelligent O&M algorithm.

1. Isolation Forest (iForest) is a fast anomaly detection algorithm. The basic idea of the algorithm is ensemble learning, so it has certain advantages in linear time complexity and accuracy [10]. The rationale for iForest is to define anomalies as “outliers that are easily isolated.” Each data point is divided into a separate space by constantly cutting the data space from different characteristics. Multiple cuts are required, and sparsely distributed points can be divided into space by a few cuts [11].
2. DT is a commonly used classification method. Through the classification results of known data and the corresponding occurrence probability, the logical judgment of if-then-else is constructed by the effect of factoring. The classification method of sample data is obtained. DT is an algorithm based on probabilistic analysis [12]. In constructing if-then-else logic, binary trees are usually used as logical structures, so the resulting algorithm is called a DT.
3. Box-plot is a statistical map based on statistical principles to show data distribution. The box-plot can display the distribution characteristics of the data to judge the two data with a small probability of abnormalities to achieve anomaly detection [13]. The plot of the box-plot is achieved by quartiles, which reduce the influence of extreme values in the sample data with quartiles. The distance judges anomalies from the upper and lower quartiles.

3.2. Technologies related to power grid data management and control.

3.2.1. Data center software definition. The existing power communication network architecture is a three-layer architecture built on the extended tree protocol. The transmission of data packets is completed through various transmission protocols [14]. However, with the increasing scale of the IoT and massive data, the routing tables in routers are becoming increasingly complex, which brings many problems to the current network framework. When tuning network devices, network administrators must configure each switch or router one by one using the command line [15]. The SDN concept is designed to solve this type of problem. Figure 3 presents the SDN three-layer network architecture.

SDN is a network virtualization technology. It strips the control functions of traditional switches and separates the data plane and control plane. SDN entrusts the function of decision control to the control layer and uses the open interface provided by the control layer to complete the delivery of decisions [16]. The network layer data of data center traffic is processed through the SDN network, combined with pooled IP. The data center’s security is ensured by decoupling the internal organization of the data center from the outside world. Figure 4 shows the specific structure diagram of the communication data center.

The network layer mainly has two parts, and one is SDN-based data center control network feeding. The central node discovery and the message transmission are part of the Peer-to-Peer network composed of blockchain

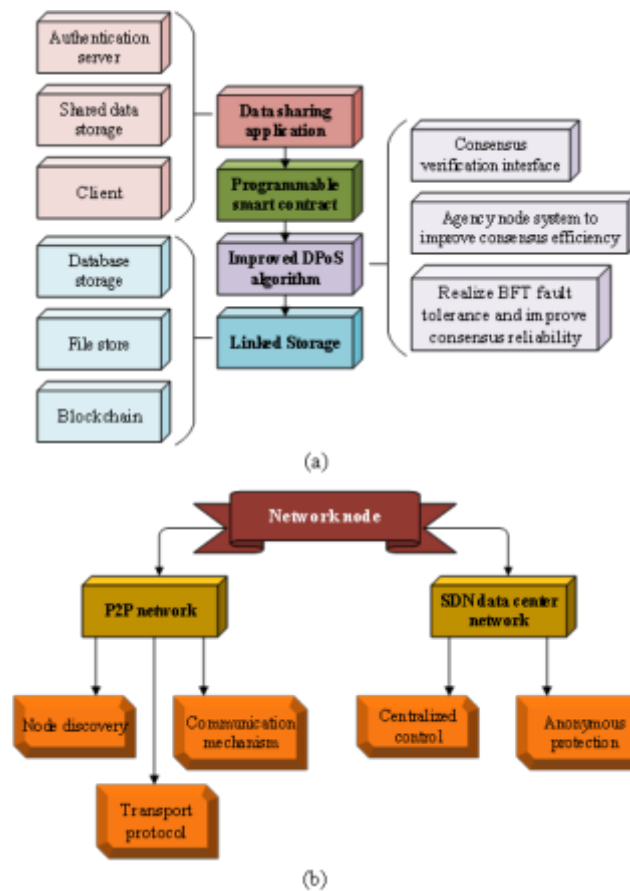

Fig. 3.4: Specific structure diagram of the communication data center

nodes responsible for node discovery, message propagation, and transmission protocol parsing in blockchain nodes [17]. The consensus layer and the data layer form the core of the blockchain data protection mechanism. The consensus layer improves the Delegated Proof of Stake (DPoS) algorithm. Based on the DPoS algorithm proxy system, the consensus layer combines the Practical Byzantine Fault Tolerance algorithm to improve the consensus efficiency and provide reliable node consensus.

3.2.2. Data copyright supervision mechanism. The center interacts with institutions in real time to fetch the returned data. These two methods are shown in Figure 3.5 for the data flow process.

The data itself has the characteristics of reproducibility and easy processing. In addition, the “see and own” nature of data makes it easier to own data than traditional goods. Agencies can move data at a lower cost [18].

4. Model design.

4.1. Simulation design of intelligent O&M service of power communication network. In the process of system implementation, for the consideration of applicability, the minimum available basic functions of anomaly detection should be provided for various types of IoT devices. As a classical algorithm with simple implementation, stable performance, and low requirements for data characteristics, box-plot has specific usability and wide applicability, which is suitable for the needs of this scenario. Therefore, the box-plot is selected as the basic algorithm for system anomaly detection. Table 4.1 records the relationship between the number of box-plot scenarios and the fluctuation of the detection accuracy of a single indicator.

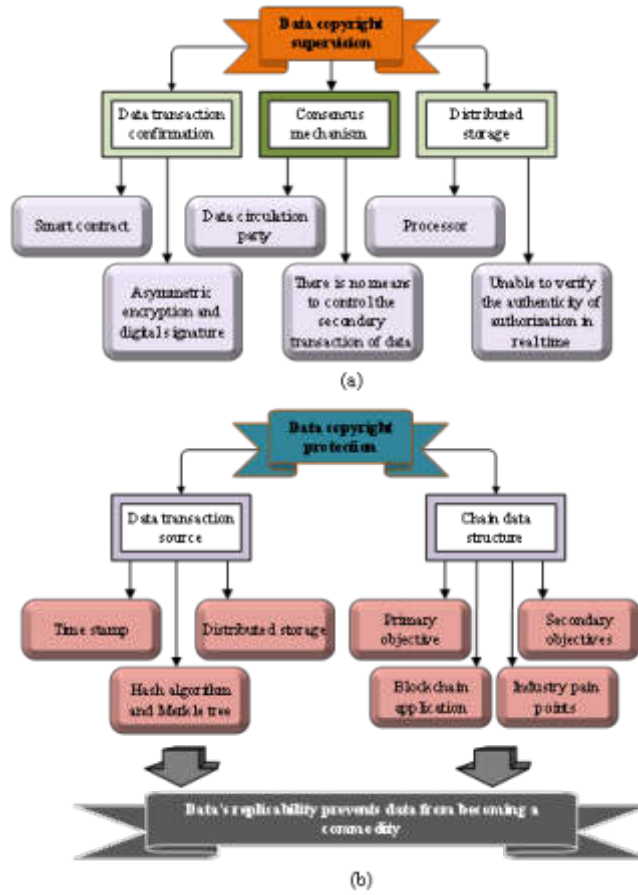

Fig. 3.5: Central interaction and real-time interactive data flow architecture diagram

Table 4.1: Box-plot sample number and detection fluctuation table

Number of scenes	50	250	750	1,500	2,500	3,500	4,500	5,500
Correct rate variance	0.045	0.017	0.014	0.006	0.002	0.006	0.012	0.008

Box-plot calculation formulas have inherent flaws. The data features cannot be effectively distinguished when the sample size is small. When the sample size is large, overfitting problems are prone to occur.

The data synchronization scheme in the data distribution scenario is designed, and the combination of synchronous calls and asynchronous callbacks is decided. Based on the message queuing transaction solution, the synchronous/asynchronous call method is improved to ensure that data can be successfully distributed to each node. Data is successfully synchronized to ensure data consistency. The specific implementation logic is demonstrated in Figure 4.1.

1. The first is the transmission of the O&M module. As the main functional module of the system, the O&M module has a higher priority than the data module. As data is the most critical dependency element of the O&M module, the real-time and accuracy of data transmission must be guaranteed.
2. The second is the transmission of data modules. The data module has a lower priority than the O&M module in system function priority. There are no requirements for data real-time. Therefore, the method of combining asynchronous call and callback confirmation is used to ensure the successful

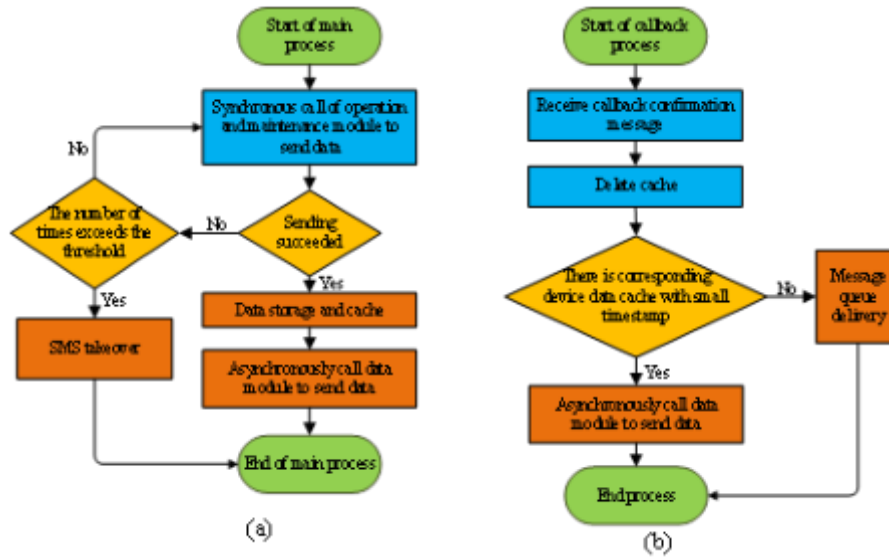

Fig. 4.1: Synchronous and asynchronous call logic flowchart (subscriber management system)

transmission of data and data consistency.

- The callback part receives an acknowledgment request after the data module receives the data. The acknowledgment request contains the device number and data timestamp. After the callback function receives the acknowledgment request, the corresponding data is deleted from the Redis cache. The data with the timestamp before the current callback data time cut-off is retrieved from the collection. It is the data that occurred before but still did not receive the callback acknowledgment.

The combination of synchronous transmission and asynchronous transmission ensures data consistency during data distribution between O&M modules and data modules, saving system overhead and shortening the time of data synchronization.

4.2. Data control center anonymization processing experimental simulation. This experiment studies the data anonymization guarantee scheme in the electromechanical engineering power system environment. The coupling relationship between network traffic is reduced by hashing and encrypting information such as account addresses and data payloads of data packets. The risk of improper in-depth analysis of data packets by the outside world is reduced to achieve the purpose of not leaking the internal information of the data control center.

The data anonymization solution is based on the SDN network. The pooled IP address is mapped in the egress switch of the data center to achieve the purpose of anonymization. Figure 4.2 shows the architecture of the anonymous service system.

SDN networks have the characteristics of centralized management and programmability, which can be used to deliver data at the data center egress gateway without the introduction of additional hardware devices. The topology and network information inside the data center can be completely shielded from the outside. The anonymization service component AnonyService is mounted on the SDN controller of the data center network. The main function of this component is to complete the mapping between Routable IP Address (RIPA) and Machine IP Address (MIPA) and the corresponding flow table delivery. MIPA is the actual address of the data center server, which is only perceived inside the data center and is shielded from the outside world. RIPA is an IP address that the outside world can access. After the controller calculates the mapping relationship between the two, it generates a flow table and delivers it.

When new traffic arrives, it determines whether the current anonymized flow table exceeds the given threshold. If it is exceeded, the timeout table is dropped. After that, determine whether the threshold has

Fig. 4.2: Data center anonymous service system architecture

Table 4.2: Mapping algorithm pseudocode

```

Start
Input: Network traffic sequence S
Output: Anonymized flow table
Begin
If AnonyService.use >= max_capacity then
    AnonyService.delete_by_time);
    If AnonyService.use >= max_capacity then
        AnonyService.destory);
        If flow_entry != null;
            AnonyService.destory();
            AnonyService.init(max_capacity);
            index=(src_ip.hashcode+timestamp)%anonyIPs.current_size;
            new_src_ip=anonyIPs.get(index);
            flow_entry=AnonyService.generate_flow_entry(src_ip,
            new_src_ip, timestamp);insert_entry(flow_entry);
        End if
    End if
End if
End
    
```

been exceeded. If it is still exceeded, a new discarded current mapping is created. The flow table is emptied, and the process is repeated. Table 2 illustrates the mapping algorithm pseudocode.

The main operations of this mapping algorithm are as follows. The first is service initialization, which is responsible for creating the initial flow table and configuring the flow table threshold. The second is invalid stream table cleanup, which is responsible for clearing stream table entries that have not been matched within a period. Unlike the expiration time specified during the flow table configuration, this cleanup is an overall active cleanup to reduce the space footprint within the switch. The third is flow table emptying. If the switch space is still occupied after the invalid flow table cleanup, the flow table emptying operation will begin. The memory space occupied by the flow table is reclaimed, and a service initialization is triggered after recycling. The fourth is flow table lookup, which is mainly to find whether there is already a corresponding flow table

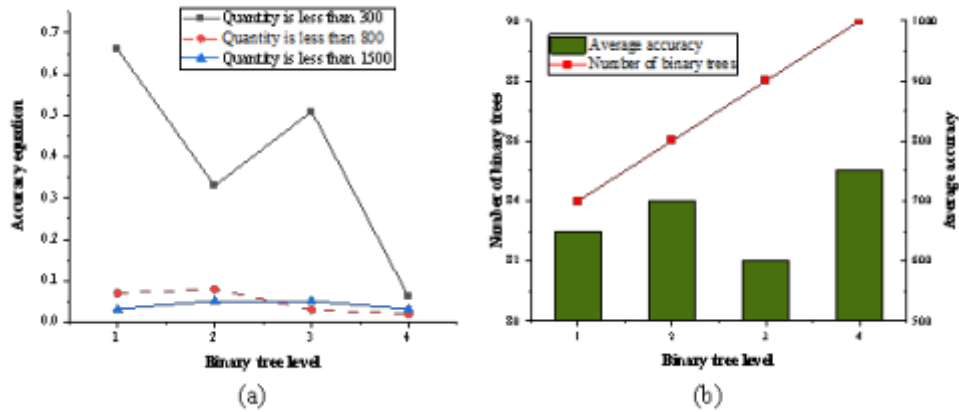

Fig. 5.1: Detection accuracy and quantitative bounds of samples under different quantities

entry based on the anonymous source IP address according to the need. If there is one, return it directly. The fifth is flow table insertion. This part is mainly for new traffic. It inserts the anonymized IP address into the switch flow table.

5. Results.

5.1. Intelligent operation platform algorithm implementation and optimization. The total number of trees in the forest affects the accuracy of the system's detection. The detection results obtained by ensemble learning with enough isolated trees are more accurate. In addition, the total number of trees also affects the system's performance. Too many trees cause additional overhead to the system and affect the system's overall performance. Therefore, the number of trees in isolated forests needs to be studied to achieve optimal detection results and minimize the waste of system resources. The most stable quantitative boundary is obtained by studying the fluctuation of the detection accuracy of samples under different quantities. The results of the study after several tests are plotted in Figure 5.1.

From Figure 5.1, when the number of binary trees is less than 700, the variance of the accuracy rate is at a large value, indicating that the anomaly detection is relatively unstable. When the number of binary trees reaches 700, the accuracy variance is relatively small. The variance corresponding to the subsequent quantity also fluctuates within a small range, and the variance as a whole shows the nature of convergence and stability. When the number reaches 700, the detection effect of the system is stable. Adding more trees in the future does not significantly improve the detection effect, which will cause additional unnecessary overhead to the system. Therefore, 700 is selected as the number of binary trees in implementing the iForest algorithm.

Apache Jmeter is used to perform network stress tests on the system. The concurrent threads are created. Users are impersonated to access server ports. A stress test is conducted. The test environment is an i5 processor and 8G memory in a Windows environment. The final stress test results are revealed in Figure 5.2.

From Figure 5.2, when the number of concurrencies exceeds 2,000, the proportion of error requests and system response time increase significantly. According to the test results, it is concluded that when the concurrent requests are less than 2,000, the system's high availability can be guaranteed. Creating a cluster can improve system availability when requests are more than 2,000.

The test data set is used to detect anomaly detection performance and test the accuracy of different levels of anomaly detection function. The test results are shown in Figure 5.3.

5.2. Power communication network data analysis. Iperf simulated network traffic is tested to study the impact of anonymization schemes on response times for external requests. During the simulation, a delay of 1 ms between the client and the data center is set. Different traffic rates are sent through control flow

Fig. 5.2: Final stress test results

Fig. 5.3: According to the test results, the box-plot has a specific usability when the sample data is small, which is suitable for early anomaly detection. Autoregressive Integrated Moving Average Model (ARIMA) detection accuracy is relatively stable and remains high. Combining ARIMA with iForest will reduce the accuracy due to false positives of the iForest algorithm when the sample size is small.

clients to test responses under various network stresses. For each flow rate, experiment one min and repeat the experiment ten times. The delay of the flow rate in each experiment is counted. Figure 5.4 shows the delay statistics.

From Figure 5.4, with or without anonymization, the response time is slightly over 1 ms. As data traffic grows, response times tend to rise. This shows that the network delay (1 ms) of the outgoing client access data center, and the internal response time of the data center is very low, about the order of 10us. The experiment is relatively small, so the delay and jitter variation of data transmission are very small. However, it can be seen overall that the loss of response time caused by anonymization processing is very small. When the data flow rate is less than 50 Mbps, the internal latency of the data center without anonymization is about 0.039 ms, and the internal delay of the anonymized data center is about 0.041 ms. The response time increases by about 5%. This performance loss is very low and within the acceptable range. The test scale is relatively small,

Fig. 5.4: Traffic delay statistics for each experiment

so the internal latency of the data center is relatively low. Iperf statistics are not accurate enough, and the performance impact should be lower in practice.

6. Conclusion. This paper studies the power communication network supporting the IoT. Based on this research purpose, the research and design are carried out by combining the current relatively complete intelligent O&M and data management concepts. The research results are as follows: (1) When the binary trees reach 700, the detection effect of the system is stable. The subsequent addition of more trees does not significantly improve the detection effect, which will cause additional unnecessary overhead to the system. So, 700 is selected as the number of binary trees in implementing the iForest algorithm. (2) When the concurrent requests are less than 2,000, the system's high availability can be guaranteed. When the number of requests exceeds 2,000, the system availability can be improved by adding servers and creating clusters. (3) When the algorithm data is increased to a specific value, the iForest algorithm improves the overall recognition rate of the system anomaly detection function. Therefore, it can be considered that the graded detection method adopted by the system is feasible and effective. (4) The internal latency of the anonymized data center is about 0.041 ms, and the response time increases by about 5%. This performance loss is low and within acceptable limits. However, due to the current status quo of software and hardware, there is still room for further optimization and improvement of the platform. First, data timing has a high dependence on the network state. Once network fluctuations occur, there will be a disorder in the data transmission process. Second, when providing O&M functions for different devices in the current system, it is necessary to redesign the algorithm and modify the source code. In the subsequent work, it is essential to improve the system and carry out additional design and implementation of functions such as data timing verification and retransmission start. Moreover, it is necessary to design and implement the algorithm training configuration module to realize the algorithm's automatic training and configuration call algorithm functions to improve the intelligence and automation of the system.

ANALYSIS OF ABNORMAL FREEZING DATA AND UPDATING ALGORITHM FOR ELECTROMECHANICAL ENERGY METER TERMINALS

SHUZHI ZHAO*, YUE DU†, SHANSHAN HE‡, JIAO BIAN§ AND JIABO SHI¶

Abstract. Due to the rapid development of science and information technology, electricity information acquisition system has been widely used in the electricity data collection of users. With the massive electricity data collection, it is difficult to adopt traditional data processing methods to meet the abnormal data processing. In order to effectively mine abnormal information in electricity consumption data, an anomaly detection model based on the Isolation Forest (iForest) algorithm is proposed. Firstly, the daily load curve with strong regularity is used as the characteristic index of anomaly monitoring, and the users with abnormal electricity consumption data are preliminarily screened. Secondly, on the basis of electrical variables, the suspected abnormal users are further analyzed, and the anomaly identification model of electricity data is established to automatically classify the voltage at the metering point. Moreover, combined with the current data, the abnormality of the electric energy metering device is identified, and then the validity of the model is determined through on-site verification. Finally, according to the participating voltage of the fault phase, the 96-point voltage data frozen during the failure period is analyzed and the correction coefficient is adjusted. The results reveal that the electricity data detection model based on the iForest algorithm has significant advantages in computational efficiency. Through the cumulative recall and Precision-Recall (P-R) curves of the model, it is found that the majority of abnormal users can be detected only by detecting a few users with high abnormal scores, which shows that the model has high efficiency. The decision tree algorithm combined with the current data can effectively identify the anomalies of the energy metering device, which verifies the validity of the anomaly identification model of the electricity consumption data.

Key words: Energy meter, Electricity information acquisition system, Abnormal electricity consumption data, Isolated Forest algorithm, Decision Tree algorithm

1. Introduction. As one of the most important technical bases in the power system, the electric energy metering technology is constantly improving with the improvement of technical and service levels [1,2]. As the basic equipment in the power automation system, electric energy metering plays a vital role in the power system, mainly responsible for data reading, processing, and storage. The application of big data technology promotes the integrity and accuracy of power-metering terminal data. The electric energy metering technology is mainly used in the electricity information acquisition system (hereinafter referred to as the “EIAS”), which is the basic platform for the collection of users’ electric power information and can acquire and real-time monitor the power information of all power consumers. The measurement anomaly detection function is principally to monitor and analyze the collected data in real-time, and report the abnormal power, load, voltage, and current of electricity users to the EIAS [3,4].

At present, there are more and more studies on the abnormality of terminal data of energy meters in the power system. Hasan et al. (2019) proposed a power theft detection system based on the Convolutional Neural Network (CNN) and Long Short Term Memory (LSTM) architecture. An LSTM model based on CNN is implemented for data classification in a smart grid. The results denoted that the proposed scheme can better classify most ordinary users and a few users with abnormal electricity consumption data [5]. Ji et al. (2021)

put forward an estimation method for real-time robust auxiliary state for power system prediction based on the Bayesian framework, deep learning, and Gaussian mixture model (GMM). By combining anomaly detection technology in machine learning (ML) with GMM, abnormal data in measurement information can be accurately determined and deleted. Numerical simulations on IEEE 118-node and IEEE 300-node test systems show that the proposed method has high accuracy and robustness [6]. Liu et al. (2021) raised a framework based on general data mining, which can extract typical power load patterns and discover the insightful information hidden in the patterns. The proposed framework was applied to analyze the time series electricity data of three practical office buildings in Chongqing, and its validity was verified [7]. Yan and Wen (2021) proposed a power theft detector using metering data based on extreme gradient lift. Preprocessing of measurement data, including recovery of missing and wrong values and normalization. Compared with 8 ML methods such as support vector machine and Decision Tree (DT), the proposed method can detect power theft with higher accuracy or a lower false alarm rate. Experimental results also manifested that the proposed method was robust when the data was unbalanced [8].

To sum up, the current anomaly detection algorithm for the energy meter's power system mainly constructs a normal data model and identifies data inconsistent with the model as abnormal data, which leads to excessive redundancy of information and low computational efficiency. At the same time, it can be found that mining abnormal electricity consumption data is helpful to improve the efficiency of power enterprises. To improve computing efficiency, an anomaly detection model of electricity data is established based on the Isolation Forest (iForest) algorithm, and users suspected to be abnormal are identified through preliminary screening combined with a daily load curve. Then, according to the electrical variable of the abnormal user, the voltage is accurately classified by the DT algorithm and determined by combining the current data, identifying the abnormal electric energy metering device. Ultimately, the calculation method of the correction coefficient of electric quantity is put forward.

2. Abnormal Detection of Electricity Consumption Data Based on the iForest Algorithm.

2.1. The data basis of the model.

2.1.1. Choice of information fields for electricity consumption data. Abnormal electricity consumption data shows high line loss, large loss of electricity sold, etc. The above phenomena are mainly caused by line and equipment quality, management loopholes, energy meter quality, and abnormal consumption behavior. Since the daily load curve is characterized by strong regularity and a more obvious shape, anomalies in electro-data can be found more easily. Therefore, the daily load curve is used to analyze electric power data [9]. The fields of the initial electricity load data set selected from the EIAS are exhibited in Table 2.1:

The data set used above retains the meter number, user type, power type, 96-point load data, and other fields [10]. The user type is three non-resident users, and the power type is positively active. Now, the main

Table 2.2: Types of dirty data

Types	Missing value	Duplicate value	Minimax	Load burr	Impact load
Presentation	The table of data has NA or blank	The data of the user's electricity load appears to be repeated at some point	Too large or too small power load data	Data increases or decreases suddenly between adjacent time periods	The meter reads down over a continuous period of time

special transformer terminals used in the system are the 96 protocol and the 05 protocol. The 96 protocol can only be used to collect the voltage, current, and electricity data of the user's energy meter at zero. The special transformer terminal of the 05 protocol collects the voltage, current, and energy data of the user's energy meter every 15 minutes, with a total of 96 points in 24 hours. To facilitate data description, the 96-point load data are reduced to 24 points.

2.1.2. Data cleaning. In the process of dirty data processing, the types of dirty data should be analyzed and summarized first, and then targeted processing should be carried out according to its manifestation. After obtaining the power load data of industrial users, dirty data is identified by data specification principles. Common types of dirty data are outlined in Table 2.2:

In the processing of dirty data, firstly, the redundant data in the data set should be deleted. In a data set, the customer name and time uniquely determine a data record. If multiple records are the same, the redundant data needs to be deleted. Secondly, it is necessary to maintain the integrity of the data set. The problem of missing data in the data set must be properly handled according to the current situation. Every user must have the electricity reading data for every hour per day. If there is a small amount of missing data, the severity of the missing should be analyzed. The missing severity is as follows:

1. The curve is missing 20% of its reading points;
2. The curve continuously misses more than 2 consecutive readings.

If the data missing reaches the above two conditions, the user will be excluded from the research range, and the remaining load curves containing missing data will be repaired by the multi-stage Lagrange interpolation method. The repair of the missing value of the load curve is written as Equation 2.1:

$$P_t = \frac{\sum_{k=1}^{m_1} P_{t-k} + \sum_{i=1}^{m_2} P_{t+i}}{m_1 + m_2} \quad (2.1)$$

m_1 and m_2 refer to the number of forward periods and backward periods, and t stands for the time when the load data is missing. After data cleaning, X is recorded as $(n - \lambda) \times 24$ th order effective load curve matrix composed of $(n - \lambda)$ effective daily load curves.

2.1.3. Data dimension reduction. Electricity load data is easily affected by many factors such as income, price policy, and temperature. The results caused by these influences cannot be fully reflected through the distance, and the similarity of the shape or contour of the time series cannot be fully guaranteed. In order to fully reflect the similarity between loads while taking into account the operational efficiency, six commonly used daily load characteristic indexes are selected to comprehensively reflect the electricity consumption characteristics [11].

All-day load rate reflects all-day load variation:

$$a_1 = \frac{P_{av}}{P_{max}} \quad (2.2)$$

The maximum hourly utilization rate of the whole day reflects the time utilization efficiency:

$$a_2 = \frac{P_{sum}}{24P_{max}} \quad (2.3)$$

Fig. 2.1: Data missing pattern after dimensionality reduction of the daily load curve

The daily peak-valley difference throughout the day reflects the capacity of the peak regulating of the power grid:

$$a_3 = \frac{P_{max} - P_{min}}{P_{max}} \tag{2.4}$$

Peak load rate reflects peak load variation:

$$a_4 = \frac{P_{av.peak}}{P_{av}} \tag{2.5}$$

Normal load rate reflects the change of normal load:

$$a_5 = \frac{P_{av.sh}}{P_{av}} \tag{2.6}$$

The load rate in the valley period reflects the load change in the valley period:

$$a_6 = \frac{P_{av.val}}{P_{av}} \tag{2.7}$$

By using the load characteristic index to reduce the characteristic dimension of the effective load curve matrix, the $(n\lambda) \times 6$ th order characteristic dimension reduction matrix is obtained, which is recorded as Y. Through visualization processing of the overall situation of data after dimensionality reduction, the result is expressed in Figure 2.1:

Figure 2.1 signifies the missing pattern of the daily load curve. After dimensionality reduction, nearly 90% of the samples do not miss any information, and the 6 features of 7.7% of the samples are Not a Number (NaN), indicating that the value does not exist, which proves that there is no electricity or the account has been canceled. These users will be deleted. The remaining six missing patterns are caused by only a small amount of load during one part of the day and no power during the other. Then divided by the daily average load, it is judged by the computer as 0 / 0 type, the value does not exist, and it is displayed as a missing value, so these six types of users are listed as suspicious users.

2.2. Data anomaly detection model based on the iForest algorithm. The daily load curves of 5972 users in S City on July 18, 2021, were taken as the research object. The daily load curves were mainly selected for small and medium-sized special transformer users and three general industrial and commercial users. The sampling interval of samples was 15 minutes, and there were 96 measurement points in total. After data dimension reduction and cleaning, a total of 4872 effective daily load curves were obtained. There were 63 abnormal users, accounting for 1.29%.

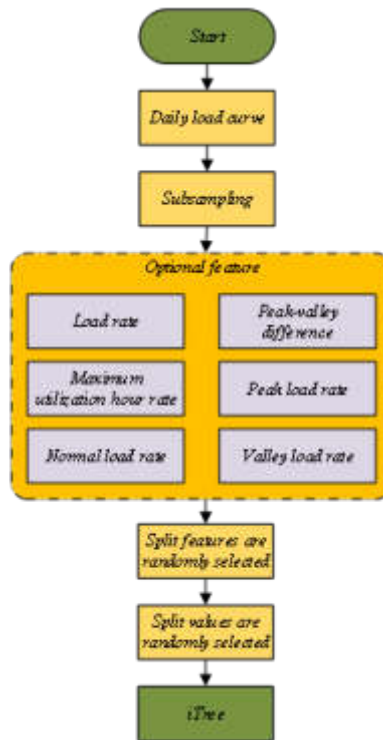

Fig. 2.2: The flow chart of the iTree construction

2.2.1. The construction of the Isolation Tree (iTree). The iForest is mainly composed of the iTree, which refers to a random binary tree in which each node contains two child nodes or leaf nodes [12]. The flow chart of the iTree construction is displayed in Figure 2.2:

Among them, the features in the data set of the daily load curve are all continuous variables. The construction steps of iTree are as follows:

- Step 1: A feature is randomly selected among the 6 daily load characteristic indexes;
- Step 2: A value k of the characteristics selected in step 1 is randomly selected;
- Step 3: According to the characteristics, records are classified every day, and records with characteristics smaller than k are placed in the left branch, and records with characteristics greater than or equal to k are placed in the right branch;
- Step 4: Then the left and right branches are constructed recursively until the following two conditions are met; There are only multiple identical records or one record in the incoming data set; The height of the tree reaches the specified height.

2.2.2. The construction of the iForest. The construction of iForest is similar to the method of random forest, both of which are carried out by random sampling. Each tree needs to be constructed through part of the data set to ensure that each tree has certain differences. The construction process of the iForest is revealed in Figure 2.3:

In the process of constructing iForest, the sampling size should be limited on the one hand, and the maximum depth should be set for each iTree on the other hand. Finally, it is necessary to calculate the power value of the tested user. In the process of evaluating the tested user, iForest can only evaluate a single customer at a time. Meanwhile, during the process of evaluation, each iTree needs to be traversed, the statistical query object is in the position of the leaf node, and then the average path length is employed to calculate the abnormal score. Finally, the user is evaluated by the value of the abnormal score, and then the user type is judged.

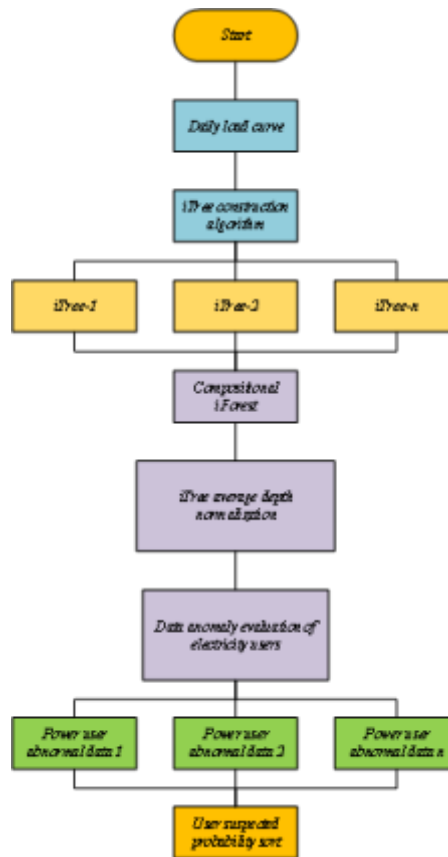

Fig. 2.3: The construction process of the iForest

2.3. Abnormal recognition of electricity consumption data based on the DT algorithm. The iForest algorithm is adopted to model the daily load curve of power users for abnormal detection, which is helpful to automatically screen users with abnormal data suspicion and realize the preliminary screening of abnormal users. Because the detection only by daily load curve is easy to cause misjudgment, the further analysis combined with other electrical variables of suspicious users can effectively improve the accuracy of detection.

The steps for the construction of the anomaly identification model of electricity power data based on the DT algorithm are demonstrated in Figure 2.4 [13].

The construction of the training set is mainly to sort out the date, meter number, and voltage data of the day in the EIAS, and sort out the transformer ratio and connection mode in the meter. Finally, the above data are combined to construct the training set of DT.

The DT algorithm is used to process the training set. Firstly, the training set is sorted, then it is divided by the threshold value of each data and the information gain is calculated. Furthermore, the threshold value is selected according to the maximum gain and the training set is divided.

The generation of DT: The root node and leaf node of DT correspond to a classification rule and synthesize all paths into a rule set, which is stored in a two-dimensional array.

Check the rationality of DT: the classification rules of DT are checked to see if there is any wrong decision. If so, the training set is adjusted until the classification is correct.

2.4. Update method for data exception. In actual work, the fault phase voltage of the data of the power acquisition system and the field measured data during the failure period is not 0, but eventually stabilizes

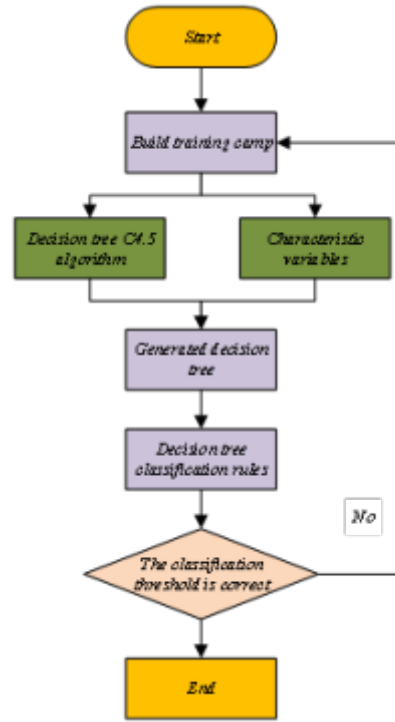

Fig. 2.4: The construction process of anomaly identification model for electricity consumption data

at a value not 0 with the change of time, which is called residual voltage [14, 15]. The residual voltage makes the amount of electricity measured by the energy meter during the voltage loss period contain the fault phase element and the amount of electricity measured by the non-fault phase element under the residual voltage. Thereupon, the calculation method of correction coefficient is determined by calculating the value of γ_{ab} , γ_{cb} according to the actual situation.

$$K = \frac{P_T}{P_F} = \frac{\sqrt{3}UI\cos\varphi}{\gamma_{ab}UI\cos(30^\circ + \varphi) + \gamma_{cb}UI\cos(30^\circ - \varphi)} \quad (2.8)$$

The determination of γ_{ab} and γ_{cb} is related to the metering principle of the intelligent energy meter, and the measured electric energy is illustrated in Equation 2.9:

$$P = \frac{1}{T} \int_0^T u(t) \cdot i(t) dt \quad (2.9)$$

T represents the cycle of Alternating Current (AC) voltage and current.

By taking Δt as the sampling interval for voltage and current, the left discretization of Equation 2.9 is as follows:

$$P = \frac{1}{T} \sum_{k=1}^N u(k) \cdot i(k), T = N\Delta t \quad (2.10)$$

It can be seen that the determination of the correction factor is related to the current and voltage data during the failure. Through the EIAS, the frozen AC data of the Potential Transformer (PT) during the failure of voltage breakdown and loss can be known. Since the fusing on the PT side is independent of the current,

(b) Computation time and AUC

Fig. 3.1: Different iTree quantities

the calculation of the correction factor only needs to consider the voltage. The voltage curve can be obtained by freezing the voltage data of the electricity acquisition system. Through linear regression or piecewise linear regression on the voltage change curve, the average value γU of voltage during fault is obtained.

3. Results and Discussion.

3.1. Model parameter analysis. The iForest algorithm is mainly based on the thought of ensemble learning. There are two extremely important parameters in the anomaly detection model of electro-data, iTree sampling scale Ψ and the integration scale t . The simulation experiment is carried out on the system based on a Central processing unit (CPU) of dual-core 2.3GHz with 8GB memory, and the program is written through R language.

3.1.1. Quantity t of the iTrees . The iForest algorithm forms iForest by generating a certain number of itrees. It is mainly by means of random sampling to extract Ψ subset and construct iTree, and guarantee the diversity of iTree. Therefore, the number of iTree determines the size of the ensemble learning of the model. The Receiver operating characteristic curve (ROC) of the iTree with different numbers is portrayed in Figure 3.1.

Figure 3.1a portrays that the ROC curve is very close. The Area Under Curve (AUC) is obtained by calculating different numbers of iTrees respectively. According to the data in Figure 3.1b, the length of the path can be well covered when the number of iTrees reaches 100. After that, increasing the number of iTrees does not significantly improve the AUC, which is about 0.93 at this time. The cumulative recall ratio curve and Precision-Recall (P-R) curve of the iForest algorithm under different iTree numbers are shown in Figure 3.2.

In Figure 3.2a, when the number of iTrees is greater than 100, the gap between curves is very small. When the detection rate is less than 0.03, the curve has a very large upward trend, and when the detection rate is greater than 0.03, the curve tends to be flat. In the phase where the detection rate is less than 0.03, only the top 3% of users need to be detected to detect about 80% of abnormal users. At the stage where the detection rate is greater than 0.03, only 20% of abnormal users can be detected by detecting the remaining 97% of users. Thereby, the research focus of cumulative recall ratio is the stage where the detection rate is less than 0.03. As can be seen from the P-R curve in Figure 3.2b, when the iTree reaches more than 100, the precision ratio can exceed 80% when the recall ratio is 70%. Combined with Figure 3.2a, it can be found that 80% of abnormal users can be detected by detecting the top 2.5% of users for the abnormal score. When the detected users reach 3.5%, the precision ratio decreases significantly, only about 40%.

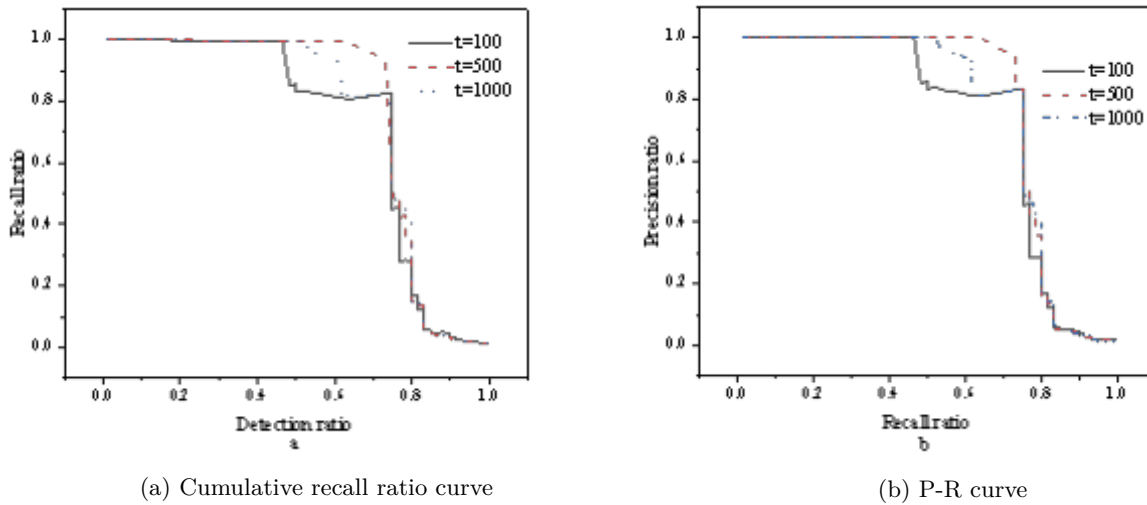

Fig. 3.2: The iForest algorithm with a diverse number of iTrees

3.1.2. The iTrees sample numbers Ψ . For any object in the data set, different sample numbers will affect the user's abnormal score and affect the final output of the model. Thus, it is important to study the sensitivity of model parameters. The relationship between the ROC curve and the iTrees sampling number is indicated in Figure 3.3.

In Figure 3.3a, when the collection number of iTrees is small, the performance of the model is poor, but when the number of iTrees reaches a certain value, the ROC curve will be very close. It can be seen from the data in Figure 3.3b that as the number of iTrees samples increases, the calculation time continues to increase. The area AUC under the ROC curve is not normal with the change of parameters, on the contrary, it decreases a little. The P-R and cumulative recall ratio curves of the iForest algorithm with diverse iTrees sampling numbers are implied in Figure 3.4.

The cumulative recall ratio curve in Figure 3.4a shows that when the sampling number is 100, 65% of abnormal users can be detected by detecting 2% of users. When the number of samples is much larger than 100, only 42% of abnormal users can be detected by detecting the top 2% of users. The P-R curve in Figure 3.4b can be more significantly found that when the sample numbers of iTrees is too large, the performance of the model is poor. The reason for the above phenomenon is primarily that the purpose of iTrees sampling is to better separate normal users from abnormal users, and the more sampled data, the worse the ability of the iForest algorithm to identify anomalies.

3.2. DT of voltage classification for power users. For the sake of explanation, the training set mainly covers 10kV three-phase measurement points. The model is constructed by using R language, and the DT of voltage classification is obtained, as plotted in Figure 3.5.

The output results in Figure 3.5 are voltage classification, where N, H, and L represent normal voltage, high voltage (HV), and low voltage (LV), respectively. The judgment condition of DT is the value between each node, and the whole DT mainly contains 10 decision points. Taking the left-most root node as an example, when the voltage value is less than 51V, the phase sequence is B and the connection mode is three-phase and three-wire, the voltage is normal; If the phase sequence is B and the connection mode is three-phase and four-wire, it is LV. If the phase sequence is A or C, it is LV. The confusion matrix of performance evaluation of the voltage classification model is expressed in Table 3.1.

Table 3.1 exhibits that there are 1166 data in the DT training set of voltage classification, and the classification accuracy is 100%. In general, the classification model is an overfitting phenomenon when the success rate

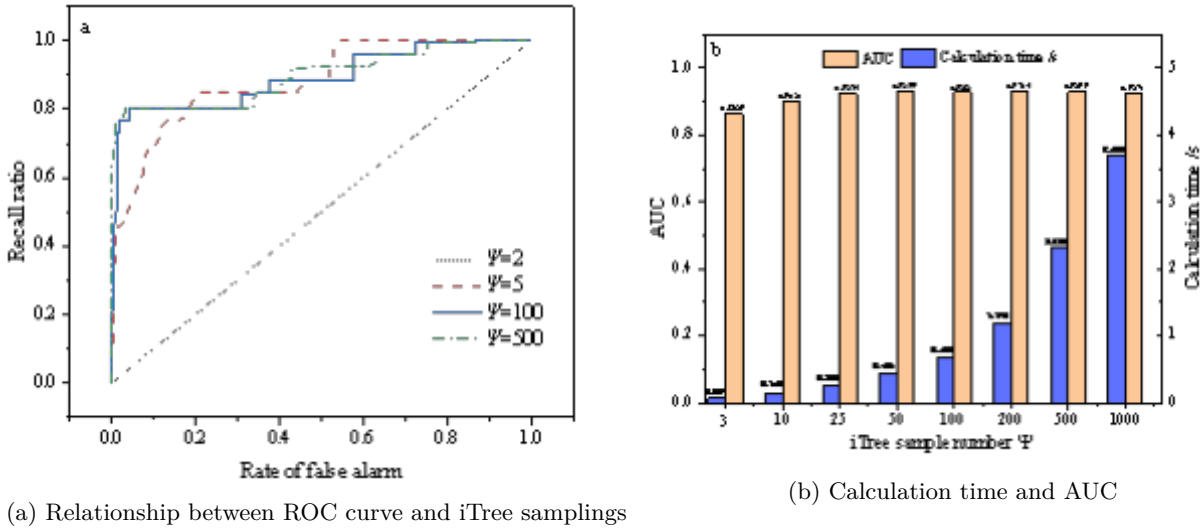

Fig. 3.3: The iForest algorithm with different iTree sampling numbers

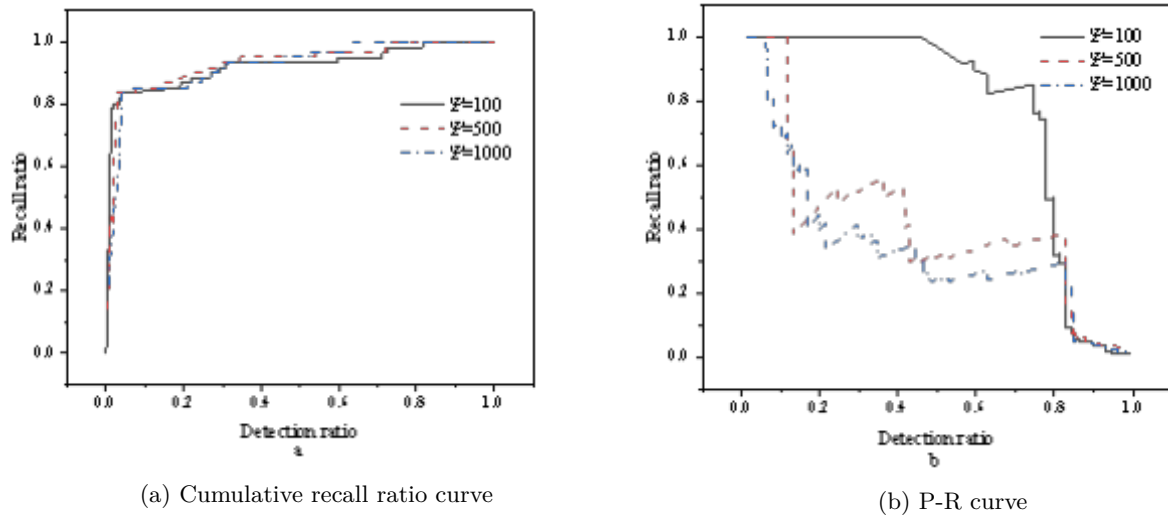

Fig. 3.4: The iForest algorithm with various iTree sampling numbers

of the classification reaches 100%, which is the characteristic of DT. The fitting phenomenon is more beneficial to the accurate classification of voltage between different measurement points, and the DT is more sensitive to the training set, which is conducive to the dynamic adjustment of voltage judgment rules.

3.3. Data anomaly detection of power users. Through iForest algorithm, data anomalies of users of special transformers in S City are detected. After preliminary screening, 179 suspected abnormal users are detected. According to the energy meter number of the abnormal user, the date and 96-point voltage in the EIAS of the user are sorted out. The voltage transformer ratio and connection mode of the meter in SG186 are also sorted out, and the above two parts are combined. Then DT algorithm is used to identify the voltage anomaly of the metering device of the suspected abnormal users, and 65 abnormal users are output. Finally,

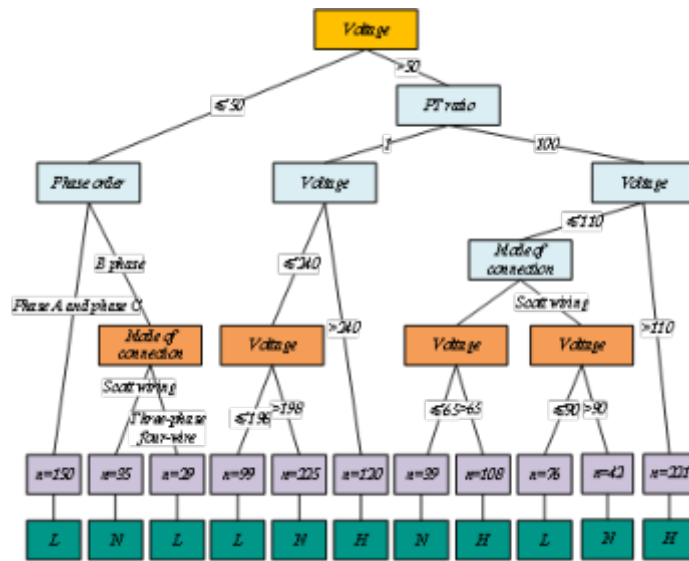

Fig. 3.5: The DT of voltage classification for users

Table 3.1: The confusion matrix of performance evaluation of the voltage classification model

Prediction	Normal voltage N	HV H	LV L
Normal voltage N	339	0	0
HV H	0	451	0
LV L	0	0	354

45 users with the highest degree of suspicion are sent out operation and maintenance work orders after manual review. After on-site verification, 37 abnormal users are identified. Figure 3.6 demonstrates the statistics of the feedback results of abnormal troubleshooting for users of special transformers:

3.4. Update of abnormal electricity consumption data for energy meters. Among the anomalies determined by the energy meter, the fuse failure of the voltage transformer is broken the most. Taking a case of fuse burn-out of a voltage transformer verified in S City as an example, it is found that there has an LV phenomenon through model recognition. The 96 points of voltage and current are obtained and sorted out from the EIAS. From A certain time period, the C-phase voltage has a large jump, the A-phase voltage is normal, and the current of the A and C phases is normal, indicating that the power supply of the user is normal, but the electric energy metering device is abnormal. The user data and file information obtained through the EIAS and SG186 are signified in Table 3.3:

According to the 96-point voltage data of the abnormal user, after the fuse on the primary side of C-phase PT is blown, the voltage between C and B phases on the secondary side quickly drops to about 14V and remains stable. The voltage data collected by the EIAS every 15 minutes during the fault period are statistically analyzed. It can be seen that the average voltage between C and B phases during the failure period is 14V, namely $\gamma_{cb} = 0.14$. It means that the power factor of the user is relatively stable, and the average value is $\cos\varphi = 0.85$, obtained after conversion $\varphi = 31.79^\circ$.

4. Conclusion. With the swift growth of the power industry, a variety of power equipment terminals have appeared. Based on the analysis and research status of electro-data anomalies, the data anomalies of energy meter terminals are studied. Firstly, the data of the daily load curve is preprocessed and the iForest algorithm is selected to construct the abnormal detection model of electricity data. Additionally, the accuracy

Fig. 3.6: Abnormal feedback results of electric energy metering device

and calculation time of the model are explored by analyzing the different values of the sample numbers of iTrees. Secondly, on account of the voltage and current data of suspected abnormal users initially screened, the anomaly identification model of electricity consumption data of the DT algorithm is implemented. Besides, the voltage at different metering points is classified and judged in combination with current data to identify abnormal energy metering devices. Finally, the case of an abnormal user in S City is analyzed, and the 96-point voltage data of the EIAS during the fault period are studied. Furthermore, the correction coefficient is adjusted on the basis of the participating voltage of the fault phase. The results manifest that the anomaly detection model of electricity power data constructed by the iForest algorithm has high validity and computational efficiency. The traditional recharge method does not consider the residual voltage, but the recharge method proposed here makes the recharge more accurate by determining the residual voltage and ensuring the accuracy of the charge. However, since only electrical variables such as voltage and current are considered in the analysis of anomalies in electricity data, the accuracy of identification needs to be improved. It is hoped that more in-depth exploration can be carried out in the subsequent research, and more variables can be introduced to improve the accuracy of recognition.

PROCESS TESTING AND ALGORITHM DETECTION ANALYSIS OF MECHANICAL STRENGTH OF ELECTROMECHANICAL COUPLING IN THE MAIN DRIVE OF ROLLING MILL

DONGBAO ZENG* AND HAI YAO[†]

Abstract. In order to deeply analyze the compressive strength of the electromechanical coupling system of the main drive of the rolling mill, this work takes the electromechanical coupling system of the main drive of the R2 rolling mill as a subject to study and analyze. First, experiments are designed to test the strength and some mechanical parameters of the main drive electromechanical coupling system of the R2 rolling mill, including the introduction of the main drive system of the R2 reversible rolling mill, test content, test scheme, test system framework and test materials. Next, this work analyzes the strength of the main drive shaft in the electromechanical coupling system of the main drive of the R2 rolling mill, and theoretically checks the fatigue strength of the main drive shaft, including the static strength analysis of the main drive shaft. Finally, this work analyzes the experimental data. The research shows that: (1) the peak value of the lower torque of the main drive coupling electromechanical of the R2 rolling mill is mainly distributed in the range of 650~1550 mk N. The average value of the upper torque is mainly distributed in the range of 350~1100 mk N. (2) The peak value of principal stress at 1[#] measuring point is within the range of 10-35Mpa, and the mean value of principal stress is within the range of -24-24Mpa. The peak value of principal stress at the 2[#] measuring point is in the range of 5-25Mpa, and the mean value of principal stress is in the range of -16-16Mpa. (3) When the upper drive shaft of the rolling mill runs at a working angle of 1.02°, the maximum Von Mises Stress of the drive shaft of the rolling mill is 95.10MPa. When the drive shaft of the rolling mill operates at a working angle of 3.14°, the maximum Von Mises Stress of the drive shaft of the rolling mill is 95.15MPa. This work aims to provide a theoretical reference for enhancing the compressive strength of the electromechanical coupling system of the main drive of the rolling mill.

Key words: electromechanical coupling system of the main drive of the rolling mill, compressive strength, main drive shaft, principal stress, fatigue strength

1. Introduction. The main characteristics of modern rolling mills are large, heavy load, high speed, continuous automation, precision and poor working conditions. These characteristics require the long service life of the main parts of the rolling mill. In order to achieve this goal, it is the most effective and convenient means to use modern mechanical methods and fully use the idea of the finite element method (FEM) and its generated software to study classical mechanical problems. Meanwhile, it is essential to apply advanced test technology for equipment diagnosis to provide conditions for analyzing the mechanical behavior of equipment [1]. In the past decade, the rapid development of computer hardware technology and the rapid decline of computer costs have greatly driven the development of finite element calculation software, and the function of display programs has also been increasingly enhanced. It provides a broad platform for the use of FEM to solve practical engineering problems [2]. Besides, as early as the 1960s, foreign steel companies noticed the impact of torsional vibration on the main drive system of the rolling mill, and have conducted massive experimental studies. At that time, the research level was limited to experimental measurement and the establishment of simple mechanical models, and there was no more in-depth theoretical exploration [3]. For example, in the 1960s, the Bethlehem Steel Corp of the United States conducted field tests and theoretical analysis on the rolling mill, and analyzed the resonance problem caused by the coupling of the frequency of the rolling mill drive system and the natural vibration frequency of the motor riser [4]. In 1973, the Association of Iron & Steel Engineers in America and Jones&Lauhlin Iron and Steel Company studied the torsional vibration of a rolling mill. They reached the following conclusions: the head of the hot top is conducive to reducing part of the mechanical coefficient; it is important to eliminate the clearance in the transmission link to reduce the value; shear parts should not be used as mechanical insurance parts [5].

Table 2.1: Main technical parameters of R2 reversible rolling mill

Parameter name	Specific value
Working roll diameter	1200/1100 mm
Support roll diameter	1600/1440 mm
Roller length	2250 mm
Rolling force	45000 kN
Motor power	2×7500 KW
Motor speed	0~45/100 rpm
Balance coefficient of balance cylinder	1.1 (test condition), 1.3 (damage condition)

It was not until the 1970s that the torsional vibration of the rolling mill was paid attention to in China. In particular, several serious equipment accidents related to system torsional vibration have occurred in several domestic steel rolling plants in the past decade, which has caused people to study the impact of torsional vibration load on the system [6]. For example, the University of Science and Technology Beijing has studied the main drive system of the blooming mill of Baotou Iron and Steel Company and the second blooming mill of Anshan Iron and Steel Company. It is found that the self-excited vibration caused by roll slipping is the main cause of the main drive torsional vibration damage [7]. Professors at the University of Science and Technology Beijing adopted the rolling mill's shafting parameter optimization design method to predict and reduce the torque amplification factor in the design [8]. Wuhan University of Science and Technology studied the vibration of the arc joint shaft of the 1700 cold chain mill drive system of Wuhan Iron and Steel Company. It is found that the rolling speed greatly impacts the vibration of the shaft. The misalignment of the arc joint shaft causes polarization and gearbox meshing excitation [9].

In the rolling system, due to the manufacturing process, assembly and other factors, there is often a certain gap at the system's connection, which will make the stiffness of the main transmission system behave as nonlinear. Hence, the system cannot be simply described by a linear model. Avoiding the resonance synchronization phenomenon in the working process of the system, the reasonable control of the main drive system of the rolling mill, the establishment of the vibration simulation mechanical model and the torsional vibration of the system in case of slipping. Based on the above contents, for the frequent fracture accidents and fatigue damage of the main drive system of the rolling mill, this work takes the R2 four-roll reversing roughing mill of a certain unit as the research object. Then, based on the field test, combined with the worldwide torsional vibration research of the main drive system of the rolling mill, the dynamic characteristics analysis of the main drive system of the R2 rolling mill is conducted. Moreover, the FEM analysis software ANSYS is adopted to carry out three-dimensional (3D) FEM analysis on the spider universal joint of the main drive system of the R2 rolling mill. Moreover, the strength and fatigue check of the drive shaft in the main drive system of the R2 rolling mill are analyzed in detail. This work aims to design relevant simulation experiments to study the vibration of a rolling mill and analyze its strength to make a beneficial combination and supplement between theory and practice. It has crucial engineering practical significance and theoretical research significance.

2. Design of process test and simulation model.

2.1. Parameters test of mechanical mechanics in main drive electromechanical coupling system of R2 rolling mill .

(1) Main drive system of R2 reversible rolling mill.

1. Schematic diagram of the main drive system of the R2 reversing rolling mill

The main drive system of the R2 reversible rolling mill adopts two synchronous motors to directly drive the upper and lower rolls. Figure 2.1 is the structure diagram.

2. Main technical parameters of R2 reversible rolling mill

Table 2.1 displays the main technical parameters of the R2 reversible rolling mill.

(2) *Field test content.* The test content of this experiment mainly includes the torque M1 and M2 of the upper and lower drive shafts of the R2 reversible rolling mill, the stress σ of the lower connecting shaft, and rolling force P.

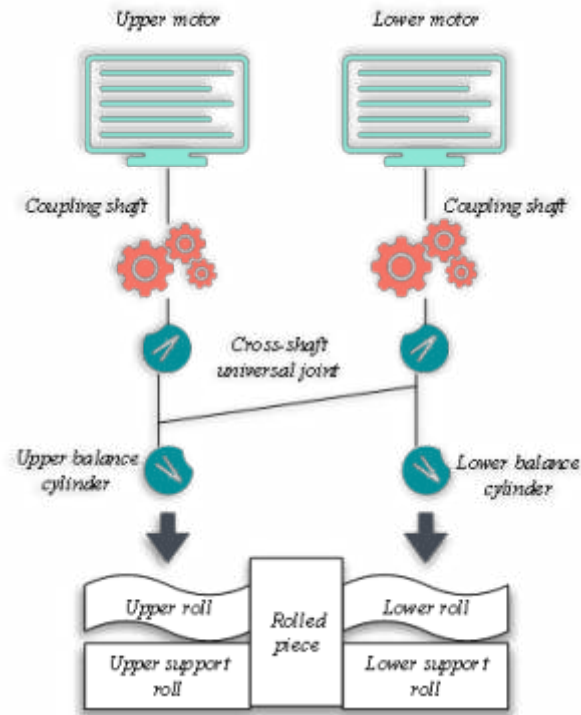

Fig. 2.1: Structural diagram of the main drive system of the R2 rolling reversible mill

(3) Test plan.

1. Measuring point position and testing method of main drive torque of R2 rolling mill:

The test positions of the upper drive shaft torque and the lower drive shaft torque are as follows.

The measuring point is located at the hollow shaft section with an outer diameter of $D=930\text{mm}$ and an inner diameter of $d=736\text{mm}$. On this shaft section, four resistance pieces are pasted in the direction of $\pm 45^\circ$ with the axis to form a full-bridge test circuit. The signal is input into the YD-28A dynamic strain gauge through the slip ring, and then recorded by the computer after A/D conversion. The calibration is carried out with a constant-strength graduated beam. Resistance strain gauges, R1+R3 and R2+R4, are respectively attached to the constant strength beam's upper (tension) and lower (compression) sides, forming a full-bridge test circuit. Then, it is calibrated with standard weight loading. The torque calibration value of the upper drive shaft is $K=24.237\text{MPa/V}$, and the torque calibration value of the lower drive shaft is $K=24.190\text{MPa/V}$.

2. R2 rolling force:

After the rolling force P of the R2 rolling mill is isolated through the isolator, it is led from the main electrical room to the test site through the shielded cable and connected to the computer. The calibration value of the rolling force is 450t/V (provided by a two-roll hot-rolling electrical workshop).

3. Location and test method of main drive stress measuring point of R2 rolling mill:

The stress is measured through resistance strain. Because the stress situation of the shaft is complex and the direction of the principal stress is unknown, the strain rosette is adopted to measure the stress at this point. The distance between the main drive shaft 1[#] stress measuring point and the center line of the main shaft arm is 793 mm. The signals corresponding to the strain gauges in the horizontal direction (0°), 45° and vertical direction (90°) are 3[#], 4[#] and 5[#], respectively. The distance between the main drive shaft 2[#] stress measuring point and the center line of the main shaft arm is 643mm. The

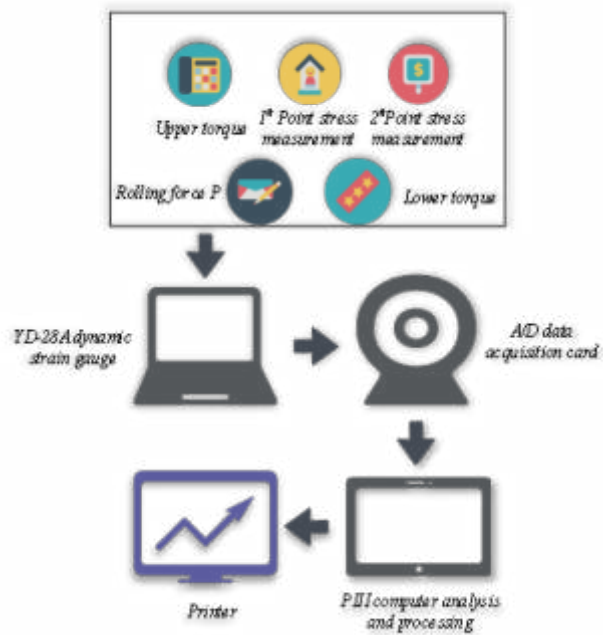

Fig. 2.2: Test system framework

signals corresponding to the strain gauges in the horizontal direction (0°), 45° and vertical direction (90°) are 2#, 7# and 6#, respectively. Considering that the temperature of the measuring point will change during the rolling process, in order to compensate for the test error caused by the temperature change, a small steel block (without stress) is placed near the measuring point as the temperature compensation block (the same as the temperature of the measuring point). Three resistance strain gauges are pasted on each temperature compensation block, and a half-bridge test circuit is formed with the three working pieces of the strain rosette at the measuring point.

The calibration is conducted with a constant-strength graduated beam. On the constant-strength graduated beam, a resistance strain gauge R1 is pasted and a temperature compensation block is placed near the measuring point. The resistance strain gauge R2 is attached on the temperature compensation block, and R1 and R2 form a half-bridge test circuit. The stress calibration value of each measuring point can be obtained by using standard weight loading for calibration. The calibration value of 3# is $K=97.087\text{MPa/V}$, that of 4# is $K=97.276\text{MPa/V}$, that of 5# is $K=96.712\text{MPa/V}$, that of 2# is $K=96.900\text{MPa/V}$, that of 7# is $K=97.466\text{MPa/V}$, and that of 6# is $K=97.087\text{MPa/V}$.

(4) *Test system block diagram.* The stress signal of each measuring point is connected to the dynamic strain gauge and recorded by the computer after A/D conversion. The sampling frequency of each channel is 100Hz. Figure 2.2 displays the system test block diagram.

(5) *Test materials.* The force and energy parameters of the main drive system during the rolling process of 174 steel billets of 11 rolling varieties produced by a certain unit were tested. Table 2.2 shows the specification and quantity of the test billet.

2.2. Research on strength and fatigue strength check of the main drive shaft of the R2 rolling mill.

(1) *Mechanical analysis of the main drive shaft of the rolling mill.*

1. FEM software

With the continuous progress of computer technology, the theoretical technology of Computer Aided Engineering (CAE) is also maturing [10]. Many kinds of FEM software can be used in the project,

Table 2.2: Specification and quantity of test billet

Material and model	Product specification (thick \times wide \times Length) (mm)	Slab quantity (block)
DC01	250 \times 1300 \times 8600	2
Q235A	230 \times 1550 \times 8600	2

08AL	230 \times 1550 \times 10800	4
RCL380	230 \times 1550 \times 10800	6

such as Hyper Mesh, ANSYS, and ANSYS Workbench [11,12,13]. Here, Hyper Mesh and ANSYS are adopted to analyze the main drive shaft of the rolling mill under dangerous working conditions.

FEM software ANSYS is an excellent numerical analysis and calculation software. In the field of linear computing, the position of ANSYS is quite stable [14]. ANSYS is a multi-physics field analysis package that integrates structure, fluid, electromagnetism and acoustics. Its common applications include industrial manufacturing, nuclear industry, household appliances, aerospace, and biomedicine. It has the most users in the world and is also a very successful FEM software [15].

Hyper Mesh software is a general FEM analysis software developed by Altair. It can be applied in the fields of modeling, visualization, automation and manufacturing, and is recognized and applied by the world industry. The shape of the drive shaft and bearing seat in the main drive device of the rolling mill is not too regular. Rough grids have low credibility and are likely to lead to incorrect calculation results. Since the quality of finite element mesh will directly affect the accuracy of final calculation results, finite element mesh is the key to analysis and calculation. The mesh quality greatly impacts the calculation results, and Hyper Mesh has the characteristics of a high-quality mesh division. It has a complete interactive two-dimensional and 3D cell division tool [16]. The user can adjust the mesh parameters of each face during the division process, such as cell density, cell offset gradient and mesh division algorithm. The 3D cell generation method provided by Hyper Mesh is employed to build high-quality tetrahedral and hexahedral meshes and Computational Fluid Dynamics meshes [17].

2. FEM model creation

The R2 rolling mill used in this section has a motor power of 7500kw and a motor speed of 45~90rpm. According to the calculation equation, the maximum torque output at the motor end of the mill drive shaft is 1591000N \cdot m. According to the functional relationship and parameters between the balance force on the drive shaft of the rolling mill and the driving force of the hydraulic cylinder, it is calculated that the balance force provided by the bearing seat is 348520N under the dangerous angle of the upper drive shaft of the rolling mill. The balance force provided by the bearing seat of the lower drive shaft of the rolling mill at a dangerous angle is 350100N. The material of the drive shaft in the main drive device of the rolling mill is 42Cr Mo. According to the manual, the elastic modulus of the drive shaft material in the main drive device of the rolling mill is 2.06×10^{11} Pa, Poisson's ratio is 0.3, the maximum tensile strength of the material is 1080MPa, and the yield limit of the material is 930MPa. Other properties of materials can be calculated by empirical equation, such as torsion fatigue limit 301.5MPa, and fatigue limit 542.7MPa.

According to the calculated dangerous working condition angle of the rolling mill drive shaft, in the 3D software Solid Works, the drive shaft and bearing seat are virtually assembled. Then, it is saved to the file in .iges format to facilitate the reading of FEM software Hyper Mesh.

Fig. 2.3: Mesh element model and contact element (a) Mesh element model; (b) Contact element

FEM software Hyper Mesh is started. Because the solution and calculation phase need to be carried out in ANSYS, the ANSYS panel is selected in the Load User Profile. When importing a model, the iMPortgeometry option is selected to import the .iges format file previously saved through Solid Works into Hyper Mesh. The mesh of the rolling mill's imported main drive shaft and the bearing seat model are divided. In order to make the divided element mesh neat and regular, the area where the balance force is added in the bearing seat is coupled with the bearing seat by establishing a contact surface, as shown in Figure 3(a). The cell type selected is SOLID185 cell. There is contact between the drive shaft and the bearing seat, so it is essential to establish contact between the bearing and the drive shaft, as shown in Figure 3(b). The contact pairs are CONTA173 and TARGE170.

Then, the dangerous angle of the upper drive shaft and the lower drive shaft of the rolling mill can be judged according to the theoretical calculation results. Then, through rotation in Hyper Mesh, the data file of dangerous working conditions of the main drive shaft of the rolling mill is obtained. In order to add the constraints of the two dangerous angles of the main drive shaft of the rolling mill correctly, it is necessary to establish a local coordinate system at both ends of the drive shaft. The number of the local coordinate system at the motor end and at the roll section is set to 20 and 21, respectively, to prevent errors in the simulation. The constraint added at the motor end is to limit the three degrees of freedom of displacement of the motor end face. The constraint added at the roller end is to limit the three degrees of freedom of displacement of the roller end and the degrees of freedom of rotation in the Z-axis direction (axial direction).

3. Static strength simulation analysis

After the preprocessing of Hyper Mesh, it is essential to open the saved data file in ANSYS and solve it. After the solution is completed, the stress change nephogram of the main drive shaft of the rolling mill can be obtained under the dangerous working angle of the drive shaft in the main drive device of the rolling mill. The material selected is 42Cr Mo, which is plastic material. The fourth strength theory (Von Mises) is used as the criterion for strength judgment. It is believed that the density of distortion energy or the specific energy of shape change is the main reason for material yield failure. Von Mises Stress is output in the post-processing [18].

(2) *Fatigue strength check of the main drive shaft of the R2 rolling mill.* First, the final element calculation of the drive shaft at a dangerous angle is conducted to determine whether the design strength of the drive shaft meets the requirements. Then, through the analysis of the working state of the drive shaft, the bending moment of the drive shaft of the rolling mill is the alternating stress. As the rolling mill is reversible, the torque of the drive shaft is also alternating stress. The fatigue strength of the drive shaft at the dangerous angle of the mill drive shaft is checked.

According to the fatigue limit σ_{-1} of the material under symmetrical cyclic alternating stress, the fatigue

limit $(\sigma_{-1})_G$ and allowable stress $[\sigma_{-1}]$ of the drive shaft can be calculated. Their values are:

$$(\sigma_{-1})_G = \frac{\varepsilon_\sigma \beta}{K_\sigma} \sigma_{-1} \quad (2.1)$$

$$[\sigma_{-1}] = \frac{(\sigma_{-1})_G}{n} \quad (2.2)$$

n represents the allowable safety factor. Generally, according to the regulations, when the material quality is uniform and the calculation accuracy is high, $n=1.3\sim 1.5$. According to the engineering calculation, the allowable safety factor is 1.5. ε_σ is the size factor of the component, with a value of 0.53. β is the surface processing coefficient, and the value is 1.

When the rolling mill is at a dangerous working angle, the bending moment of sections A-A and B-B are calculated. Since the direction of gravity is not perpendicular to the axis direction, the gravity component perpendicular to the axis direction is adopted to calculate the bending moments of the transmission shaft sections A-A and B-B when calculating the bending moments of the above sections. Finally, according to the theoretical data, the maximum working stress of the rolling mill drive shaft at the dangerous section A-A and B-B can be calculated.

In order to calculate the safety factor closer to the real situation, the maximum working stress and maximum shear stress of the dangerous section are extracted from the post-processing of ANSYS. The post-processing interface of ANSYS is opened. In the command flow window of ANSYS, RSYS,20 are input to make the stress distribution of the drive shaft along the axial direction. It is convenient to extract the stress distribution diagram of the rolling mill drive shaft in the dangerous area to complete the fatigue strength check of the rolling mill drive shaft.

3. Simulation experimental results.

3.1. Test results of mechanical mechanics parameters of main drive electromechanical coupling system of R2 rolling mill .

(1) *Distribution probability of peak and average rolling force.* Figure 3.1 presents the distribution probability results of the peak and average rolling force of the electromechanical coupling system of the main drive of the R2 rolling mill.

Fig. 3.1: Distribution probability diagram of peak and average rolling force

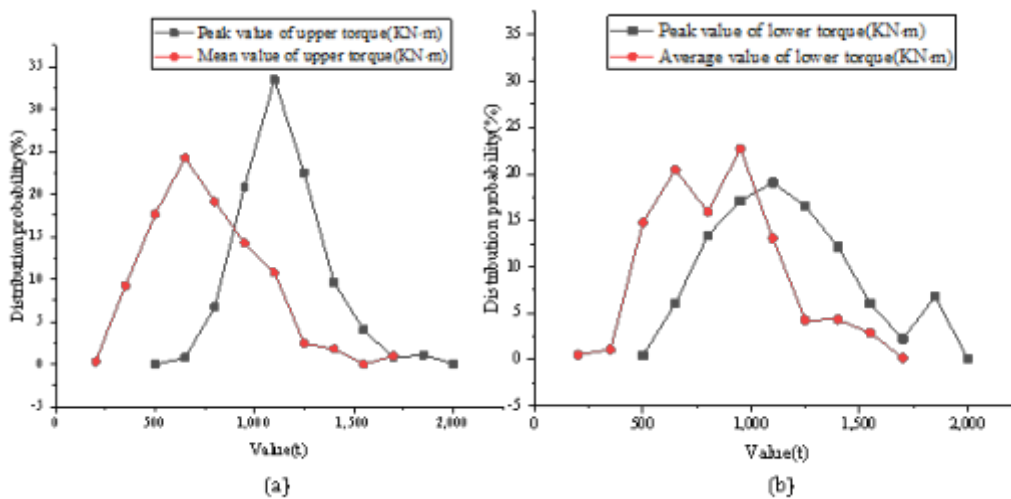

Fig. 3.2: Distribution probability of torque peak value and average value (a) Distribution probability of peak value and the average value of upper torque; (b) Distribution probability of the peak and the average value of the lower torque

Figure 3.1 reveals that the measured average value of rolling force is in the range of 1230~2660t, and the peak value is in the range of 1400~3620t. The results of the probability distribution of the peak rolling force show that the peak rolling force is mainly distributed in the range of 2300~2750t. The average distribution probability of rolling force suggests that the average distribution of rolling force is mainly in the range of 2000~2400t.

(2) *Distribution probability of torque peak and average.* Figure 3.2 displays the probability results of the peak and average distribution of the upper torque and lower torque of the electromechanical coupling system of the main drive of the R2 rolling mill.

Figure 3.2 illustrates that the peak value of the upper torque is mainly distributed in the range of 800~1400

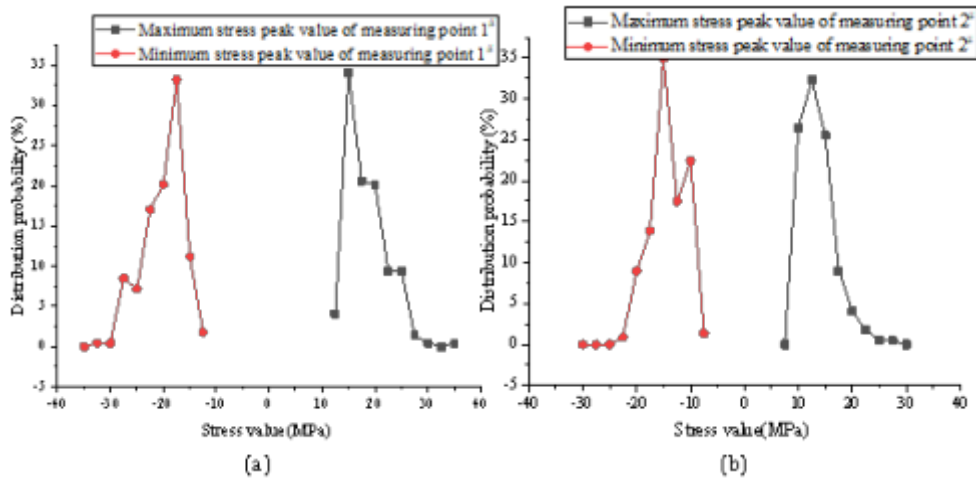

Fig. 3.3: Distribution probability of stress peak at different measuring points (a) Distribution probability of stress peak at measuring point 1[#]; (b) Probability of stress peak distribution at measuring point 2[#]

mk N, and the average value of the upper torque is mainly distributed in the range of 350~1100 mk N. The peak value of the lower torque is mainly distributed in the range of 650~1550 mk N, and the average value of the lower torque is mainly distributed in the range of 500~1100 mk N.

(3) *Distribution probability of stress peak.* The fatigue of metal structure is closely related to the main cycle characteristics of structural stress, and the small fluctuation of stress has little effect on fatigue life. Hence, the change of stress amplitude at each measuring point during the rolling process is recorded, and the stress equivalent curve of each measuring point is made.

Figure 3.3 displays the distribution probability of the maximum principal stress peak at different measuring points (near the drive side) after testing.

Figure 3.3 suggests that the maximum principal stress peak value of 1[#] measuring point is within the range of 10-35Mpa, and the minimum principal stress peak value of 1[#] measuring point is within the range of 10-30Mpa. The maximum principal stress average value is 24Mpa, and the minimum principal stress average value is -24Mpa. The maximum principal stress peak value of 2[#] measuring point is in the range of 5-25Mpa, the minimum principal stress peak value of 2[#] measuring point is in the range of 8-22Mpa, the maximum principal stress average value is 16Mpa, and the minimum principal stress average value is -16Mpa. During idling, the maximum and minimum principal stress values of 1[#] and 2[#] measuring points are 8Mpa.

(4) *Torsional vibration power change of main drive system of R2 rolling mill.* The first natural frequency of the upper and lower main drive systems can be obtained by power spectrum analysis of the measured torsional vibration waveforms of the upper and lower main drive systems, as shown in Figure 3.4.

Figure 3.4 suggests that the torsional vibration power spectrum of the upper and lower main drive systems of the R2 rolling mill is basically similar, and both reach a peak at about 17.5Hz.

3.2. Strength simulation analysis results of the main drive shaft of the R2 rolling mill. Figure 3.5 presents the stress distribution nephogram of the drive shaft of the rolling mill when the upper drive shaft is at different working angles.

Figure 3.5 suggests that when the upper drive shaft of the rolling mill is at a working angle of 1.02°, the maximum Von Mises Stress of the drive shaft of the rolling mill is 95.10MPa. It appears in the transition shaft shoulder’s fillet area where the main drive shaft of the rolling mill contacts the bearing seat. When the lower drive shaft of the rolling mill is at a working angle of 3.14°, the maximum Von Mises Stress of the rolling mill drive shaft is 95.15MPa. It appears in the transition shaft shoulder’s fillet area where the main drive shaft of the rolling mill contacts the bearing seat. The analysis reveals that the Von Mises Stress value of the rolling mill drive shaft is far less than the yield limit of 930MPa.

Fig. 3.4: Torsional vibration power spectrum of upper and lower main drive systems of R2 rolling mill

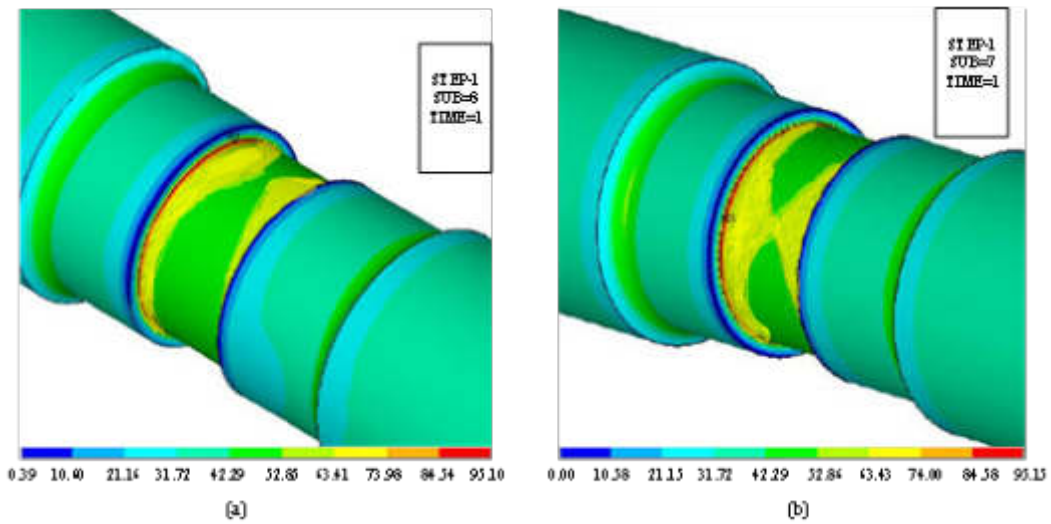

Fig. 3.5: Stress distribution nephogram of rolling mill drive shaft under different working angles (a) Stress distribution nephogram of rolling mill drive shaft at 1.02° working angle; (b) Stress distribution nephogram of the lower drive shaft in the main drive device of the rolling mill at a working angle of 3.14°

4. Conclusion. This work further analyzes and tests the compressive strength of the electromechanical system of the main drive coupling of the R2 rolling mill through testing and simulation experiments based on previous scholars' research on the electromechanical system of the main drive coupling of the rolling mill. Besides, the strength of the main drive shaft in the main drive coupling electromechanical system of the R2 rolling mill is analyzed. The research results show that the peak value of the lower torque of the main drive coupling electromechanical of the R2 rolling mill is mainly distributed in the range of 650~1550 mk N, and the average value of the upper torque is mainly distributed in the range of 350~1100 mk N. When the upper drive shaft of the rolling mill runs at a working angle of 1.02°, the maximum Von Mises Stress of the drive shaft of

the rolling mill is 95.10MPa. When the drive shaft of the rolling mill operates at a working angle of 3.14° , the maximum Von Mises Stress of the drive shaft of the rolling mill is 95.15MPa. The research deficiency is that only the whole part of the main drive coupling electromechanical system of the R2 rolling mill and the strength of the rotating shaft have been studied, while the strength of other structures has not been studied. Later, it will be studied and analyzed to provide some reference for improving the strength of the main drive coupling electromechanical system of the rolling mill.

RESEARCH ON POWER LINE COMMUNICATION BASED ON DEEP LEARNING FOR ELECTROMECHANICAL EQUIPMENT ELECTRICITY ACQUISITION TERMINALS

CHENGFEI QI^{*}, XIAOBO YANG[†], XIAOKUN YANG[‡], CHAORAN BI[§] AND WENWEN LI[¶]

Abstract. The purpose is to use power line communication technology to re-optimize the power acquisition terminals of electromechanical equipment and improve the efficiency of information acquisition and management of the system grid. This paper analyzes the power and signal composite modulation mode of power line data communication in distributed power grids. Combined with the topology of the communication network in the power transmission process, the management mode of integration of power lines and wireless communication equipment is redesigned. Firstly, the characteristics of power line communication and wireless channel are analyzed. Aiming at the problem that most communication network operators use the fixed relay for communication, the main network communication mode is selected for optimization. Then, the information fusion method is adopted to integrate the network structure of the enterprise, network, and physical layer. The management of wireless communication equipment is carried out by reasonably allocating power resources. Additionally, the structure of the power acquisition terminal model is designed based on strict standards and practice. Finally, the communication fusion method is used for experimental simulation. The results show that when the input current is 1A, the experimental, theoretical value of the system is 3A, and the actual instrument output is close to 5A. When the input current is 6A, the instrument output of the system is 7.5A. Therefore, loading a reasonable load impedance value in the system can optimize the current output value of the model. The paper has important reference value for optimizing electromechanical equipment and power acquisition terminal.

Key words: power line communication, electromechanical equipment, power acquisition terminal, management efficiency, communication integration

1. Introduction. WWith the development of power line communication technology and the Internet of Things (IoT), the management and collection of energy resources have begun to develop in the direction of intelligence [1]. Based on the re-optimization of wireless networks and power infrastructure, the efficiency of information exchange and resource exchange of power, transportation, and the IoT can be greatly improved. At present, the existing power communication network structure in China is complex and widely distributed, which brings great inconvenience to the use of individual users and the collection of power consumption information. Therefore, optimizing electromechanical equipment management strategy using power line communication is the key to solving the power problem.

Power line communication technology has the advantages of small investment, strong flexibility, and wide coverage. It is widely used in communication and data transmission between the power grid and the IoT [2]. However, due to the power grid's serious electromagnetic interference and channel attenuation, the communication quality is relatively poor. In order to solve the problems such as coverage and reliability of the power line communication network of the distribution grid, power line communication can be combined with the collection of electrical information from mechanical and electrical equipment. By designing the corresponding power line communication protocol, networking process, and route reconstruction strategy, the automatic networking and dynamic maintenance of the network can be realized, which is of great significance in improving the reliability of the power line communication network [3].

This paper makes an intelligent evaluation of the power line communication system based on relevant literature. Electromechanical equipment is used to optimize the relevant structure of the acquisition terminal.

According to the power grid intelligent sensing technology requirements, the combined network distribution strategy of power equipment and intelligent power acquisition terminal is optimized. Section 1 introduces the background of power line communication technology and the development of IoT networks. Section 2 sorts out the literature on power line communication technology and power acquisition terminals of mechanical and electrical equipment and finds the practical application scenarios of power consumption monitoring in large power system networks. Section 3 analyzes the characteristics of power line communication and wireless channel and uses information fusion to design a power load management system and data acquisition terminal. Section 4 compares and discusses the simulation results of the electricity acquisition terminal. Section 5 analyzes and discusses the experimental results and draws experimental conclusions. This paper has practical reference value for promoting the digital and intelligent transformation of electromechanical equipment in the power grid.

2. Recent related work.

2.1. Relevant research on power line communication technology. Oliveira et al. (2018) [4] studied the access control protocol of power line communication media. They studied the design of new requirements related to the media access control layer and physical network system through the analysis of the time-varying behavior of load in the power system and high-power impulse noise. The results show that the development of power line communication technology can solve the problem of network resource sharing by comparing the access control protocols of smart grids and multimedia devices. Ghasempour (2019) [5] studied the architecture and application of the IoT in the smart grid and built a dynamic global network based on Internet entities with network services. The results show that IoT devices have limitations in computing and storage. Therefore, it is necessary to design or use security solutions so that IoT devices can safely conduct power communication transmission. Matheus et al. (2019) [6] studied the concept, application, and challenges of visible light communication. They explored the security architecture of power line communication by improving mobile communication architecture and wireless service infrastructure. Based on the redesign of the IoT communication architecture, the results show that the proposed model can promote the optimization of wireless networks.

Kolade et al. (2020) [7] studied the indoor amplification, forwarding power line, and visible light communication channel model. With the help of software-defined radios, they obtain measurements in an indoor testbed from different locations between powerline communication transmitters and receivers. The results show that the error-free operation distribution and the error probability of the measurements in the proposed mixed channel are far lower than those in other models. Therefore, the effectiveness of the experimental results is verified. Yu et al. (2021) [8] studied the power and signaled composite modulation mode of power line data communication in the distributed grid. They are based on a single generator and load design of the converter, using a power spectral density approach to demodulate useful data for transmission lines. Hardware experiments verify the effectiveness of the proposed signal composite modulation strategy. Koshkouei et al. (2022) [9] evaluated the in situ power line communication system of lithium-ion batteries and combined it with the real-world dynamic drive configuration experimental files. The results show that an increase in the quality and quantity of battery characteristic data available at runtime can improve the accuracy of the system's assessment of Li-ion battery health. Fei et al. (2022) [10] used the missing value pattern and non-technical structure loss of neural structure search to conduct research and adopted a detection algorithm and supervised learning technology to process distribution network data. The results show that the analysis of the relationship between various power theft techniques and data loss can use the missing value location information to enhance the model's performance further.

In order to improve the effectiveness and reliability of power line communication, the existing research generally starts from two aspects improving the point-to-point communication quality of power line communication physical layer and data link layer and network layer performance. Therefore, in order to improve the communication speed and reliability of the power line communication network, the paper can optimize the power resource acquisition efficiency of the power acquisition terminal from the network layer.

2.2. Recent research on power acquisition terminal of electromechanical equipment. In the study of mechanical and electrical equipment and electrical acquisition terminals, Shi et al. (2018) [11] studied the data acquisition system of high-precision electrical impedance tomography. They used a high-precision digital synthesis method and digital demodulation technology with high immunity to eliminate random errors,

focusing on the main problems encountered in electrical impedance tomography data acquisition. The conclusion has practical application value for promoting the intelligent development of data acquisition systems. Zhang et al. (2020) [12] studied the electrical equipment identification system based on K-means clustering in intelligent buildings. They analyzed the load characteristics of the system and extracted the electrical characteristics for equipment identification from the collected data. The successful application of the system verifies the effectiveness of the proposed identification method. Budiman et al. (2021) [13] studied the monitoring and data acquisition information system. The experiment used Codeigniter for framework construction. System tests show that the design functionally generates 79.74% value, meets good standards, and is feasible. Herman et al. (2021) [14] studied the improved method of medical mask pressure for automatic data acquisition and analysis measurement. They created a simple pressure device with a three-dimensional (3D) printing model method. They used Python and MatLab scripts to acquire real-time pressure drop data and analyze multiple samples or batches. This paper has important reference value for improving the efficiency of medical data collection and processing.

In addition, in the research on intelligent manufacturing and the use of transmission lines in the power transmission process, Parveen et al. (2021) [15] explored the possibility of enhancing power transmission and multi-terminal power systems. They proposed to increase the use of existing transmission lines in addition to the independent control of AC alternating current/ direct current (DC) power flows. The results show that their proposed scheme can also meet the increase in electricity demand by increasing the use of existing transmission lines. Jiang et al. (2021) [16] studied the current compensation control strategy of electricity collection terminals for mechanical and electrical equipment in rectifier terminals. They proposed a current DC bus compensation control scheme and applied it to the rectifier terminal. In this scheme, the DC bus impedance gain at the rectifier end is reduced to balance the impedance at both ends and improve stability and controllability. Zhang et al. (2022) [17] used the energy-saving production architecture for the intelligent manufacturing process to describe the configuration of the data acquisition network. This approach enables the combination of social manufacturing and real-time energy profiling. Additionally, the energy consumption characteristics provide the decision-making basis for the energy-saving control of intelligent manufacturing workshops. Cao et al. (2022) [18] studied the wind farm data acquisition and management system based on edge computing. Firstly, the principles and advantages of edge computing technology are introduced. Then, they proposed to apply the technology to the wind farm data acquisition so that the data acquisition and management work could be carried out normally. Finally, the application of edge computing technology in wind farm data acquisition and management is simulated. The results show that the application of edge computing in wind farm data acquisition and management can improve the data transmission difficulties of electromechanical equipment during data acquisition.

According to the power grid smart sensing technology requirements, the current electromechanical equipment uses the power grid smart sensing terminal based on the power line and wireless communication integration technology. The designed terminal carries out power consumption monitoring and energy efficiency analysis in the large-scale power system network. Based on typical application scenarios such as power resource dispatching, power equipment, and intelligent power acquisition terminals have been widely promoted and applied.

3. Design of power load management system and data acquisition terminal based on power line communication.

3.1. Characteristic analysis of power line communication and wireless channel. At present, the topology of the power line communication network is complex and changeable. The network topology affects the transmission of communication channels in the current network, which changes with the distribution area [19]. Generally, this is a hybrid tree topology. Suppose the power communication network's distance between the source node and the target node is too large. In that case, reliable signal transmission between different nodes in the power network cannot be guaranteed. The power line communication network mainly includes a communication channel, an edge server, and a mobile base station. The structural framework of the power line communication network is shown in Figure 3.1.

Fig. 3.1: Structural Framework of Power Line Communication Network

3.2. Management mode of power line and wireless communication equipment using information fusion. Enterprise, network, and physical layers are different levels of power line and wireless communication management structure. The existing research on power line communication combined with electromechanical equipment usually involves only one or two aspects, network or physical layers. The layer integration research on the power line and wireless network communication management model has not been fully launched. In order to improve the understanding of the complexity and reliability of network information, low-voltage line and microelectronic radio communication are deeply integrated by using multi-level and combined network and distribution strategies [20]. This is achieved by combining the concept of unified communication protocol, adopting the strategy of reasonable allocation of power resources, and understanding the network information of communication objects. For the management mode of wireless communication equipment, the structure is shown in Figure 3.2:

3.3. Structural design and research of power acquisition terminal model. Technically, the power acquisition terminal model is a centralized, spatially evenly distributed real-time computer control system. One of the technical bases of centralized monitoring of power load is the data communication between computers. A communication disk is established between the main system of the operating company and the locally distributed user data terminals to realize the centralized equipment management during the data exchange between the headquarters and the end users. Strict standards and practices must be followed; the system must receive data correctly before the timer locks. If the output power consumption data is inaccurate or lost, the timer will specify a timeout, and the system administrator will resend the power consumption data. By transmitting communication protocols between the application, data link, and physical layers, the structure of the power acquisition terminal model can be optimized. The structure of the power acquisition terminal model in the system network is shown in Figure 3.3.

3.4. Design of simulation experiment. The electromechanical power line communication equipment includes a timer and an external interrupt service program. Based on the timer interrupt service program, the data type conversion needs to be started when the timer stops in the model. A fixed number of network nodes in the weekly signal wave can be uniformly sampled. The power acquisition terminal module adopts a special power measurement chip. The power consumption can be measured by capturing the voltage and current of the integrated three-phase voltage sensor and external current sensor. The parameters of power, power supply, reactive power, and reactive voltage factor can be calculated. In the dynamic input range, the nonlinear measurement error of the chip is less than 0.1%.

In order to facilitate the verification of the communication fusion method proposed, the simulation experiment is based on the following assumption. Each node can calculate the communication rate, delay, and bit

Fig. 3.2: Management Mode Structure of Wireless Communication Equipment

Fig. 3.3: Network structure of power acquisition terminal model

error rate between it and the previous node after receiving the data packet and storing it in the corresponding routing table. In order to research the power acquisition terminal of electromechanical equipment, Visual C++ is used as the experimental simulation environment. The modular design method is adopted, which is divided into power information acquisition, Bluetooth wireless communication, and system debugging modules. The main function is to display and verify the AC sampling value and detect other power data. The microprocessor system realizes the communication with the wireless Bluetooth HC-05 debugging communication module or serial port through the RS-232 serial interface, mainly realizing the parameter setting of the intelligent perception terminal. In addition, in order to compare the performance of power acquisition terminals, the system performance is tested under different current values, voltage values, and load impedance, and the results are analyzed and discussed. The scene structure of the simulation experiment application is designed, and the

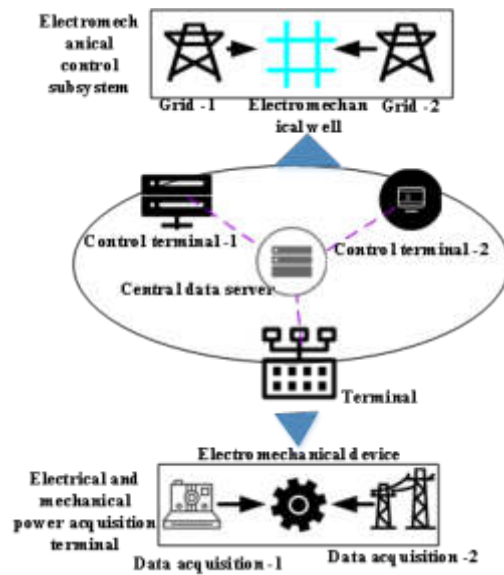

Fig. 3.4: Scene structure of simulation experiment application

Fig. 4.1: Current and voltage value change curve of electric power acquisition terminal under different input values (a. comparison of terminal output current values under different current input values of the system; b. comparison of terminal output voltage values under different voltage input values of the system)

structure is shown in Figure 3.4.

4. Results and Discussion.

4.1. Comparison between current and voltage value of power acquisition terminal. In order to test the performance of electromechanical equipment combined with the power line communication proposed, it is necessary to compare the current and voltage value of the power acquisition terminal under different input values. Compare the results of the current and voltage values of the power acquisition terminal under different inputs, which are shown in Figure 4.1. In addition, in order to analyze the instrument power change of the power acquisition terminal, the instrument power change data of the power acquisition terminal under different current and voltage values are sorted out. The results are shown in Figure 4.2.

Fig. 4.2: Instrument power change curve of power acquisition terminal under different current and voltage values (a. comparison of instrument power change results of power acquisition terminal under different current input values of the system; b. comparison of instrument power change results of power acquisition terminal under different voltage input values of the system)

In Figure 4.1, when the input current value of the system is increasing, the data output results of the experimental theoretical and the instrument display value show an increasing trend. When the input current is 1A, the experimental, theoretical value of the system is 3A, and the actual instrument output is close to 5A. When the input current is 6A, the instrument output of the system is 7.5A. In addition, when the system input voltage is 100V, the theoretical output value is 110V, and the actual instrument output value is 140V. Therefore, the power acquisition terminal designed by the research can reasonably dispatch and allocate power resources.

In Figure 4.2, the theoretical output power value of the acquisition terminal and the actual instrument output value will fluctuate under different current and voltage values. When the system input current is 1A, the theoretical output value of the system is 800W, and the actual output value is 1300W. In addition, when the system input voltage is 1V, the theoretical power output value of the terminal is 850W, and the actual instrument output value is 1480W. The influence of the voltage input value on the system output power is analyzed. When the voltage input is 6V, the theoretical power output value of the terminal is 1100W, and the actual instrument output value is 1680W. Therefore, the results show that the system's output power can be effectively adjusted with the help of experimental instruments.

4.2. System performance analysis under different load impedance. In order to further analyze the system performance of the electrical acquisition terminal, the gap between the experimental theoretical value of the system and the instrument display value is compared under different load impedances. The data change curve is shown in Figure 4.3. The change curve of output power and output voltage value of the system under different input power is shown in Figure 4.4. In addition, the data receiving accuracy and data detection error rate change data of the power acquisition terminal are sorted out. The data results are shown in Figure 4.5.

In Figure 4.3, the difference between the experimental theoretical and the instrument display value under different load impedances will cause certain fluctuations. When the load impedance of the system is 20, the theoretical current of the instrument of the electric data acquisition terminal is 0.58, and the current value of the terminal data acquisition instrument is displayed as 0.98. In addition, when the load impedance of the system is 180, the current value of the terminal data acquisition instrument is displayed as 0.44. When the capacitance is removed, the load impedance range of the system changes from 100 to 600. When the load impedance is 200, the theoretical current of the instrument at the electric data acquisition terminal is 2.5, and the actual current of the terminal data acquisition instrument is 4.25. Therefore, the reasonable load impedance value loaded in the system can optimize the model's current output value and improve the resource utilization rate.

Fig. 4.3: Comparison of the gap between the theoretical, experimental value and the instrument display value under different load impedances of the system (a. the curve of the data changes between the theoretical, experimental value, and the instrument display value under different load impedances of the system after adding capacitance; b. the curve of the change of the data between the theoretical, experimental value, and the instrument display value under different load impedances of the system after removing capacitance)

Fig. 4.4: Comparison of the system's output power and output voltage under different input power of the terminal (a. the change curve of the output power value of the system under different input power of the terminal; b. the change curve of the output voltage value of the system under different input power of the terminal)

In Figure 4.4, under the different input power of the electricity acquisition terminal, the system's output power and voltage value vary greatly. When the terminal input power is 10W, the theoretical output power of the system is 112.5W, and the actual output value is 133W. Currently, the theoretical output voltage of the system is 12.5V, and the actual model output voltage is 13.2V. When the terminal input power is 60W, the output power of the actual model is 130W, and the output voltage of the actual model is 14.25V. Therefore, reasonable allocation of grid resources can improve the working efficiency of power acquisition terminals and promote the rapid transformation of power resources.

In Figure 4.5, under the increasing input of the power acquisition terminal, the system's data-receiving accuracy is constantly improving, and the error results of data detection are constantly decreasing. When the

Fig. 4.5: Comparison of data receiving accuracy and data detection error of electric power acquisition terminal (a. change curve of data receiving accuracy of electric power acquisition terminal; b. change curve of data detection error of electric power acquisition terminal)

input power of the system is 10W, the accuracy of the experimental, theoretical output data is 20.5%, and the accuracy of the actual output data is 43.3%. At this time, the error rate of theoretical detection data is 13.7%, and the detection error rate of the actual data acquisition terminal can be reduced to 7.2%. In addition, when the system input power is 60W, the theoretical error detection rate of the data acquisition terminal of the system is 8.7%. The error detection rate of the actual terminal can be reduced to 4.3%, which is much lower than the previous data detection error rate. Therefore, using power line communication technology to optimize the power acquisition terminal of electromechanical equipment is conducive to improving the accuracy of power resource data transmission.

5. Conclusion. With the progress of the times and the rapid development of power supply technology, users have put forward higher requirements for power load resource management and power resource transmission. The paper adopts power line communication technology to analyze the transmission efficiency of resources in the current network. Based on the optimization of network topology, the main and fixed relay communication modes are selected to transmit power resources in the network. The electromechanical equipment type of power line communication is studied with the form of information fusion and structure optimization of power acquisition terminal model. The results show that the difference between the experimental theoretical and the instrument display value under different load impedances will cause certain fluctuations. When the load impedance of the system is 20, the theoretical current of the instrument of the electric data acquisition terminal is 0.58, and the current value of the terminal data acquisition instrument is 0.98. In addition, when the load impedance is 200, the theoretical current of the instrument of the electrical acquisition terminal is 2.5. The actual current of the terminal data acquisition instrument is 4.25. This paper has practical application value for promoting the deep integration of electromechanical equipment and power line communication technology. However, there are some deficiencies in the research. The main disadvantage is that in the actual power system network, the actual distribution network impedance is affected by many factors. Here, only a specific length of the power cable is simulated. In future research, more powerful system network data should be combined to optimize the model management strategy.

A FAULT MONITORING SYSTEM FOR MECHANICAL AND ELECTRICAL EQUIPMENT OF SUBWAY VEHICLES BASED ON BIG DATA ALGORITHMS

GENG LI^{*}, YA LI[†] AND HONGXUE BI[‡]

Abstract. This paper uses big data technology to extract the electromechanical fault characteristics of metro vehicles and analyze the current situation under different fault conditions to ensure the operation quality and safety of metro operations. It also establishes a simulation model to simulate the current waveform of metro vehicles under different fault conditions and analyze the fault phenomenon. The simulation test results show that: (1) The current waveform of a single transistor with the hard fault is compared with the simulated current waveform under a normal state. The upper part of the A phase current waveform is lost when T1 fails. When T2 fails, the current waveform in the lower half of the C phase current is lost. When T3 fails, the upper half of the B phase current waveform is lost. (2) The current waveform in the hard fault's upper and lower bridge arms will have phase loss. In the T25 fault, the C phase current is completely lost. In the T14 fault, the phase A current waveform is completely lost. In the T36 fault, the phase B current is completely lost. (3) The current waveform of a single transistor with a soft fault is complete, but the overall current amplitude is reduced. When a T1 fails, the A phase current tends to rise first and then fall. Compared to normal, the amplitude of the current decreases, and the peak decreases slightly. (4) The current values of phase B and phase C of the two transistors on the same bridge above and below the soft fault are mostly the same. The phase A current output value decreases in both the positive and negative half cycles. This paper aims to improve the monitoring ability of the monitoring system of electromechanical equipment of metro vehicles, which plays a specific role in maintaining the safety of subway operations and improving the quality of subway operations.

Key words: Big data technology, metro vehicles, electromechanical equipment, monitoring systems, simulation

1. Introduction. With the development of urbanization, the role of urban rail transit in cities is becoming increasingly important. The metro is the backbone of public transportation in modern large cities and the backbone of passenger transportation within the city [1,2]. Metro vehicle Electromechanical Equipment (EE) is a general term for electrical and mechanical equipment that converts electricity and other energy. It is indispensable equipment for maintaining metro operations. The failure of electrical equipment in a metro train will directly affect the operational safety of the city's rail vehicles. Therefore, fault monitoring of electrical equipment in metro trains is critical. The converter is the core component of controlling multiple components in the metro electrical equipment. Monitoring the condition of the converter can prevent possible electromechanical failures during metro operation.

At the end of the last century, big data technology began to develop. Big data has a wide range of applications, for example, in healthcare. Analyzing big data through machine learning can help evaluate large amounts of complex healthcare data to improve medical diagnosis and disease classification [3]. During the 13th Five-Year Plan period, big data technology was widely used in urban rail transit. Through big data analysis, South Korea could review the operation of express trains and detect the trend of train traffic [4]. Big data analysis can plan metro travel routes [5]. Advanced big data technology can detect defects in metro tunnels [6]. In terms of metro operation, based on big data technology, an automatic toll collection system with stable system operation, relatively small memory, fast response speed, and low delay can be designed to improve the convenience of residents' lives and accelerate the process of urban construction [7]. Using big data technology can realize the intelligent management of metro operations, which plays a vital role in alleviating traffic congestion, reducing traffic accidents, and reducing energy consumption [8,9]. In addition, in terms of electromechanical fault detection, the detection system can be highly adaptable based on big data technology.

Fig. 2.1: Characteristics of big data technology

It can predict the early electromechanical failure of the aircraft and improve the fault diagnosis performance of the electromechanical system [10,11]. When dealing with complex classification problems, the use of big data technology can realize real-time fault detection of key components of the electromechanical traction system of high-speed trains, which is of great significance for improving the reliability of train motors and reducing the cost of support [12,13]. Electromechanical faults can be monitored using big data technology to establish simulation models.

Firstly, this paper uses big data technology to extract the electromechanical fault characteristics of metro vehicles and analyze the current situation under different fault conditions to ensure the operation quality and safety of metro operation and improve the monitoring of metro EE. Secondly, a simulation model is established to simulate the current waveform of metro vehicles under different fault conditions and analyze the fault phenomenon. The innovation point is to combine big data technology with the electromechanical fault monitoring system of metro vehicles and analyze the current waveform of the converter under different faults through simulation models. The monitoring of EE of metro vehicles has been improved, which has played a specific role in maintaining the safety of metro operations.

2. Establishment of the electromechanical fault simulation model for metro vehicles.

2.1. Big Data Technology. Big data technology refers to the application technology of big data, including various big data platforms, big data index systems, and big data application technology. As one of the leading development directions in the information field, big data technology can be applied to data mining, data analysis, and data sharing in massive data. It leverages the potential value of data to create substantial economic benefits. Big data can optimize resource utilization while making informed decisions [14,15]. In the oil and gas industry, big data technology can be used to analyze seismic and microseismic data, reduce drilling time and improve drilling safety, optimize the performance of production pumps, improve asset management, and improve transportation safety [16,17]. Big data technology can promote students' interest in learning and improve their concentration on learning in college education. Big data management in big data technology can organize and analyze mining data well. Big data technology is one of the promising technologies that could reshape the entire mining landscape.

The characteristics of big data technology are shown in Figure 2.1.

Big data technology has many data processing methods, such as Bayesian networks, random forests, decision trees, Principal Component Analysis (PCA), Gaussian mixture models, and regression analysis models. Here, the PCA and the Weibull distribution method are mainly used for data preprocessing.

PCA is a statistical method that can comprehensively analyze the problem, save calculation time and cost by reducing the dimensionality of the data set, and improve the accuracy of the calculation. As a basic mathematical analysis method, PCA has applications in the fields of demographics, quantitative geography, mathematical modeling, and mathematical analysis. It is a commonly used multivariate analysis method. PCA has three main functions: reducing the dimensionality of the data space, analyzing the relationship between variables, and using graphics to represent multidimensional data.

Suppose $X_1, X_2, \dots, X_i (i = 1, 2, \dots, j)$ is the eigenvector corresponding to the eigenvalues of the covariance matrix of M . $M_1, M_2, \dots, M_i (i = 1, 2, \dots, j)$ is the normalized value of the original variable. Then, the following relationship exists when normalizing.

$$F = X_1 * M_1 + X_2 * M_2 + \dots + X_i * M_i \quad (2.1)$$

The Weibull distribution method is the theoretical basis of reliability analysis. It is suitable for inferring the wear of electromechanical products, industrial manufacturing, predicting the weather, predicting technological changes, and modeling the received clutter signal. The Weibull distribution method was proposed in 1927 and explained in detail by the Swedish engineer and mathematician Waloddi Weibull in 1951. According to the form, it can be divided into three types: the one-parameter Weibull distribution, the two-parameter Weibull distribution, and the three-parameter Weibull distribution or mixed Weibull distribution.

The Weibull distribution is a continuous probability distribution. Suppose x is a random variable, $y > 0$ is the scale parameter, and $z > 0$ is the shape parameter. When $z=1$, the probability density function is an exponential distribution; when $z=2$, it is a Rayleigh distribution. The probability density is calculated as follows.

$$f(x, y, z) = \begin{cases} \frac{z}{y} \left(\frac{x}{y}\right)^{z-1}, & x \geq 0 \\ 0, & x < 0 \end{cases} \quad (2.2)$$

γ is the gamma function, and the mean is calculated according to Equation 2.3.

$$E = y\gamma\left(1 + \frac{1}{z}\right) \quad (2.3)$$

If the time is t , m is the standard parameter, and s is the positional parameter. Then, the continuous distribution function $f(x)$ is:

$$f(t) = \frac{z}{m} \left(\frac{1-s}{z}\right)^{z-1} E^{-\left(\frac{t-s}{m}\right)^z} \quad (2.4)$$

2.2. Metro EE. Metro EE is mainly divided into ventilation and air conditioning systems, water supply and drainage systems, power lighting systems, elevator and screen door systems, automatic ticket vending systems, power supply systems, communication signals and other weak current systems, civil air defense projects, and subway vehicles [18,19]. Metro trains mainly use automation equipment with electronic computer processing technology as the core. The role of this equipment is to replace manual labor with mechanized and electrified systems to ensure the operation and safety of trains. Metro trains mainly include car bodies, power bogies and non-power bogies, traction buffer connection devices, brake devices, current receiver devices, internal vehicle equipment, and electrical systems. Among them, the electrical system is divided into the main, auxiliary, and electronic and control circuits. Converters are auxiliary circuit systems.

The characteristics of EE failures are the characteristics of the occurrence, development, and change of faults in a complete life cycle of EE from use to no longer use. Figure 2.2 shows the classification of fault characteristics of EE.

The auxiliary power supply system of the metro train receives the current of the high-voltage power supply network. These currents are transmitted by a pantograph or a third rail catenary. The controller controls the inverter circuit. The voltage on the catenary of the auxiliary inverter is changed to a medium-pressure flow.

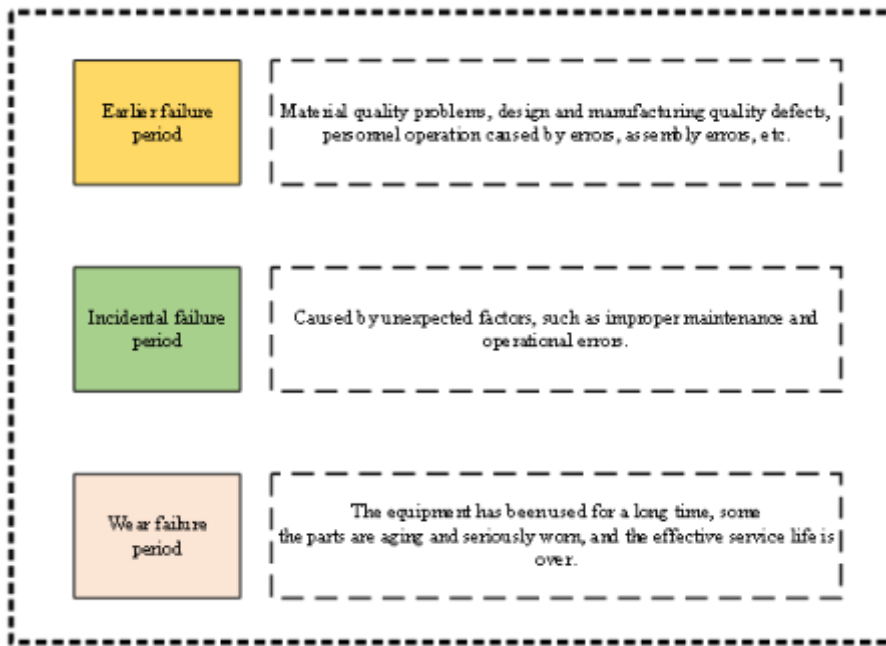

Fig. 2.2: Classification of electromechanical fault characteristics

The auxiliary power supply system is divided into the grid-connected, cross-power, and extended power supply. A bus bar connects the grid-connected power supply to the whole vehicle. There is no contactor in the middle, and the two auxiliary inverters work together. The cross-power supply is the direct power supply from the busbar to the trunks that have been grouped. Under normal circumstances, the vehicle alternating current load is divided into two groups on average according to the equipment's power. Two auxiliary inverters supply power to each of the two sets of equipment. The extended power supply is a more complex way of supplying power to two independent units using a bus bar. There is a contactor between the two auxiliary inverters. When the contactor is turned off, the malfunctioning auxiliary inverter stops working, and another auxiliary inverter is responsible for the entire vehicle.

Among them, the power supply switching mode of cross-power and grid-connected power supply is the simplest, and no additional hardware is required. When switching the expansion circuit, it is necessary to set up the expansion contactor, and the auxiliary inverter must also stop working.

The specific power supply system load is presented in Figure 2.3.

The fault characteristics extraction of the metro electrical system can be carried out through three aspects: time domain, frequency domain, and time-frequency domain. The time domain mainly describes the relationship of mathematical functions or physical signals to time. Time is the independent variable, and signal change is the dependent variable. Time domain analysis uses the time axis as the coordinate to represent dynamic signal changes. The frequency domain is a coordinate system used to describe the frequency characteristics of a signal. The independent variable is the frequency, and the dependent variable is the change amplitude of the frequency signal. It is also a spectrogram, which describes the frequency structure of the signal and the relationship between the frequency and the amplitude of the frequency signal, mainly used in electronics, control system engineering, and other aspects. The time-frequency domain combines time and frequency to express information about frequency over time. The time domain process is straightforward, and the frequency domain process needs to be transformed. The time-frequency domain process is more complex, but the resulting signal quality is higher. Therefore, the fault characteristics of the metro electrical system are extracted from the perspectives of time-frequency and time domains.

Time-domain fault feature extraction is to count the different feature manifestations of signals in different

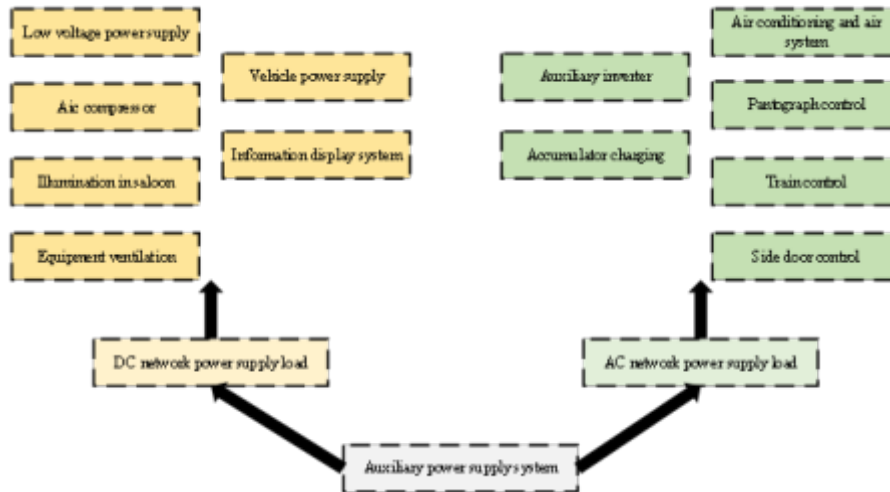

Fig. 2.3: Auxiliary power supply system load

states in the time domain. There are two main indicators of time-domain signals: dimensioned and dimensionless parameters. Dimensioned parameters have unit values and are easily affected by environmental interference. Dimensionless parameters are values without units and are not affected by interference factors.

Dimensioned parameters are calculated according to Equation 2.5-Equation 2.7.

$$A = \int_{-\infty}^{\infty} AP(A)dx \tag{2.5}$$

$$\alpha = \int_{-\infty}^{\infty} A^3 P(A)dx \tag{2.6}$$

$$\beta = \int_{-\infty}^{\infty} A^4 P(A)dx \tag{2.7}$$

In Equation 2.5-2.7, P(A) is the probability density function, A is the mean of any sample, α is the degree of skewness, and β is the steepness.

Dimensionless parameters are calculated according to Equation 2.8-Equation 2.10.

$$X = \frac{A_{RMS}}{|\bar{A}|} \tag{2.8}$$

$$L = \frac{A_{MAX}}{A_{RMS}} \tag{2.9}$$

$$K = \frac{e[(A - U)^4]}{\sigma^4} \tag{2.10}$$

In Equation 2.8-Equation 2.10, U is the mean, U^4 is the fourth-order center distance of the random variable A, e is the expectation, A_{RMS} is the square root of the mean, σ is the standard deviation, X is the waveform index, L is the peak indicator, and K is the steepness factor.

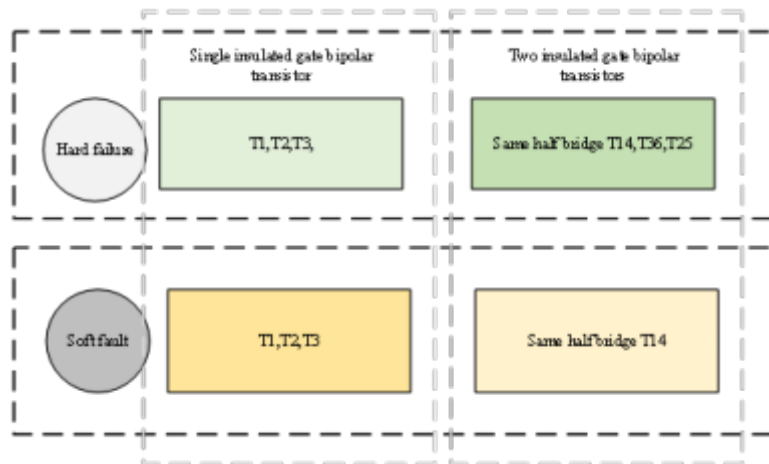

Fig. 2.4: Electrical system fault classification

Time-frequency domain fault feature extraction uses Short-time Fourier Transform (STFT), S transform, Empirical Mode Decomposition (EMD), and other methods to extract signals.

The STFT refers to a mathematical transformation related to the Fourier transform to determine the frequency and phase of a sine wave in the local area of a time-varying signal. The uncertainty criterion limits the STFT window function, and the area of the time-frequency window is not less than two. Therefore, the time and frequency resolution of the STFT window function cannot be optimized simultaneously.

The S transform replaces wavelet basis functions with Gaussian windows. It is also known as the "phase orthogonal" continuous wavelet transform. The signal is divided into many small time intervals, and each time interval is analyzed with the Fourier transform to determine the frequency at which the time interval exists. The feature quantity extracted by the S transform is not sensitive to noise.

EMD is a novel adaptive signal processing method for nonlinear and nonstationary signals. It decomposes the signal based on the timescale characteristics of the data itself. It does not require pre-setting. Compared with the previous two methods, the data of EMD is more intuitive.

Figure 2.4 demonstrates the fault classification of the metro electrical system.

2.3. Simulation model establishment. Matrix Laboratory (MATLAB) simulation tool is a commercial mathematical software produced by MathWorks in the United States. It is mainly used in data analysis, deep learning, control system design and simulation, data image processing, and data signal processing. MATLAB, along with Mathematica and Maple, is known as the three major mathematical software. MATLAB integrates matrix calculations, numerical analysis, modeling and simulation of nonlinear dynamic systems, and scientific data visualization in an easy-to-use windowed environment, largely freeing itself from the editing mode of traditional non-interactive programming languages.

The advantage of MATLAB is its efficient numerical and symbolic computing capabilities. It can handle complex and tedious mathematical operations. It has complete graphics processing functions to visualize calculation results. MATLAB also has a feature-rich toolkit that simplifies data processing.

MATLAB has five major system structures: development environment, mathematical library, language, graphics processing system, and application programming interface. The specific system structure is shown in Figure 2.5.

With the help of the Simulink module in the MATLAB tool, simulation models of auxiliary inverter circuits can be built. The simulation model is divided into two inverter modules: the inverter control module and the inverter output module.

Pulse-width modulation control is implemented in the inverter control module using the pulse-width modulation generator in the module library. The input of the pulse-width modulation generator is set with a sine

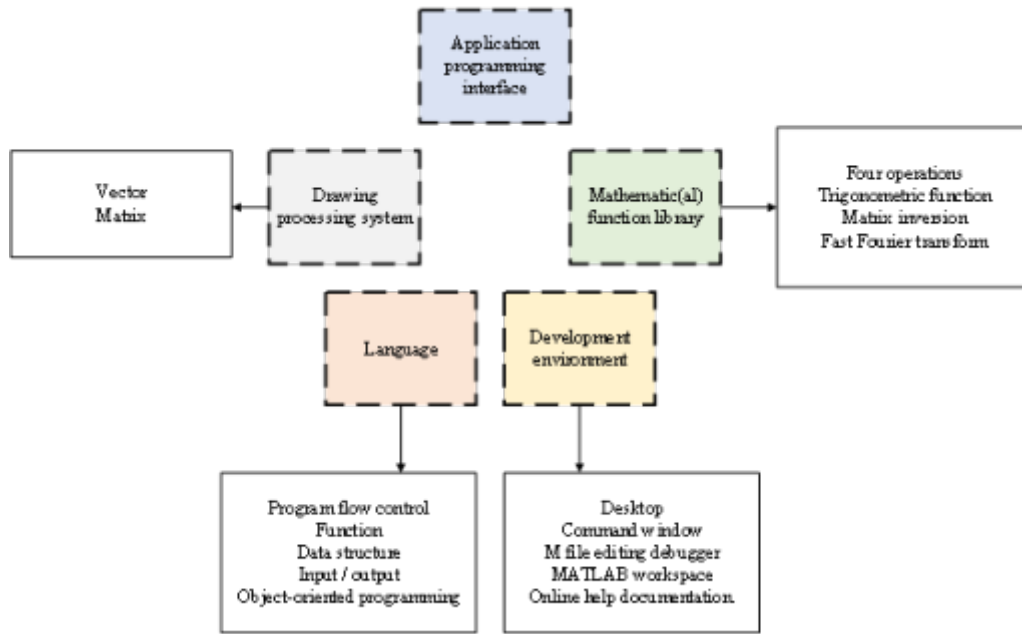

Fig. 2.5: MATLAB system structure

wave with a difference of 120° to control the Insulated Gate Bipolar Transistor (IGBT). The generator output is connected to the gate. It is necessary to prevent the reduction of harmonic content and power life problems of the inverter simulation output voltage caused by the excessive switching frequency of the components in the actual experiment. Therefore, the carrier frequency in the pulse generator is set to 0.6, the modulation wave frequency is set to 50, and the generation period mode is selected as the 3-arm bridge of six pulses.

In the inverter output module, the main circuit is set as a three-phase bridge inverter circuit. IGBT modules include gates, collectors, generators, module test terminals, and module monitoring terminals. The internal resistor size is set to 0.02Ω , and every six IGBT modules form a complete three-phase bridge inverter circuit.

A filter circuit that combines inductors and capacitors is built using modules in the component library. The input voltages of interfaces one, two, and three at the left end are set to the output voltage of the inverter circuit, and the output voltages of four, five, and six after the interface at the right end are set to sine waveforms.

In the simulation model, the grid voltage output of the auxiliary inverter system is set to 1,500V. The direct current voltage changes from 300V to 600V through the battery circuit and resonant converter. In the simulation experiment, the maximum voltage is selected as the input voltage value, set to a purely resistive load. The resistor size is 0.6, the total simulation time is 0.1 seconds, and waveforms are recorded every 0.01 seconds. The output of the simulation circuit is given in Figure 2.6.

3. Simulation results of electromechanical faults of metro vehicles.

3.1. Hard fault simulation results. The variation in the current waveform of a single insulated-gate bipolar transistor is shown in Figure 3.1.

From Figure 3.1, when the power tube T1 fails, the current fluctuation range of phase A is between 0 and -400A, the upper part is lost, and the changing trend will repeat every 0.02s. Phase B current fluctuates from 300 to -300A. The current change showed a trend of increasing first and then decreasing, repeating every 0.02s and five times within 0.1s. The C phase current range and repetition are consistent with the B phase current, but the trend is first falling and then rising. When the power tube T2 fails, the current change trend of phase A is first increasing and then decreasing, and it repeats every 0.02s. The current varies from 300 to -300A. The current change trend of phase B is first falling and then rising, which coincides with the phase A current about every 0.01s. The current varies from 300 to -400A. The C-phase current varies from 400 to 0A. The

Fig. 2.6: Output of simulation circuit

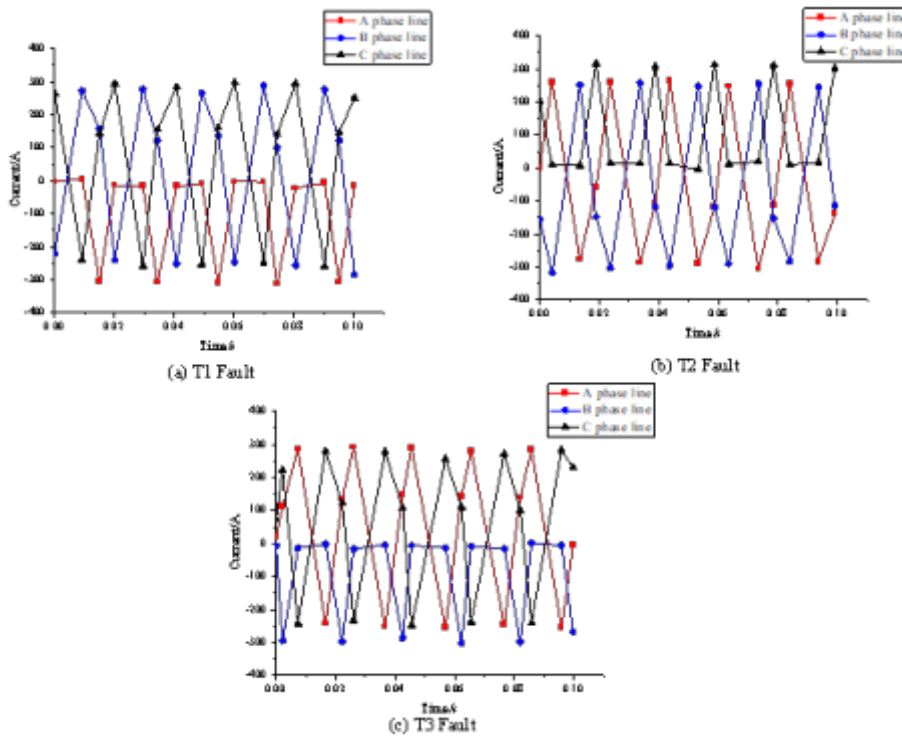

Fig. 3.1: Change in the current waveform of a hard-faulted single-insulated-gate bipolar transistor

current coincides every 0.02s, and the lower half of the current waveform is lost. When the T3 fault occurs, the current trend of phase A is consistent with that of the T2 fault. The specific current values are slightly different, but the overall range is the same. The waveform in the upper half of the phase B current is lost, and the current trend is first to fall and then rise. After rising, the current value remains 0.01s and drops again, and the consumption time of each process is about 0.02s. The trend of the current change in phase C is similar to the change in phase C at the T1 fault. In general, compared with the simulated current waveform under normal conditions, waveform loss of different phases will occur under different faults. The fault type can be

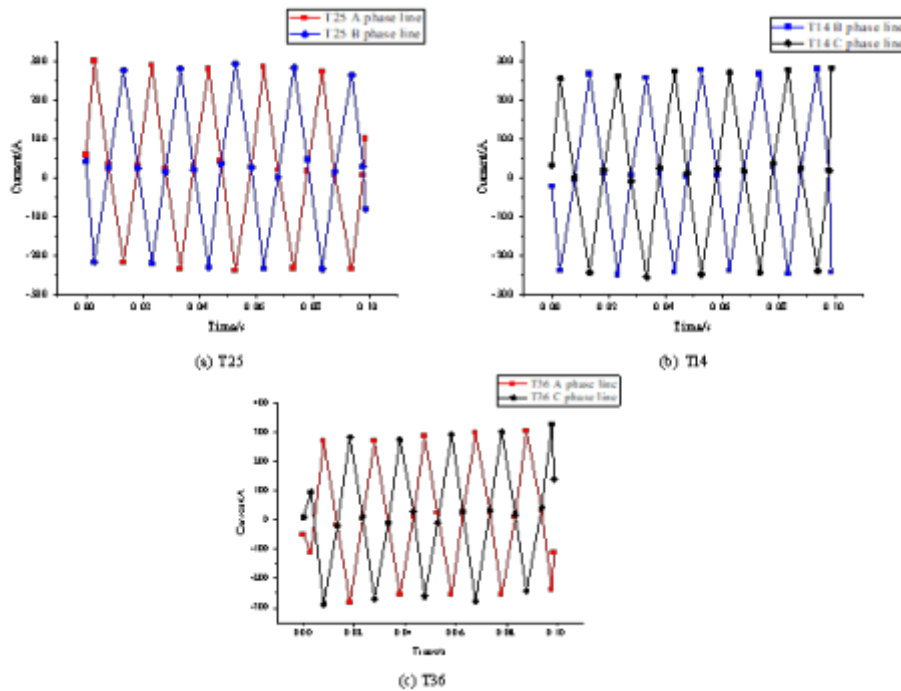

Fig. 3.2: Changes in current waveforms of two insulated-gate bipolar transistors on the upper and lower legs of a hard fault

reversed according to the waveform loss.

The current waveforms of the two insulated-gate bipolar transistors are plotted in Figure 3.2.

From Figure 3.2, in both transistor faults on the upper and lower bridge arms, the T25 fault shows only phase A current and phase B current, and the phase C current is completely lost. Phase A's current trend is first up and then down, and the current range is between 300 and -250A. There is no waveform loss. The current trend of phase B is completely opposite to the current trend of phase A. The current range of both is consistent, and the waveform is complete. In the T14 fault, only the B phase current and the C phase current are present, and the A phase current waveform is completely lost. The current trend of phase B is consistent with the current trend of phase B of the T25 fault, but the lower limit of the variation range is slightly lower than that of the T25 fault. The current trend of phase C is first rising and then decreasing. The overall current range is approximately 250 to -250A, and the waveform is complete. In the T36 fault, the A phase current and C phase current remain intact, and the B phase current is completely lost. Phase A's current change trend is to decline and then rise. The current variation range is about 300 to -300A, with large fluctuations in the middle. The current trend of phase C is first increasing and then decreasing, the lower limit of the current range exceeds -300A, and the waveform is complete. In general, the current waveform in the fault of the upper and lower bridge arms will have phase loss, and the phase loss of different power tubes will be different. In real circuits, this type of fault will cause a current short circuit.

3.2. Soft fault simulation results. The variation in the current waveform of a single insulated-gate bipolar transistor is revealed in Figure 3.3.

From Figure 3.3, in soft faults, resistance is mainly considered. At a thermally stable operating temperature of 30°C, the thermally stable resistance exceeds 0.004Ω. When a T1 fault occurs, the current in phase A tends to rise first and then fall. The current range is between 300 and -300A. Compared to normal, the amplitude of the current decreases, and the peak decreases slightly. The current trend of phase B is opposite to the current trend of phase A. The current range is consistent. The current amplitude is small compared to the simulated

Fig. 3.3: Variation of the current waveform of a soft-faulted single-insulated-gate bipolar transistor

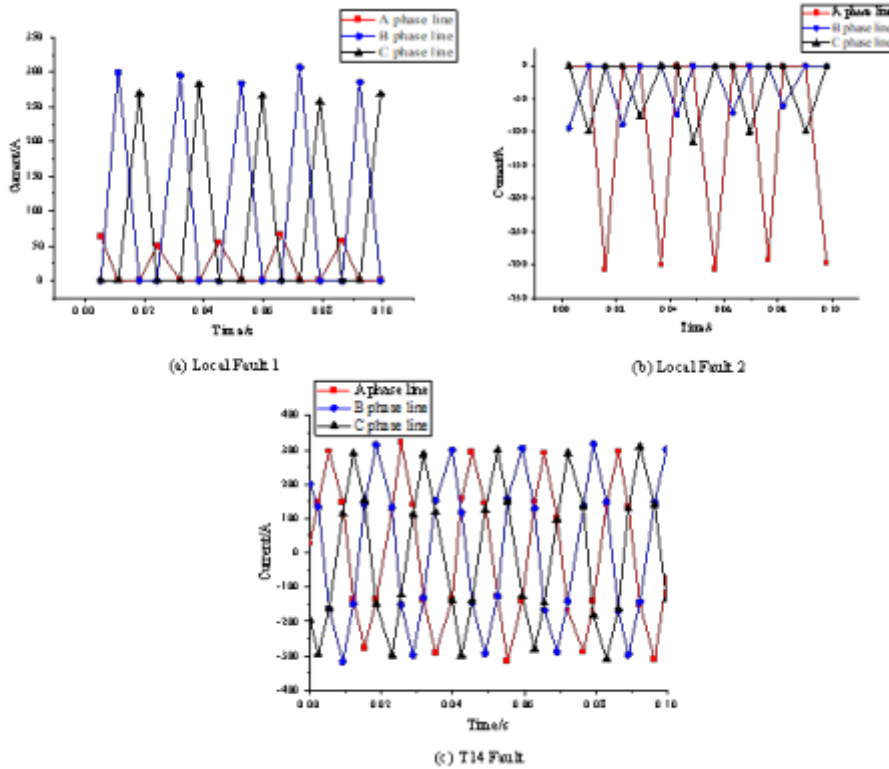

Fig. 3.4: Changes in current waveforms of two insulated-gate bipolar transistors with the same bridge above and below the soft fault

current waveform under normal conditions. The current variation trend of phase C is quite different from that of the simulation circuit under normal conditions, and the lowest value occurs when it is close to 0.02s. Overall, the soft-fault single transistor current waveform is intact, but the overall current amplitude is reduced.

The current waveforms of the two insulated-gate bipolar transistors are shown in Figure 3.4.

From Figure 3.4, when both transistors on the same bridge of the soft fault have a fault problem, the

current change trend of phase A increases first and then decreases, which is similar to the waveform of a single transistor with a soft fault[20]. Phase A currents range from 300 to -300A. Compared to the simulated current waveform under normal conditions, the current output value decreases in both the positive and negative half cycles. The current trend of phase B is completely opposite to the current trend in normal conditions. The current trend of the C phase is consistent with the case of a soft fault single transistor, and the current value at 0s is slightly different. On the whole, the current value of phase A of the two transistors with the same bridge above and below the soft fault will decrease, and the current value of phase B and phase C will not change much.

4. Conclusion. In this paper, the electromechanical fault characteristics of metro vehicles are extracted by big data technology, and the current situation under different fault conditions is analyzed. The simulation model is established. Additionally, the Simulink module in the MATLAB tool is used to simulate the current waveform of metro vehicles under different fault conditions and analyze the hard and soft fault phenomena. The simulation results show that: (1) The current waveform of a single transistor with the hard fault is compared with the simulated current waveform under a normal state. Waveform loss of different phases occurs under different fault conditions. The fault type can be reversed according to the waveform loss. When power tube T1 fails, the upper half of the phase A current waveform is lost. When the power tube T2 fails, the C-phase current coincides every 0.02s, and the lower half of the current waveform is lost. When T3 fails, the waveform in the upper half of the B phase current is lost. The current trend is first to fall and then rise, and the consumption time of each process is about 0.02s. (2) The current waveform in the hard fault's upper and lower bridge arms will have phase loss, and the phase loss of different power tubes is different. At the T25 fault, only phase A current and phase B current are shown, and phase C current is completely lost. In the T14 fault, only the B phase current and the C phase current are present, and the A phase current waveform is completely lost. In the T36 fault, the A and C currents remain intact, and the B phase current is completely lost. (3) The current waveform of a single transistor with a soft fault is complete, but the overall current amplitude is reduced. When T1 fails, the current trend of phase A rises first and then falls. Compared to normal, the amplitude of the current decreases, and the peak decreases slightly. The current trend of phase B is opposite to the current trend of phase A. The current variation trend of phase C is quite different from that of the simulation circuit under normal conditions, and the lowest value occurs when it is close to 0.02s. (4) The current value of phase A of the two transistors on the same bridge of the soft fault will decrease, and the current value of phase B and phase C will not change much. The current trend of phase A is to increase first and then decrease. Compared to the simulated current waveform under normal conditions, the current output value decreases in both the positive and negative half cycles.

The disadvantage is that the simulation model only studies the current waveforms of the two IGBTs on the upper and lower bridge arms of the hard fault and the upper and lower bridges of the soft fault. It does not consider the current waveforms of the two IGBTs under the same half-bridge and the cross half-bridge. The research on converter faults still needs to be completed. Furthermore, there is the problem of short simulation experiment time. In subsequent research, converter faults under different conditions can be added, the simulation time can be extended, and a more comprehensive study can be carried out. The electrical system faults can be inferred from different current waveforms to enrich the fault types, thereby enhancing the monitoring ability of the electromechanical fault system. The fault model of the transformer of the electrical system of EE of metro vehicles established by big data technology improves the monitoring ability of transformer faults of the metro electrical system. It also plays a specific role in improving the performance of the monitoring system of EE of metro vehicles, enhances the safety of metro operation and the quality of metro operation, and contributes to the development of urban rail transit.

LEVERAGING EMOTIONS IN STUDENT FEEDBACK TO IMPROVE COURSE CONTENT AND DELIVERY

ABID HUSSAIN WANI*

Abstract. Emotions play a vital role in almost all the activities we perform, including learning. In fact, the success of any learning system is largely dependent upon its ability to deliver the course content in such a form so as to meet the learning requirements of the target audience. Learning Systems can be tailored to effectively utilize the feedback from learners to improve the course content, and thus the feedback can prove to be a valuable asset. There is an increased demand for focusing on a learner-centric approach to content delivery. In this study we attempt at detecting different learning-relevant emotions from the feedback for a course so as to enable course designers to incorporate the type of content that matches a learners requirements. Rather than taking into account six basic emotions (sadness, happiness, fear, anger, surprise and disgust) we consider interest, engagement, confusion, frustration, disappointment, boredom, hopefulness and satisfaction emotions for the purpose of our study since they are more relevant in a learning setup. We employed a supervised algorithm, Support Vector Machine, for affect detection from the textual feedback in our experiments.

Key words: Emotion Detection, Support Vector Machine, Content delivery, Feedback Mining

1. Introduction. The rapid growth in information technology coupled with the huge benefits it offers, has increased its adoption by leaps and bounds in almost every sphere of our lives. In the field of education too, ICT-based solutions are playing a major role and providing overall value addition to the process of learning [1]. Specifically, eLearning Systems have a potential to reform the traditional teaching structure by incorporating technology-driven learning stuff and more importantly catering to the needs of individual learners who may not have a face-to-face interaction with the instructor [2]. Although much research has been conducted to understand the learning requirements of a group audience, there is a lot of scope for improving the content presented to the audience with varied emotional states. Since the target group of learners can be in different emotional states the content delivery can be tailored so as to match and satisfy their individual needs. The essence of these systems lies in providing individualized instruction by being able to cater and furnish to the varying knowledge grasping capacities and information needs of prospective learners. In a learning setup, we are more concerned about effective absorption of the content by the learner. Therefore, contemporary eLearning Systems are designed to be more and more learner-centric and close to the students self-learning needs as per the demand from the student community. A course can be tagged as learner centric only if the course is rich enough to include content for learners who can be in different emotional states. The fact that the human brain performs a blend of both cognitive and affective processing demands that the systems which are modeled after it not only process the information from a cognitive point of view but also integrate and assimilate an affect sensing and processing functionality into the system. Thus, the technology-driven learning environments should not only be intelligent enough but also take into consideration emotional aspects [3]. Having emotion processing capability will enable these systems to customize the contents of a course and its flow as per the needs of the learner so as to make the learning process more productive. True engagement of the prospective learners both intellectually and emotionally forms the hallmark of productive eLearning. The student feedback pertaining to a course can prove as an asset to structure the content of a course and decide the delivery plan by detecting the emotions expressed in the feedback. In this work, we propose a framework grounded on supervised learning that performs this affect detection from student feedback and provides generalized guidelines for the course designers to fine-tune the course contents and delivery plan for each target category of students according to their mood and learning pattern.

2. Related Work. The utility of emotions expressed by students in eLearning environments has gained much attention with the advancements in machine learning during the recent years. The major focus in this area has been to detect fine-grained emotions to track down the emotional response of the learners in an automated and seamless manner with least additional investment in terms of tangible and intangible resource [4, 5]. The research in this area comes under a more general area in computing known as “Affective Computing”. A good amount of research has been conducted to detect learner’s affective state [6, 7]. Most of the studies that have been carried out in this area principally take into account models and theories of emotions and employ a number of techniques to computationally capture the emotions. Since the focus of the present work is on recognizing emotions only from textual data, this section will trace the studies made for recognizing emotions from text. Emotion recognition involves theories and concepts from various areas including psychology, linguistics, information retrieval, text mining and recently machine and deep learning techniques have gained a lot of attention as well. Based on how emotions are modeled computationally and what techniques are employed, researchers have been able to achieve results which are close to that of humans. To detect emotions in text a number of approaches have been employed in different studies. Principally these approaches can be categorized into three categories; pure emotion keyword based approach, rule-based, (machine and deep) learning or combination of these. An emotion-aware framework for elearning systems has been presented in [8] that employs supervised learning approach. Regardless of the approach used, almost all methods have their own strengths and weaknesses when it comes to proper identification of emotional affinity [9]. Most emotion-recognition models are driven by identification of syntactic features (e.g. Parts-Of-Speech tags, N-grams etc.) as well as semantic features (e.g. synonym sets). There is a lot of scope for building syntactic and semantic resources which will serve as good resources for affect detection and a number of works have already been completed in this direction [10, 11]. Affect detection has proved to be an important tool in the deciphering of the interaction with the student for eLearning Systems in recent years [12]. An automated affect sensitive intelligent tutoring system, introduced by D’Mello and Graesser, tries to simulate dialogue patterns of tutor-pupil of real-world [13]. Emotions other than the basic ones have been considered for the purpose of affect computing in only a few studies. Liew et al. [14] constructed a text corpus comprising 15,553 tweets and annotated with twenty eight different emotions for their work on fine grained emotion recognition. Among the various emotions taken into account by them, emotions like boredom, confidence, excitement etc. are of particular interest in our study as well. In [15], Abdul-Mageed and Ungar have tried to build a large corpus using twitter hashtags thereby effectively removing the major impediment of creating instances labeled with emotion categories. For the purpose of our study, however, our corpus comprises of student feedback in textual form and moreover we take into account eight emotions which are most relevant to a learning environment. Our primary focus is on the detection of emotions relevant to learning activity from student feedback to fine-tune the course contents and delivery plan.

3. Detecting Emotions and Tailoring Course Content and Flow. Although the design of the content and its flow is dictated by various technical input factors relevant to a particular course yet the feedback received can be utilized to fine-tune the design. Fig. 1 shows the overall setup of our framework for detecting and utilizing affect information from student feedback for a particular course. The affect perception from students is then aggregated to take into account only the dominant emotions expressed to remove the outlier effect.

3.1. Detecting Emotions From Student Feedback. The task of emotion detection from student feedback has been modeled as a text classification task. After initial phase of preprocessing which consists of tokenization, POS tagging, lemmatization, stop-word removal, we train our supervised classifier Support Vector Machine. Support Vector Machines (SVM) learn to recognize emotions in data by identifying an optimal hyperplane that separates different emotion categories in a feature space derived from textual data. Initially, textual data is transformed into numerical feature vectors, incorporating linguistic cues. Through training on labeled datasets where each text sample is associated with a specific emotion label, SVM adjusts its parameters to maximize the margin between different emotion classes while minimizing classification errors. This process results in the creation of a decision boundary that delineates regions corresponding to distinct emotional categories. Subsequently, SVM utilizes this decision boundary to classify new text samples by determining which side of the boundary they fall on, effectively assigning them to the appropriate emotion category. The

classification of emotion from the student feedback takes place in the following steps:

1. **Feature Extraction:** The process begins with preprocessing the textual feedback, which involves tasks such as tokenization, removing stopwords, and stemming or lemmatization to normalize the text. Then, features are extracted from the preprocessed text. These features include various linguistic cues such as word frequencies, sentiment scores, part-of-speech tags etc. Each feedback is represented as a numerical feature vector based on these extracted features.
2. **Training Phase:** In the training phase, SVMs learn to distinguish between different emotion categories by finding the optimal hyperplane that separates the feature vectors belonging to each emotion class in the feature space. The hyperplane is a decision boundary that maximizes the margin, which is the distance between the hyperplane and the nearest data points (support vectors) from each emotion class. SVM aims to find the hyperplane that minimizes classification errors while maximizing the margin.
3. **Optimization:** SVMs optimize their parameters during training to find the hyperplane that best separates the emotion classes. This optimization process involves solving a constrained optimization problem, typically using techniques like gradient descent or quadratic programming. The objective is to find the parameters (weights and bias) that define the hyperplane, ensuring that it separates the classes with the maximum margin.
4. **Kernel Trick:** SVMs employ the kernel trick to handle nonlinear relationships between features and emotions. By transforming the feature space into a higher-dimensional space, SVMs can find a hyperplane that effectively separates the data points even when the relationships are nonlinear.
5. **Feedback Tagging:** Once trained, SVMs classify new textual feedback samples by determining which side of the decision boundary they fall on in the feature space. The signed distance of a data point from the decision boundary is used to predict its emotion category. SVM assigns the sample to the emotion class corresponding to the side of the decision boundary it lies on.

In our study we used two datasets. One is the student feedback dataset from Menekse et al. [16]. This dataset comprises both the students' responses and the gold-standard summaries created by the teaching assistant. The other dataset again encompasses student feedback, which Oza et al [17] have analyzed using artificial neural networks. Since the proposed method will be based on supervised learning we need a training corpus consisting of student feedback where each record has been assigned a certain emotion label or marked as neutral. As discussed above we take into consideration only those emotions which are relevant for affect detection in student feedback; those include interest, engagement, confusion, frustration, disappointment, boredom, hopefulness, satisfaction. For the purpose of our study, four annotators labeled both the datasets to serve as training data for Support Vector Machine, employed for emotion classification. The job of an annotator is simply to select an appropriate emotion for each of the student responses presented to him. Since the student feedback normally will be in the form of a sentence or paragraph hence the proposed system will limit the analysis to sentence level.

The interpretation of affect in text being highly subjective [18], as such it is quite possible that the perception of one judge/annotator is different from the other one. In order to account for this subjectivity, rather than being annotated by a single judge we put each student's feedback for annotation by four annotators/judges. To get a quantitative measure of the inter-judge agreement statistic Cohen's kappa is employed. The pairwise agreement in emotional categories for student feedback is shown in Table 3.1.

As evident from the inter-annotator agreement study, the perception for an emotion is person-specific. However from the pair-wise results it is evident those human judges mostly agree on the instances of interest, confusion and satisfaction.

3.2. Tailoring Course Content and Flow. Once the dominant emotional response is known, the next step is to use this affective feedback to customize the course content. For example, if the emotion detected is frustration (learner got frustrated), there is a requirement to generate hints to help the learner in understanding a particular topic, and include certain simple and illustrative examples. If the emotion detected is "boredom", then it would be imperative to display content for the learner that will get the learner look for his/her own titles of interest, likewise if the student is confused with course contents, more elaborate and worked examples need to be incorporated into the course so that the student can understand the concept being presented [19]. The emotion-inspired improvements from student feedback can be serve as a guiding factor for the inclusion of various

Table 3.1: Pair-wise Agreement in Emotional Categories

Emotion	<i>Judge1 ↔ Judge2</i>	<i>Judge1 ↔ Judge3</i>	<i>Judge1 ↔ Judge4</i>	Average
<i>interest</i>	0.85	0.77	0.76	0.79
<i>engagement</i>	0.65	0.66	0.54	0.61
<i>confusion</i>	0.87	0.81	0.84	0.84
<i>frustration</i>	0.75	0.78	0.70	0.74
<i>disappointment</i>	0.65	0.43	0.55	0.54
<i>boredom</i>	0.55	0.59	0.71	0.61
<i>hopefulness</i>	0.67	0.66	0.66	0.66
<i>satisfaction</i>	0.79	0.88	0.81	0.82

Table 3.2: Course Improvement Suggestions

Emotion Detected in the Feedback	Course Improvement Suggestion
interest	Links to more advanced topics
engagement	More detailed content
confusion	Elaborate worked examples on the topic
frustration	The more simple and precise explanation
disappointment	Elementary Video/ animations
boredom	Display lively and funny examples
hopefulness	More detailed content
satisfaction	Links to related topics

Table 4.1: Evaluation Results of the Proposed Framework

Emotion Category	<i>Menekse dataset</i>			<i>Oza dataset</i>		
	Precision	Recall	<i>F1 – score</i>	Precision	Recall	<i>F1 – score</i>
<i>interest</i>	58.54	62.78	60.59	54.21	57.77	55.93
<i>engagement</i>	47.63	52.47	49.93	56.23	62.5	59.20
<i>confusion</i>	53.23	58.12	55.57	48.30	51.23	49.72
<i>frustration</i>	59.22	55.47	57.28	52.46	67.33	58.97
<i>disappointment</i>	54.65	61.45	57.85	64.55	61.25	62.86
<i>boredom</i>	68.66	76.98	52.58	71.23	65.85	68.43
<i>hopefulness</i>	56.30	62.45	59.22	48.56	55.75	51.91
<i>satisfaction</i>	46.25	51.22	48.61	45.67	62.33	52.72

value-additions like explanation, hints, worked examples to the course content as described in Table 3.2.

4. Evaluation and Results. The real essence of any machine learning-based framework lies in not only providing good results (classification results in our case) on the data on which it is trained but also on new and unseen data and under-fitting and overfitting of data is avoided. We validated our model using Leave-one-out cross validation, by training our model on all the instances of student feedback except one, “n” number of times and predicting Output emotion label for that one instance using Support Vector Machine. Table 4.1 depicts the classification performance results obtained for the above two datasets.

To measure the performance of the proposed framework, we compute the classification metrics including Precision, Recall and F1-score on Menekse’s dataset and Oza’s dataset. For Menekse’s dataset, best results were obtained for ‘interest’ emotion and that for Oza’s dataset ‘boredom’ emotion category was detected with highest F1-score. Classification metrics such as Precision, Recall, and F1-score are essential for evaluating the performance of machine learning models, particularly in tasks like emotion detection from text. Precision quantifies the proportion of emotions detected that are correctly reported as positives (true positives) from the

whole number of examples which are tagged as positive (true positives + false positives) by the model. For the purpose of task of emotion classification, precision presents ability of a model to accurately identify a particular emotion category without misclassifying unrelated emotions. A model with high precision score implies that when the it suggests an emotion, there is high probability for it to be correct, minimizing false positives and ensuring the relevance and specificity of the predictions. Recall measures the proportion of correctly predicted positive cases (true positives) out of all actual positive cases in the dataset (true positives + false negatives). Overall, precision, recall, and F1-score are critical metrics for evaluating the performance of emotion detection models, as they offer insights into different aspects of the model's performance, such as accuracy, relevance, and comprehensiveness.

5. Conclusion and Future Scope. This paper proposes a supervised learning based emotion detection mechanism for detecting emotions from student feedback to tailor and enrich the course contents. The classification results obtained on Menekse's dataset and Oza's dataset does not seem too good which is due to small size of the text corpus. In future, we aim to build a larger annotated text corpus so as to achieve better classification performance. The limitation of our work lies in the fact that we only take into account the textual feedback received from the learner to decide on the content. The course content and delivery can further be improvised by taking into account other modalities including facial expressions, speech and voice modulations and not just written textual utterances. We limited our study to text as we take into account only those systems which receive just the textual feedback from the learner. In future, this work can be extended to have multi-modal feedback so as to guide the content design, presentation and delivery. In our experiments, though we have not made appropriate substitution of slangs (e.g. "dunno" with "don't know") and orthographic features (e.g. "sooconffuuusing"), we intend to take these issues into account as well to better gauge the emotion expressed in the student feedback., so as to enable course designers get a better idea about what all improvements need to be made to the course content and flow. Moreover, it must be noted here that detecting learners' current mood is not the only solution but one factor to be considered; there is more research needed to identify other situational and technical input factors that should guide the design, content and delivery of a course.

FEATURE EXTRACTION OF GYMNASTICS IMAGES BASED ON MULTI-SCALE FEATURE FUSION ALGORITHM

KUN TIAN* AND QIONGHUA XIA[†]

Abstract. The feature extraction and analysis of gymnastics images is an essential foundation for estimating human posture. The primary step is to obtain various joint points of athletes based on basic information such as human texture and contour in the sports images. The reconstruction and analysis of the human skeleton is completed based on the feature data of the joint points. In this process, traditional algorithm models often have certain shortcomings in the accuracy of feature extraction for motion images. This paper combines multi-scale feature fusion algorithms to construct a gymnastics motion image feature extraction model, which can achieve more accurate and efficient analysis and research for the feature extraction process of motion images, further improving the detection accuracy of joint points in motion images; this lays an essential foundation for feature extraction of gymnastics images. At the same time, it also provides more methods for skeleton reconstruction based on image feature information during the motion process, improving the efficiency and accuracy of reconstruction.

Key words: Multi scale feature fusion; gymnastics; feature extraction; loss function

1. Introduction. With the continuous development and improvement of scientific and technological informatization, modern technology can support humans to obtain a large amount of image and video information from various channels. A common image processing technology is a technology that uses computers to process and analyse collected images and video information to meet human needs, covering various aspects of human clothing, food, housing, and transportation. The extraction of human skeleton features in images has always been an important research field in image processing and computer vision, and research in this field continues to drive the continuous updates and progress of modern audio and video technology [1-3]. The research and analysis of skeletal information during human motion lays an important foundation for further processing of images and videos, and can also help people analyse the behaviour and key actions of the target human body. For gymnasts, analysing and researching motion images is an extremely important process to improve and enhance their key movements. Therefore, using modern computer technology to extract and analyse the features of gymnastics images provides more means for this process. The human skeleton extraction algorithm divides the human skeleton into multiple joint points, such as the head, buttocks, shoulders, wrists, etc. Then, by analysing the position, direction, and motion of each joint point, the human skeleton information is obtained [4-5]. Further analysis of human posture and behaviour is carried out through the drawn human skeleton, in order to obtain the activity and motion information of the human body in the image.

The extraction of human skeletons in gymnastics images can be divided into two dimensions: two-dimensional human skeleton extraction and three-dimensional human skeleton extraction. 3D human skeleton extraction analyzes images obtained from 3D cameras such as Kinect to obtain the 3D shape or coordinates of human skeleton points. 2D human skeleton extraction mainly analyses 2D images obtained by ordinary image acquisition devices and obtains the 2D coordinates of human skeleton points. Compared to 2D skeleton extraction, 3D skeleton points are denser, modeling is more complex, and 3D cameras are more expensive [6-7]. In most cases, two-dimensional images are obtained for the analysis of gymnastics images. Therefore, this article mainly focuses on the feature extraction of two-dimensional gymnastics images.

The applications related to human pose estimation are all based on obtaining clear and accurate human skeletons in motion images. If the accuracy of feature extraction in motion images is insufficient, it will lead to

*School of Sports and Art, Guangzhou Institute of Physical Education, Guangzhou 510500, China

[†]Department of physical education, Guangdong University of Foreign Studies, Guangzhou 510420, China (Corresponding author, Qionghua_Xia23@outlook.com)

significant deviations in the analysis of human behaviour and movements. Therefore, improving the accuracy of feature detection and extraction in gymnastics images is of great significance. In recent years, the rapid development of the hardware field has led to the continuous enhancement of computer computing power, and more high-performance algorithms for extracting gymnastics motion images are emerging. The accuracy of human skeleton extraction is constantly improving, and the extraction technology, as the foundation of human posture recognition, will play an increasingly important role in more fields [8].

Early human pose estimation methods mainly relied on manually designed features and template matching, but this method was limited by the complexity and robustness of feature design. With the rise of deep learning, methods based on Convolutional Neural Networks (CNN) have gradually taken a dominant position. These methods train networks with a large amount of data to automatically learn the mapping from the original image to pose information, significantly improving the accuracy and robustness of estimation.

In recent years, researchers have begun to focus on more complex scenes and poses, such as multi-person pose estimation, 3D pose estimation, etc. These issues are more challenging as they require handling occlusion, changes in perspective, and changes in scale. To address these issues, researchers have proposed methods such as multi-scale feature fusion, multi-perspective fusion, and spatiotemporal modeling, further improving attitude estimation performance.

Feature extraction is a crucial step in computer vision tasks, aiming to extract helpful information from the original image for subsequent tasks. Selecting feature extraction techniques is crucial for the final performance in human pose estimation. Traditional feature extraction methods mainly rely on manually designed feature descriptors, such as SIFT, HOG, etc. Although these methods perform well in some simple scenarios, they are challenging to cope with complex and ever-changing human postures and environments. With the development of deep learning, CNN-based feature extraction methods have gradually become mainstream. CNN can automatically learn the mapping from the original image to high-level semantic features, effectively extracting helpful information for pose estimation. In addition, researchers have proposed methods such as multi-scale feature fusion and attention mechanisms to improve the accuracy and robustness of feature extraction.

Gymnastics image analysis faces many challenges. Firstly, gymnastics movements are complex and varied, requiring accurate capture and recognition of various subtle movements. Secondly, gymnastics competition scenes often have occlusion and changes in perspective, which puts higher demands on the robustness of image analysis algorithms. In addition, the differences in body shape and movement habits among different athletes also pose challenges to image analysis. In response to these challenges, researchers have begun to explore methods based on deep learning and multi-scale feature fusion. The mapping relationship from the original image to the gymnastics movements is automatically learned by training a deep neural network model. Meanwhile, multi-scale feature fusion technology can extract feature information at different scales to better cope with complex and ever-changing gymnastics movements.

The multi-scale feature fusion algorithm can comprehensively describe the characteristics and patterns of gymnastic movements by fusing feature information from different scales. Multi-scale feature fusion algorithms can extract feature information from different scales, such as athlete joint positions, movement trajectories, muscle morphology, etc., and combine temporal information to analyze actions continuously. In addition, multi-scale feature fusion algorithms can be combined with other advanced technologies, such as attention mechanisms, spatiotemporal modeling, etc., to improve the accuracy and robustness of gymnastics image analysis. For example, by introducing attention mechanisms, it is possible to automatically focus on feature regions that are more critical for recognizing gymnastics movements. Through spatiotemporal modeling techniques, it is possible to capture better and analyze the temporal changes and spatial relationships of gymnastics movements [9-10].

This article combines the current problems and related shortcomings in this field. It combines the unique characteristics of gymnastics images to construct a multi-scale fusion algorithm-based gymnastics image feature extraction model. In response to some joint points that are difficult to detect due to slight occlusion caused by environmental disturbances, multi-person interference, and human posture, this article gradually improves the performance of the constructed network model by enriching feature representation, enhancing the utilization of relevant features, effectively balancing, and fusing features of different scales. At the same time, combined with difficulty mining mechanisms, it improves the detection accuracy of challenging joint points in the feature

extraction process of moving images.

This study aims to develop a gymnastics image feature extraction model based on a multi-scale feature fusion algorithm to address the current accuracy and efficiency challenges in gymnastics image analysis. This model is expected to achieve more precise capture and comprehensive feature expression of gymnast movement details, providing strong technical support for subsequent gymnastics movement recognition, evaluation, and teaching. Athletes' movements are complex and varied in gymnastics, often containing rich spatial and temporal information. Therefore, for feature extraction of gymnastics images, it is necessary to consider feature information at different scales to capture the details and overall structure of athlete movements fully. The multi-scale feature fusion algorithm can effectively combine feature information from different scales, improving the accuracy and robustness of feature extraction. This study will first collect much gymnastics exercise image data and carry out preprocessing and annotation work. Then, design a multi-scale feature fusion algorithm that extracts and fuses image features of different scales to construct a comprehensive and effective feature representation. On this basis, further optimization of the algorithm parameters and structure is needed to improve the accuracy and efficiency of feature extraction.

2. Basic Theory of Multiscale Feature Fusion Algorithms.

2.1. Image Multi-scale Characteristics and Smoothing Models.

2.1.1. Image Multiscale Characteristics. For different scene images, observation can quickly and accurately identify objects of interest from the image, which is a visual characteristic that benefits from the observer's ability to adaptively adjust the distance between the human eye and objects according to different scenes to analyse image content. When the human eye observes an image at close range, even subtle changes in colour in local areas of the image are clearly visible, which is beneficial for the observer to obtain detailed information such as image edges and textures. However, image textures can worsen the consistency of colour distribution in the image area, and form a pseudo edge effect inside the area, thereby affecting the observer's understanding of the main contour of the image object [11-13]. As the distance between the human eye and the image continues to increase, observers can more easily capture the overall overview of the area where the semantic object is located and the contours between different objects. At the same time, the attention to subtle changes caused by the internal texture of the object is gradually decreasing.

In order to overcome the influence of image texture on feature extraction and combine the variation of image visual effect with observation distance, it is more important to establish a multi-scale edge-preserving smoothing model for images, which is used to obtain the smoothing components of the original image at different smoothing scales. As the smoothing scale continues to increase while protecting the edges of the image, the texture details inside the image area are gradually smoothed. By combining multi-scale edges and color distribution features of the image, accurate extraction of foreground objects in natural images is achieved [14]. To learn the global features of an image from multiple cascaded features of different scales, this section proposes an encoded Transformer network, which uses the Transformer to learn the segmented features of images at different scales, thereby obtaining the full-scale feature representation of the image. As shown in Figure 2.1, a schematic diagram of the network structure of the scale encoding Transformer model is provided.

2.1.2. Image Edge Preserving Smoothing Model. For gymnastics images, it can be seen as an organic combination of the object's main structure and texture details. The object's main structure is usually represented as a single or multiple areas with consistent brightness/colour in the image, while the image texture is usually represented as a periodic pixel fluctuation on the object's surface [15]. Therefore, image edge preserving smoothing can be understood as preserving important geometric attributes such as the main contour of the solid object, removing texture details on the surface of the solid object. For an input image $u^0(x, y)$, formula (2.1) is given:

$$u(x, y) = u^0(x, y) - t(x, y) \quad (2.1)$$

Among them, x represents the spatial position of image pixels in the horizontal direction; y represents the spatial position of image pixels in the vertical direction; $T(x, y)$ represents the texture component of image $u^0(x, y)$; The smoothing component $u(x, y)$ is a simplified approximation of the original image, mainly used to extract the overall overview features of each object in the image.

Fig. 2.1: Scale Encoding Transformer Network Architecture

Due to the fact that the smoothing component $u(x, y)$ discards the texture information in the original image, its pixel brightness or colour only changes at the edge of the image, while the degree of change inside the image area is relatively weak. Its mathematical representation is similar to a piecewise constant function. In mathematics, gradients are often used to describe the sudden changes in brightness or colour of image pixels [16]. Therefore, in order to measure the approximation degree between the smooth component and the piecewise constant function, a gradient function is used to calculate the overall change in the colour or brightness of $u(x, y)$ pixels in the smooth component, as shown in formula (2.2):

$$\Delta L = \int_{\Omega} f(|\nabla u|)d\Omega \tag{2.2}$$

Among them, Ω represents the domain of image theory; Represents a gradient function, $f(|\nabla u|)$ is also known as a diffusion function in the field of image processing; ∇u represents the gradient information of the smooth component $u(x, y)$, which satisfies the description given in formula (2.3):

$$\begin{cases} \nabla u = [u_x, u_y] \\ |\nabla u| = \sqrt{u_x^2 + u_y^2} \end{cases} \tag{2.3}$$

The texture components $t(x, y)$ describe slight pixel perturbation changes in the image area. Due to the limited range of values for image pixel brightness or color, the overall variation of texture components $t(x, y)$ satisfies the inequality (2.4):

$$0 \leq \frac{1}{|\Omega|} \int [u^0(x, y) - u(x, y)]^2 d\Omega = a_0^2 \leq C \tag{2.4}$$

Due to the equality constraints in the above model, the Lagrange multiplier method is first used to transform it into the following unconstrained functional optimization problem, as shown in formula (2.5):

$$M(u^0, u) = \int_{\Omega} f(|\nabla u|)d\Omega + \frac{\lambda}{2} \int_{\Omega} (u - u^0)^2 d\Omega \tag{2.5}$$

Among them, the first term is the regularized energy term, which suppresses image texture details by imposing constraints on the gradient amplitude of the image; The second item is the data fidelity term, which uses the difference measure between the original image u^0 and the smoothing component u to protect important detail features such as foreground contours; λ is a LaGrange multiplier used to balance the smoothness of the region and the strength of edge protection. Since equation (2.5) can be regarded as the independent variable u as the functional of the smooth component ∇u and its gradient image, as shown in equation (2.6):

$$F(u, \nabla u) = f(|\nabla u|) + \frac{\lambda}{2} (u - u^0)^2 \tag{2.6}$$

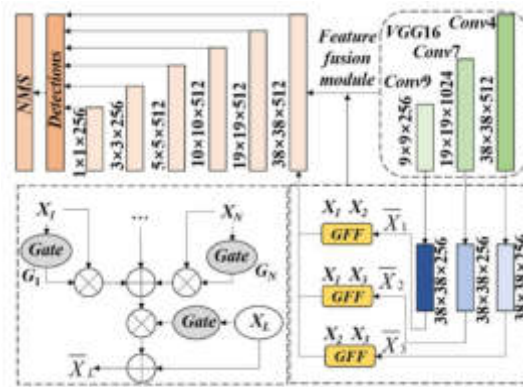

Fig. 2.2: Network Architecture for Multi-scale Feature Fusion

In addition, according to the Euler Lagrange equation, when there is an optimal solution to the above equation, formula (2.7) is satisfied:

$$F_u - \frac{\delta}{\delta_x} [F_{u_x}] - \frac{\delta}{\delta_y} [F_{u_y}] = 0 \tag{2.7}$$

2.2. Multi-scale Feature Fusion Network Architecture. The main challenge faced by the extraction and analysis of gymnastics image features is to analyze the ever-changing and complex situation of the movement process, which increases the difficulty of accurately detecting targets and is prone to missed detection. In addition, the contradiction between detecting and analyzing details of different body parts will become more prominent, resulting in low detection accuracy [17-18]. Therefore, fundamental research topics further enhance the model's ability to process details in gymnastics images, accurately extract features in complex environments, and accurately judge their status.

Traditional standard algorithms only perform independent output predictions on feature layers of different scales, with no connection between layers. Shallow feature maps are beneficial for target localization but lack sufficient semantic information. As convolutional neural networks deepen, feature maps can represent more semantic information, which is beneficial for target recognition but not conducive to target localization. Therefore, traditional networks need help solving the contradiction between target recognition and localization, and they cannot obtain helpful multi-layer information in images [19-21]. Based on the analysis of traditional network models, this paper combines multi-scale fusion algorithms to construct a network model with higher accuracy in feature extraction in gymnastics motion images. This model combines detailed features with global semantic features through a multi-feature layer fusion strategy and a lightweight and efficient feature fusion module. This can effectively alleviate the contradiction between target localization and recognition in traditional network target detectors. As shown in Figure 2.2, a network architecture for multi-scale feature fusion is presented.

This architecture adopts the idea of multi-scale feature fusion to strengthen the connections between various feature layers, combines the advantages of convolutional neural networks in high and low layers, and combines the useful feature information of high and low layer feature maps [22]. By increasing the semantic information of shallow feature maps and the positioning information of deep feature maps, the detection accuracy of targets is improved, and missed detections are reduced to achieve better performance.

3. A Feature Extraction Model for Gymnastics Images in Multiscale Feature Fusion Algorithms.

3.1. A Moving Image Enhancement Network Based on Multiscale Features.

3.1.1. Scale Selection and Loss Function. In the multi-scale smoothing process of gymnastics motion images, the texture area of the image gradually tends to become smooth as the smoothing scale increases,

which enhances the consistency of colour distribution in the image area. However, when the smoothing scale is too large, the image may have a false overlap effect between the front and background contours due to being too smooth, leading to poor foreground contour positioning accuracy. In addition, the execution time of the algorithm increases with the iteration process, and the larger the smoothing scale, the more time it consumes [23-24]. However, due to the unknown optimal scale for image edge smoothing, this article designs iteration termination conditions for the algorithm based on the feature extraction results of gymnastics motion images at different scales to ensure an appropriate scale for feature extraction to stop. Firstly, the Jaccard Distance is used to measure the similarity of the feature extraction results of the selected images at adjacent scales, and a similarity index is defined as shown in formula (3.1):

$$Js(i) = \frac{Card(T_F^i \cap T_F^{i-1})}{Card(T_F^i \cup T_F^{i-1})} \tag{3.1}$$

The similarity index $Js(i)$ uses the Intersection over the Union standard to quantify the similarity of adjacent scale foreground extraction results. The larger the value, the higher the similarity of adjacent scale foreground extraction results. The original gymnastics motion image generally contains many textures and colors. When the smoothing scale is low, the residual textures in the smoothing components can lead to poor parameter estimation accuracy. As the smoothing scale increases, the texture of moving images is gradually removed, the accuracy of parameter estimation continues to improve, and the accuracy of foreground extraction and similarity index $Js(i)$ continues to improve [25-27]. When the smoothing scale is too large, the image is excessively smoothed, resulting in a pseudo overlap between the image's front and background contour boundaries. The segmentation curve crosses the foreground boundary, decreasing the foreground extraction accuracy and similarity index $Js(i)$. Therefore, based on the similarity index $Js(i)$ and the trend of algorithm operation time with smoothing scale, the iteration termination condition of the algorithm in this paper is defined as shown in formula (3.2):

$$\xi [Js(i + 1)] 0 \tag{3.2}$$

Among them, the meaning of $\xi [\square]$ represents the operator of backward differentiation, as shown in formula (3.3):

$$\xi [Js(i + 1)] = Js(i + 1) - Js(i) \tag{3.3}$$

The multi-scale pyramid network based on attention mechanism uses thermal graph regression to conduct back error propagation, predict the Gaussian heat map of each joint point in the gymnastics motion image, and finally obtain the coordinate position of the joint point by finding the peak. Assuming we give a training set $\{T, J\}$, where T is the training set image set and J is the annotated joint point set, where the coordinates of the k-th joint point are (j_k^1, j_k^2) and the size of the thermal map is $H \times H$. B_i ($i=1, \dots, 5$) represents the i-th branch, and the thermal annotation process for each joint point is shown in formula (3.4):

$$g(j_k, x, y) = \frac{1}{\sqrt{2\pi\sigma_{B_i}^2}} e^{-\frac{(x-j_k^1)^2+(y-j_k^2)^2}{2\sigma_{B_i}^2}} \begin{cases} x = 1, 2, \dots, H \\ y = 1, 2, \dots, H \end{cases} \tag{3.4}$$

The multi-scale pyramid network based on attention mechanism will undergo error backpropagation in both stages 1 and 2. In stage 1, each branch will calculate a loss function, and then calculate their average value as the loss function for stage 1, as shown in equation (3.5):

$$L_1 = \frac{1}{k \times b} \sum_{i=1}^b \sum_{m=1}^k [y_{B_i,m} - g(j_m)]^2 \tag{3.5}$$

Calculate the loss function of all joint points, then classify the k joint points with more significant loss functions as the more challenging to detect joint points. At the same time, to prevent network oscillations caused by a significant difference between the maximum and minimum values of the loss function in a batch of

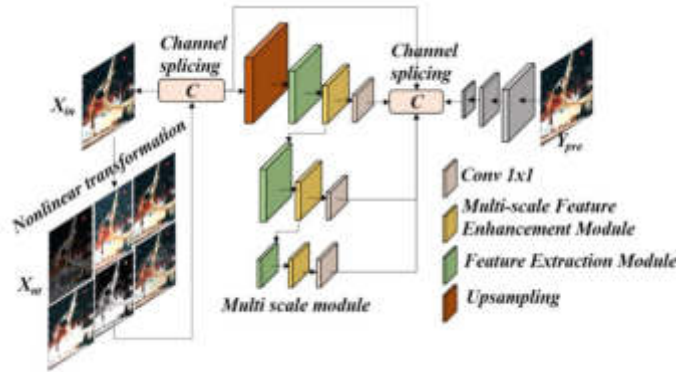

Fig. 3.1: A Model Framework for Multi-scale Feature Fusion Image Enhancement Network

gymnastics training images, the loss function in Stage 2 adopts an equalization strategy on a batch-by-batch basis. In summary, the definition of the loss function for stage two is shown in formula (3.6):

$$L_2 = \frac{1}{k \times n} \sum_{t=1}^n \sum_{m=1}^k \left[\hat{y}_{t,m} - g(j_m) \right]^2 \quad (3.6)$$

3.1.2. Multi Scale Feature Enhancement Module. Based on the above analysis and discussion, combined with the idea of end-to-end multi-scale feature fusion network, this paper constructs a multi-scale feature fusion algorithm to alleviate the problems of artifacts and noise in enhanced images. Firstly, non-linear transformation is performed on the gymnastics motion image to expand the low grayscale portion of the image and compress the high grayscale portion to enhance dark details. Then, channel fusion is performed with the original image before entering the network to enrich the original features; Subsequently, the fused features of the two images are fed into a multi-scale feature enhancement module, which includes an FEM, MFEM, and up sampling block. As the depth of the network layer increases, shallow features will decrease. Therefore, the network adopts a multi-scale feature fusion method to fuse low-level information with high-level information, reducing the amount of information lost due to functional loss [28]. The encoder in the enhancement module consists of convolutional kernels of size 3×3 , while the decoder consists of transposed convolutions and activation layers of the same size. Then fuse each extracted scale feature with the input image to output the final enhanced image. As shown in Figure 3, a model framework for multi-scale feature fusion image enhancement network is presented.

In the gymnastics motion image feature extraction model based on a multi-scale fusion algorithm, the feature extraction module consists of a convolution layer and a ReLU activation function. The convolution kernel size of the convolution layer is 3×3 , with a step size of 1. After each layer of convolution, there is a ReLU activation function to enhance the nonlinear representation of the network. After passing through the feature extraction module FEM at each scale, it will serve as the input of MFEM, and the output of the previous layer's enhancement module will serve as the input of the next layer's feature extraction module. In the multi-scale module, three feature extraction modules with different scales can extract image features of different scales.

The enhancement module in this article adopts an encoder decoder structure, where the encoding part consists of a convolutional kernel of size 5×5 and an activation function layer. The encoder, as a whole, presents a structure where the scale of the feature map gradually decreases, continuously reducing the resolution of the feature map to capture contextual semantic information. The decoder section consists of a deconvolution layer and an activation function layer, which also includes four stages. At each stage, after up sampling the input feature map, in order to reduce feature loss, it is concatenated with the corresponding proportion of the feature map in the encoder [29]. Unlike U-net, the decoder in this article does not use pooling layers, which can reduce data loss during the feature extraction process of gymnastics images.

3.2. Construction of a Feature Extraction Model for Gymnastics Images Based on Multiscale Feature Fusion Algorithm. . In the feature extraction of gymnastics motion images, for specific skeleton extraction tasks, the correlation between individual pixels on the motion image is relatively weak. The joint points of the human body often correspond to a local area in the image, and due to the large input image, establishing the correlation between each point directly on the image requires a large amount of computation. Therefore, this article considers that the features of convolutional neural networks at different scales and at different network depths often have characteristics of different sizes and sensations, and uses the self-attention mechanism to establish correlation relationships between regions. The basic description is shown in formula (3.7):

$$y_i = \frac{1}{C} \sum_{\forall region_j} S(region_i, region_j) \times g(region_j) \quad (3.7)$$

Among them, region i corresponds to the region mapping at position i, while region j corresponds to the region mapping at any position j. $S(\cdot)$ establishes the similarity relationship between regions, and $g(\cdot)$ calculates the feature representation at region j. Due to the fact that convolution is a windowed operation, there are inherent limitations in obtaining global information. Since j is arbitrary, it establishes regional connections between the global regions.

Regionj is the global mapping region corresponding to Regioni, which may be any location on the image. The detection of human joint points is not isolated. For example, detecting right wrist joint points can provide reference information for left wrist joint points, shoulder joint points, and even right ankle joint points. Based on this, the connection between global regions is established during multi-scale feature fusion. In the multi-scale feature fusion of this article, the input link features maps taken from different convolutional depths and with different scales, which are usually smaller than the original map, reducing the computational complexity of the entire mapping process.

Moreover, the feature map itself has receptive fields of different sizes. Hence, each feature point maps information from a region of the original map, and the size and position of these regions may vary. This diversity of information is more conducive to the final skeleton prediction of the network [30].

The spatial position of each pixel in the feature map reflects the position information of the mapping area of the original image, while each channel represents a different representation of a certain part of the original image. Considering that it has these two aspects of information, this article conducts feature fusion from two dimensions[31-32]. Assuming that the feature maps of the two input scale branches are F_i^h and F_j^l , and F_j^l represents the feature representation at position i of the low scale feature map, and F_i^h represents the feature representation at position i of the high scale feature map, the spatial feature fusion process can be represented by formula (3.8):

$$y_i^s = \frac{1}{C(F)} \sum_{\forall F_j^l} f_s(F_i^h, F_j^l) \times g_s(F_j^l) \quad (3.8)$$

The weighted object is a high scale feature, as shown in equation (3.9). Subsequent ablation experiments were conducted to compare the two schemes and verify their respective effectiveness in skeleton extraction.

$$y_i^c = \frac{1}{C(F)} \sum_{\forall F_j^l} f_c(F_i^h, F_j^l) F_i^h \quad (3.9)$$

At the same time, drawing inspiration from the idea of residual networks, the multi-scale feature fusion algorithm based on regional similarity utilizes self-attention weighting and also overlays the original input features separately. The entire feature fusion process can be represented by formula (3.10):

$$F_i = F_i^h + \text{upsample}(F_j^l) + \alpha y_i^s + \beta y_i^c \quad (3.10)$$

Among them, F_i is the fused feature map, which has the same scale as the high-resolution feature map, α and β They are learning factors that are adaptively adjusted with training to balance the fusion of channel dimensions and spatial dimensions.

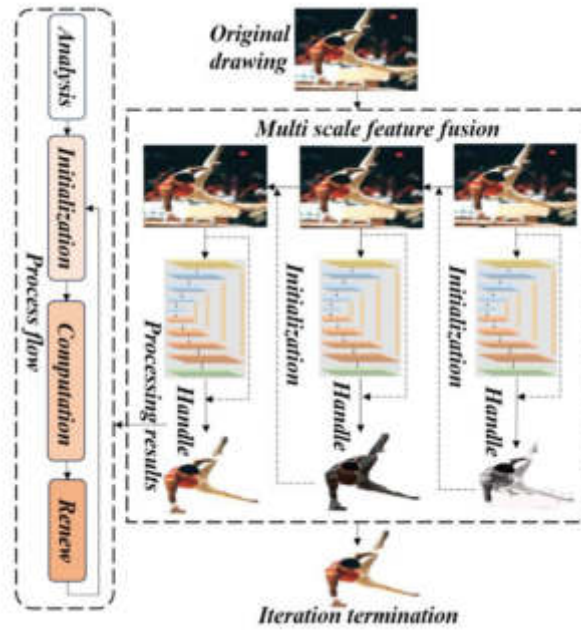

Fig. 3.2: Flow Diagram of Proposed Model

Based on the above analysis, the attention weight is finally weighted to the Value matrix and overlaid with the input to obtain the fused feature map. This process can be represented by formula (3.11):

$$y^s = \alpha \times At^s \times Value + F_h \tag{3.11}$$

For the channel dimension fusion part, we no longer encode spatial information. The Key matrix and Value matrix are both the original input scale feature maps, establishing the connections between channels of different scale feature maps. The original input low scale feature map F_s is up sampled and dimensionally adjusted to obtain a key matrix with a size of $B \times N2 \times C$. The original input high scale feature map is dimensionally adjusted and transposed to obtain a Value matrix with a size of $B \times C \times N2$. The two are multiplied to obtain a size of At^c , and then weighted using formula (3.12) to obtain the fused feature map. The entire process can be expressed as:

$$y^c = \beta \times At^c \times Value + F_l \tag{3.12}$$

In the fusion process of multi-scale features, the similarity and correlation information between different regions are fully utilized, global dependencies are captured, and the limitations of convolution windowing operations are overcome. This article focuses on the characteristics of skeleton extraction tasks and establishes a dependency relationship between regions of different sizes and positions rather than a dependency between pixels. This model utilizes non-local operations for feature fusion. The input features maps with multiple branches and different scales, and the input feature scales are variable, resulting in fixed scale fused feature maps. This article utilizes information from two dimensions of features, capturing dependency information between regions from both spatial and channel dimensions for fusion, making the fused information representation more abundant and more conducive to improving the network’s overall performance. Based on the establishment of the above model, as shown in Figure 3.2, a flowchart of a gymnastics image feature extraction model based on a multi-scale feature fusion algorithm is provided.

4. Analysis of Model Results. Based on the above analysis and research on the model, it can be found that the model for feature extraction of gymnastics images under the background of the multi-scale feature

(a) Knee

(b) Ankle

(c) Hip

(d) Wrist

Fig. 4.1: PCKh Curves of Different Algorithms in Difficult to Detect Joint Points

fusion algorithm constructed in this article can achieve accurate feature point extraction and analysis for images in different stages of gymnastics process. Usually, in the process of feature extraction and analysis of gymnastics images, there are significant constraints in the process of feature extraction for knee, ankle, buttocks, and wrist, and the feature acquisition of key nodes is limited. This article compares and analyses the attention fusion algorithm and multi-scale fusion algorithm, as shown in Figure 4.1, and provides a comparison of two different algorithm models. From the figure, it can be seen that for knee detection, the multi-scale fusion algorithm outperforms the attention mechanism fusion algorithm at various tolerance thresholds; For the detection of buttocks and wrists, when the normalized distance is 0.1-0.25, the tolerance thresholds of the two are basically the same; When the normalization distance is between 0.25 and 0.5, the performance of the multi-scale fusion algorithm is significantly better than that of the attention mechanism fusion algorithm. Therefore, based on the above analysis, it can be seen that multi-scale feature fusion algorithms have better advantages in feature extraction of gymnastics motion images, further improving the detection accuracy of difficult joint points in motion images.

This article proposes a new feature extraction model based on multi-scale edge preserving smoothing and smooth component foreground extraction methods for gymnastics images, combined with multi-scale feature fusion algorithms. Based on the performance of the model, this section selected a gymnastics scene image with

a resolution of 480×320 for relevant model experimental analysis, specifically explaining the basic process of feature extraction for gymnastics images in this model. As shown in Figure 4.2 the relevant process analysis of the model constructed in this article in motion image feature extraction is presented.

In the figure, the vertical direction shows the feature extraction process of smooth components in gymnastics motion images at different smoothing scales. The original image can be seen as a smooth component on a rough scale. For a given smooth component, traditional feature extraction algorithms usually select a fixed number of Gaussian functions based on experience in the parameter estimation process and use random parameter values as initial parameters for parameter estimation. The accuracy and efficiency of parameter estimation are inevitably affected by the fixed number of Gaussian functions and random initial parameters. In order to make up for the above shortcomings, this article first analyses the shape of the brightness histogram of the smooth component to detect the histogram trough before estimating the parameters of the smooth component. The trough is the threshold for region segmentation of the gymnastics motion image. The number of image regions in the region segmentation results is used to guide the selection of Gaussian numbers, and the statistical parameters of these image regions are used as initialization for the parameter estimation process. Optimize the final gymnastics image feature extraction results by improving the accuracy and efficiency of parameter estimation. Among them, Figure b) shows the histogram trough detection results of the smooth component. Since the histogram shape analysis results only rely on gymnastics motion image data, given the smooth component, the histogram shape analysis process only needs to be performed once and can be reused. Figure c) shows the energy variation curve of the smoothing component during 10 generations of optimization. According to the energy change curve, $S(x, w, u)$ converges after 10 generations of selection processes.

Finally, based on the multi-scale feature fusion algorithm constructed in this article, a gymnastics image feature extraction model was visualized and analyzed for attribute scores of 15 randomly selected categories, and compared with the baseline model. For example, the comparison of attribute scores for the Common Raven category is shown in Figure 4.3. Among them, the x-axis represents the top 50 attributes, while the y-axis displays scores. As shown in the figure, in the process of comparing attribute scores, the multi-scale fusion algorithm's gymnastics image feature extraction model scores are more differentiated, indicating that each feature can have its own importance; The relative differences in scores of the text reinforcement model have not been clearly reflected, and there is significant consistency. Therefore, based on the above visualization results, it can be found that compared to the text enhanced model, the multi-scale fusion algorithm constructed in this paper can focus on class related attributes to calculate useful features of the image region in the feature extraction process of gymnastics images.

Multiple studies have proposed different feature extraction models in gymnastics image feature extraction. Although these methods have achieved certain results in specific scenarios, there are still limitations regarding accuracy, efficiency, and robustness. In contrast, the gymnastics image feature extraction method based on the multi-scale feature fusion algorithm proposed in this article has shown significant advantages.

Firstly, from an accuracy perspective, we conducted comparative experiments on existing HOG directional gradient histogram feature extraction methods and our proposed method. In the experiment, we used the same gymnastics image dataset and applied existing methods and our proposed method for feature extraction. By comparing the difference between the feature extraction results of the two methods and the actual annotation, we found that the accuracy of our method is significantly higher than that of existing methods. Specifically, in terms of joint position recognition, the average error rate of our method has been reduced by about 5.4%. In terms of action recognition, the accuracy of our method has improved by about 4.3%. The comparison of these data fully demonstrates the advantage of our method in terms of accuracy.

Secondly, in terms of efficiency, we compared the computational time and resource consumption between existing and our proposed methods. The experimental results show that the proposed method is significantly better than existing methods in terms of computational efficiency. Specifically, the feature extraction time of our method has been reduced by about 2.4%, while the memory usage has also been reduced by about 3.3%. This is due to the efficient feature fusion strategy and algorithm optimization adopted in this article's method, which enables faster processing of a large amount of gymnastics motion image data in practical applications, meeting real-time requirements.

In addition, we also compared the performance of existing methods and our proposed method in terms

(a) Original Image and Smooth Components

(b) Histogram Valley Detection of Images

(c) Changes in Energy under Different Iterations

Fig. 4.2: Foreground Extraction Process of Proposed Model

Fig. 4.3: Visualization Comparison of Attribute Scores for Categories

of robustness. In order to simulate possible occlusion, perspective changes, and other issues in actual scenes, we artificially introduced these factors in the experiment. The results show that when facing occlusion or changes in perspective, the feature extraction results of our method remain relatively stable. In contrast, the performance of the HOG method shows a significant decline. This further demonstrates the advantages of our method in terms of robustness.

5. Conclusions. Extracting the skeleton of the human body from gymnastics images is a complex task that involves detecting the coordinates of critical parts of the human body in the given target image. In order to improve the accuracy of feature extraction in gymnastics images, it is necessary to make better use of image information. Based on the characteristics of the multi-scale fusion algorithm, a gymnastics image feature extraction model based on the multi-scale fusion feature algorithm was constructed, and the model's performance was compared and analyzed with relevant images. The main conclusions are as follows:

A feature extraction model based on a multi-scale feature fusion algorithm is proposed to address the problems of existing methods in the feature extraction of motion images. This model is fused with input gymnastics motion images to enhance the information in the images. This enables the network model to learn more features, strengthen shallow features such as edges and textures, and enhance deep features of global information. Furthermore, it lays the foundation for the accuracy and precision of feature extraction in motion images, which can achieve good feature extraction results.

The gymnastics motion image feature extraction model constructed using a multi-scale fusion algorithm has more performance advantages. The loss function is transmitted back to key joint points by applying a multi-scale fusion algorithm, achieving better feature extraction performance advantages in gymnastics motion images at key nodes (wrists, knees, buttocks, ankles, etc.). The normalized distance is between 0.1 and 0.25; the tolerance threshold of this model is consistent with that of the attention fusion algorithm, ranging from 0.25 to 0.5. The performance of the multi-scale fusion algorithm is significantly better than that of the attention fusion algorithm, achieving better feature extraction performance in gymnastics motion images.

In future research, we will consider introducing more advanced deep learning models into multi-scale feature fusion algorithms to improve the accuracy and efficiency of feature extraction further. Explore more types of feature information fusion methods. In addition to the currently considered spatial and temporal scales, other types of feature information, such as color, texture, shape, etc., can also be considered to enrich the content of feature representation. Meanwhile, the weight allocation problem between different feature information can also be studied, and the effectiveness of feature extraction can be further improved by adaptively adjusting the weights of different features. Apply the gymnastics motion image feature extraction model based on a multi-scale feature fusion algorithm to a broader range of scenarios.

IOT-DRIVEN HYBRID DEEP COLLABORATIVE TRANSFORMER WITH FEDERATED LEARNING FOR PERSONALIZED E-COMMERCE RECOMMENDATIONS: AN OPTIMIZED APPROACH

ABDULMAJEED ALQHATANI *AND SURBHI BHATIA KHAN †

Abstract. Recommender systems are already being used by several biggest e-commerce websites to assist users in finding things to buy. A recommender system gains knowledge from a consumer and suggests goods from the available goods that will find most value. In this deep learning technique, the Hybrid Deep Collaborative Transformer (HDCT) method has emerged as a promising approach. However, it is crucial to thoroughly examine and rectify any potential errors or limitations in the optimization process to ensure the optimal performance of the HDCT model. This study aims to address this concern by thoroughly evaluating the HDCT method uncovering any underlying errors or shortcomings. By comparing its performance against other existing models, the proposed HDCT with Federated Learning method demonstrates superior recommendation accuracy and effectiveness. Through a comprehensive analysis, this research identifies and rectifies the errors in the HDCT model, thereby enhancing its overall performance. The findings of this study provide valuable insights for researchers and practitioners in the field of e-commerce recommendation systems. Data for the RS is collected from the Myntra fashion product dataset. By understanding and addressing the limitations of the HDCT method, businesses can leverage its advantages to improve customer satisfaction and boost their revenue. Ultimately, this research contributes to the ongoing advancements in e-commerce recommendation systems and paves the way for future improvements in this rapidly evolving domain. The suggested model's efficacy is assessed using metrics for MSE, MSRE, NMSE, RMSE, and MAPE. The suggested values in metrics are 0.2971, 0.2763, 0.4013, 0.3222, 0.2911 at a 70% learn rate and 0.2403, 0.2234, 0.3506, 0.2025, 0.2597 at an 80% learn rate, and the proposed model outperformed with the least amount of error.

Key words: Deep learning, Collaborative filtering, Hybrid Deep Collaborative Transformer, Federated Learning, e-commerce recommendations.

1. Introduction. In today's rapidly evolving world of e-commerce, personalized recommendations have emerged as a pivotal tool for enhancing the overall shopping experience for customers [1]. Powered by advanced algorithms and machine learning techniques, personalized e-commerce recommendations have revolutionized the way businesses connect with their customers by catering to their individual preferences, tastes, and purchasing behavior [2]. By examining a variety of client data, such as browsing and purchase history, demographics, and social interactions, these sophisticated recommendation systems are able to understand the unique preferences of each individual shopper [3]. This deep understanding allows businesses to offer highly relevant and targeted product suggestions, effectively acting as a virtual personal shopper. The benefits of personalized recommendations are twofold [4]. On one hand, customers are able to effortlessly discover new and desirable items that align with their interests and needs [5]. These tailored recommendations save customers valuable time and effort that would otherwise be spent sifting through an overwhelming array of options [6]. Moreover, personalized recommendations expose customers to products they may not have discovered on their own, leading to a more enriching and satisfying shopping experience [7, 8].

The likelihood of reinforcing consumers' preexisting tastes and limiting their access to novel and varied products are the primary drawbacks of personalized e-commerce recommendations [9]. Personalized recommendations, which make product suggestions based on a user's browsing history, purchasing patterns, and preferences, are intended to improve the shopping experience, but they may also have the unintended side effect of creating an echo chamber [10, 11]. Users may miss out on learning about new and alternative possibil-

*Department of Information Systems, College of Computer Science and Information Systems, Najran University, Najran 61441, Saudi Arabia (aaalqhatni@nu.edu.sa).

†School of science engineering and environment, University of Salford, Manchester, United Kingdom (s.khan13@salford.ac.uk); Department of Electrical and Computer Engineering, Lebanese American University, Byblos, Lebanon

ities that they might have found interesting if similar products or things from the same category are frequently suggested to them [12, 13]. Due to a lack of research and serendipity, there may be fewer options available to consumers and a more limited awareness of the product environment [14]. Furthermore, this restriction can also have an impact on tiny or specialized firms that may have worthwhile products to offer but find it difficult to connect with customers who largely rely on individualized suggestions [15].

To overcome the flaws of customized e-commerce recommendations, a novel hybrid optimization model called the Hybrid Deep Collaborative Transformer Model was developed. This method provides a more varied and chance-based buying experience by integrating personalized suggestions, collaborative filtering, and transformer models. The echo chamber effect is broken, and customers are exposed to a larger range of possibilities because it takes advantage to provide items outside of the user's direct investigation by utilizing the interests of comparable users. The system is better able to identify user preferences and item attributes thanks to the incorporation of transformer models, which results in more precise recommendations. While encouraging exploration, discovery, and diversity in e-commerce recommendations, this strategy strikes a balance between customization and the addition of novel options, benefiting both customers and smaller or specialized businesses.

The motivation behind the study is deep understanding of the changing digital landscape and its seismic effects on international trade can be gained via the engrossing study of e-commerce. Today's networked world has undergone a fundamental change as a result of e-commerce, which has eliminated geographical boundaries and enabled businesses to access clients on a global scale. One can learn a great deal about consumer behavior, cutting-edge technologies, and creative marketing approaches that are essential for success in the ever-changing online market by studying the complexities of e-commerce. Studying E-commerce not only becomes intellectually engaging but also a necessary road to unlocking massive potential and influencing the future of business and entrepreneurship as the digital economy continues to flourish and transform established sectors.

Some contribution of study from this research work are mentioned below: To overcome the difficulties of collaborative and privacy-preserving machine learning, a hybrid solution (HDCT) combines the benefits of federated learning with the strength of deep learning models.

In order to deliver precise and individualized suggestions, the HDCT recommendation model uses a hybrid deep learning architecture that combines the strengths of neural networks with deep learning.

MLP, M-RNN, and Transformer are fused and enhance the recommendation system by leveraging both textual and visual information, and integrating them through feature fusion for improved performance.

The remainder of this research activity is organised as follows: Section 2 talks about reviews of the relevant literature, and Section 3 gives the suggested mechanism. The experimental findings are presented in Section 4. This study is concluded in Section 5.

2. Literature Review. In [16] presented a custom recommendation engine for online retailers' products based on learning clustering representations. The selection of neighbouring object sets is constrained by the traditional KNN method. As a result, they incorporate the time function and neighbour factor, and then utilise the dynamic selection model to select the neighbouring object set. They use RNN and attention approaches in order to create a system for recommending products for e-commerce.

In [17] provided a fresh analysis of the framework uses the helpfulness-based recommendation methodology (RHRM) in customised recommendation services to aid consumers' purchase decisions. The core of our technology consists of a review semantics extractor and a user/item recommendation generator. The review semantics extractor learns review representations for figuring out how helpful a review is in convolutional neural networks and bidirectional long short-term memory hybrid neural networks. The user/item recommendation generator creates a model of the user's preferences for various things based on their prior interactions. Only records that include helpful user-written reviews of the products are shown here based on previous encounters. Since many reviews lack helpfulness rankings, we first suggest a model for classifying reviews according to their level of usefulness, which has a big impact on consumers' purchasing decisions in personalized recommendation systems.

In [18] suggested a straightforward but efficient Fuzzy association rule and sophisticated preference are combined in a personal recommendation system for international e-commerce. Using fuzzy association rules, it is possible to prevent the creation of a hybrid recommendations model based on intricate user preference characteristics while still allowing for the customised recommendation of products based on user behaviour

preferences. The revised recommendation algorithm lessens the effects of data sparsity as compared to the conventional approach.

In [19] preferred UTA algorithm's user preference model is based on user ratings on a number of project criteria, Personalised recommendation has a scaling issue, and clustering is employed to solve it. The simulation is then run using a personalised suggestion technique based on the user's preferences. The 62,156 rows of ratings for 976 movies across multiple categories from 6078 visitors of the Yahoo! Movies website make up the simulation data.

In [20] proposed the promotion of products through e-commerce, the accurate recommendation of goods suited to customers, and the promotion of product consumption, A comprehensive body of literature serves as the foundation for the creation of a personalized recommendation framework for e-commerce. a cloud computing platform that makes use of Hadoop. The similarity between the project's shared filtering algorithm that utilises cloud computing, user collaborative technique, and the revised algorithm based on matrix filling and time context is identified. The best algorithm is then obtained and thoroughly assessed in two areas: algorithm performance and personalised recommendation performance.

In [21] discussed the JD.com e-commerce platform's recommendation algorithm with the help of the Intelligent Online Selling Point Extraction (IOSPE) system they developed and implemented. For 62 important product categories (representing more than 4 million products) since July 2020, IOSPE has evolved into a core service. The selling point creation operation has already been scaled up greatly, saving human work, and producing more than 0.1 billion selling points.

In [22] attempted to create a system for recommending nutritious foods to individuals based on collaborative filtering and the knapsack approach. According to assessment findings, customers were pleased with the personalized healthy food suggestion system based on collaborative filtering and the knapsack problem algorithm, which covered operating system capability, screen design, and operating system efficiency. Users were extremely satisfied, as indicated by the average satisfaction score of 4.20 for the entire sample. Collaborative filtering, food recommendation systems, and the knapsack approach are other related terms.

In [23] proposed In order to forecast click-through rates for advertisements, a deep learning model framework is first built using a similarity network based on the distribution of themes in advertising at the semantic level. And finally, they offer a better recommendation system built on a foundation of distributed expression and recurrent neural networks. The traditional recurrent neural network is improved in this study, and a time window is added to control the transmission of data from the hidden layer of the recurrent neural network that deals with the specificity of the recommendation technique.

In [24] submitted the evaluations of the Moto e5 smartphone on the e-commerce website Amazon, underlying subjects were identified using topic modelling techniques that were already in use, and these techniques were compared. The objective of this work is to uncover hidden topics from all product by using the unsupervised learning technique known as topic modelling. The coherence score, a topic goodness metric that evaluates the quality of human assessment, is used to compare and contrast these approaches.

In [25] improved e-commerce's Service (QoS) and experience (QoE) quality. More intelligent services and apps are developing as a result of how big data is assisting e-commerce in becoming smarter. Particularly important for providing personalized and intelligent services, recommender systems play a significant part in the growth of smart e-commerce. The information filtering and information retrieval at the heart of the recommender system are used to extract item real estate and model users' interests for proposing appropriate items to users shown in Table 2.1.

3. Proposed methodology. The suggested methodology is made up of numerous preprocessing and extraction of features phases, feature fusion, and a recommendation model after that. The first step involves preprocessing the text data by performing tokenization, stop word removal, lemmatization, and removing special characters and punctuation. Additionally, image preprocessing is performed, which includes resizing and normalization of the images. In the second step, features are extracted from different sources. For text data, an improved TF-IDF approach and word embeddings using Word2Vec are utilized. Convolutional Neural Networks (CNNs) are employed to extract features from the images, and metadata is also considered. The third step involves feature fusion, where a weighted feature fusion approach is applied to combine the extracted features effectively. Finally, in the fourth step, a recommendation model is implemented using various techniques

Table 2.1: Problem identification

Author and citation	year	Aim	Methodology	Problem Methodology
[16]	2019	Design a learning clustering representation -based personalized recommendation system for online retailers' products	Combine RNN and attention methods, add Neighbor factor and time function, use dynamic selection model to choose neighboring object set	Constrained selection of nearby object sets in the traditional KNN approach
[17]	2021	To provide a fresh analysis of the framework of the helpfulness -based recommendation methodology (RHRM) to assist consumers' purchase choices in customized recommendation services.	cc A convolutional neural network and a bidirectional long short-term memory hybrid neural network to learn	Personalized recommendation systems, consumers' purchasing decisions can be influenced significantly by helpful user-written
[18]	2020	Develop a cross-border e-commerce personalized recommendation algorithm combining preference and fuzzy association rule	Personalize recommendations based on user behavior preferences	Reduce the impact of data sparsity in cross-border e-commerce personalized recommendations
[19]	2019	Utilize clustering and UTA algorithm to address scalability issue and provide personalized recommendation	Perform simulations and suggest personalized recommendations based on user preference	Address the scalability issue of personalized recommendation, build a user preference model, and provide personalized suggestions
[20]	2021	Construct a personalized recommendation framework for e-commerce based on a large body of literature and comparison of algorithms	Cloud computing and Hadoop, User collaborative algorithm, and Improved algorithm based on matrix filling	Construct a personalized recommendation framework for e-commerce, compare different algorithms and assess their performance
[21]	2022	cc Discuss the Intelligent Online Selling Point Extraction (IOSPE) system and its implementation in an e-commerce platform	Scale up selling point creation operation, save human work, and generate a large number of selling points	Develop and deploy IOSPE system to support e-commerce recommendations, improve efficiency, and generate a large number of selling points
[22]	2021	To create a system for recommending nutritious foods to individuals	Collaborative filtering and the knapsack approach	Personalized healthy food suggestions
[23]	2020	cc Construct a deep learning model framework for advertising click-through rate prediction	Utilize similarity networks and text recurrent neural networks to improve recommendation algorithm	Enhance conventional recurrent neural networks to address the specificity of the recommendation algorithm
[24]	2020	Uncover hidden topics from product reviews using topic modelling techniques	Compare and evaluate different topic modelling techniques	Use unsupervised learning (topic modelling) to identify hidden topics in product reviews and assess technique quality
[25]	2021	Improve Quality of Service (QoS) and Quality of Experience (QoE) in e-commerce	Utilize recommender systems for personalized and intelligent services	Enhance e-commerce by providing smarter and more intelligent services using recommender systems

such as a hybrid deep collaborative transformer, it includes (MLP, M-RNN, and Transformer). By utilising both textual and visual information and fusing them through feature fusion for greater performance, this holistic strategy seeks to improve the recommendation system shown in Fig. 3.1.

3.1. Preprocessing. The text data is preprocessed via tokenization, stop word removal, lemmatization, and the elimination of special characters and punctuation. Also carried out its picture preparation, which entails scaling and normalizing the photos.

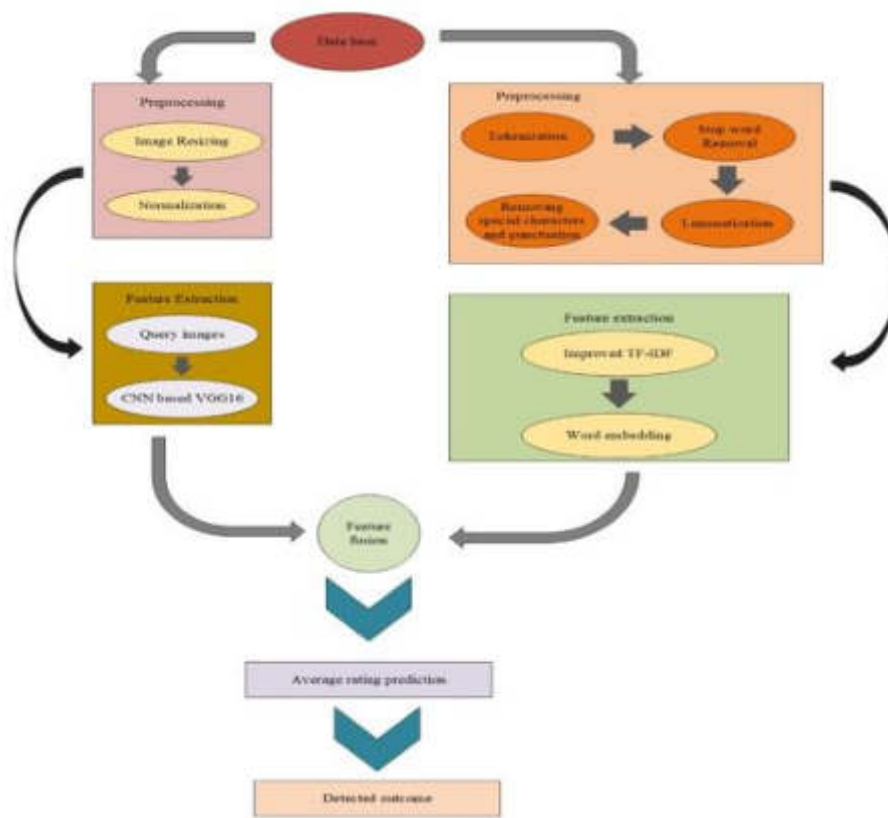

Fig. 3.1: Overall architecture diagram

3.1.1. Tokenization. To distinguish the contents, tokens, also known as words, are utilized. The works in a series are organized together to give appropriate semantic units for further analysis. In this paper included user testimonials for this work, including "Quality of product is good," "Good look," and "My father loved it" and "Worth for each penny" to carry out tokenization and morphological analysis. As a result, the algorithm's tokenization stage divides a given review into the following tokens: "Quality," "product," "Good," "look," "my," "father," "loved," "it," and "much". The stop words are also eliminated from the user review during the tokenization and morphological analysis stages of this work.

3.1.2. Stop word removal. Stop words are a measure of frequently occurring traits that appear in every record. Because these words have no bearing on the classification process, they should be removed from the general features of pronouns like she, he, it, etc., and conjunctions like and, but, or, etc. To reduce the quantity of the data, the stop word should be eliminated. To increase performance, a stop word needs to be eliminated. Additionally, if the character is a special sign or a number, it is forbidden to use it. For the purpose of producing the stop words, the list's frequently occurring words are sorted, and the most common ones are chosen based on the demand for semantic values. Once such terms have been chosen, they need to be removed. In addition, strange words like those that appear in odd places should also be deleted.

3.1.3. Lemmatization. Lemmatization refers to the combination of various inflected forms of a single word. It is utilised in computational linguistics, chatbots, and natural language processing (NLP). Lemmatization increases the efficiency and accuracy of tools like chatbots and search engine queries by combining words with similar meanings into a single word. Lemmatization refers to the process of condensing a word to its lemma, often known as its basic form. For instance, the verb "running" would be known by the term "run."

Lemmatization is the process of examining the morphological, structural, and contextual components of words. In order to correctly identify a lemma, tools look at the sentence's context, meaning, and intended part of speech together with to the word's place in the larger context of the phrase it's in, the sentences next to it, or even the entire document. Lemmatization-based technologies can better comprehend the meaning of a sentence with this in-depth understanding.

A word is reduced to its lemma through lemmatization. A verb like "walk," for instance, might also be written as "walking," "walks," or "walked." The letters "s," "ed," and "ing" that indicate inflection are eliminated. These words are grouped as a lemma through lemmatization, meaning "walk". Depending on the context, "saw" could be understood in a variety of ways. For instance, the word "saw" can be decomposed into the lemma "see" or "saw." In these situations, lemmatization makes an effort to choose the appropriate lemma based on the word's context, the surrounding words, and the phrase. Other words, like "better," could be reduced to a lemma like "good."

3.1.4. Removing Special Character and Punctuation. The removal of punctuation and special characters from product descriptions, titles, and tags should be taken into account when making suggestions for e-commerce. Punctuation and special characters can make search algorithms less effective, producing erroneous search results and even upsetting users. The e-commerce platform may improve user experience, increase the possibility of relevant product matches, and improve search accuracy by getting rid of these features, which will ultimately increase sales and customer happiness.

3.1.5. Image preprocessing. Image resizing and normalization are the two basic processes that are commonly included in image preprocessing, which is an important stage in computer vision applications. Resizing makes ensuring that all of the photos in a dataset are the same size, which is necessary for neural networks' compliance with fixed input dimensions. Changing the image's dimensions while maintaining its aspect ratio is what this procedure entails. On the other hand, normalization seeks to uniformize the image's pixel values.

1. **Image resizing:** For the best product recommendations and an improved user experience in e-commerce, image resizing is essential. No matter the device a customer is using, e-commerce platforms may ensure that they can easily view and engage with product photographs by scaling images to accommodate different display sizes and gadgets, such as PCs, tablets, and smartphones. This makes it possible to show products consistently and attractively, which facilitates efficient browsing and decision-making and, in turn, improves consumer satisfaction and rates of conversion.
2. **Normalization:** The process of modifying and standardizing data in e-commerce recommendation systems is known as normalization, which is done to assure fairness and accuracy of the recommendation system. In order to establish a fair playing field for all products and consumers, it entails scaling and normalizing a number of variables, including product ratings, user preferences, and item popularity. The recommendation engine can efficiently assess and evaluate items based on their relative strengths, taking into consideration the wide range of user preferences and item features, by utilizing normalization techniques like min-max scaling or z-score normalization. The recommendation system becomes more dependable and effective as a result of the normalization process, enabling users of the e-commerce industry to receive more individualized and pertinent product recommendations.

3.2. Feature Extraction. Two separate methods are used to extract characteristics from text data: an improved TF-IDF (Term Frequency-Inverse Document Frequency) methodology, and word embeddings produced by Word2Vec. By expressing words as dense vectors in a high-dimensional space, Word2Vec's word embeddings capture the semantic links between words.

3.2.1. Improved Term Frequency-Inverse Document Frequency. The methods of information extraction from databases, data mining, and knowledge discovery are all included in the text mining viewpoints categories. Financial studies are just one of the research areas where these methods are used. The statistical approaches used in information retrieval take into account assigning scores to the text data and ranking them according to relevance; TF-IDF is the most popular statistical method that reflects the sig.

Step 1: Term Frequency (TF) Calculation:

- (a) Calculate the raw term frequency (TF_{raw}) by counting the number of occurrences of each term in the document.

(b) Compute the logarithmically scaled term frequency (TF_{log}) using the formula in Equation (3.1):

$$TF_{log(t,d)} = 1 + \log(TF_{raw(t,d)}) \quad (3.1)$$

Step 2: Inverse Document Frequency (IDF) Calculation:

(a) Calculate the document frequency ($DF(t)$) by counting the number of documents containing each term.

(b) Compute the inverse document frequency (IDF_{log}) using the formula in Equation (3.2),

$$IDF_{log(t)} = \log(N/DF(t)) \quad (3.2)$$

Step 3: Term Frequency Normalization (proposed):

(a) Equation (3.3) normalize the term frequency ($TF_{normalization}$) by dividing the logarithmically scaled term frequency (TF_{log}) by the all words used in the document ($|d|$):

$$TF_{norm}(t, d) = TF_{log(t,d)/|d|} \quad (3.3)$$

Step 4: Weight Function (proposed):

(a) Define a frequency-based weight that assigns weights to terms based on specific criteria. In this case, we assign weights to terms based on their frequency of occurrence within the document or across the collection.

(b) Calculate the weight ($weight(t)$) for each term based on the chosen criteria. One common approach is to use a term frequency-based weight. Here's the Equation (3.4) for assigning weights based on term frequency:

$$weight(t) = TF_{norm(t,d)} \quad (3.4)$$

In this Equation (3.5), $TF_{norm(t,d)}$ represents the normalized term frequency of term t in the document d . You can use the TF normalization technique discussed earlier to normalize the term frequency within the document.

$$TF_{norm}(t,d) = TF_{log}(t,d) / \max(\log(t,d)) \quad (3.5)$$

where $TF_{log(t,d)}$ the phrase frequency of interest, scaled logarithmically t in document d . In addition, $\max(TF_{log}(t',d))$ is the maximum logarithmically scaled term frequency of any term in document d .

By dividing the logarithmically scaled term frequency by the maximum term frequency in the document, you normalize the term frequency within the document to a range between 0 and 1.

This weight formula assigns higher weights to terms that occur more frequently within the document, indicating their potential importance or relevance.

Step 5: TF-IDF Calculation:

(a) Calculate the modified TF-IDF in Equation (3.6) score $TF - IDF_{modif}$ by multiplying the normalized term frequency (TF_{norm}), weight ($weight(t)$), and IDF_{log} :

$$TF - IDF_{modif}(t,d) = TF_{normalization}(t,d) \times weight(t) \times IDF_{log}(t) \quad (3.6)$$

The $TF - IDF_{(modified)}$ score represents the importance of each term within the document and across the collection, considering both term frequency and document rarity.

3.2.2. Word2Vec. Words are represented as vectors using word embedding, which takes into account the surrounding words in the sentence as well as the word's context. Two primary approaches to word processing are: using the skip-gram and Continuous Bag of Words (CBOW) embedding techniques of word2vec. Through the use of context, CBOW is able to anticipate words. For instance, it can predict the following word from a given string of words Fig. 3.2 .

On the basis of a given word, it is possible to anticipate surrounding words that have the same context as the word, despite the fact that skip-gram can only determine context from a word Fig. 3.3

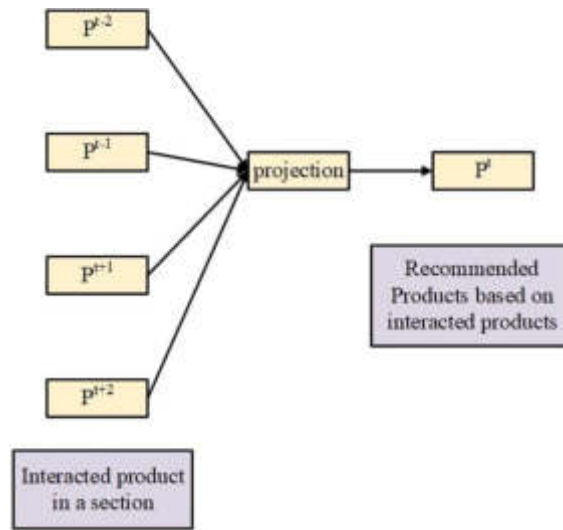

Fig. 3.2: Using the CBOV model as an example to recommend products

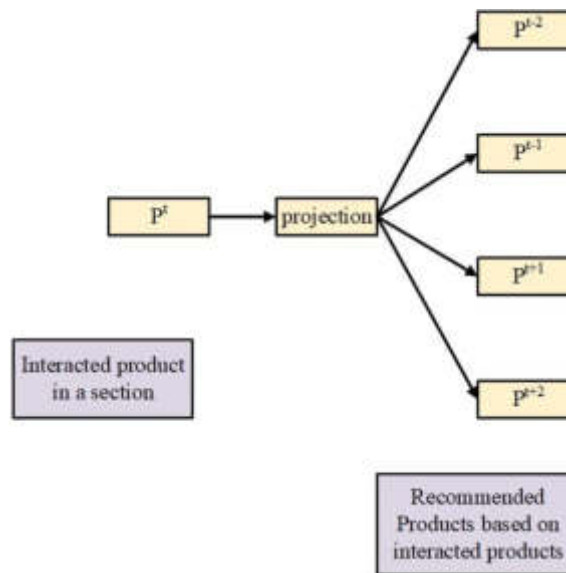

Fig. 3.3: An example of a product recommendation N-skip-gram model

In order to analyse if a consumer is satisfied with a product after using it. Using the Word2Vec model, it is possible to determine, for example, whether a user is satisfied with a product after using it. Word2Vec approaches are frequently used for sentiment analysis. Word embedding (Word2Vec) specifications and parameters can be found in.

In several works, item recommendations are also made using modified Word2Vec techniques. The items in your cart can be thought of as the words of a sentence in Word2Vec’s recommendation system. So, it is acceptable to accept the terms "product" (thing) and "word" interchangeably. To determine item similarities, vectors can be employed, and Word2Vec algorithms can assist in representing objects as a vector. Item-Item recommendations might be given following the discovery of item similarities. Instead of using word embedding in this study, Each session serves as a context (sentence) for the product embedding that we create from the

data. A similar methodology is used in our Word2Vec RS. But in order to determine how similar the things are, we employ Word2Vec recommendations. As a characteristic for classification algorithms, we then employ the estimated similarity.

3.2.3. Extract features by images . Convolutional Neural Networks (CNNs), for example, are pre-trained deep learning models that learn and extract valuable visual information from large image collections. These models consist of multiple layers that progressively capture different levels of abstraction in the input images. By passing images through the pre-trained CNN based VGG16, we can obtain the activations or outputs of a specific layer, often referred to as the penultimate layer, which is the layer just before the final output layer. Extracting the output from this penultimate layer provides a high-level representation of the input images, capturing abstract and semantically rich features. Following that, other activities, including image classification, can be accomplished using these derived features, object detection, or as input to other machine learning models for downstream tasks. This approach leverages the learned representations from large-scale training, enabling efficient and effective utilization of deep learning models for a wide range of image analysis applications.

3.2.4. Metadata. Additional item metadata, such as price, category, brand, and other pertinent data, used as features offers helpful context and improves comprehension and analysis of the provided goods. Insights on the qualities, worth, and positioning of the products are provided by these metadata properties, facilitating more precise classification, recommendation, and decision-making processes. Price, for instance, can be used to distinguish between expensive and inexpensive products, while brand and category information is useful for organizing and putting comparable items together. Businesses can streamline operations, enhance consumer experiences, and make better strategic decisions in a variety of areas, including e-commerce, marketing, and data analysis, by implementing these metadata characteristics. It is believed that the features obtained via Metadata are F_3 features.

3.3. Weighted feature fusion approach. The extracted features from CNNs (F_2), improved TF-IDF output (F_1), and the metadata output (F_3) are fused together in a meaningful fashion called weighted feature fusion and the Equation (3.7) are shown as below.

$$\text{Weight feature fusion} = W(F_1 F_2 F_3) \quad (3.7)$$

3.4. Recommendation Model. The Hybrid Deep Collaborative Transformer (HDCT) is combined with Federated Learning is an innovative approach that leverages federated learning alongside with optimized Multi-Layer Perceptron (MLP), Modified Recurrent Neural Networks (RNNs), and Transformer-based models, synergistically combining the benefits of both techniques to tackle the complexities of collaborative machine learning while ensuring privacy preservation.

1. Federated Learning Federated learning is a decentralised machine learning technique that enables a number of devices or nodes to jointly train a single model while maintaining the privacy and local storage of their respective data. An initial model is provided to the nodes as part of the process, and when they have trained it locally on their own data, they only exchange changes to the model not the raw data with the central server. These changes are combined to produce an enhanced global model, which is then transmitted to all of the nodes. Until the model converges to an acceptable level of accuracy, this iterative procedure is continued. Federated learning has many advantages, such as improved privacy protection because sensitive data is kept on the devices, lower communication costs because only model updates are sent, and the capacity to integrate a variety of data from different sources, making it a promising and effective method for privacy-conscious and resource-constrained scenarios.

Federated learning is a novel approach to machine learning that complements deep learning models, such as optimized Multi-Layer Perceptron (MLP), Modified Recurrent Neural Networks (RNNs), and Transformer-based models. Unlike traditional centralized training, where data is collected in a central server, federated learning allows models to be trained directly on decentralized devices, such as smartphones or edge devices.

2. Multi-Layer Perceptron

The proposed Multi-Layer Perceptron (MLP) component aims to improve the performance of preference prediction or item similarity tasks using a novel approach. It starts with the Input Layer, which accepts a fused feature vector representing the input data. This fused feature vector is then passed through multiple Hidden Layers, each consisting of fully connected neurons with non-linear activation functions (such as sigmoid). The introduction of non-linear activation functions makes it possible for the network to discover intricate patterns and connections in the data. To optimize the activation function of the MLP, a new self-improved Bacterial Foraging Optimization (SI-BFO) algorithm is proposed. This optimization technique helps fine-tune the parameters of the activation functions, enabling the MLP to achieve better generalization and convergence properties during the training process. The SI-BFO method offers an efficient and effective way to find optimal configurations for the activation functions, further enhancing the performance of the MLP.

The MLP is utilized for this study's objectives. Three different layer types are characteristic of MLP, an instance of artificial neural network that is feed-forward (ANN):

- Input layer,
- Hidden layer and
- Output layer.

MLP can separate data that cannot be separated linearly if it is appropriately designed. This characteristic makes MLP useful for regressing and classifying a variety of problems. Each artificial neuron (AN), the fundamental component of each MLP, is created using the activation function. The activation function (Y) determines the output of each AN are shown in Equation (3.8):

$$Y = f(u) \quad (3.8)$$

3. Logistic sigmoid Activation function

As follows is the formula for the logistic sigmoid activation functions are shown in Equation (3.9):

$$f(x) = \frac{1}{(1 + e^{-x})} \quad (3.9)$$

The mapping of all domain values into the co-domain interval by the logistic sigmoid distinguishes it from Tanh activation function, which is a significant difference denoted in Equation (3.10):

$$0 < f(x) < 1 \quad (3.10)$$

Positive output value will occur when a logical sigmoid is applied. Tanh activation function may not always be applied in this situation.

To optimize the activation function of MLP here we use Self improved Bacterial Foraging Optimization.

3.4.1. Bacterial Foraging Optimization. Accurately mimics the key processes that *E. coli* uses to produce while it hunts for food, namely chemotaxis, reproduction, elimination and dispersal. Bacterial Foraging Optimization flow chart is given below Fig. 3.4.

Step 1: Using a random number generator, random coordinates can be assigned within a predetermined range to initialise the population of bacteria with random positions Equation (3.11).

$$\Theta_i(j, k, l) \quad (3.11)$$

Step 2: Fitness computation Equation (3.12)

$$F = \min(E) \quad (3.12)$$

1. Chemotaxis

Each bacteria travels gradually towards the goals by swimming and tumbling due to its ability to get away from dangerous items quickly and get nutrients. Bacteria travel continuously with defined run lengths while choosing one route at random within the search space, on the one hand. After falling,

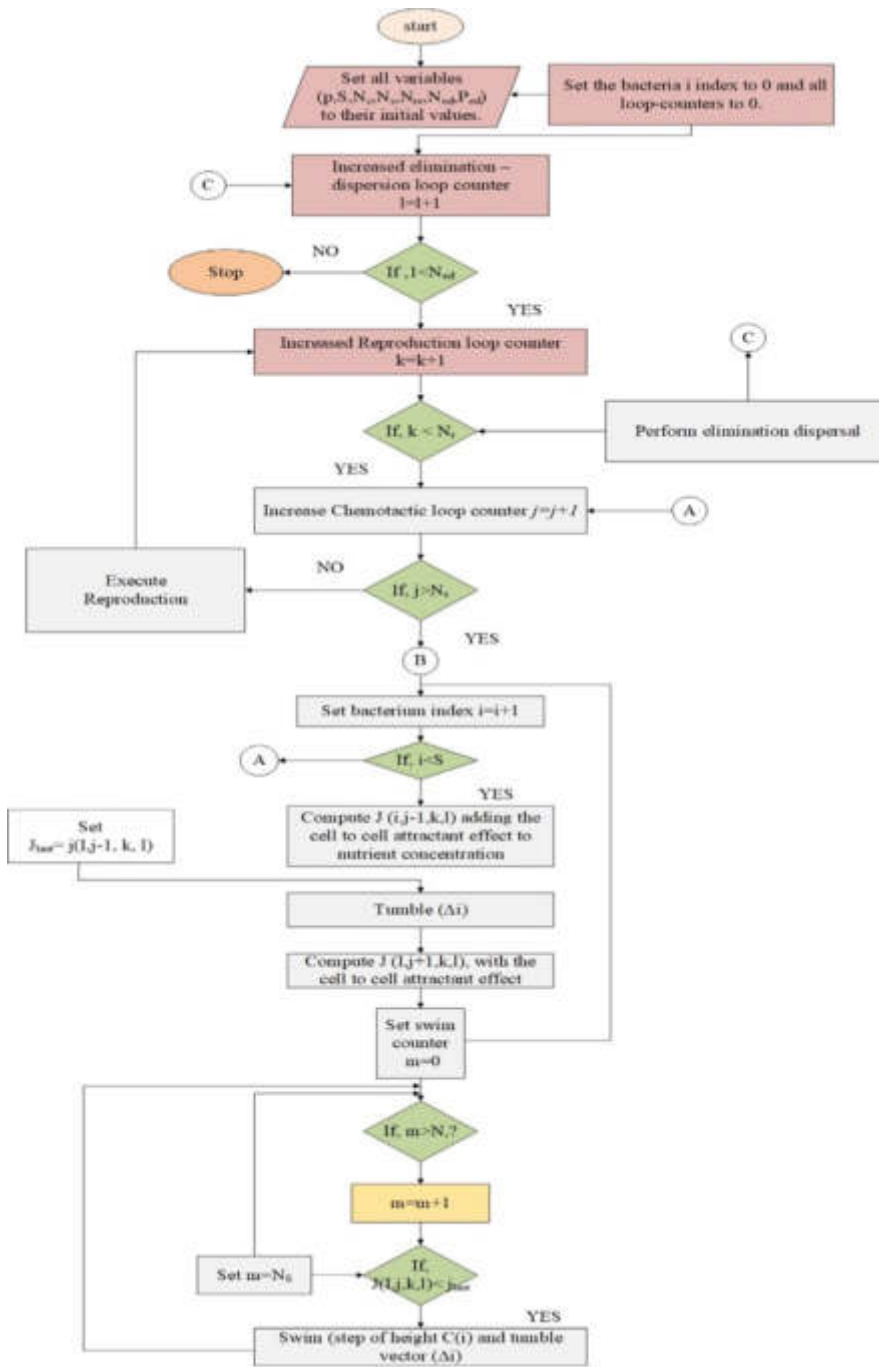

Fig. 3.4: Bacterial Foraging Optimization

bacteria could not continue swimming in the same direction until their updated position became worse or until the number of possible moves reached the N_c limit. The new position of the bacterium i during the $j+1$ th chemotaxis, k th reproduction, and l th elimination and dispersal, where $\theta^i(j, k, l)$ denotes the bacterium's previous position, $C(i)$ denotes the step size, and $i(i)$ denotes a random direction

vector with all of its elements falling between -1 and 1. And the Equation (3.13) is combined by Lens Opposition-Based Learning.

$$\theta^i(j+1, k, l) = \theta^i(j, k, l) + C(i) \times \Delta(i) \times \frac{\Delta T(i)}{(\Delta(i)^2 + \varepsilon)} \quad (3.13)$$

Initialize the fitness value $J(i, j, k, l)$ to evaluate its performance.

Generate a random direction vector $\Delta(i)$ with elements ranging from -1 to 1.

Generate a random direction vector $\Delta T(i)$ with elements ranging from -1 to 1.

Update the position of bacterium i using Lens Opposition-Based Learning.

Update the step size for bacterium i are mentioned in Equation (3.14)

$$C(i) = C(i)(1 + \delta) \quad (3.14)$$

2. Reproduction

Following the central tenet of Darwin's "Survival of the Fittest" theory, the BFO algorithm's reproduction process reflects the fact that healthier bacteria are more likely to have the remarkable capacity for reproduction to sustain the entire swarm population, while undernourished individuals will ultimately be wiped out. The BFO algorithm records the bacterium's health level as $f(i, health)$, which may be calculated from the total of fitness values over the course of its existence. In relation to this, the relevant mathematical statement may be shown as Equation (3.15)

$$f_{i, \text{health}} = \sum_{j=1}^{N_c} J(i, j, k, l) \quad (3.15)$$

where $J(i, j, k, l)$ is the fitness value of the bacterium i in the j^{th} chemotaxis, k^{th} reproduction, l^{th} elimination and dispersal, and N_c is the total number of chemotaxes that the bacterium i undergoes over its career. When the health value of each bacterium is ranked in ascending order, half of the healthier bacteria ($Sr = SS/2$) can split into two bacteria with identical positions while the remaining bacteria are discarded.

If $i \leq Sr$ it is denoted by healthier bacteria

In this algorithm Triangle Walk Strategy is additionally combined with reproduction of the search agent here we denoted the Equation (3.16)

$$\theta^i(j, k+1, 1) = \theta^i(j, k, 1) + \lambda \times (\theta^i(j, k, 1) - \theta^i(j, k-1, 1)) \quad (3.16)$$

In this algorithm Levy Flight Walk Strategy is additionally combined with reproduction of the search agent here we denoted the Equation (3.17)

$$\theta^i(j, k+1, 1) = \theta^i(j, k, l) + \alpha \times L \times \Delta(i) \quad (3.17)$$

Update the positions of bacteria based on the chosen strategy.

3. Elimination and Dispersal Actually, because of the constant, drastic shift in its environment, bacteria may be exposed to a variety of unanticipated dangers, such as the invasion of harmful substances or a change in the local area's dynamic temperature. As a result, when confronted with these unfavorable and unexpected circumstances, some germs must spread out as quickly as possible to a more favorable place. Based on it, the bacteria i randomly migrates to a new site Δ^i following the reproductive process with a specific probability P_{ed} , if not it stays in the existing position.

For each bacterium i , In a uniform distribution between 0 and 1, a random number R is produced. If the generated number R is less than or equal to the dispersal threshold P_{ed} , the bacterium performs dispersal to a new position Δ^i using the Levy Flight Walk Strategy. A mathematical simulation of the movement of organisms based on heavy-tailed distributions is the Levy Flight Walk Strategy in Equation 3.18.

$$\theta^i = \theta^i(j, k, l) + \alpha X L X \Delta^i \quad (3.18)$$

Else: Remain in the current position $\Delta^i(j, k, l)$.

4. Termination Repeat steps 3-5 until a termination condition is met, up to a certain number of iterations. Return the best solution found during the iterations.

3.4.2. Modified RNN. In a sequential user-item interaction-based recommendation system, the input layer processes the historical interaction data, capturing the sequential nature of user actions. The embedding layer transforms the user and item IDs into dense representations, enabling the model to capture latent features. LSTM layers are employed to effectively model temporal dependencies in the interactions, allowing the system to learn from past behaviors and preferences. An appropriate loss function, like mean squared error (MSE), is defined to quantify the prediction error and guide the model towards better recommendations. The fusion layer combines the final hidden states of the user and item embeddings, creating a joint representation that captures their interactions and preferences. Finally, the output layer leverages this fused information to predict user preferences or item similarities, providing personalized suggestions for users based on their prior behaviour and previous interactions. The combination of these layers enables the recommendation system to learn from sequential data, handle temporal dynamics, and generate accurate predictions to enhance the overall user experience in the e-commerce platform.

3.4.3. Collaborative Filtering. In order to offer consumers items or services, Ratings, past purchases, and browser history are all used in personalised recommendation services. Furthermore, customers who have trouble selecting between different products and services would find a solution like this that provides personalised recommendations useful. Global companies like Netflix, Amazon, and Google make money by providing tailored suggestion services in e-commerce to assist users in making decisions.

The Collaborative Filtering component utilizes an autoencoder architecture to effectively capture user-item interactions in a recommendation system. The autoencoder comprises three key components: the Encoder, Decoder, and Output Layer. The Encoder transforms user and item IDs into lower-dimensional representations, effectively compressing the information while preserving essential patterns and relationships. The Decoder then reconstructs the original input from these encoded representations, allowing the autoencoder to learn the underlying structures in the data. Finally, the Output Layer leverages the learned representations to predict user preferences for items or similarities between items, aiding in generating personalized recommendations. By employing this autoencoder-based approach, the Collaborative Filtering component can efficiently extract meaningful features from user-item interactions, providing recommendation systems with more precise and customized recommendations.

Cosine similarity. Finding things that are comparable to those that the target user has liked or interacted with during the recommendation process and recommending those items are both steps in the process. Cosine similarity is one similarity measure that can be used to determine how similar two things are showed in Eq. (3.19).

$$\theta = \frac{\vec{a} \cdot \vec{b}}{\|\vec{a}\| \cdot \|\vec{b}\|} \quad (3.19)$$

3.4.4. Item-based collaborative filtering. The idea behind the suggestion method known as "item-based collaborative filtering" is that buyers tend to favor goods that are similar to those they have already loved. This strategy uses the idea of item similarity to offer tailored recommendations. The technology finds things that have been often eaten or highly rated in tandem by examining the previous behavior and preferences of consumers. This information is then used to generate recommendations by suggesting products that are comparable to those the user has already indicated an interest in. Since this approach relies on item relationships rather than explicit user preferences, it has a number of benefits, including scalability and accuracy. Item-based collaborative filtering, which takes item similarity into account, enhances the system's ability to capture subtleties and offer pertinent recommendations.

3.5. Feature fusion. The collaborative filtering component, along with the outputs of the MLP, RNN, and Transformer-based Model components, can be integrated to produce an extensive ensemble model. A fusion approach that combines the individual model outputs, is used to achieve this integration. By combining the predictions from many models, we can take use of each architecture's advantages and provide a final prediction

that is more reliable and accurate. By maximizing the aggregate intelligence of the multiple models, this ensemble technique enhances generalization and performance on a range of tasks and datasets.

4. Result and discussion. In this section, the results of the suggested procedures are compared to those of the current methods. The implementation is done with Python. Myntra Fashion Product Dataset comprising 14,481 samples was utilized, accompanied by 14,330 metadata entries, and subjected to a rigorous data cleaning process. The feature extraction phase resulted in 6,581 relevant features. For model training and evaluation, the dataset was split into two different sets: 70% for training and 30% for testing in one experiment, and 80% for training and 20% for testing in another experiment. This separation allowed for the assessment and comparison of the models' performance under different learning rate scenarios [26].

Several metrics, including Mean Squared Error (MSE), Mean square relative error (MSRE), Normalized Mean Squared Error (NMSE), Root Mean Squared Error (RMSE), and Mean Absolute Percentage Error (MAPE), are used in this e-commerce recommendation system to evaluate the accuracy and efficacy of the recommendations. These metrics give us a way to gauge how closely the real user preferences match the projected recommendations, giving us important information about the performance of the system.

4.1. Performance matrices. Evaluation is done using error measures such as Mean Absolute Percentage Error (MAPE), Mean Square Error (MSE), Normalized Mean Square Error (NMSE), Mean Square Relative Error (MSRE), and Root Mean Square Error (RMSE).

MSE: Calculated is the average squared difference between the expected and actual values. The MSE loss, which is also used to direct model training, is used to evaluate a model's performance. The better the model fits the data, the lower the MSE shown in Equation (4.1)

$$MSE = \frac{1}{N} (A_v - P_v)^2 \quad (4.1)$$

Where, A_v is the target variables actual value P_v , where N is the total number of values, and is the target variables predicted value.

MSRE: The Mean Square Relative Error (MSRE) is a metric used to measure the accuracy of a predictive model. It is particularly useful when evaluating models that make continuous predictions, such as regression models shown in Equation (4.2).

$$MSRE = \sqrt{\left(\frac{\sum [(y_{true} - y_{pred})^2 / y_{true}^2]}{n} \right)} \quad (4.2)$$

NMSE: The Normalized Mean Square Error (NMSE) is a metric for comparing two signals that is frequently used to assess how well a prediction algorithm is working. It is described as the difference between the variance of the target signal and the MSE of the forecast signal shown in Equation (4.3)

$$NMSE = \left(\frac{1}{w} \right) * \text{sum} \left(\frac{(A_v - P_v)^2}{\text{var}(A_v)} \right) \quad (4.3)$$

RMSE: In order to evaluate how different disease symptoms affect the effectiveness of the treatments used at various disease severity levels, RMSE is used in this study in Equation 4.4

$$RMSE = \sqrt{\frac{1}{N} (A_v - P_v)^2} \quad (4.4)$$

MAPE: The MAPE formula is used (individually for each period) by multiplying the demand by the total number of distinct absolute errors in Equation (4.5)

$$MAPE = \frac{1}{T_j} \sum_{j=1}^{T_j} \left| \frac{A_v - F_v}{\text{var}(A_v)} \right| \quad (4.5)$$

Table 4.1: Metrics-Learn Rate (70%)

	BFO	EO	DBN	CNN	RNN	Proposed (HDCT)
MSE	0.3360	0.3237	0.3110	0.3264	0.3090	0.2971

where T_j is the total number of occurrences for the summation iteration, A_v is the actual value, F_v is the anticipated value.

4.2. Mean Squared Error. Table 4.1 shows that the techniques are represented by the models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) that are supplied. These approaches' respective mean squared error (MSE) values are 0.3360, 0.3237, 0.3110, 0.3264, 0.3090, 0.2971. It is clear that among the dataset's most recent 70%, the proposed approach has the lowest error consumption.

Table 4.2 shows that the models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) provided represent several methods. The corresponding mean squared errors (MSE) for these methods are 0.2618, 0.2499, 0.2640, 0.2718, 0.2515, and 0.2403. It is evident that among the most recent 80% of the dataset, the suggested strategy has the lowest error consumption.

The graph represents the 70% and 80% of the learn rate of in Mean Squared Error are represented in Fig. 4.1.

4.3. Mean square relative error. The models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) that are provided are shown in Table 4.1 to reflect the methodologies. Mean square relative error values for these methods are 0.3007, 0.2797, 0.2883, 0.3186, 0.3319, and 0.2763, respectively. It is evident that among the

Fig. 4.2: Mean Squared relative Error analysis graph

Fig. 4.3: Normalized mean square error

most recent 70% of the dataset, the suggested strategy has the lowest error consumption.

Table 4.2 demonstrates that the offered models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) represent several approaches. For these techniques, the associated Mean square relative error is 0.2262, 0.2684, 0.2577, 0.2427, 0.2332, and 0.2234. It is clear that the suggested technique has the lowest error consumption among the most recent 80% of the dataset.

The graph represents the 70% and 80% of the learn rate of in Mean square relative error are represented in Fig. 4.2.

4.4. Normalized mean square error. The models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) that are provided are shown in Table 4.1 to reflect the methodologies. Normalized mean square error values for these methods are 0.4453, 0.4224, 0.4195, 0.4487, 0.4013 respectively. It is evident that among the most recent 70% of the dataset, the suggested strategy has the lowest error consumption.

Table 4.2 shows that the available models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) represent several methodologies. The corresponding Normalized mean square error for these methods are 0.3690, 0.3919, 0.3944, 0.3889, 0.3665, and 0.3506. It is evident that among the most recent 80% of the dataset, the suggested technique has the lowest error consumption.

The graph represents the 70% and 80% of the learn rate of in Normalized mean square error are represented in Fig. 4.3.

Fig. 4.4: Root Mean square error analyzing graph

4.5. Root Mean square error. Table 4.1 displays the models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) that are offered in order to illustrate the approaches. These methods' respective Root Mean Square Error values are 0.360416, 0.338242, 0.387806, 0.367417, 0.389381, and 0.322242. It is clear that the suggested technique has the lowest error consumption among the most recent 70% of the dataset.

The accessible models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) represent various methods, as shown in Table 4.2. For each of these approaches, the associated Root Mean Square Error is 0.2995, 0.3119, 0.2629, 0.2710, 0.2820, and 0.2597. It is clear that the suggested technique has the lowest error consumption among the most recent 80% of the dataset.

The graph represents the 70% and 80% of the learn rate of in Root Mean square error are represented in Fig. 4.4.

4.6. Mean absolute percentage error. Table 4.1 displays the models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) that are offered in order to illustrate the techniques. These methods' respective mean absolute percentage error values are 0.3293, 0.3172, 0.3048, 0.3199, 0.3029, and 0.2911. It is clear that the suggested technique has the lowest error consumption among the most recent 70% of the dataset.

Table 4.2 shows that the available models BFO, EO, DBN, CNN, RNN, and PROPOSED (HDCT) represent several methodologies. The corresponding Normalized mean square error for these methods are 0.2995, 0.3119, 0.2629, 0.2710, 0.2820, 0.2597. It is evident that among the most recent 80% of the dataset, the suggested technique has the lowest error consumption.

The graph represents the 70% and 80% of the learn rate of in Root Mean square error are represented in Fig. 4.5.

4.7. Existing result analysis . In the existing result analysis, two root mean square error (RMSE) values are presented: one labelled as "[5]" and the other as "PROPOSED."

RMSE: The first RMSE value, 0.2200, is associated with an unidentified method or model denoted by "[5]."

Without further context or information, it is unclear what this value represents or what specific technique or model was used to obtain it.

PROPOSED: The second RMSE value, 0.2025, is associated with the method or model labelled as "PROPOSED." This value likely represents the root mean square error achieved by the proposed method or model in a certain experiment or analysis.

5. Conclusion. In conclusion, the Hybrid Deep Collaborative Transformer (HDCT), which has been suggested for e-commerce suggestions, performs well and exceeds other models already in use. But it's critical to recognize and deal with any mistakes or restrictions that can occur while optimizing. The HDCT approach can be improved and strengthened by carefully identifying and correcting these errors in e-commerce suggestions.

Fig. 4.5: Mean absolute percentage error Analysis

This focus on the little things and ongoing development guarantees that the HDCT model will continue to be dependable and effective in giving precise and individualized recommendations to e-commerce users. The identification and resolution of potential errors contribute to the overall robustness and trustworthiness of the HDCT method, enhancing its practicality and data for the RS is collected from the Myntra fashion product dataset ability in dataset e-commerce scenarios. As the field of e-commerce continues to evolve, it is imperative to remain vigilant in refining and advancing recommendation models like HDCT, ensuring optimal performance and customer satisfaction in the ever-growing digital marketplace.

Data Availability. The data availability statement is mentioned in the paper.

BRAIN TUMOR CLASSIFICATION USING REGION-BASED CNN WITH CHICKEN SWARM OPTIMIZATION

A SRAVANTHI PEDDINTI *, SUMAN MALOJI † AND KASIPRASAD MANNEPALLI ‡

Abstract. Diagnosing and segmenting brain tumors manually through MRI imaging is a complex and time-consuming process. However, advancements in machine learning (ML) and deep learning (DL) technologies have enabled the automatic identification and categorization of brain tumors using computer-aided design. This study utilizes MRI data to develop a system for the automatic identification and categorization of brain tumors based on region-based convolutional neural networks (R-CNN). The proposed R-CNN approach, coupled with Chicken Swarm Optimization (CSO) technique, enables the identification and classification of brain tumors into stages. This method involves processing, segmenting, extracting features, and organizing the MRI images. Image preparation includes adaptive fuzzy filtering (AFF) to eliminate noise and enhance the quality of MRI images. To detect regions of brain injury, MRI scans undergo cranial segmentation and classification (CSO) based on Tsallis entropy-based image segmentation. A Residual Network (ResNet) is employed to fuse handcrafted and deep features, generating a meaningful set of feature vectors. Extensive simulations are conducted on the BRATS 2015 dataset to evaluate the improved performance in classifying brain tumors. The RCNN-CSO method demonstrates superior performance compared to other contemporary techniques, achieving a precision of 92.35%, sensitivity of 93.52%, specificity of 94.52 % and an accuracy of 96 % . This represents a significant improvement in brain tumor classification and its outomst accuracy.

Key words: Gliomas; Chicken swarm optimization; adaptive fuzzy filtering; RCNN-CSO; Residual network.

1. Inntroduction. Brain tumors, often called lesions or neoplasms, result from the uncontrolled proliferation of aberrant brain tissue. Brain tumors hurt brain function and threaten human life when abnormal tissue growth occurs in the brain. Physicians benefit from the use of computer-aided diagnosis systems that aid in the interpretation of medical images. It means that X-ray [1], ultrasound, and magnetic resonance imaging diagnostics must be dealt with by radiologists or specialists who must quickly review and analyze them to get clearance. With the emergence of machine learning algorithms and whole-side imaging, digital pathology has been approaching. Artificial Intelligence, pathological and radiological image processing, and CAD technology are merged into computer vision elements. It's becoming increasingly common for doctors to employ imaging techniques like MRIs and CT scans to identify cancers to better understand and treat patients. The non-invasive digital imaging techniques include CT scans, MRIs, X-rays, SPECTs, PETs, and ultrasounds. Machine Learning (ML) techniques can be used to improve early identification of brain cancers. Figure 1.1 depicts MRI images of the brain with a tumor and without a tumor.

The CSO algorithm is a variant of swarm intelligence optimization, initially proposed by Vasantharaj et al. [2] and further refined by Meng et al. [3]. The chicken flock's fitness ratings consider when the algorithm determines how to partition a flock of chickens into the three distinct categories of roosters, hens, and chicks. After that, each conducts their search in the solution space. Each particle in the algorithm indicates a different approach that could be taken to solve the issue. In the final step, a detailed comparison of the three groups' fitness values is performed to identify the globally ideal particle and the globally optimal value. The individuals with the highest overall fitness levels are designated as roosters among the flock. They can locate food across a greater area. The contributions of proposed RCNN-CSO for classifying the brain tumors:

- Deep learning algorithms use a revolutionary concept known as prediction at the pixel level.

Fig. 1.1: Brain Tumor low intensity images.

- This study utilized a deep Convolutional Neural Network (CNN) known as RCNN-CSO to enhance the output process. Specifically, CNN was trained using MRI scans to classify brain tumors accurately.
- Pre-processing images with adaptive fuzzy filtering (AFF) removes noise and improves the quality of MRI images.
- MRI images are segmented using a technique called chicken swarm optimization (CSO), which uses Brain injury can be localized using Tsallis entropy-based picture segmentation.

The remaining sections are as follows: a discussion of relevant literature in Section 2, a presentation of the suggested method in Section 3, a display of results and discussions in Section 4, a performance validation in Section 5, and finally, a summary and conclusion in Section 6.

2. Related Works. The existing MRI-based brain tumor segmentation [4] approaches are divided into three groups: traditional techniques, classification strategies, cluster analysis, and deformable model methods. Demirhan et al. [5] classified brain MR images as tumors, white matter, grey matter, CSF, and edema. Since tumor growth on healthy brain tissues was studied, healthy and malignant brain tissues identifies. This information is crucial for treatment planning. Twenty glioma patients were examined using T1, T2, and FLAIR images.

In another study, Srinivas and Sasibhusana Rao [6] used K-means & Fuzzy C-means clustering for tumor detection in MRI scans. K-means and FCM clustering algorithms were compared using relative area, PSNR, segmented area, and MSE. Particle Swarm Optimization- With PSO, finding the best answer is more accessible, while Genetic Algorithms (GAs) get a near-optimal but not exact answer. Combining GAs and PSO determined the optimal degree of attraction. Combining The k-means & fuzzy c-means algorithms improved the precision with which tumor stages & sizes were determined. This method allows accurate and repeatable tumor tissue segmentation, like manual segmentation. It accelerates segmentation.

Abhishek Bal et al. [7] developed an automated method for segmenting brain tumors (RFCM). Using fuzzy membership and A rough set with a high and low bounce, rough-fuzzy C-means can address overlapping division. Both hard lower estimation and the fuzzy border have been helpful for RFCM brain tumor segmentation. C-means algorithm initial centroids may need to be revised. This work was used to speed up RFCM execution by picking starting centroids. Manocha et al. [8] mapped the tumor using automated segmentation in a different study. Brodmann area identification was included in the GUI technique for brain tumor segmentation. The research used 15 patients' T2-weighted images. Based on ethnicity, gender, and age, these data were divided into three groups. The "fuzzy" C indicates tumor clustering. Normalizing tumor segmentation data reduces image artifacts. This project's main benefit was a simple, user-friendly GUI simplifying the entire procedure.

Shree et al. [9] system for detecting, segmenting, & identifying neoplasms in the brain took time and effort.

Seeing abnormal brain tissue is difficult. Radiologists can't do further research using current procedures due to a lack of information on tumor grades. Justyna Tomicka J et al. [10] have proposed MRI modalities like The fields of Magnetic Resonance Spectroscopy (MRS), Diffusion Tensor Imaging (DTI), and Perfusion Imaging (PI) are gaining ground in the field of brain tumor segmentation. These methods have been used to localize tumors in the brain successfully. Kumar et al. [11] first proposed using optimization-driven deep convolutional neural networks to classify brain tumors. The MRI scans used for the analysis came from both the BRATS database and the Sim BRATS.

Rammurthy et al. [13] introduced the hybrid Whale Harris Hawks optimization (WHHO) for diagnosing tumors in the brain by exploiting MR imageries. The DCNN method was contemplated for the identification of tumors. The classification along segmentation method has been presented by Deb et al. [14] as a method for identifying malignant growths in the brain. Images' abnormality or normalcy establishes using a frog-leap-optimized Adaptive fuzzy deep neural network. Yin et al. [15] have shared their research in diagnosing brain tumors at an early stage. Here, early detection consists of 3 steps: reducing the noise in the background, extracting relevant features, and classifying them using a multi-layer perceptron NN. Using a deep neural network, Sultan et al. [16] demonstrated multi-classification of images of brain tumors. In this instance, they used a Deep Learning (DL) model and a convolutional neural network (CNN) to assign categories to the photographs.

Pandiselvi et al. [15] suggested an ACRC method for adaptable convex region contour. The normality or abnormality of this case was determined by using a Support Vector Machine (SVM) to slice categorization. Deepak et al. [17] employed a combination of convolutional neural networks and support vector machines. Brain tumor MRI data is automatically classified. In this study, classification was accomplished by using a computer-aided diagnostic (CAD) method for the human brain. CNN was utilized to extract the features. In addition to that, an SVM classifier uses to categorize the characteristics.

To classify brain tumors using MRI scans, Narmatha et al. [18] describe a hybrid fuzzy brain-storm optimization technique. The fuzzy brain-storm optimization algorithm is used to maximize the undefined parameters' effectiveness (FBSO). From the above discussion, we observed that the limitations in finding the usual medical imaging dataset for an analysis of a method can be complex. Therefore, many approaches test on a few data sets with varying metrics. Because of these challenges, comparisons between the presented methods and manually segmented medical images cannot be straightforward. Neural networks, clustering techniques like K-means and FCM, support vector machines, and deep learning algorithms like CNN can help enhance MRI picture quality by isolating the brain tumor. [19].

3. Proposed Methodology. This approach includes training a model built of numerous neural network processing layers. Creation of an automated Using MRI scan images, we present a deep learning-based method for tumor detection and classification in the brain. The stages of a brain tumor's development can identify and categorized using the RCNN-CSO method that has been proposed. Before the MRI scans can be processed to reduce noise and enhance the image quality, they must be pre-processed with AFF (Adaptive Fuzzy Filtering). MRI images are segmented using chicken swarm optimization (CSO), which uses picture segmentation using entropy to identify damaged brain sections. As can be seen in Figure 3.1, a valuable set of feature vectors are generated by employing a Residual Network (ResNet) to fuse both handcrafted and deep features.

3.1. Chicken Swarm Optimization (CSO). By utilizing the fractional-CSO algorithm, this paper presents a unique tumor classification methodology that is more accurate than existing methods. According to [20, 21], CSO is a single-objective optimization technique with biological impacts. It imitates how a flock of hens behaves hierarchically while hunting for food, with each chicken standing in for a potential optimization solution. CSO defines four guidelines for the perfect chicken behavior:

- A dominant rooster, hens, and chicks are present in every chicken swarm group.
- The fitness of each chicken determines whether it belongs to a group of hens, roosters, or chicks. The group is led by the roosters, which are the fittest chickens. A chick is a lesser chicken. Some are hens.
- Every G step, mother-child connections, dominance, and hierarchical relationships should shift.
- For nourishment, chickens follow their rooster. We expect that chickens will steal food from one another. Near their moms, chicks go foraging. The rooster wins the food fight. We distinguish between the following numbers in a swarm of N chickens: There are a total of RN roosters, HN hens, CN chicks,

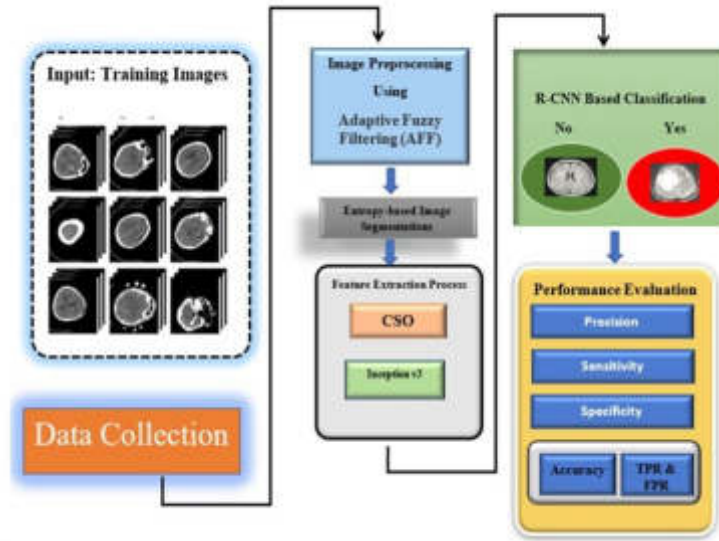

Fig. 3.1: RCNN - Methods for Detecting and Classifying Brain Tumors.

and MN mother hens. The x_{ij} coordinates of each chicken ($I [1,..N]$, $j [1,..D]$) describe their location in D -dimensional space. Chickens come in three different varieties in CSO. Each species has its distinctive dance.

3.2. Rooster Movement. The roosters with the best fitness ratings can find food in more locations than those with lower fitness ratings. Eqs. (1) and (2) describe their motion.

$$x_{ij}^{t+1} = x_{ij}^t * (1 + \text{Randn}(0, \sigma^2)) \quad (3.1)$$

In this context, k is an arbitrary rooster index, and $\text{Randn}(0, 2)$ is a zero-mean Gaussian distribution. A minor constant, 2, and the rooster's fitness, f_i , are denoted below.

Hen movement. Hens engage in foraging behavior in the presence of another group member. In addition, they would strategically appropriate the high-quality food provided by their bird counterparts, all the while being constrained by their fellow gallinaceous companions. The more dominating chickens would triumph over obedient hens in a food fight. The equations (3.1) – (3.5) can be used to mathematically explain the movement of elements.

$$x_{ij}^{t+1} = x_{ij}^t * (S_1 + \text{Randn} * (x_{n,i}^t - x_{n,i}^t) + S_2 + \text{Randn} * (x_{n,i}^t - x_{n,i}^t)) \quad (3.2)$$

$$S_1 = \exp\left(\frac{f_k - f_{r1}}{|f_{r2} + f_1|}\right) \quad (3.3)$$

$$S_2 = |f_{r2}| + f_1 \quad (3.4)$$

The variable Randn represents a random number that follows a uniform distribution between 0 and 1. While $r2$ is an index of a chicken, The variable $r1$ represents an index that relates to the rooster, explicitly referring to the groupmate of the I -th hen. (rooster or hen). It gets picked at random from the swarm ($r1, r2$).

Chick movement. Young chicks perform exploratory behaviors to find sustenance, often venturing away from their maternal figure. The movement of the chick is defined by Equation (3.6).

$$x_{ij}^{t+1} = x_{ij}^t + FL * (x_{m,j}^t - x_{ij}^t) \quad (3.5)$$

where $x_{(m,j)}^t$, The position of the mother of the i -th chick, denoted as m , is defined within the range of 1 to N . FL , a parameter that quantifies the extent to which a chick will mimic the speed of its mother. To examine the distinctions among the several chicks, a random selection is made for the variable FL within the interval $[0,2]$.

3.3. Pre-Processing of Brain Tumor Images. Tumor classification begins with pre-processing because making the subsequent procedure more realistic is crucial. We use the brain imaging dataset to obtain the input image of the brain. During the pre-processing stage, significant tumor sites are extracted [22]. Consider the database E of brain images, which it denotes as, and contains B_n images with $[Q \times R]$ dimensions.

$$F = \{C_1, C_2, \dots, C_i, \dots, C_n\}; [Q \times R] \quad (3.6)$$

C_n represents the data set containing a cumulative count of brain images, denoted as the total number. In contrast, variable F indicates the database's specific quantity of brain photographs. In this scenario, the pre-processing function uses the image B_i from the database. Cropping the regions of interest from image C_i results in an image designated as C_i with the dimension $[Q \times R]$, which is the output of the pre-processing phase. $C_i = b_1, b_2, \dots, b_j, \dots, b_P$ the pre-processed image C_i is characterised by its M number of pixels.

$$\max_R \sum_{K=1}^Q b_j(X_c(R)) \quad (3.7)$$

where $b_j(X_c(R))$ The passage discusses an objective function that is specifically associated with the K th feature of the data, denoted by (R) . The standard parameter.

$$\max_{x,R} \sum_{K=1}^Q w_j, b_j(X_c(R)) \quad (3.8)$$

the pixel values being represented by w_j . To help with clustering model regularization, the expression of the sparse FCM is presented in eq 3.7 to 3.9.

$$\max H(X, R, g) = g^m \lambda(R) \quad (3.9)$$

3.4. Feature extraction for brain tumor classification. The segmented image C^*_{kl} is subsequently transmitted to the feature extraction stage, where the most salient characteristics are extracted from the segmented outcomes. Using feature extraction, we may simplify brain MRIs by eliminating unnecessary data. The mean value of the pixels is represented, which is shown in eq 3.10 to 3.13.

$$g_1 = \frac{1}{Q} \sum_{k=1}^Q C^*_{kq} \quad (3.10)$$

where C^*_{jq} denotes the q th picture element of the image C_j segmentation variance The dimension of feature f_2 is determined by its mean value of $[2 \times 1]$

$$g_2 = \left(\frac{1}{Q} \sum_{k=1}^Q \sqrt{C^*_{kq}} \right)^2 \quad (3.11)$$

Entropy is used to determine which pixels contain the most information.

$$g_3 = - \sum_{k=1}^{Q \sum_{kq}^*} C^*_{kq} \log \quad (3.12)$$

The coverage feature determines the tumor region by calculating the total number of pixel positions and segmented points. The term "coverage" refers to the method used to determine the width and length of a tumor. On the other hand, the coverage characteristics of dimension [2x1] are stated as,

$$g_4 = \sum_{k=1}^Q \frac{w_j}{C_{kq}^*} \tag{3.13}$$

3.5. Fitness Functions. The fitness function is employed to determine the optimal selection of female chicks, hens, and male roosters based on chicken swam groupings. The chicken with the highest fitness grade is classified as a rooster, and each rooster is the group's leader. Chickens classified as chicks have a low fitness value, while hens have a high fitness value.

$$Qg = \frac{1}{d} \sum_{y=1}^d P_d - \varsigma \tag{3.14}$$

Initialization of the population lets us begin by populating the populace with D roosters, Y chicks, S hens, and Z mother hens.

3.6. Fitness Evaluations. It is analyzed to determine the ideal chickens, as indicated in Equation (9). We've updated the rooster's location. The roosters with the most significant fitness values receive priority over the hens with the lowest fitness values when it comes to eating. On the other hand, the chickens keep to the group's rooster in quest of food. However, they protect their food from other chickens. Birds randomly take food from other chickens. Simply put, roosters with a higher fitness value seek food in more locations than those with a lower fitness value. As a result, the corrected rooster equation 3.14 to 3.17 is as follows:

$$h_{x,y}^r = h_{x,y}^r \times (1 + \delta(0, l^2)) \tag{3.15}$$

$$h_{x,y}^{r+1} = h_{x,y}^r + h_{x,y}^r \delta(0, l^2) \tag{3.16}$$

$$h_{x,y}^{r+1} - h_{x,y}^r = h_{x,y}^r \delta(0, l^2) \tag{3.17}$$

where $\delta(0, l^2)$ specifies with the mean 0 and standard deviation l^2 for Gaussian distribution.

$$U^\beta [h_{x,y}^{r+1}] = h_{x,y}^r \delta(0, l^2) \tag{3.18}$$

$$h_{x,y}^{r+1} = h_{x,y}^r (\beta + \delta(0, l^2)) + \frac{1}{2} \beta h_{x,y}^{r-1} + \frac{1}{6} (1 - \beta) h_{x,y}^{r-2} + \frac{1}{24} \beta (1 - \beta) (2 - \beta) h_{x,y}^{r-3} \tag{3.19}$$

In this context, let y represent the most minor constant and m be the rooster index., p is the fitness value of the associated g order between [0, 1].

$$h_{x,y} = \left\{ 1, \exp\left(\frac{qm - qlxx}{qx + y}\right), \text{otherwise}^{if qx \leq qmim \in [1, B], m \neq y} \right\} \tag{3.20}$$

The location of Hen has been changed. Hen accompanies their groupmate rooster on his food seek. By and large, the Hen snatches food that other chickens randomly discover. In comparison to submissive hens, dominant hens have an advantage. As a result, the equation for the hen update is as follows: and shown in eq 3.18 to 3.22.

$$r + 1_{x,y} = h_{x,y}^r + K1 \times l \times (h_{xm,y}^r - h_{x,y}^r) + K2 \times l \times (h_{x2,y}^r - h_{x,y}^r) \tag{3.21}$$

where the term k1 and k2 are specified as,

$$k1 = \exp\left(\frac{(q_x - q_{h1})}{bs(q_x) + y}\right) \tag{3.22}$$

$$k1 = \exp(q_{h2} - q_x) \quad (3.23)$$

where k is a number between 0 and 1, the x th hen group's mate is identified by the rooster index $h1$. Furthermore, the variable $h2$ represents the chicken index of the swarm, indicating whether the individual is a hen or a rooster, so $h2$, $h1$, and $h1$ all equal $h2$. Changes in chick position These dominant chicks have an advantage over other chicks regarding food completion. As a result, as illustrated in the equation below, the chicks travel about the mother looking for food.

$$h_{x,y}^r + l \times (h_{u,y}^r - h_{x,y}^r) \quad (3.24)$$

where $h_{u,y}$ is the position of the mother of the x th chick can be represented as u , where u is an element of the interval $u \in [1, A]$. The parameter L , which lies within the interval $L \in [0, 2]$, indicates whether the chick forages with its mother. As a result, each chick's parameter L randomly selects values between 0 and 2 $h(r+1)_{(x,y)}$ shown in eq 3.23 and 3.24

3.7. Pseudocode for Classification.

Algorithm – RCNN Based Brain Tumor Classification. Input: Feature set (set of optimize feature and the area of the tumor)

Output: Decision on the tumor type

- 1: Initialize weight vector $Q = 0$;
- 2: Select data points in the coordinate of B_i, C_i
- 3: if Selected vector x_i if misclassified then
- 4: Select $Q \leftarrow B + \text{sign}(f(B_i, C_i))(B_i, C_i)$
- 5: else
- 6: Repeat from step 2 until all the data are classified correctly
- 7: end if
- 8: After convergence or classification of data select Equation

3.8. Classification Algorithms Process.

The process of the algorithm is as follows:

- Step 1: Initially, Convert medical images of the brain tumor to the DICOM file format.
- Step 2: Deal with medical images of a size similar to the brain. Differentiate normal from abnormal MRI pictures.
- Step 3: Process the images using CSO feature extraction optimization by taking mathematical derivation using equations from 3.1 and 3.12.
- Step 4: Calculate the elapsed time and use equation 3 to find the best-produced image.
- Step 5: The impacted region can readily be separated by selecting the best-generated image and using the appropriate filtering algorithms.

4. Results and Discussion.

4.1. Data Collection. The collection of Dataset from the data underlying this article is available in BRATS 2015 at <https://www.smir.ch/BRATS/Start2015> and <https://github.com/topics/brats>, respectively. Meningiomas, gliomas, and pituitary gland tumors are all in this group [23]. Rembrandt [24] includes data from 874 tumor examples from the glioma molecular diagnostic effort. This includes 566 X 566 gene expression arrays, 834 arrays of copy number data, and 13,472 points of clinical phenotype. Many deep learning-DL methods exist to find and classify brain tumors [25-28].

4.2. Experimental Setup. To implement the proposed methodology, we used the Google Colab environment. The following are the configuration details for the simulation trials that were used:

- Implementation environment and packages
- Google Colab
- Tensor flow
- Numpy
- Pandas, matplotlib
- Input Dataset : BRATS 2015

5. Performance Validation.

5.1. Precision. The precision analysis of the RCNN approach with existing techniques is shown in Table 5.1 and Figure 5.1. The results prove that the RCNN approach has improved precision with all training datasets. For example, the RCNN technique with a 40% dataset has achieved a superior precision of 91.23%, whereas the CNN, K SVM, SVM, and RF methods have achieved lesser precisions of 90.56%, 87.84%, 84.94%, and 83.71%, respectively. Similarly, using an 80% dataset, the RCNN approach achieved the highest precision of 92.11%, while the CNN, K SVM, SVM, and RF procedures achieved lower precision of 91.73%, 89.11%, 88.93%, and 87.90%, respectively.

5.2. Sensitivity. The sensitivity analysis of the RCNN approach with existing techniques is shown in Table 5.2 and Figure 5.2. The results prove that the RCNN approach has an improved sensitivity with all training datasets.

5.3. Specificity. Table 5.3 shows the Specificity of different machine learning algorithms on an image recognition task when trained on different percentages of the training data. The table shows the following: The method or percentage of training data used to train the model The Specificity of a RCNN model trained on 40

Fig. 5.1: Precision Analysis of RCNN technique with existing methods

Fig. 5.2: Sensitivity Analysis of RCNN technique with other existing methods.

%, 50 %, 60 %, 70 %, and 80 % of the training data The Specificity of a CNN model trained on 40 %, 50 %, 60 %, 70 %, and 80 % of the training data The Specificity of a KSVM model trained on 40 %, 50 %, 60 %, 70 %, and 80 % of the training data The Specificity of a SVM model trained on 40 %, 50 %, 60 %, 70 %, and 80 % of the training data The Specificity of a RF model trained on 40 %, 50 %, 60 %, 70 %, and 80 % of the training data In all cases, the Specificity of the model increases as the percentage of training data used increases. This is because the model has more data to learn from, which allows it to better generalize to unseen data. The RCNN model achieves the highest Specificity overall, with a Specificity of 96.43 % when trained on 80 % of the training data. The CNN model is a close second, with a Specificity of 94.28 % when trained on 80 % of the training data. The KSVM, SVM, and RF models all have lower Specificity, but still achieve good performance. It is important to note that this table only shows the results for one image recognition task. The Specificity of these models would likely vary depending on the specific task and dataset. However, the table does illustrate the general trend that machine learning models tend to perform better when trained on more data. Here are some additional things to consider when interpreting this table: The specific image recognition task that the models were trained on is not shown in the table. This could be an important factor in how well the models perform. The size and quality of the training data is not shown in the table. These factors can also affect the

Table 5.2: Analysis of how sensitive the RCNN method is to current methods.

Method or % of training data	40 %	50 %	60 %	70 %	80 %
RCNN	92.92	93.49	94.18	95.27	96.15
CNN	90.23	91.33	91.89	92.61	93.18

performance of machine learning models. The hyper parameters of the machine learning models are not shown in the table. Hyper parameters are settings that can be tuned to improve the performance of a model.

The specificity analysis of the RCNN approach with existing techniques is shown in Table 5.3 and Figure 5.3. The results prove that the RCNN approach has an improved specificity with all training datasets.

5.4. Accuracy. The accuracy analysis of the RCNN approach with existing techniques is shown in Table 5.4 and Figure 5.4. The results prove that the RCNN approach has improved accuracy with all training datasets.

5.5. Overall Accuracy Analysis. The overall accuracy analysis of the RCNN approach with existing techniques is shown in Figure 5.5. The result depicts that the RCNN approach has improved overall accuracy with all training datasets, where the RCNN technique has achieved a superior accuracy of 95.78%, while the CNN, K SVM, SVM, and RF methods have achieved lesser accuracy of 93.23%, 92.67%, 91.14%, and 92.93%, respectively.

5.6. TPR and FPR Analysis. The True Positive Rate and False Positive Rate Analysis of the RCNN Method with Current Methods is shown in Figure 5.6. The results prove that the RCNN approach has an improved TPR with all training datasets. The complete analysis is shown in the table Table 5.3 and 5.4 as figure 5.6.

It is a medical image segmentation competition where researchers develop algorithms to automatically segment brain tumors from magnetic resonance imaging (MRI) scans. In the challenge, participants submit models that are evaluated on a held-out test set. The models are evaluated on how well they can segment four different regions of the brain tumor: the whole tumor (WT), the tumor core (TC), the enhancing tumor (ET), and the necrotic and non-enhancing tumor (NET). The bar graph in the image shows the average accuracy of each model across all four subregions. As you can see, the average accuracy of a model is about 95 %, while the average accuracy of another model is about 70 %. Overall, the accuracy of the models ranges from about 60

Fig. 5.4: RCNN technique’s accuracy compared to current methods.

Table 5.4: RCNN technique's accuracy compared to current methods.

Method or % of training data	40 %	50 %	60 %	70 %	80 %
RCNN	95.29	92.33	87.91	94.13	93.66
CNN	95.14	93.33	88.31	94.96	93.75
KSVM	95.58	94.82	89.47	95.21	93.9
SVM	95.77	95.41	90.63	95.71	94.14
RF	96.49	96.19	91.36	96.1	94.62

% to 97 %. Here are some additional things to consider when interpreting this bar graph: The specific models being compared are not shown in the image. The BRATS challenge is a competition, so the models shown in the graph are likely to be state-of-the-art models. However, it is important to remember that machine learning is an active area of research, and new models are being developed all the time shown in figure 5.4. The accuracy of a brain tumor segmentation model is just one measure of its performance. Other important factors include the sensitivity and specificity of the model. Sensitivity is the ability of the model to correctly identify people who have a brain tumor. Specificity is the ability of the model to correctly identify people who do not have a brain tumor shown in figure 5.5 and figure 5.6.

6. Conclusion. The proposed RCNN-CSO approach is an effective and automated way of classifying and segmenting brain tumors. The MRI pictures are enhanced by applying the Adaptive Fuzzy Filtering (AFF) approach. MRI images are segmented using a technique called chicken swarm optimization (CSO), which uses Tsallis uses entropy-based picture segments to find the damaged parts of the brain. The goal here is to examine the RCNN method, which boasts better results. A thorough experimental analysis is performed, and Several ways are used to look at the information. The overall accuracy of the RCNN technique compared to the other methods is 95.78%. The simulation results demonstrated that the suggested RCNN strategy outperformed the existing methods. The presented approaches in this paper can be used in the future to examine the influence of strokes caused by tumors on brain imaging.

IMPROVING DATA SECURITY AND SCALABILITY IN HEALTHCARE SYSTEM USING BLOCKCHAIN TECHNOLOGY

K.R.ROHINI *, DR.P.S.RAJAKUMAR † AND DR.S.GEETHA ‡

Abstract. The wearable tech revolution and the proliferation of Internet of Things (IoT) gadgets have created exciting new opportunities for remote patient monitoring. Healthcare providers are increasingly utilizing wearable technologies to expedite the process of diagnosis and treatment. The healthcare and research fields have been substantially impacted by emerging technologies. On the other hand, there are legitimate worries regarding the security of data transfers and transaction recording upon using these technologies. Healthcare departments need easy data interchange for interoperability. Protecting data security and integrity is crucial when exchanging information with authorized parties. In many existing solutions, patients' sensitive data is collected and stored in smart healthcare systems. Scalability, breach or unauthorized access to this data can compromise privacy. The adoption of blockchain technology is one way to safeguard patient privacy in healthcare. Also, by facilitating the safe and secure exchange of data, blockchain technology is revolutionizing the healthcare industry by making traditional methods of diagnosis and treatment more reliable. However, blockchain has serious problems with its highly limited scalability. This article suggests a new method "SHORTBLOCKS" depending on blockchain technology for the safe administration and analysis of data. To circumvent the security-scalability issue and achieve high throughput, this study employs the newly introduced protocol "SHORTBLOCKS", which extends blockchain concept to a direct acyclic graph of blocks. The proposed system uses both a private and a public blockchain that are created on the new protocol. In order to analyze patient health data, a system using smart contracts and a private blockchain is built. The system logs the occurrence to the public blockchain in the case that the smart contract raises an alarm due to an unusual reading. This will fix the scalability issue with initial blockchain as well as the security and privacy issues involved in remote patient monitoring. Simulation results shows the performance of the proposed system by comparing with existing solutions, SPECTRE protocol and GHOSTDAG protocol.

Key words: Healthcare, Remote patient monitoring, Security and privacy, interoperability, Private blockchain, Public blockchain, Smart contracts, Shortblocks.

1. Introduction. Clinical data is abundant in the healthcare industry due to the regular generation, access, and dissemination of enormous volumes of data. Due to privacy and security concerns, as well as the sensitive nature of the data, storing and distributing this enormous amount of data is not only necessary but also extremely challenging [1].

A wide variety of resources are available to various healthcare providers, including hospitals, pharmacies, and insurance providers [2]. The rapid development of ICT has allowed for the widespread use of wearable sensors to link many physical objects. Data processing, collecting, and creation on a massive scale are made possible by the electrical devices and software employed for this purpose. Although there are many healthcare facilities, the prevalence of lethal diseases such as pneumonia, influenza, cancer, heart diseases, etc. has risen dramatically [3]. Constant vigilance and tracking of vital signs has been made possible with the use of sensing devices that can gather, and analyze patient data, due to the technological revolution. Hospitals and other related departments receive this data for the purpose of delivering healthcare. Problems with legal interoperability are present here. Healthcare service delivery will be more efficient with a centralized system for managing and exchanging medical data [4].

In healthcare and clinical settings, safe, secure, and scalable (SSS) data-sharing is critically necessary for diagnosis and integrated clinical decision making. The ability for medical professionals to transmit patient

‡Professor, Dept. of CSE, , Dr. M.G.R. Educational and Research Institute, Maduravoyal, Chennai, Tamil Nadu, India. (*somangeetha@drmgrdu.ac.in)

medical records to the relevant authority for expedited follow-up makes sharing of data, a crucial activity. Both primary care physicians and other medical professionals should have the ability to securely and quickly transmit their patients' clinical data to one another, so that everyone involved has access to the most current and accurate information regarding their patients' health. During treatment, doctors and hospitals need access to patients' medical records, but individuals also have a right to feel safe sharing their personal information with these institutions.

Conversely, e-health and tele-medicine are two popular areas where patients can get their clinical data reviewed by a specialist located far away. A "store-and-forward technology" or online healthcare monitoring in real-time (e.g., tele-monitoring, telemetry, and the like) is used to transmit patient data in these two online clinical setups [5]. Clinical specialists are able to remotely perform patient diagnosis and treatment in these online clinical contexts by exchanging clinical data. Because patient data is unique to each individual case, ensuring its confidentiality, integrity, and availability in all such therapeutic arrangements is a top priority. In order to facilitate relevant and healthy therapeutic discussions pertaining to instances involving faraway patients, the capacity to securely and scalably transmit data is of the utmost importance. For the simple reason that better diagnosis and more efficient treatment are the outcomes of secure data transmission, which aids in clinical communication by soliciting opinions or confirmations from a group of clinical experts [6].

Additionally, several interoperability problems crop up frequently in this domain. The secure and reliable transfer of patient records between hospitals and universities, for instance, can be fraught with practical difficulties. Such exchanges of clinical data need considerable, trustworthy, and healthy collaboration between the entities involved. Difficult patient matching algorithms, ethical policies, legislation, and processes; sensitive clinical data; and data sharing agreements are all potential roadblocks. Prior to establishing a clinical data exchange, it is essential that all stakeholders agree on these and other important matters [7].

The proliferation of remote devices linked to the internet for data and access transfer has been greatly enhanced by the persistent developments in the IoT domain. Thus, from the field of education to that of supply chain management, the Internet of Things (IoT) has transformed and shaken up nearly every industry on the planet. Internet of Things (IoT) has also shown to be highly effective in the healthcare industry, streamlining diagnostic processes and effectively tracking patients' activities. In addition, the main point we want to make about the Internet of Things is that it helps with patient monitoring even when the patient isn't actively using their devices, which may be a real challenge with the current system. Additionally, there are vast opportunities for improved diagnostic and treatment efficiency that arise from remote access to data and ongoing analysis of it.

Blockchain applications have recently garnered a lot of interest for safe healthcare data transmission [8], biological data sharing [9], e-health data sharing [10], and general activities. A peer-to-peer (P2P) network is the foundation of a blockchain. In essence, it is a cryptographic, algorithmic, and mathematically expressed multi-field network architecture that aims to address the constraints of standard distributed database synchronization methods through the use of distributed consensus techniques.

With the introduction of blockchain, the technology recently assumed full control of all storage, transactions, and access. Additionally, blockchain technology has demonstrated tremendous promise in a variety of industries, that includes retail, healthcare, supply-chain management, finance, and more. The privacy and security of data is a constant concern in healthcare because many parties rely on it to carry out their own objectives. For instance, insurance companies play a crucial role in the delivery of a specific service to patients; in order to do their jobs properly, they need access to patients' data for analysis and service planning. Unfortunately, it is not uncommon for companies to manipulate or even leak this data. Consequently, this system is an authentic answer to the problem of data misuse and to the problem of keeping the many stakeholders' faith in one another. With the use of Blockchain technology, healthcare organizations may eliminate the need for reconciliation, rework, and repetition. We can find the optimal level of service intensity in a predictive healthcare setting with the help of artificial intelligence (AI). It is important to communicate with patients, professionals, and careers in a way that is appropriate for each setting.

Consider a case study pertaining to the COVID-19 case as an example. When it comes to COVID-19-safe clinical practice, blockchain technology is crucial. The integration of Blockchain technology with AI has the ability to speed up the process of diagnosing and treating COVID-19 patients, while also helping to create

therapeutic guidelines for future outbreaks that could be similar to coronavirus.

Blockchain technology allows for the secure and private sharing of data from many sources, including hospitals, primary care physicians, pediatricians, clinical laboratories, and others. Artificial intelligence solutions are utilized for data analysis.

Take the COVID-19 case study as an example. Cryptography is the backbone of Covid-19-safe medical practice. Rapid diagnosis and treatment of COVID-19 patients is possible with the use of Blockchain and AI, which also assists in developing treatment recommendations for future outbreaks (like coronavirus). With a blockchain-based system, pediatricians, primary care physicians, hospitals, and clinical laboratories may all securely share patient data. Data analysis makes use of AI solutions. The paradigm promotes research into appropriate medicines, helps with risk management, and inspires the development of new drugs.

The use of Internet of Things and Blockchain technologies for secure data transmission in smart health care systems is proved to be effective. However, with the concept of blockchain, scalability problem arises. Many existing solutions are not addressing properly the problem of scalability and secure communication in smart health care system. Hence, a sophisticated method is required to console the problem of scalability while transferring the data security using Internet of Things and Blockchain in Smart health care Systems.

This study proposes a novel approach called "SHORTBLOCKS" that incorporates the blockchain concept. Its purpose is to offer scalable and secure communication in the healthcare domain using blockchain as a paradigm. Here is the breakdown of the remaining sections of the paper: Section 2 provides a synopsis of relevant background material and related work in the healthcare domain that makes use of blockchain technology. In Section 3, the proposed method's framework is described in terms of how healthcare and the medical industry might use blockchain technology. Section 4 lays out the strategy that has been suggested. The suggested protocol is demonstrated in Section 5. In Section 6, we go over the findings from comparing the current state of blockchain technology with the suggested technique "SHORTBLOCKS" that incorporates blockchain technology. In Section 7, we lay out the final thoughts, and in Section 8, we look forward to the potential applications of blockchain technology in healthcare, and finally, we provide a list of references.

2. Related Work. The paper's primary rationale for investigating blockchain technology's potential use in healthcare is based on the work of [11], who comprehensively outlined several current tendencies in this field of study. Since Bitcoin's inception in [12], the potential applications of the underlying technology have been practically limitless, even beyond the financial sector.

Public blockchains are decentralized database systems that let anyone with an internet connection to determine who may access the data stored on them. Ivan [13] also showed how to encrypt health data using this method. This approach creates a PHR (personal health record) based on blockchain by publicly storing encrypted healthcare data. The patients were able to gain improved access to their clinical data through the way they suggested. Patients can now freely observe and manage their information, as well as take part in maintaining their data and making it available to any associated healthcare provider. Another study by Chen et al. [14] suggested a system for managing and sharing patients' confidential medical data that incorporated blockchain technology with cloud storage. Ensuring the secure storage and communication of personal medical data is a potential use case for the suggested approach. The proposed method is novel because it eliminates the need for a middleman by providing patients full access to and management of their own medical records.

In order to streamline the administration of electronic health record transactions, Dey et al. [15] suggested a blockchain-based Internet of Things model. As a principal agent for linking the bio-sensors to the IoT platform, the architecture suggested using the MQTT protocol. In addition, the design included the IPFS (InterPlanetary File System), which may identify state entries or block modifications caused by certain transactions appended to blocks in order to decrease stored transaction deduplication. In [16], Gem, a provider of enterprise blockchain solutions, announced that Philips Blockchain Lab, a research and development centre of healthcare massive Philips, would be the first major healthcare operator to join the Gem Health network. Gem Health is an Ethereum-powered network for developing healthcare applications and shared infrastructure.

To assess the current state of patient healthcare, Wang et al. [17] laid forth a blockchain architecture that uses AI healthcare systems and parallel execution instead. In order to aid in clinical decision-making, the suggested method evaluates the patient's general status, diagnosis, and treatment plan while also analyzing the related therapeutic processes carrying out computational trials in parallel. To assess the precision of diagnosis

and efficacy of therapy, the suggested approach has undergone testing on real and virtual healthcare networks.

The use of blockchain technology to verify the achievement of clinical trial endpoints was introduced in [18]. The method was put to the test by Irving and Holden using a clinical trial methodology that had previously documented result switching. Scientific research' credibility and the application of blockchain technology as an inexpensive, independently verifiable auditing tool were both validated.

A healthcare system controlled by the Internet of Things was suggested by Budida et al. [19] in an interactive environment. The suggested design is based on generative data ingestion from biosensors and smart wearables, which then provides patients with clear feedback and simple solutions. In order to provide patients with quicker and more accurate recommendations, A Smart Hospital system, proposed by Sivagami et al. [20], would combine human reaction suggestions with the efficiency of sensors. The proposal proposes a system that uses radio frequency identification (RFID), wireless sensor networks (WSN), and smart wearables to accomplish a number of goals. These goals include smart sensing of the patient's environment, ward allocation according to doctor placement requirements, movement monitoring, and report analysis based on calculated data, after data has been uploaded by the sensors.

An innovative platform for the exchange of healthcare information, BloCHIE was created by Jiang et al. [21]. Using blockchain technology embedded in many sources, the proposed platform assesses the needs for healthcare data exchange, particularly with regard to electronic medical records and personal healthcare data, but also handles a wide range of other data types. They integrated on-chain and off-chain verification procedures into the platform to ensure it met the desired standards of privacy and authenticity. All parties involved in the healthcare system, from payers to providers to patients, stand to benefit from blockchain technology's revolutionary potential in the areas highlighted by Nichol in [22]. In order to transform healthcare, Nichol amplifies the principles and applies examples that are at the forefront of a new frontier. Written in the style of his articles, blogs, and thoughts, the book lays forth the groundwork for an internal revolution in healthcare.

Discussing the foundations of all the different kinds of blockchains and how they might be utilized in the healthcare industry for data maintenance, validation, and storage. The various blockchain designs that are currently available were discussed by Zainab Alhadhrami et al. [23]. Furthermore, the consortium blockchain was found to be the solution that was essentially pre-built for healthcare data storage. To put it simply, a consortium blockchain is a valid blockchain in which the node owner and miners share control of access. Furthermore, the operation of the consortium blockchain is predicated on the consensus principle, which requires the approval of the majority of stakeholders or blockchain nodes.

Clinical professionals and healthcare entities can significantly enhance medical data sharing, privacy, and security by utilizing blockchain technology. In a similar vein, Cryan, M.A. [24] suggested a novel and methodical design based on blockchain technology to secure private patient information, resolve pressing data security concerns, and integrate blockchain software into an entire healthcare organization's infrastructure.

In order to address the privacy requirement imposed by HIPAA, Ahram et al. [25] created a healthcare blockchain that controlled the access to patients' demographic and racial information. The study also demonstrated the generative design of a blockchain network that included three distinct kinds of nodes: those for primary care physicians, referral services, and urgent care.

For the purpose of diagnosing and treating malignant tumors in distant patients, Shubbar introduced a healthcare framework based on blockchain technology in [26]. Patients' data at both specialty medical centers and their homes may be reliably and securely verified using the proposed protocol's use of smart contracts and blockchains. As a last point, Taylor unveils a new initiative in [27] that will utilize blockchain technology to strengthen the safety of the pharmaceutical distribution network. Still in its early phases of development, the initiative aims to streamline the process of tracing the origin and manufacturing date of medicines by utilizing blockchain monitoring and time stamps.

Healthcare applications serve a variety of objectives, including but not limited to pharmaceuticals, biomedical research, neurology, genomics, EHRs, clinical facts, processes, and decision-making [28]. By standardizing data and establishing communication protocols, Internet of Things (IoT) technology can improve healthcare efficiency. More effective healthcare services lead to less data interoperability, safer patient data, improved connectivity, and user interfaces. The healthcare industry and the development of trustworthy healthcare applications receive a lot of attention from researchers [29]. Ensuring that stakeholders, such as pharmacies,

Fig. 3.1: Smart Patient Health Care Monitoring

hospitals, and patients, can access healthcare records securely and without data tampering is of the utmost importance. It is possible to overcome these obstacles with blockchain technology [30].

Omar et al. (2019) [31] suggested a blockchain-based system for EMR maintenance. A patient-centric healthcare data management system was created by the authors. This system uses blockchain technology as a storage method to promote privacy. Under this system, patients will have full authority over their information. This method improves privacy, security, accountability, and integrity while increasing patient interest in EMRs.

In [32], GHOSTDAG protocol is employed which uses a public and a private blockchain. The authors proposed a method that utilizes a private blockchain, the system logs the event to the public blockchain for data transfer. The drawback of this system is privacy and security concerns surrounding remote patient monitoring. In [33], the use of blockchain technology to verify the achievement of clinical trial endpoints was introduced with SPECTRE protocol. By analyzing a clinical trial protocol that has previously documented outcome switching, Irving and Holden conducted an empirical evaluation of this strategy. They validated the validity of scientific research and the usage of blockchain technology as an inexpensive, independently verifiable auditing technique. However the security and privacy concerns remain still unanswered.

With the introduction of smart contracts, Blockchains can now store data that can be retrieved at will (Li et al., 2019) [34]. Nevertheless, smart contracts necessitate expert assistance for administration and maintenance and might be a pain to set up. Several scholarly articles present potential frameworks for health-related IoT applications. Due to the extra permission-based security they provide, private Blockchains form the basis of these concept designs. One such approach was to develop and manage a separate set of smart contracts for each Internet of Things (IoT) device.

3. Framework. Patients are finding it increasingly difficult to get an appointment with a primary care physician or other healthcare provider due to the massive growth in the patient population in many nations. The proliferation of Internet of Things (IoT) and wearable technology in the last several years has enhanced the care quality for patients using remote patient monitoring. More people can be treated by doctors because of this. Patients can be monitored and cared for outside of the typical clinical setting (such as at home) with smart patient monitoring. The primary benefit is the inherent ease of service it provides to patients. Patients have the option to remain in touch with their healthcare providers as needed. Additionally, it enhances the quality of care while decreasing medical expenses. This is the primary motivation for healthcare providers looking at ways to make remote patient monitoring accessible to everyone. A remote patient monitoring system could primarily consist of a smartphone, an app for remote patient monitoring, and a specifically developed device that can record and send health data to smart contracts as shown in Fig 3.1. When it comes to remote patient monitoring, wearable technology and the internet of things are crucial. For the purpose of health monitoring, illness diagnosis, and treatment, wearable devices transmit data collected from patients to healthcare facilities.

Smart electronic devices with microcontrollers that may be worn as accessories or implanted into garments are known as wearable gadgets in healthcare. They have sophisticated capabilities including built-in alerting systems, real-time feedback, and wireless data transmission, and they are easy to use and barely noticeable. A variety of vital signs, including respiration rate, blood sugar, and pressure, can be transmitted to medical professionals by means of these devices.

Fig. 3.2: Different Wearable Devices

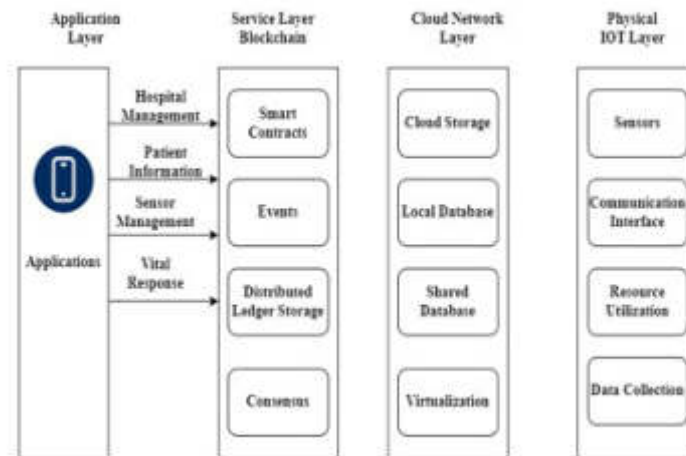

Fig. 3.3: Proposed Framework

Wearable devices are a part of the Internet of Things (IoT). These devices can connect to each other and share data through the software, electronics, sensors, actuators, and connectivity they contain as shown in Fig 3.2. Such infrastructure necessitates secure data sharing in order to manage such patient data with other institutions. The risk of exposure can increase if health data is shared, and the data is very sensitive. The second issue is that trust must be centralized in the present data sharing system because of its centralized architecture.

Blockchain technology may hold the key to ensuring the privacy and security of personal information. Blockchain technology ensures that data is secure and resistant to failures. In terms of data storage, it's a decentralized architecture. The healthcare system is the ideal fit for blockchain technology since data cannot be removed or altered from blocks. Nevertheless, blockchain's scalability and security remain unresolved. Blocks must propagate to all miners promptly for blockchain to be scalable and secure. Before the next block is formed, all honest nodes receive a message from the miner, who is responsible for maintaining the blocks, extending it to the blockchain. The scalability and processing performance issues are brought about by the proliferation of such lengthy blockchains in the existing approach. Consequently, we present a more sophisticated and extensible blockchain solution for the Remote Patient Monitoring system. For this purpose, we have adopted the SHORTBLOCKS protocol [33], a safe method of transaction confirmation that works at any network rate.

As an alternative to lengthy blockchains, SHORTBLOCKS organizes all blocks into a DAG, which is a Directed Acyclic Graph. The suggested healthcare system's design is shown in Fig. 3.3, where each layer represents the integration of multiple technologies. With the decoupled capability, developers can add or remove modules from the system as needed without impacting other modules or the system as a whole. Application, cloud-based network blockchain-based service, and Internet of Things (IoT) physical layers make up the suggested paradigm [34]. Computing healthcare equipment, data storage, and communication infrastructure make up the Internet of Things (IoT) layer. Connectivity, storage, a blockchain engine, and virtualization capabilities are all provided by the cloud-based network layer. Services such as consensus, identity management, distributed ledger technology (DLT), peer-to-peer (P2P) communication, and blockchain are provided by the blockchain-based service layer.

4. Proposed Methodology. The scalability and security of blockchain, however, remain unresolved. Fast block propagation to all miners is crucial to blockchain's scalability and security. Prior to the creation of the next block, any new blocks that are extended to the blockchain by a miner (the node responsible for maintaining them) are broadcast to all honest nodes. The issue of scalability and poor computational performance arises with the proliferation of such lengthy blockchains. As a result, we provide a blockchain system that is both more sophisticated and more scalable for use in smart health care system. The proposed method 'Smart Transfer' employs a new protocol, SHORTBLOCKS. It is a secure mechanism for transaction confirmation that can withstand any network throughput. The existing system uses traditional lengthy blocks whereas the proposed new protocol, SHORTBLOCKS integrates all blocks into a Directed Acyclic Graph.

As part of the proposed system, patients can access a variety of wearable medical equipment, including insulin pumps, blood pressure monitors, and more. A smartphone or tablet receives the health records and sends them to an application that formats and aggregates them. The finalized data, along with the specified threshold value, is transmitted to the appropriate smart contract on the private blockchain for thorough investigation. If the value is less than or equal to the threshold, the health reading is considered to be outside the normal range.

A public blockchain event will be created and alerted to smart devices and hospitals via the smart contract if the health reading is aberrant. Oracle [2] is one example of a smart contract that can talk to smartphones and other Oracle smart devices directly.

When an alert is issued, the public blockchain will only store the event. Certain Electronic Health Record (EHR) storage will receive the health data measured by wearable devices. Furthermore, electronic health record storage will receive treatment instructions from smart contracts or hospitals, and the blockchain will record the transactions. Integrating blockchain transactions with EHR ensures the integrity of patient medical records. As a result, it's easier to keep patient records in EHRs confidentially and to spot any unauthorized changes. Only designated nodes are able to execute smart contracts. Another responsibility of these selected nodes is to validate the new block. Care professionals, device manufacturers, and patients themselves are some of the potential viewers who could assist in limiting data exposure.

4.1. Components. The proposed system 'SHORTBLOCKS' consists of the following components:

- a) **Wearable Sensors:** In order to communicate medical history, people are increasingly turning to wearable health devices. Smartphones link these devices, and raw health data is sent to them. These cutting-edge gadgets will soon be able to detect heartbeats, breast cancer through an implant worn in clothing, and glucose readings without ever collecting blood.
- b) **Patient:** When a patient uses the system, it will record all of their medical history. Such information could include, among other things, heart rates, sleeping circumstances, and distance travelled. The onus for authorizing, rejecting, or revoking data access from third parties like insurance companies or healthcare providers should be on the patients themselves. After all, patients are the rightful owners of their personal data. In the event that medical attention is required, the patient will divulge their personal health information to the doctor of their choice. A patient has the right to cut off any communication with their healthcare provider, insurance company, or doctor once treatment has ended.
- c) **Health care Assistant:** Health organizations and insurance companies employ healthcare providers to conduct diagnostic tests and treatments. The healthcare provider can initiate a request for access to patient's medical records and treatment history. They treat them as soon as they receive the signal alert from the organization.

- d) Proposed SHORTBLOCKS: We employ two protocols based on blockchain technology: first, a private blockchain where all experiments involving patient health data are executed using smart contracts; second, a public blockchain where alerts are written and sent to smart devices and hospitals in the event that smart contracts issue them. These blockchains are built on proposed protocol.
- e) Healthcare organization: Any time a patient needs medical attention or would need a competitive price for future coverage, they can contact their health insurance provider. The insurance provider may request access to customer data, such as health data from wearable devices and medical treatment history, in order to offer the finest healthcare facilities. It is also possible to store insurance claim occurrences in the blockchain.

4.2. Requirements. The following are the essentials in the proposed method:

- Health or treatment data stored on the blockchain can only be accessed by authorized entities. Secure logging of Internet of Things (IoT) devices, such as smart contracts, is essential for maintaining an accurate timeline of events and safeguarding the integrity of patient care. The patient must grant access to their healthcare provider or insurance company before they can see their medical records or treatment information.
- Accurate and hacker-proof medical gadgets and health data are essential. Blockchain is the ideal technology for healthcare systems since it is impossible to remove or alter data from individual blocks. Unfortunately, blockchain's poor processing speed means it cannot be relied upon in isolation. To achieve this goal, we are utilizing the SHORTBLOCKS protocol, which outperforms the original blockchain technology in terms of speed and security.

4.3. Algorithm. Patient information is collected through wearable devices and the information is sent to smart applications for processing. The processed information is sent to smart contract for further examination using private blockchain. If the readings exceed the abnormal value, then alert is raised. The alert event is then stored in public blockchain and alert is sent to the patient.

Shorblocks method will work as

1. Patient information is collected from wearable devices implanted in patients body
2. Smart Devices placed in the hospitals will collect the patients data. This information is placed in private blockchain.
3. After full examination of the patients data, if any emergency found, an event is raised.
4. An event is written in public block chain and alert is raised to the hospital(H), patient and mobile device for information.
5. Thus Shortblocks ensures the scalability, security and privacy of smart health care system.

Algorithm SHORTBLOCKS

procedure SHORTBLOCKS (P, PrB, PuB, H)

{

// P = Patient

// PrB= Private Blockchain

// Pub= Public Blockchain

// H=Hospital

Step:1 Patient(P) information is collected using wearable smart devices.

Step:2 Information is sent to the Smart devices, smart contracts

Step:3 The formatted information from the smart contract is sent to the private blockchain (PrB) for full examination

Step:4 If the information received, after full examination is found above the threshold, then it is declared as abnormal condition of the patient, needs treatment.

Step:5 An event is written in the public block chain(Pub) and alert is raised to the hospital(H), patient and mobile device for information.

}

end procedure

Fig. 5.1: SHORTBLOCKS cluster arrangement

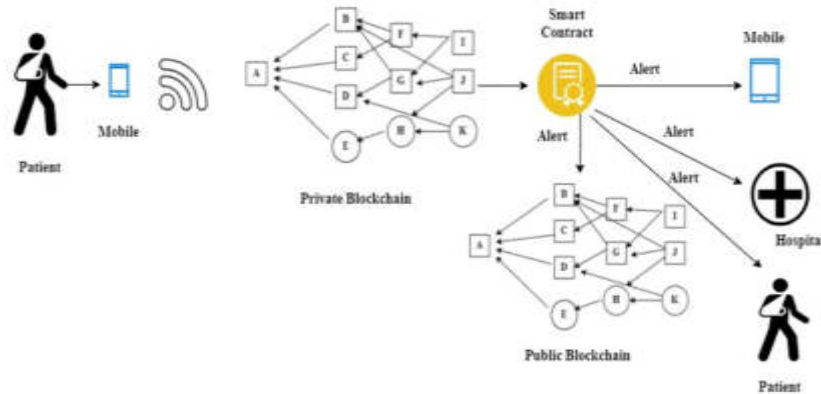

Fig. 5.2: SHORTBLOCKS process

5. Implementation. The efficiency with which each block is sent to all network miners prior to its creation determines the protocol’s security. The process of creating blocks is tedious because a proof-of-work is required for each new block. A secure blockchain will have a block propagation time that is less than or equal to the time it takes for the entire network to generate a new block. With only three to seven transactions per second, blockchain is severely limited in its throughput.

The proposed SHORTBLOCKS protocol, on the other hand, is more suited to blockchain deployment in practice. A Directed Acyclic Graph, is used to arrange blocks in the proposed new protocol instead of a lengthy chain of blocks. The blocks are organised into a k-cluster via SHORTBLOCKS protocol, with blocks outside the cluster being indicated by square and those inside the cluster being indicated by oval, as depicted in Fig 5.1.

Patients in our proposed system use a variety of wearable medical devices, including but not limited to blood pressure monitors, insulin pumps, and others. The application formats and aggregates the health information that is provided to smart devices like smartphones and tablets. After finishing, the applicable smart contract receives the formatted information and sends it to the private blockchain for full examination, together with the threshold value as shown in Fig. 5.2. If the health reading is below the threshold value, it is considered abnormal compared to standard readings. Appropriate treatment will be suggested. An event will be created on the public blockchain and alerts smart devices and hospitals if the health reading is aberrant.

When an alert is issued, the public blockchain will only store the event. The data collected from wearable health monitors will be sent to a specific Electronic Health Record, EHR system for storage. Along with the transaction event being saved on the blockchain, smart contracts or hospitals will also transmit treatment commands to EHR storage. The integration of blockchain technology with electronic health records (EHR) allows for the verification of personal health information. Protecting and identifying changes to patient records in electronic health records is made easier with this. Not all nodes can execute smart contracts. Additionally, it is the responsibility of these selected nodes to validate the new block. One way to limit the exposure of data

Table 6.1: Input Patient Data for the Experimental Analysis

Patient	A	Threshold
Heartbeat	80	>100
Blood Group	A	-
Blood Pressure	130/75	150/100
Diabetic Level	320	>200
Temperature	99	>103

Table 6.2: Avg Time Compariso

Data Type	Proposed method – ‘SHORTBLOCKS’ protocol (with Blockchain Avg Time in Sec)	SPECTRE protocol Avg Time in Sec	GHOSTDAG protocol Avg Time in Sec	Simple – Blockchain Avg Time in Sec
Block creation	0.643	0.665	0.687	0.736
Block updating	0.476	0.492	0.517	0.537
Block sharing	0.491	0.503	0.512	0.523
Block deleting	0.679	0.702	0.728	0.754

is to limit who can view it. This includes healthcare practitioners, manufacturer of the devices, and patients themselves.

6. Result Analysis. The proposed method “SHORTBLOCKS” and the existing simple blockchain method are compared in terms of performance parameters viz. Avg. time, Latency, Processing Overhead. The input data collected from the Patient A, using wearable devices for the experimental analysis is tabulated below in Table 6.1.

As the diabetic levels are above the threshold from the above input data, alert will be raised to the patient, using the public block chain for preserving the event.

a) Avg. Time. Based on the change in treatment registration requests (Transactions count) received, Fig 6.1 shows the time-to-mine comparison of two ways on existing method of using blockchain and proposed method of blockchain with SHORTBLOCKS protocol. The results are shown in seconds. On one side, we have processing time, and on the other, we have the number of treatment registration requests, transaction count. From the graph, it is clear that both methods show a trend towards increasing treatment registration requests after the first 100 or so numbers. By lowering the waiting time in the mining queue, the proposed method with SHORTBLOCKS protocol offers higher performance as compared. The Avg. time comparison between the proposed and existing methods is tabulated in Table 6.2.

b) Latency. Figure 6.2 and Table 6.3 shows the results of an investigation on the invoke transaction execution latency for the suggested system, and the existing system, broken down by user groups: 10, 20, 30, 40, and 50 users. Increasing the average latency in relation to the number of users makes change.

c) Processing Time. The results of the simulations for evaluating the systems’ performance in terms of processing overhead are shown in Figure 6.3. Many resource metrics, such as processing time, bandwidth, indirect memory, and an excess memory, may be necessary for the validation of new blocks in blockchain. The technical term for this is processing overhead. This value is discovered to be less in the suggested model when contrasted with certain current approaches. In contrast to the present models, the suggested solution outperforms them in terms of processing speed and data security. Table 6.4 depicts the statistics.

7. Conclusion. This article proposed that smart contracts built on the ‘SHORTBLOCKS’ blockchain be used to analyze patients’ health data in real-time. Using the ‘SHORTBLOCKS’ protocol, the system records the data of transactions on the blocks and utilizes smart contracts to generate notifications for the healthcare provider and patient as needed. This methodology ensures that health-related notifications are sent in a secure way in compliance with safety regulations. This method provides safe and secure patient data transmission and

communication using two blockchain viz. private and public blockchain. Due to the enormous size inflation that would result from storing complete health records on a blockchain, which would necessitate substantially more storage space at each node, we do not keep patient health information in the blockchain. Only the event raised will be facilitated in the public blockchain.

As a result, EHR (Electronic health record) gets the health data. The use of blockchain technology as a ledger and the integration of electronic health records (EHR) for the purpose of authenticating patient medical history data is only documenting the occurrence of events. Consequently, this will aid in the detection and prevention of data tampering with patient records in EHR. When energy consumption and sluggish computing are big issues, our model offers a quick, secure, and high-throughput alternative to standard blockchain-based remote patient monitoring.

Acknowledgment. The authors acknowledge the support and cooperation rendered by all the members directly and indirectly.

ENHANCED THROTTLED LOAD BALANCING FOR VIRTUAL MACHINE ALLOCATION IN MULTIPLE DATA CENTERS

P.HANUMANTHA RAO *AND DR.P.S.RAJAKUMAR †

Abstract. "Cloud computing" hosts software and other services in remote data centers that customers can access worldwide. The user may access all the services and applications online. The IT industry has benefited greatly from the proliferation of cloud computing. On the flip side, organizations moved their operations to the cloud as a result of industrial automation. A surge in demand for cloud computing was directly correlated to the quick migration of businesses. Businesses looking to minimize expenses without sacrificing service quality will find this approach to be ideal. Considering the meteoric rise of cloud computing, service providers are delighted. Contrarily, distributing resources is a challenging task. Cloud computing overcomes some of its most fundamental obstacles, one of which is the load-balancing approach employed by load-balancers to economically optimize costs while minimizing time expenditures. Quick services for cloud customers and minimal cost for cloud providers are the goals of the optimal resource allocation method. This research suggests a novel approach to increase task processing time, which can aid in increasing cloud computing's load balancing capabilities. The proposed method Enhanced Throttled Load Balancing Algorithm (ETLBA) is an upgrade to the original Throttled Algorithm, which efficiently performs resource allocation and load balancing. The proposed ETLBA is contrasted with the existing algorithms, Round Robin, Active Monitoring Load Balancing Algorithm (AMLBA) and Throttled Load Balancing Algorithm (TLBA) to display the efficacy. Cloud Analyst tool simulates the proposed and existing methods. According on the results of the simulations, the proposed algorithm ETLBA achieves better outcomes than the popular existing algorithms in terms of processing time, request processing time, and datacenter cost. It shows 18% reduction in response time, 7% reduction in data center processing time, 16% reduction in data center request processing time and 4% less data center cost compared to the existing solutions. ETLBA performs better by selecting virtual machines using a prioritized index table and consumption index. It limits idling resources, improves response as well as reduces processing times, and cloud costs compared to conventional solutions.

Key words: Cloud Computing, Resource Allocation, Round Robin, Load Balancing, Throttled Load Balancing, Enhanced Throttled Load Balancing, Improved Response time, Data center Cost.

1. Introduction. "Cloud computing" is a system that lets people share and access large amounts of data and other resources. After using a service, users only pay for what they spent. The open environment of cloud computing allows to demonstrate how data, software packages, and distributed resources are stored.

Many multinational corporations (MNCs) offer cloud services, including Microsoft, Amazon Web Services, and many more [1]. "Software as a service," "infrastructure as a service," and "platform as a service" are the three most prevalent models of cloud computing [2]. In this context, "Infrastructure as a service" is exemplified by AWS EC2 instances. Google Apps is an example of software as a service, while Microsoft Azure is an example of a platform as a service.

Cloud computing primarily assists in the sharing of resources, data, and internet-based applications. Using web-based apps, it offers consumers on-demand services. Concerns regarding data backup and restoration are unfounded. Fig. 1.1 shows the elaborated infrastructure of the cloud computing with all the components included.

The benefits of cloud computing is its usability and cost-effectiveness of its administration. It features many desirable traits, including, but not limited to, reliability, virtualization, multitasking, improved framework cost, and referenced highlight assistance. The innovation that is stepping forward is cloud computing. A large number of startups nowadays use cloud computing. Instead of purchasing the foundation, business innovators are saving time, money, and office space by connecting the cloud benefits using PCs. In cloud computing, users

Fig. 1.1: Cloud Computing Infrastructure

can access services on an as-needed basis and pay for them in advance. This is why cloud computing services are becoming increasingly popular among customers with occasional needs.

Cloud computing aims to improve efficiency, decrease computational power requirements for thin devices, decrease operational expenses, increase security, and speed up data processing. In addition to these benefits, it makes the system more resilient to changes, faster at processing various data sets, less expensive overall (hardware, software, and maintenance costs), more energy efficient and less space hungry on discs [21].

In order to keep up with demand, organizations are distributing the burden among multiple servers. A technique known as "load balancing" is employed to ensure that no single server is overwhelmed. Delays, request drops, or even crashes may occur if the system is overloaded. In order to distribute the processing load among numerous servers, Load Balancing makes use of network connections. It reduces total response time and maximizes throughput [3]. To avoid any server going down due to overload, load balancing is essential.

When it comes to cloud environments, load balancers are efficient. Servers can be rendered inoperable due to crashes caused by extremely heavy workloads. All procedures rely on consistently fast response times and high availability of services. In addition to detecting downed servers, load balancers can reroute requests to up and operating servers. If one server is too busy, a load balancer can send requests to another. Load balancers primarily aim to ensure that servers are in better health. Servers and users are regulated by a load balancer.

It processes data packets sent by networks and applications. In order to perform multi-server request distribution, a load balancer employs a number of techniques. There are two tiers to load balancing: Level one, which entails establishing a link between the applications or services and the virtual machines that are being requested. Layer 2 entails establishing a link between physical hosts and virtual machines [4],

Load balancing is a vital component of cloud computing, for efficient resource allocation across multiple data centers. Many existing and popular load balancing techniques are used for resource allocation. But response time is the crucial factor that evaluates the efficiency of these techniques. The primary objective of this article is to present a novel approach for improvising the response time and optimizing the data center costs when compared with existing algorithms. The proposed method Enhanced Throttled Load-Balancing Algorithm (ETLBA) aims at efficient load balancing by improvising the existing throttled load balancing technique. This study presents a contrary of outcomes obtained through the use of "Cloud-Analyst Simulator". The results demonstrate that the suggested algorithm decreases the total processing time spent for the requests and response time of the datacenter.

This is the remaining structure of the paper: Section 2 presents work in this area along with the description of the several load-balancing algorithms. The proposed algorithm, along with its flowchart and pseudo-code, is presented in Section 3. The paper's section 4 details the experimental setting. While the results of the

Fig. 2.1: Round Robin Algorithm Process

comparison and analysis are presented in Section 5. The paper is concluded in Section 6.

2. Literature Review.

2.1. Load-Balancing Algorithms. There are a plethora of loadbalancing techniques available in the cloud. Active Monitoring LoadBalancing (AMLB), Round Robin (RR), and Throttled (TLB) are the three most used load-balancing algorithms [5]. The algorithms that were employed are evaluated using "Cloud Analyst Simulator".

2.1.1. Round-Robin Algorithm. When it comes to time-sharing systems, the useful and most popular load-balancing method is Round-Robin. With Round-Robin, virtual machines (VMs) are distributed fairly in a circular order. Assuming the processing powers of the virtual machines are equal, this method provides benefits such as being easy to understand and implement, guaranteeing fairness in operations, and handling tasks promptly.

Distributing client requests among servers is made easy with this method. Requests from clients are received sequentially by each server. Since it is simple to both understand and apply, it ranks high among the most popular algorithms [6].

This method iteratively routes client requests to the servers that are available. When server processing and storage capacities are close to one another, it works well. This process sends requests to the node with the fewest connections, which means that at any one moment, a few of nodes can be experiencing excessive load, while others are completely unoccupied. Fig. 2.1 depicts the process of Round Robin Algorithm.

Within this algorithm, there is no famine. Round Robin's drawbacks include a lack of scalability and flexibility, the fact that some nodes may be under tremendous strain while others sit idle, and the fact that the former allocation status of the virtual machine is not preserved.

2.1.2. Weighted Round-Robin Algorithm. The Weighted Round-Robin algorithm takes its cue from the Round-Robin method and employs a weight table to allocate tasks to virtual machines according to their capacities. It executes circular distribution using this table. The algorithm's benefits: enhances the Round-Robin algorithm by incorporating a weight-table of virtual machines' processing capacities into its rotational operation; this makes the method more efficient than the original in situations when the processing powers of the virtual machines vary. The lack of scalability and flexibility, as well as the inability to restore the prior allocation status of virtual machines, are further drawbacks. Fig. 2.2 depicts the process of the algorithm.

2.1.3. Active Monitoring Load Balancing Algorithm. Because of the unpredictable nature of cloud computing, certain servers may experience excessive load during equally distributed current execution, while others may be inactive or barely touched. Similarly, by shifting resources from overburdened to underutilized servers, load distributing boosts performance. One important characteristic of cloud computing is efficiently distributing resources in the cloud and scheduling, which is used to evaluate the system's performance [7].

Fig. 2.2: Weighted Round Robin Algorithm Process

Optimization of costs, as a result of faster response and processing times, is affected by the attributes taken into account.

Clients submit their jobs to the computer system here. Each job that is submitted to the cloud is added to a stack and queued as it arrives. After making an estimate of the job's size, the cloud manager verifies the virtual machine's availability and capacity. The job scheduler assigns the specified resource to the queued work without delay as soon as the job size and the size of the accessible asset (virtual machine) are in agreement [8].

The major drawback of this algorithm is, in order to assign resources to a free virtual machine, it sequentially evaluates each virtual machine which is time consuming process.

2.1.4. Throttled Load Balancing Algorithm. A static load-balancing method best describes this technique. Here, we begin by verifying the values of each virtual machine's index. For system resource allocation, the a request has been forwarded to the point where the load balancer parses a table. To update the allocation policy, a particular load balancer is notified of the request, which then either returns it to the requester or processes it in reverse [9]. The complete procedure of deallocating the system begins once the allocation of the system is successful.

The increased performance and utilization are the results of this mechanism's provision of more sharing and allocation of system resources. The throttling threshold is typically set at 1. The threshold might be set to a user-specified value with little configuration.

At all times, this algorithm's fixed quantity of cloudlets are allotted to a single virtual machine. The quantity of virtual computers (VMs) available at the datacenter determines how incoming requests are dealt with if there are more request groups. Aside from that, it waits for the next available virtual machine to become available.

In comparison to the Active Monitoring Load Balancing (Optimal) technique, this algorithm represents an incremental improvement. Initially, this algorithm begins its search from the most recently allocated virtual machine all the way up to the n th virtual machine. Nevertheless, there is still a problem, and that is the fact that it does not make use of those virtual machines that become available subsequently to the execution of the request. The below Fig. 2.3 represents the procedure of Throttled Load-balancing algorithm.

2.2. Related Work. Using a throttled load balancing method in a multiple data centers, the study [10] optimized response time by distributing workloads across virtual machines. After much deliberation, they settled on the throttled load balancing algorithm as the best option for the data center in terms of processing time for requests and total response time, with minimal processing expenses.

The authors of [11] presented their idea for the Advanced Throttled Load Balancing Algorithm in the year. A priority is given to every virtual machine. Depending of the capacity of the virtual machine (VM) as well as the number and size of tasks that have been given to the operation, the priority is determined. Among the several virtual machine (VM) sets that are accessible, the enhanced tuning scheduler chooses the VM that has the highest priority. In addition, a level of priority is established in order to prevent overloading. On the other

Fig. 2.3: Throttled Load-Balancing Algorithm Process

hand, if the virtual machine's priority is lower than the priority level, then the job will not be assigned to that virtual machine.

The paper [12] suggested an effective procedure for load balancing that is dependent on two distinct characteristics. The time it takes to respond to queries is the first distinguishing feature, and the second characteristic is the load distribution among the virtual machines that are already in existence. They contrasted the throttled variant with the Round Robin approach and suggested a tweaked version of the throttled algorithm.

Furthermore, it was discovered that the utilization of virtual machines (VMs) is more effective when using the Round Robin algorithm and the changed Throttled algorithm in comparison to the Throttled algorithm. In addition, out of the three algorithms tested, the Modified Throttled method yielded the best average reaction time.

The review study conducted in [13] demonstrates that load balancing is an essential technique of the cloud computation environment. It contributes to the improvement of load distribution and the efficient allocation of resources, particularly with regard to the enhancement of response time for cloud users. According to the article, there are a great deal of problems associated with LB. Some of these problems include the scheduling of activities, migration, and the utilization of resources, among other things. Research and studies on load balancing that have been conducted over the previous six years are surveyed and analyzed by the writers. This analysis's findings also show that intelligent methods, including AI and ML, have potential for cloud-based learning analytics. In particular, this study benefits researchers in identifying research topics connected to load balancing, particularly with regard to reducing the response time and avoiding breakdowns in the servers. Another benefit of this research that supports our idea is the availability of tools required for simulation and experimental contexts. This research focuses on the modelling resources.

The exceptional quality of Cloud Analyst and Cloud Sim as top-tier resources for this area of research is another thing that they demonstrate. This is the advantage of employing these tools.

A modified throttled balancing technique was proposed in [14], which they then implemented with the help of the CloudAnalyst tool of CloudSim. Following this, they checked it against other methods of load balancing and confirmed that a tweaked throttled algorithm outperformed the more traditional approaches.

The paper [15] suggested using a neural inference fuzzy system for load effective balancing. In this study, the authors also discuss the safety of virtual machines (VMs) within cloud-hosted environments. There is a correlation between load balancing and the NP-hard optimization issue. According to Forbes, they are following the news regarding the implementation of the Protection of Personal Information Act. Security of the cloud continues to be a problem, and the current system makes use of a hybrid-based fuzzy LB, but this does not satisfy those requirements. In order to improve CPU utilization and turnaround time, the authors proposed their work, which they referred to as MANFIS (Modified Adaptive Neuro Fuzzy Inference System).

In addition, they focused on increasing the level of security that their work offered. Utilizing the Fire-fly Algorithm allows for the optimization of the parameters of the MANFIS system. Utilizing the Enhanced Elliptic Curve Cryptography allows for the implementation of security measures for user authentication. Users can be authenticated using this method, which does not require a password. Based on the findings, the authors inform

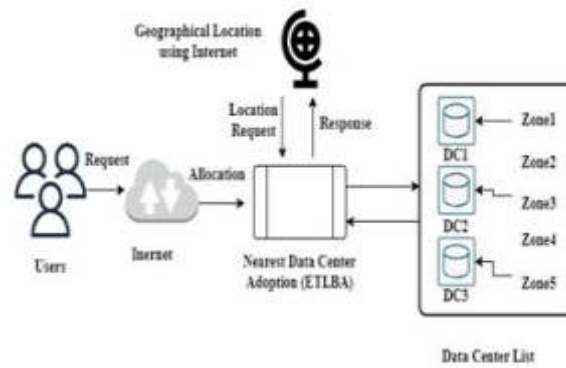

Fig. 3.1: Nearest Data Center Adoption (ETLBA)

us that cloud security has been enhanced and meets our expectations. Further, the experimental results reveal that they outperform the current system in terms of resource utilisation, cost, and execution time.

In their study, the authors of [4] introduced three algorithms for load balancing. These algorithms find use in cloud computation. Here are three algorithms: RR, AMLB, and TLB, which stand for “round-robin, active load-balancing monitoring, and throttled load-balancing”, respectively. Following an analysis of the three load balancing algorithms’ performance, it was determined that TLB outperformed the others in terms of data centre time and reaction time.

3. Proposed Method - Enhanced Thottled Load Balancing Algorithm (ETLBA). We propose an Enhanced Thottled Load Balancing Algorithm (ETLBA) as a solution to the problem that arises while utilizing the throttled load balancing algorithm. The proposed method consists of three major components:

1. Nearest data center adoption
2. Load Balancer with availability index
3. Usage index of Virtual Machines.

3.1. Nearest Data Center Adoption. The rapid development of cloud platforms has resulted in service providers maintaining many data centres spread out over the globe. The data centers that make up the cloud computing environment are dispersed throughout multiple regions.

The proposed work implements the nearest data center (DC) adoption such that to improvise the response time. The DC-1 server is hosted in zone 1, the DC-2 server is hosted in zone 3, and the DC-3 server is hosted in zone 5. The allocation of virtual machines in accordance with the proposed policy for the data center is done based on which are geographically nearest [16].

The procedures that make up the suggested algorithm for selecting the data center that is geographically nearest to the user, is listed below

1. The request is presented by the first user.
2. The database of Internet characteristics will be responsible for maintaining the table of region proximity
3. The request was forwarded to the data center that was found to be the closest.
4. In the event when multiple DC is experiencing the same network delay.
In order to maintain a balanced load,
 - a) Assign the DC in a random fashion.
 - b) Give the DC with the lowest possible network latency
5. Make sure the data center policy is keeping up to date.

The process is depicted in the Fig. 3.1.

3.2. Load Balancer with availability index. The databases of virtual machines provide the basis of a throttled algorithm. Load balancers keep track of virtual machine identifiers and the status of their services, such as whether they are available or busy [17].

The following steps depict the role and process of load balancer with availability index in the proposed ETLBA.

1. Load Balancer creates and updates an table of index for each virtual machine. Additionally, it monitors the availability and busyness of each virtual machine. When the programme began running, every single virtual computer was online.
2. User initiates the request and that will be allocated to nearest Data Centre as mentioned in part 1. Now Data center Controller is then assigned a new user request.
3. The Data Centre Controller will call the Load Balancer in order to allocate the virtual machine to the next available slot.
4. After that, when all available virtual machines are ready, the Efficient throttled load balancer will begin to build a new map.
5. Then, if the length of the available VM map is larger than zero, the efficient throttled load balancer will deconstruct the map and retrieve the first VM ID from it. After that, the process will be taken up by part 3 of the proposed method ETLBA

3.3. Usage Index of Virtual Machine. In this part, the proposed ETLBA maintains the usage list of all available VMs. The most recent task's total processing time is used to compute usage. The overall cost of a datacenter is determined by adding up the costs of data transfer and virtual machine rental.

1. The efficient load balancer monitors the usage of the VM who's ID was retrieved. If the selected one is with the lowest usage, it retrieves its ID from the "Available Index" table and returns it to the datacenter controller (DCC).
2. Otherwise the available virtual machine with lowest usage is searched again in the index table and retrieved, further for forwarding to the data center controller.
3. The Data Centre Controller receives the VM id from the Enhanced Throttled Load Balancer.
4. Based on that identifier, the Data Centre Controller will pass the call on to the appropriate virtual machine.
5. After the new VM_ ID has been allocated, the data center controller informs the enhanced throttle load balancer and removes the corresponding entry from the available virtual machine map. And keeps the status as 'Busy'.
6. After the Enhanced Throttled Load Balancer receives the request from the Controller of Data Centre, it upgrades the VM map of the available virtual machines accordingly.
7. The following procedures are executed in the event that the virtual machine (VM) in Fig. 3.2 requested does not appear in the VM Map:
 - a) The Enhanced Throttled Load Balancer returns 1.
 - b) The database administrator will then add the request to a queue.
 - c) The Enhanced Throttled Load Balancer receives a alert from the Data Centre Controller when the processing requests of each virtual machine are finished and the response has been received. It then de-allots the respective virtual machine and adds its ID to the available VM Map.
 - d) In the instant after a VM is de-allocated, the Data Centre Controller examines the request queue. If there are any calls in the pending queue, processing will start at the third phase and continue thereafter.

3.4. Procedure - ETLBA.

Procedure Enhanced Throttled Load Balancing (ETLBA)_Part 1.

- Step 1: Users sends requests from different regions for resource allocation.
 Step 2: Database of Internet characteristics will maintain the table of region proximity
 Step 3: While(New request are received by the Nearest Data Center Adoption Method)
 Step 4: Check (Nearest Data Centre =available)
 Step 5: Allocate the user request to the nearest Data Centre with low latency
 Step 6: In case of multiple nearest data centre with same latency
 Step 7: Allot the nearest data center on random basis
 end procedure

Fig. 3.2: Procedure of ETLBA

Procedure Algorithm Enhanced Throttled Load Balancing (ETLBA)_ Part 2.

- Step 1: Make sure that all virtual machines are first assigned the state of "AVAILABLE" in the VM State list; otherwise, set it to "BUSY."
- Step 2: While(New requests are received by the data center Controller)
- Step 3: If (available VMArray () >0)
- Step 4: If 'Yes' :
- Step 5: Check (Usage_VM.Selected =least)
- Step 6: Return the VMID to the data centre
- Step 7: else : Search for the next least usage available VM
- Step 8: If (available VMArray () =0) Data Centre Controller queues the request
- Step 9: Repeat Step 3
- end procedure

Procedure Enhanced Throttled Load Balancing (ETLBA)_ Part 3.

procedure Enhanced Load Balancer_Usage Index

Begin

- Step 1: VM_Id = 1; Min = 0; i=0;
- Step 2: For each VM_selected in VMList
- Step 3: usage = vm.getUsage();
- Step 4: vmId = vm.getId();
- Step 5: If i== 0 then
- Step 6: min = usage;
- Step 7: Else

```

Step 8: If min > usage then
Step 9: min = usage;
Step 10: End If
Step 11: End If
Step 12: i++;
Step 13: End For
Step 14: Return VM_Id;
Step 15: End

```

The proposed method “ETLBA” allocates resources efficiently as mentioned in the above procedure. In detail the above procedure works as: User sends request from different regions for resource allocation. All these requests are maintained region wise by the internet database. If the nearest data center is free, then it is allocated to the user request based on priority. All the user requests are queued by the data center controller. If more than one nearest data center is free, then the nearest one is allotted on random basis. All the data centers are tagged with index of availability and busy status. The data center with index available are chosen for allocation in response to user request. If two or more datacenters nearer to the user region are available with availability index then their usage is checked to choose for allocation. Once data center is allocated to the user, then its status is marked as busy and if freed, as available by data center controller.

4. Experimental Setup. Data center load balancing techniques can be cost-effectively tested using simulation. A simulated data center environment can be modelled using a variety of tool sets. Cloud Analyst simulation makes it easier and faster to examine the data. Cloud Analyst Simulator makes use of a number of technical phrases, so let’s review them.

4.1. Simulator - Cloud Analyst . The cloud computing environment ‘simulator’ that is most often used is Cloud Analyst [18]. It is an event driven simulator [19].

The major considerations are:

1. There are six distinct regions on the Earth map in the Cloud Simulator. Data centers and user bases can be located in any of the six zones.
2. The internet as it exists in the real world serves as the model in Cloud Analyst Simulation. The transmission delay and latency are caused by the traffic on the internet.
3. In the Cloud Simulator, a collection of users is referred to as a User Base. Hundreds of users could make up a single user base at times. One tool for producing load is the user base.
4. An Digital cloud-let is a user’s collection of requests. Execution commands, input files, and output files are all carried over the Internet cloud
5. Cloud Analyst Simulator revolves around its controller. It will oversee operations in the data-center setting, like the creation and deletion of virtual machines.
6. The Controller determines which virtual machine (VM) should execute the cloud task by using a virtual machine load balancer (VmLoadBalancer).

4.2. Simulation Settings. Zone1, Zone2, Zone3, Zone4, Zone5, and Zone 6 were labelled on the global map [20]. The social media platform X, which boasts over 300 million active users globally, is worth considering. The same is depicted in Fig. 4.1 [20] and Table 4.1.

For cloud usage and load balancing simulation, 5% of ‘X’ users are used. Additional assumptions include 10% of users being online at the busiest times and 10% being inactive during peak hours. We will define six in total, user databases for the six available zones, using the specifications in Table 4.2.

Fig. 4.2 displays the sample settings of the primary configuration section, which includes the following: user bases, application deployment configuration, and simulation duration.

The user requests are generated by each userbase and delivered to the processing facility for data storage. The various configurations of data centers are detailed in Table 4.3, which includes information such as the operating system, hardware type, and the cost of individual operations.

5. Results and Performance Analysis. After running simulations with the aforementioned parameters, we compared the results based on Data processing time, Overall response time, Data Center request servicing time, and Data Centre cost for the following load balancing algorithms: Round Robin, AMLBA - Active

Fig. 4.1: DC1, DC2, DC3 cloud analyst simulation

Table 4.1: X Users

Zonal Name	Zonal-Id	Registered -U sers	Sample-data (5%)
North America	1	95 Million	35,00,000
South America	2	25 Million	15,00,000
Europe	3	75 Million	25,00,000
Asia	4	35 Million	18,50,000
Africa	5	6 Million	3,50,000
Australia	6	10 Million	6,00,000

Monitoring Load Balancing Algorithm, TLBA-Throttled Load Balancing Algorithm, and the proposed method, ETLBA-Enhanced Throttled Load Balancing Algorithm.

In terms of the performance parameters mentioned earlier, the results based on simulation show that the suggested method Enhanced Throttled Load Balancing Algorithm (ETLBA) performed better than the existing methods Round Robin, Active Monitoring Load Balancing Algorithm (AMLBA), and Throttled Load Balancing Algorithm (TLBA). Below, we'll go over the same.

5.1. Overall Response Time. The amount of time it takes for the desired process to finish processing is known as response time. Round robin has an average reaction time of 179.34 milliseconds, AMLBA is 177.43 milliseconds, throttled is 171.61 milliseconds and the proposed ETLBA is 164.53 milliseconds. Based on our findings, the load balancing algorithm is not well-suited to Round Robin, AMLBA, TLBA, due to the increased response time it requires. Consequently, the proposed Enhanced throttled load balancing algorithm ETLBA outperform the other three existing in terms of response time. Fig. 5.1 graph express the performance of proposed method ETLBA in terms of Avg. Overall Response Time.

5.2. Data Center Processing Time. A load balancer's processing time in a data center is the amount of time it takes to handle all of the necessary requests. The proposed method ETLBA consumes 16.32 milliseconds, TBLA takes 23.89 milliseconds, AMLBA takes 41.12 milliseconds, and Round-robin takes 43.35 milliseconds. When compared to the RR, AMLBA and TBLA algorithms with respect to processing time in the data center, ETLBA is appropriate. The same is shown in the below graph in Fig. 5.2.

5.3. Data Center Request Servicing Time. Service time for request is also determined by the datacenter's serving time, which does not include the time it takes to transport data to the user. The proposed method ETLBA consumes 216.28 milliseconds, TBLA takes 37.17 milliseconds, AMLBA takes 45.36 milliseconds, and Round-robin takes 52.25 milliseconds. When compared to the RR, AMLBA and TBLA algorithms with respect

Table 4.2: User Database Configuration

User Database	Zonal Id	Requests per user per Hx	Data Size per request (byte)	Peak Hour (GMT)	Avg. Users in peakbss	Avg. Users nonpeals hrs
UB 1	1	60	100	13: 00 15: 00	5,00,000	50,000
UB 2	2	60	100	15: 00 17: 00	2,00,000	20,000
UB 3	3	60	100	20: 00 22: 00	3,00,000	30,000
UB 4	4	60	100	01: 00 03: 00	2,35,000	23,500
UB 5	5	60	100	21: 00 23: 00	35,000	3,500
UB 6	6	60	100	09: 00 11: 00	80,000	8,000

Name	Data Center1	Data Center2	Data Center3
Region-ID	1	3	S
Configuration	X86	X86	X86
Operating System	Linux	Linux	Linux
Virtual Machine	Xen	Xen	Xen
Cost of VM	0.2 \$ / hr	0.2 \$ / hr	0.2 \$ / hr
Cost in terms of Mernory	0.10 \$ / sec	0.10 \$ / sec	0.10 \$ / sec
Cost of Data Transfer	0.2 \$ / GB	0.2 \$ / GB	0.2 \$ / GB

Fig. 5.1: Avg. Overall Response Time Comparison

Fig. 5.2: Avg. Data Center Processing Time Comparison

Table 5.1: Overall Response Time

Algorithm	Overall resp onsetime(ms)		
	Avg(ms)	Min(ms)	Max (ms)
Round Robin	179.34	46.43	671.56
AMLBA	177.43	45.24	669.46
TLBA	171.67	43.63	663.45
ETLBA	164.53	41.28	651.43

to requests processing time in the data center, ETLBA outperforms the existing algorithms and the same is depicted in the below graph in Fig. 5.3.

5.4. Data Center Request Servicing Time. The datacenter cost is determined by adding up all the works performed by the virtual machines. These works can include diverse tasks including ALU operations, CU operations, storage operations, and more. Round robin method has incurred cost of 29.03 \$, while 26.82 \$, 23.93 \$ for AMLBA and TLBA respectively, whereas the proposed ETLBA is 21.78 \$. Based on simulation findings, the Round Robin, AMLBA, TLBA, are not cost effective, compared with the proposed Enhanced throttled load balancing algorithm ETLBA. The graph in Fig. 5.4 shows the data center costs of all the existing and proposed algorithms.

Fig. 5.3: Avg. Data Center Request Processing Time comparison

Fig. 5.4: Data Center Cost comparison

Table 5.2: Data Center Processing Time

Algorithm	Data Center Processing Time		
	Avg(ms)	Min(ms)	Max (ms)
Round Robin	43.35	8.89	251.33
AMLBA	41.12	8.89	252.15
TLBA	23.89	7.92	242.28
ETLBA	16.32	7.14	233.64

5.5. Analysis and Discussion. Table 5.1, 5.2, 5.3, 5.4 shows simulation results of all the four algorithms, Round robin, AMLBA, TLBA and the proposed ETLBA in terms of Overall response time, Data Center Request servicing time, Data Center Cost, and Data processing time. Out of the four methods under comparison, the ETLBA algorithm consistently produces the lowest level of outcomes. Since the four performance scenarios chosen are significantly distinct from one another, we can observe that ETLBA remains stable despite the variable inputs and performs well in all cases.

Table 5.3: Data Center Request Processing Time

Algorithm	Data Center Request Processing Time		
	Avg(ms)	Min(ms)	Max (ms)
Round Robin	52.25	10.19	263.27
AMLBA	45.36	10.09	243.27
TLBA	37.17	9.14	232.58
ETLBA	21.28	8.26	223.24

Table 5.4: Data Center Cost

Algorithm	Data Center Cost		
	VM Cost (\$)	Data Transfer Cost (\$)	Total (\$)
Round Robin	179.34	46.43	671.56
AMLBA	177.43	45.24	669.46
TLBA	171.67	43.63	663.45
ETLBA	164.53	41.28	651.43

6. Conclusion. A novel method ‘Enhanced Throttled Load Balancing Algorithm’ for effective load balancing is provided in this article. This method implements the strategy of allocating the resources to the priority user requests based on nearest data center, index and usage of the datacenter and its virtual machines. It delves into the strategy of enhancing load balancing to boost cloud computing performance in terms of response time, data center costs. Various load balancing approaches are simulated along with the proposed method for showcasing the performance, using the Cloud Analyst tool. These techniques include Round Robin, Active Monitoring AMLBA, TLBA (Throttle Load Balancing Algorithm), and the proposed ETLBA (Enhanced Throttled Load Balancing algorithm). Better time response, less resource starvation, more powerful virtual machines to handle more requests, and cost savings are all achieved by using the suggested algorithm (ETLBA). Consistently decreasing datacenter costs with this approach demonstrate the practical applicability and future development prospects of the ETLBA algorithm. ETLBA has the possibility of using and implementing the results of future research and testing. ETLBA can further be enhanced by including the region proximity based on the data centers. Real-world testing and research can be conducted with the proposed ETLBA in a datacentre.

DESIGN AND DEVELOPMENT OF AN UNMANNED/AUTONOMOUS OCEAN SURFACE VEHICLE USING SELF-SUSTAINING DUAL RENEWABLE ENERGY HARVESTING SYSTEM

KAMALAHASAN M ^{*}, MANIVANNAN S [†] AND SWAPNA B [‡]

Abstract. This study pioneers a breakthrough in sustainable energy solutions by developing a cutting-edge system for powering autonomous Smart Ocean surface vehicles. The research delves into the exploration of renewable energy harvesting techniques, specifically focusing on solar and hydro flow energy systems, with the aim of creating a self-sustaining power infrastructure. Through rigorous experimentation and modeling, we design and implement a versatile test rig setup to analyze the efficacy of these techniques under varying surface water conditions. Additionally, we investigate and assess distributed solar power systems ranging from 100W to 700W, as well as hydro flow power systems within the same power range, to ascertain their viability for real-world applications. Furthermore, we engineer and optimize the necessary electronic hardware utilizing IoT and industry-grade components, enabling efficient harnessing of dual renewable energy sources to power propulsion systems for our autonomous vehicles. This research introduces novel approaches to energy sustainability for autonomous ocean surface vehicles. The study disregards traditional methods and instead aims to unveil unconventional solutions for powering these vehicles. Through a series of experimental investigations, we seek to redefine the boundaries of renewable energy utilization in marine environments. By leveraging cutting-edge technologies and industry-grade components, our work aims to establish a new paradigm in the propulsion systems of autonomous oceanic vehicles.

Key words: Autonomous, vehicle, unmanned, underwater, renewable energy, IoT.

1. Introduction. The exploration and utilization of the world’s oceans have long been of paramount importance for scientific research, commercial ventures, and national security interests. In recent years, technological advancements have revolutionized our ability to navigate and understand the vast expanses of the underwater realm [1]. Among the most groundbreaking innovations are Unmanned Underwater Vehicles (UUVs) and Autonomous Underwater Vehicles (AUVs), which have emerged as indispensable tools for a wide range of maritime applications [2].

UUVs and AUVs are equipped with sophisticated sensor payloads, enabling them to conduct observation, surveillance, monitoring, and inspection tasks with unparalleled precision and efficiency. From assessing marine ecosystems and monitoring underwater infrastructure to conducting reconnaissance missions and detecting underwater threats, these vehicles play a pivotal role in expanding our understanding of the oceans and safeguarding maritime interests.

However, despite their undeniable utility, UUVs and AUVs face significant operational challenges that limit their effectiveness and autonomy [3]. Chief among these challenges are the constraints imposed by their reliance on battery power. The limited energy storage capacity of onboard batteries restricts the range and duration of autonomous missions, necessitating frequent recovery for recharging and data offloading. This reliance on support vessels not only introduces logistical complexities but also incurs substantial operational costs, particularly in remote or inaccessible marine environments [4].

Moreover, the data storage capabilities of UUVs and AUVs are often insufficient to accommodate the vast amounts of information collected during extended missions. This limitation hampers the vehicles’ ability to

Fig. 3.1: Schematic Conceptual Design

conduct prolonged monitoring or surveillance operations autonomously, necessitating frequent data transfer and processing, further exacerbating the reliance on support infrastructure [5].

In light of these challenges, there is a pressing need to develop innovative solutions that enhance the autonomy, endurance, and operational efficiency of UUVs and AUVs. By addressing the limitations associated with battery capacity, data storage, and operational autonomy, researchers and engineers aim to unlock the full potential of unmanned underwater vehicles, paving the way for transformative advancements in ocean exploration, environmental monitoring, and maritime security.

This paper explores the current state of UUV and AUV technology, identifies key challenges and limitations, and proposes novel approaches to overcome these obstacles [6]. Through interdisciplinary collaboration and technological innovation, the goal is to usher in a new era of autonomous underwater exploration and observation, facilitating advancements in scientific research, commercial applications, and national defense strategies.

2. Related Work. A remodeled acoustic energy decay model preserved relative in acoustic energy attenuation inverse of distance square is used to generate training data. Multilayer perceptron (MLP) is the model to train these data and predicts accurate relative 3D space coordinates [7].

In depth discussion about AI chips and AI hardware. An improved controller design method based on echo state network with delay output (DO- ESN) is proposed for designing the controller of a class of nonlinear system [8]. The survey provides a comprehensive literature review on combined MBC-ANN techniques that are suitable for UAV flight control, i.e., low-level control [9].

The objective is to pave the way and establish a foundation for efficient controller designs with performance guarantee. The application of artificial intelligence (AI) in unmanned aerial vehicle (UAV) is discussed [10].

The basic connotation of AI technology is introduced. Review the history and classification of machine learning, and talk about the most recent applications of machine learning to UAVs for autonomous flight [11].

Paper reviews AI-enabled routing protocols designed primarily for aerial networks, including topology predictive and self-adaptive learning-based routing algorithms, with an emphasis on accommodating highly dynamic network topology [12]. An algorithm of a model reference adaptive controller for nonlinear systems based on Radial Basis Function (RBF) Neural Networks (NN) is proposed [13].

A nonlinear adaptive controller for an unmanned aerial vehicle (UAV) has been developed using Echo State Network (ESN), which is a form of three-layered recurrent neural network (RNN) [14]. Application of echo state network (ESN) for the nonlinear control of a fixed-wing unmanned aerial vehicle (UAV) is presented. The data required for the network training is generated using a validated flight dynamics model of the UAV [15].

3. Methodology. The project describes to harvest dual renewable energy from solar and hydro-turbine, the fig.3.1.a shows the schematic figure of the conceptualized design.

The proposed design integrated with solar panel and whereas the hydro flow duct turbine will be mounted at water-line area at the bottom portion [16]. The energy generated from solar power pack will be stored in the solar back-up battery, whereas the platform cruises the water flows in to duct chamber and the water streams cuts the turbine fin blades and rotational flow of the shaft coupled with the generator will produce the hydro energy and stores in the battery [17]. Functional flow of the system describes the solar power pack

Fig. 3.2: Functional Lay-out

Fig. 3.3: Indigenously developed DC generator

system and hydro-duct flow turbine coupled to the ocean surface platform integrated with Battery Management System (BMS) and Switch Over Circuit (SOC) will enables the system to monitor the battery management and switching of the battery from one source to another [18].

3.1. Battery Charging. The battery needed to be charged in volts of 1.5 times so 24V. The amp needed must be at least 50% of the current rating of the battery, so we choose 18A since this can only be made in our hull. To increase the amp, we need to increase the solar cells [19].

3.2. Selection of DC Generator. The DC generator selected is practically constant speed, regardless of the load, which would produce consistent power generation [20]. The generator load calculations are arrived to the speed significant to produce the power output required, the fig.3.2.a. Shows the indigenously developed DC generator, which produces 300 watt with 15 VDC. The generator is a PMDC (Permanent Magnet Direct Current Generator) [21].

3.3. Selection of Battery Pack. The battery pack unit will be a three-unit system, where the primary battery will be initially full charged and battery-A & Battery-B is charging through solar panel and hydro duct turbine. The lithium-ion battery was selected for efficient charging and customized indigenously developed with 14.8V/18Ah rating. The system architect was conceptualized from above parametrical studies and flow of the working was schematized.

The system architecture consists of 4 major packs as shown in Fig 3.5:

- Battery Management pack
- Energy (solar and hydro) harvesting pack
- Control and communication pack
- Propulsion pack

The functional working of the system is that the microcontroller-processing unit will be charging from solar panel and hydro-turbine through generator to the battery sources initially assigned will be charging. The Battery Management System (BMS) will be monitoring the battery source, as initial primary battery drains out the Switch over Circuit (SOC) will be switching the primary battery source to battery-A and battery-B

Fig. 3.4: Battery pack unit

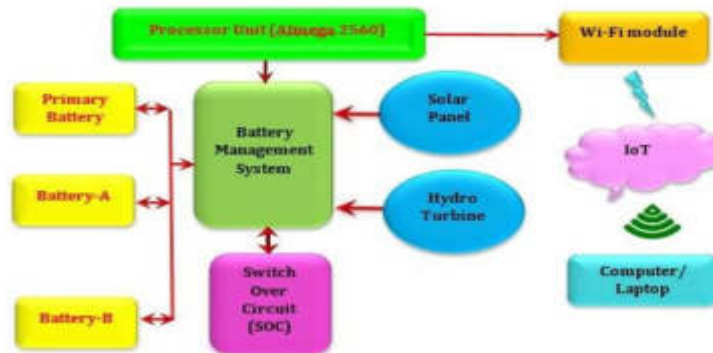

Fig. 3.5: System Architecture

and vice-versa the charging will be relayed from one source battery to other. The wireless Wi- Fi module will be transmitting the data to shore computer/ laptop.

3.4. Solar Energy Harvesting System Design. The connection of solar arrays selected with 156*156 mm monocrystalline cell is follows:

- Connecting 48 cells in series with 4 cells in an array gives 24V/9A. -12 Arrays
- Connecting another 48 cells in parallel with 4 cells in array gives 24V/18A-24 Arrays.

In the existing hull the 24 arrays can be placed in both sides and in middle bars. Each array would be in a square configuration and also the system would be engaged in a straight line of arrays on the bar with angled rotating system as per the sun movement in the sky.

The basic idea developed was to create a set of arrays which would be able to independent and connected in series or parallel which ever fitted the role accordingly. It was devised to make sure that in an active war zone, if any one array also gets damaged the remaining arrays would support the recharging system. This concept is meant to increase the reliability and endurance and not by using a single panel which would be a liability.

The mount for the solar system will have 5 parallel cylinder pipes and 2 perpendiculars main structure. The structure is strategically mounted on to the three bars by means of adjustable clamps and tightly mounted. On top of each pipe, one end of the pipe will have a bearing housing to hold the shaft that is clamped with the solar array. The other end is mounted with a servo motor housing where it can be hinged with the rotating shaft. The length of the occupied solar area in the middle section is 1600mm and breadth is 630 mm approximately. The servomotor is connected to the micro controller with input feed data according to the azimuth angle of the sun's rays the solar panels will be aligned according to the highest efficiency angle.

4. Results and Discussion. The circuit designed, were developed shown in fig 4.1 which is significant function for switching between input renewable energy sources and batteries, based on operating conditions. The Battery Management System (BMS) with Switch Over Circuit (SOC) manages to monitor the operation of the Battery with high voltage will be utilized for load and low voltage for charging and the other battery in idle.

Fig. 3.6: Solar array layout of single panel

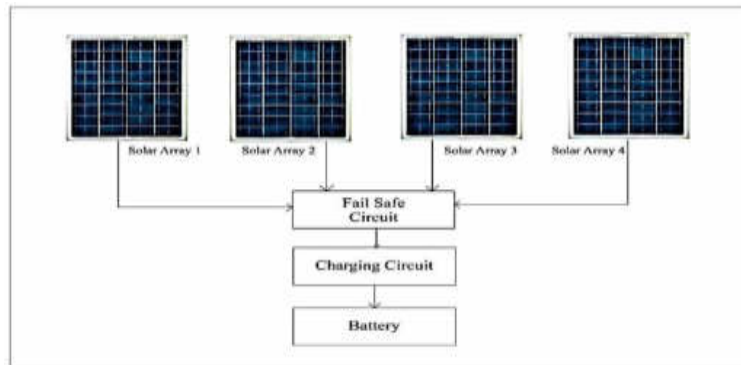

Fig. 3.7: Basic block diagram of the distributed solar array concept

The developed circuit focus on the power produced from solar energy and hydropower which stored in batteries. Since battery is the primary component for energy supply, we should have an alternate source for emergency. Hence, a second battery is used in case of low power or a failure in first battery. Thus, the SOC circuit switch between two batteries, after switching, the disconnected battery will be charged using the power from DC Generator.

The fully charged battery will be automatically cut-off from DC Generator using transistor and voltage regulator. Fig. 4.1 indicates the test evaluation carried out on the electronic hardware unit developed, which the Visual Basics (VB) displays the BMS and SOC working and data stored.

The figure 4.2 displays data from hardware testing of the Battery Management System (BMS) with the Switch Over Circuit (SOC). The plotted data likely includes voltage levels, current measurements, or other relevant parameters monitored during the testing phase. The trends in the data could provide insights into the performance and efficiency of the BMS and SOC in managing the battery system under different operating conditions.

Fig. 4.3 illustrates the voltage levels of the solar power system over time. The curve might show how the voltage fluctuates throughout the day as solar energy is harvested and stored in the battery. The trend could reveal patterns in solar power generation and help assess the effectiveness of the solar panel array in charging the battery under varying sunlight conditions.

The web-page data display (Fig 4.4) presents real-time or logged data from the IoT monitoring system. It includes parameters such as battery voltage, energy consumption, or system status, transmitted wirelessly to a web interface for remote monitoring and analysis. The displayed data provides valuable insights into the performance and operation of the renewable energy harvesting system, facilitating remote monitoring and management.

The trial fetches the solar panel data and performance of BMS with SOC were tested, and stored data were evaluated with IoT monitoring were checked.

- Developed web page performance for getting values from the boat while running were interpreted.
- The Values will be automatically stored in an Excel sheet

Fig. 4.1: BMS and SOC connected to Primary Battery, Solar battery, and Turbine battery

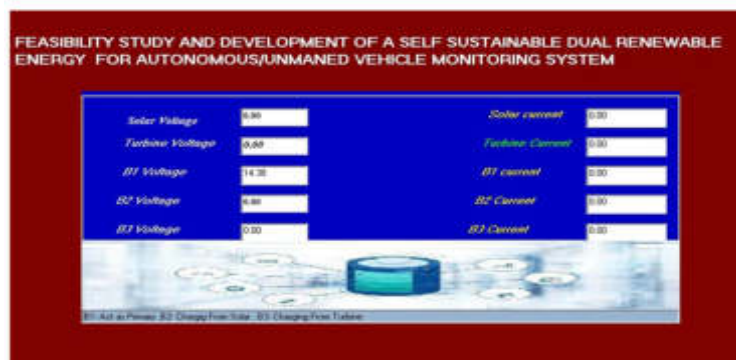

Fig. 4.2: BMS with SOC hardware testing data

- Whenever we need the data, the data sheet can be downloaded.

The performance of hydro-duct turbine was not evaluated in the phase I trial, since the floating platform (existing platform within the University) were not compatible, due to that performance of the hydro-duct turbine study were not carried out. Feasibility study on dual-renewable energy harvesting were carried out successfully. As Dual renewable energy source emphasis, as solar power system drops, the hydro-turbine energy charged system utilization will fetch the Ocean surface platform further.

5. Conclusion. Earlier the existing floating platform available with university has been utilized, where non- compatibility of the platform was studied. Further, a 50W platform was designed. Overall achievement

Fig. 4.3: Solar Power Charged Graph Plotted Voltage vs Time

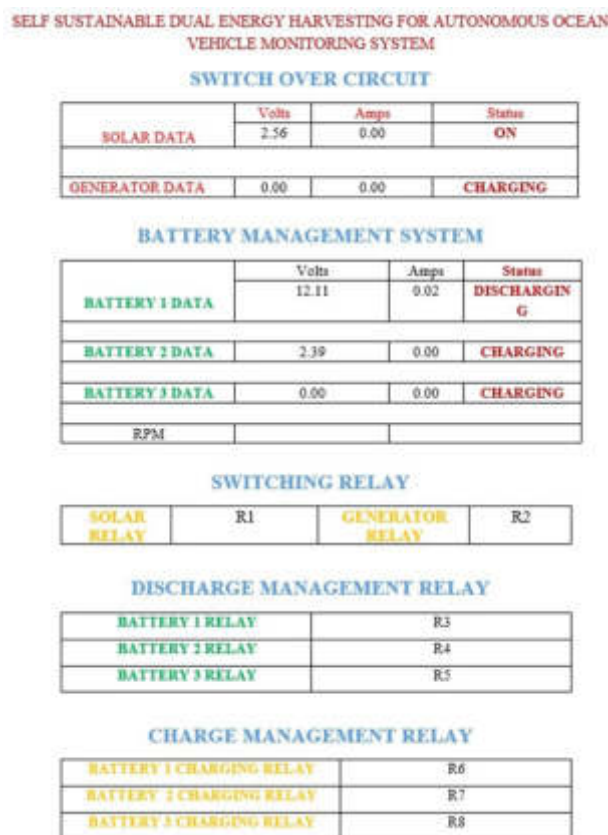

Fig. 4.4: IoT Web-Page Data Display (IoT web link: <https://in.000webhost.com/cpanel-login>)

of the project is in case of absence of solar power, the power generated during running of the boat, the power stored in the battery-B through turbine rotation will provide power after sunset. Solar system was developed and integrated on the boat. Feasibility study on dual-renewable energy harvesting was carried out. Technology demonstrated can be adopted to a bigger ocean surface vehicle will enhance the more efficient result. Higher rate of power harvest feasible with larger platform. Incorporating an ocean surface platform with ducted Hull at the bottom, for hydro turbine integration will increase flow more laminar and better energy produce can be achieved.

HYBRID ELECTRIC VEHICLE ENERGY MANAGEMENT STRATEGY BASED ON GENETIC ALGORITHM

YINGZHE LUO* AND CHAOXIONG FAN†

Abstract. A genetically optimized fuzzy control algorithm is used to realize the parallel hybrid system's real-time energy distribution between the engine and the electric motor. This paper first adopts fuzzy control to improve the robustness and real-time performance of the entire system. Then, a membership function optimization method based on a genetic algorithm is proposed by simulating the working state of CYCUDDS. Simulation experiments show that compared with unoptimized fuzzy control, the improved fuzzy controller can improve the vehicle's fuel economy and prevent continuous battery discharge, thereby improving battery endurance.

Key words: Genetic Algorithm; Hybrid electric vehicle; Battery optimization; Energy management; Fuzzy control

1. Introduction. Hybrid vehicles use a design that combines an internal combustion engine with an electric transmission, making the structure of the entire vehicle more complex. As the core of new energy vehicle control, its energy management method is the focus of its research. Adjusting and operating the motor within the effective range can save energy and reduce emissions. Literature [1] studies the operation mode of hybrid drive military hybrid vehicles. Improve vehicle fuel economy by building logical connections and state transitions between operating modes. However, its theoretical basis is based on experience. Literature [2] established a regular energy consumption control model for HEV and used algorithms such as genetic algorithm and quadratic programming to optimize the model's threshold value to improve the vehicle's fuel economy. However, the author only optimized it under local working conditions. Literature [3] uses wavelet analysis to separate high-frequency and low-frequency signals in load forecasting. Use wavelet transform to establish load forecasting model. using neural networks to train and predict high-frequency and low-frequency signals. The project achieved a 2.37% reduction in fuel consumption. Literature [4] combines variable prediction area RBF network and Q-learning to construct a battery state-of-charge energy management strategy under dynamic operating conditions. The project results achieved improvements in fuel economy. Therefore, this project plans to take the single-row star hybrid vehicle system as the research object and use the working condition information obtained from the actual vehicle test. Working condition information trains, the vehicle speed prediction model [5]. Genetic algorithm fuzzy control and other methods are used to establish the optimal optimization control problem in the short-term forecast area. A hybrid power system's energy consumption management method is studied using working condition speed prediction and differential evolution methods. The hybrid vehicle system's energy-saving and emission-reduction goals can be achieved.

2. Vehicle parameter matching and modeling. The main parameters of the vehicle in the hybrid system are directly related to the working status of the system, so how to select appropriate parameters is a critical link in the development of the entire system.

2.1. Maximum speed is used as the basis to calculate the total power of the system. When half the vehicle's weight is $m_a = 1750$ kg, the maximum speed V_{\max} of the vehicle is expected to reach 200 km/h, and the total electric power $P_{v \max}$ with speed as the target can be determined by formula (2.1).

$$P_{v \max} = \frac{1}{\zeta_T} \left(\frac{m_a c h V_{\max}}{3600} + \frac{Z_\beta A V_{\max}^3}{76140} \right)$$

*School of Mechanical and Electrical Engineering, Shijiazhuang University of Applied Technology, Shijiazhuang, Hebei, 050081, China (Corresponding author, pig1e1987@163.com)

†Great Wall Motor Company Limited, HAVAL R&D Center, Baoding, Hebei, 071000, China

ζ_T is the overall efficiency of the entire power system, and 0.9 is selected as the calculation parameter. c represents the gravitational factor, $N/kg.h$ is the rolling resistance factor. Z_β is the drag factor. A is the headwind side of the car, m^2 .

2.2. Determine the total power based on the maximum gradient. The obstacle-crossing performance of a car is the maximum slope it can climb on a good road. Due to the total weight $m_h = 2000$ kg, its maximum climbing slope can reach $\theta_{\max} = 35\%$ when the speed is $V_\delta = 30$ km/h, and the total power $P_{\delta \max}$ taking the slope as the target is determined by the formula (2.2).

$$P_{\delta \max} = \frac{1}{\zeta_T} \left(\frac{m_a c h V_\delta}{3600} + \frac{Z_\beta A V_\delta^3}{76140} + \frac{m_a c \theta_{\max} V_\delta}{3600} \right)$$

The total power $P_{\delta \max} = 67$ kW with the slope as the target can be calculated from formula (2.2). The maximum power of the power supply must meet the following dynamic index:

$$P_{\max} > \max(P_{v \max}, P_{\delta \max})$$

3. Battery model. A lithium-ion battery energy storage system is proposed using the constant rate method. If it is driven at a constant speed at a speed of $V_e = 60$ km/h in a pure electric state, it is expected to cover 60 kilometers. In this process, the electric motor supplies all the power required by the vehicle [6]. The total capacity required by the battery at this time is obtained through formula (2.4).

$$\begin{cases} W_\varphi \zeta_\varphi = \int_0^T P_m dT \\ P_m = \frac{V_e}{3600 \zeta_T} \left(m_a c h + \frac{Z_\beta A V_e^2}{21.15} \right) \\ T = 3600 \frac{S}{V_e} \\ Z = \frac{1000 W_\varphi}{U} \end{cases}$$

ζ_φ is the battery discharge efficiency. T is the driving time. P_m is the motor working power, kW. W_φ is the total energy required by the battery, kW · h. Z is the battery capacity. U is the voltage level, V.

3.1. Transmission system model. The maximum power point also corresponds to the maximum rotational speed, so when the maximum vehicle speed $V_{\max} = 200$ km/h, the rotational speed n is 6000 .

$$V_{\max} = 0.377 \frac{nd}{\theta_c \theta_0}$$

d is the radius of the wheel rotation. θ_c is the speed of the transmission system. θ_0 is the transmission ratio of the main reduction gear transmission. The maximum reduction ratio calculation formula is based on the maximum climbing slope.

$$\frac{T_{\max} \theta_c \theta_0 \zeta_T}{d} = m_h c h \cos \delta + m_h c \sin \delta$$

4. Calculation of vehicle torque. The torque required by the vehicle is calculated based on the vehicle operating equilibrium equation of the vehicle power system [7]. This provides a basis for the formulation of energy control plans.

$$T_{tq} = \frac{d}{\theta_c \theta_0 \zeta_T} \left(Gh + \frac{Z_d A V_e^2}{21.15} + Gi + \delta m \frac{du}{dt} \right)$$

T_{tq} is the torque required by the entire vehicle. θ_c is the transmission ratio. θ_0 is the primary reducer speed ratio. ζ_T is the drive train efficiency. G is the gravity of the vehicle. h is the rolling resistance coefficient. Z_d is the air resistance coefficient. A is the windward area of the vehicle. u is the vehicle speed. θ is the slope. δ is the car rotation mass conversion coefficient. m is the vehicle mass.

Fig. 5.1: *Input variable membership function.*

5. Fuzzy control algorithm. The energy flow distribution rules of internal combustion engines and electric motors under different working conditions are studied to achieve adequate control of energy saving and emission reduction [8]. Therefore, this paper proposes a method based on fuzzy control.

5.1. Input and output of variables. The fuzzy control method can ensure that the engine operates within the efficient range and the balance of the battery charge state [9]. This paper uses the torque S_d required by the car and the battery charging status as input quantities and carries out fuzzy control based on this. Take the engine torque S_a as the output variable.

5.2. Membership function. In designing the fuzzy controller, we must first determine its degree of belonging and, secondly, determine the segmentation point appropriately and try to select the appropriate fuzzy subset [10]. The membership degrees of input and output are partitioned based on the actual working conditions of parallel hybrid vehicles. The demand torque S_d is divided into five fuzzy subgroups $\{\alpha, \beta, \gamma, \delta, \varepsilon\}$, whose domains are $[-60, 60]$, respectively. The adaptive battery state of charge of the battery pack is divided into five fuzzy subsets $\{\zeta, \eta, \theta, l, \kappa\}$, whose domains are $[0, 1]$, respectively. The engine's range output depends on its accurate output torque, and its range is $\{40, 43, 45, 48, 51, 53, 56, 58, 60\}$. According to the characteristics of the fuzzy sub-region, the ladder-like membership function is selected to obtain accurate control output. Figure 3.1 shows the input variable membership function.

5.3. Fuzzy control rules. It is necessary to fully use the control system's actual work experience and fully consider the input and output characteristics of the controlled system. One is that the engine drives the car independently while the battery is charging. When the required torque exceeds the maximum torque the engine can carry, the motor will assist the engine in driving the car. Second, when the battery charge is small, and the power characteristics of the electric vehicle are maintained, the engine distributes appropriate torque to the battery for charging. When the maximum torque equals the required torque, the engine's power characteristics should first be considered [11]. Third, the engine will automatically stop when the speed is low. In this case, the engine runs independently, reducing fuel consumption. Fourth, the engine and motor drive the car together to achieve high-load operation. An input/output relationship mapping diagram (Figure 3.2) was developed for the abovementioned situation.

Fig. 5.2: *Input/output relationship map diagram.*

6. Membership function optimization based on fuzzy control. Due to the traditional manual judgment method, selecting member weights in fuzzy control systems is often subjective, and it isn't easy to achieve the overall optimal. Therefore, it must be optimized to achieve the system's optimal control effect [12]. It is often difficult to obtain optimal results using classical optimization methods for more complex problems, such as parameter optimization of membership functions. This paper proposes a multi-objective optimization method based on genetic algorithms at this time.

6.1. Initialize the overall. This paper proposes a fuzzy controller design method based on a genetic algorithm. Since the decimal chromosome has a short length, high accuracy, fast operation speed, and good stability to the population of mutation operations, we use the decimal encoding method. As can be seen from Figure 4.1, X1, X2, X3, and X4 each represent subdivisions corresponding to their respective functions. Since all lines of input and output need to be encoded, a one-dimensional decimal matrix with a length of 49 is finally generated [13]. In this matrix, X1-X20 is the code of the required torque membership function, and X21-X40 is the membership of the battery. Degree function codes, X41-X49, are engine output torque membership function codes.

6.2. Selection of fitness function. Optimum fuel consumption and minimum exhaust emissions conflict with each other in most operating ranges and are consistent in only a few. The engine must be kept within this range as much as possible to achieve optimal control [14]. For this purpose, the exhaust gas, fuel consumption and other indicators under actual working conditions are selected, and the optimized objective function is obtained by weighting each indicator.

$$G(x) = \frac{1}{\psi_1 + \psi_2 + \psi_3 + \psi_4} \times \left(\psi_1 \int_0^s \frac{Q}{\bar{Q}} dt + \psi_2 \frac{HC}{\bar{HC}} dt + \psi_3 \int_0^s \frac{NO_x}{\bar{NO}_x} dt + \psi_4 \int_0^s \frac{CO}{\bar{CO}} dt \right)$$

x represents a marker that corresponds to the chromosome number. $\psi_1, \psi_2, \psi_3, \psi_4$ represents the corresponding weighted value. Q is fuel consumption. HC stands for hydrocarbon emissions. NO_x stands for the release of nitrogen oxides. CO stands for the release of carbon monoxide. $\bar{Q}, \bar{HC}, \bar{NO}_x, \bar{CO}$ is the optimal reference value corresponding to each parameter. $\psi_1 = 0.7, \psi_2 = \psi_3 = \psi_4 = 0.1$ is used to determine the weight of each optimization index when performing optimization.

6.3. Operation parameter setting. The group size is directly related to species diversity and production efficiency. If it is too small, the species diversity of the species will decrease, and if it is too large, it will be detrimental to production. The roulette method is used for personal selection. When performing crosses, two cut-point crosses were selected, and the probability of crosses was 0.9; because the mutation rate of this variety is relatively low, it was set at 0.01; the maximum number of gene generations was set at 50.

Fig. 6.1: *Decimal encoding method.*

Fig. 6.2: *Optimized input variable membership function.*

6.4. Optimization results. Genetic algorithms optimize and adjust it continuously, taking parallel hybrid power as the object. Finally, the optimal membership function is given, as shown in Figure 4.2.

7. Simulation analysis. This project plans to use Intel(R) Core (TM) i7-9700CPU@3.00GHz computer, use Python language to implement the rate prediction of GRU-NN and implement rapid prediction of the model through Python programming [15]. Call the data of the genetic algorithm speed prediction model for simulation. The primary performance indicators of the car and the relevant parameters of the differential evolution algorithm are shown in Table 5.1 and Table 5.2.

This project plans to use a combination of genetic and differential evolution algorithms to compare fuel

consumption with three optimization methods: optimal system dynamics optimization and minimum equivalent fuel consumption, in which the adaptive battery state of charge is taken as 0.55. This project plans to use a reverse algorithm to analyze the optimal driving parameters of each stage and the minimum fuel consumption value of each stage from the final state. A forward iteration method obtains the optimal driving mode under each operating condition. And optimize each operating condition of this mode to achieve the optimal configuration of the best operating mode for each working condition [16]. This enables effective control of the startup MG1 and MG2 operating modes. Fuel consumption is shown in Table 5.1. The power distribution of the engine, motor MG1 and motor MG2 is shown in Figure 5.1, and the motion trajectory of the adaptive battery state of charge is shown in Figure 5.2.

The final value of the adaptive battery state of charge controlled by the genetic algorithm fuzzy control is 0.5448, the fuel consumption is 3.4510 L/100 km, and the fuel economy is 93.04%, which is 4.55% lower than the differential evolution and dynamics planning (Table 5.3). Figure 5.1 shows that the starting power of the differential evolution and dynamic planning strategies is maximum in the first 300 seconds, while the genetic algorithm fuzzy control maintains the engine power's stability, and power planning reduces the engine starting time. The MG1 motor using differential evolution produces large oscillations during operation, but using genetic algorithm fuzzy control can keep the output of MG1 stable. Therefore, the adaptive battery state of charge under fuzzy control in Figure 5.2 will experience more excellent attenuation in the early stages, and the power planning will undergo more significant changes. At the same time, the differential evolution algorithm maintains a stable, highly adaptive battery charge—electrical state. In the subsequent high-speed range, the genetic algorithm fuzzy control is used to maintain a more stable number of starts and a more appropriate engine power. At the same time, differential evolution has problems with the high number of starts, high starting power consumption, and adaptive battery state-of-charge changes during working conditions—big questions. During the entire driving process, the output power of the engine when starting and stopping the dynamic planning

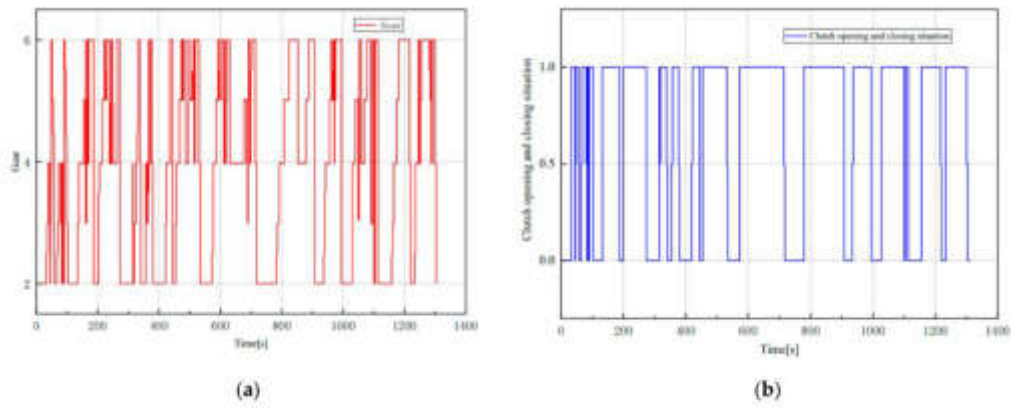

Fig. 7.1: Power distribution under different methods and strategies.

Fig. 7.2: SOC trajectory.

Table 7.3: Experimental results.

Method strategy	Final value SOC (T)	Fuel consumption/[L · (100km) ⁻¹]	Fuel economy/%
Dynamic programming	0.573	3.361	100
Genetic Algorithm Fuzzy Control	0.568	3.595	96.917
Differential Evolution Algorithm	0.563	3.766	88.490

strategy is greater than the other three control methods, resulting in high fuel consumption, while the genetic algorithm fuzzy control always maintains a small adaptive battery state-of-charge change interval, thereby preventing the harm to the battery caused by changes in the adaptive battery state of charge.

8. Conclusion. It was found that all three solutions can keep the battery’s state of charge at equilibrium. Before and after optimization, the SOC value decreased by 0.0427 and 0.0063. By improving this method, the battery’s state of charge changes significantly, thereby improving the battery’s endurance. In addition, the battery’s state of charge before optimization was finally 0.6865. After optimization, the battery state of charge showed a trend from low to high over time and finally stabilized around 0.7260, indicating that the optimized

electric vehicle braking system performs better. The working condition distribution of the optimized engine is relatively scattered, making it difficult to always be in an efficient working range when facing various working conditions. Each working point can work in a relatively dense area, and most of the working points are located in the high-efficiency area using this method.

DATA PROTECTION AND PRIVACY PROTECTION OF ADVERTISING BASED ON CLOUD COMPUTING PLATFORM

ZHISHE CHEN*

Abstract. This paper uses the hybrid leapfrog algorithm to mine user information in encrypted advertisements effectively and intelligently. This method handles the nonlinearity of the original data by mapping it into kernel space. The representation of the original ciphertext in the kernel space is obtained by sparsely reconstructing the encrypted original advertising data. Build a corresponding scoring mechanism and select the best advertising data characteristics. The selected data were clustered using the data fuzzy clustering method based on the improved hybrid leapfrog. Set the adjustment coefficient to improve the local optimization performance of hybrid frog leaping. This algorithm uses the tightness and separation in genetic algorithms and constructs a fitness function to determine the clustering critical value. This enables the practical, intelligent mining of homomorphic passwords with privacy protection. Experimental results show that the method proposed in this article can effectively improve the convergence speed and accuracy of clustering. Improve Blowfish by combining multi-threading, sharing encryption and other methods. This enables encryption and decryption of large amounts of model data. The research of this project has very important research value in improving the security performance and effectiveness of cryptographic algorithms.

Key words: Privacy-preserving deep learning; Precise advertising; Secure computing; Privacy protection; Data mining

1. Introduction. Advertising data mining technology has become an emerging research direction. Advertising data mining technology has been widely used in many fields, such as engineering, scientific research, etc. This provides users with revenue. But when this method is used for ad mining, it can also have adverse effects, like the security of personal information. Technicians can speculate that it may contain private or sensitive information. There is a potential risk of leakage when mining advertising data with homomorphic passwords, so it must be protected. It is necessary to conduct data mining while ensuring the security of ciphertext information. Especially with the rapid development of network technology, scientific researchers can obtain massive amounts of information from various web pages. Traditional advertising user data mining methods to mine privacy protection data based on ciphertext may cause data leakage and affect the accuracy of data mining. Literature [1] uses homomorphic cryptography technology on the lattice to mine data. It implements data mining for privacy-preserving data cluster analysis. The user encrypts the data before transmitting it to the provider. After using Blowfish-based confidentiality and data mining technology, network service providers cannot obtain user data. Compared with existing data publishing methods, Geji data mining technology has significant advantages in information security. This algorithm ensures the accuracy of the spacing of integer encrypted ciphertext. Experiments have shown that the computing speed of the lattice mining algorithm is significantly higher than that of other algorithms, but there are also problems with low accuracy. Literature [2] proposed a time series data mining algorithm for differential privacy—screening of sequential patterns from candidate templates. Geometric principles are used to add noise to selected mode support values to interfere with their generation. The simulation results show that the proposed algorithm meets the differential confidentiality requirements. Although it has a good mining effect, the accuracy is not high [3]. This paper proposes homomorphic encryption data privacy protection technology and model privacy protection technology based on the Blowfish algorithm.

2. Homomorphic encryption technology. Homomorphic encryption is an encryption method based on computational complexity. Perform corresponding operations on the homomorphically encrypted data and then decode it. A similar conclusion was made for the unencrypted raw material [4]. Homomorphic encryption is a

Fig. 2.1: Homomorphic encryption intelligent reasoning architecture.

new computing method that has emerged in recent years. It can effectively ensure the security of information transmission and calculation [5]. Homomorphic ciphers can be used to encode ciphertext directly. Ciphertext calculation eliminates the cumbersome process of decrypting large-scale ciphertext, then calculating, and then encrypting. This algorithm saves the amount of calculation while ensuring safety. This method can provide ideas for research on privacy protection issues of advertising users in the network environment. Any individual server can hide trained models. These models can be secretly exchanged between multiple servers to ensure model security. Figure 2.1 shows the intelligent inference architecture based on homomorphic cryptography.

The implementation process of homomorphic encryption advertising user data privacy protection technology for intelligent algorithms is as follows: (1) Use methods such as homomorphic addition and homomorphic multiplication to establish convolution and pool and approximate different excitation functions; (2) Based on security, Verify the security of ciphertext through comprehensive multi-party computation; (3) Study the security and privacy protection mechanism based on ciphertext. The above process applies to 6 different machine learning algorithm scenarios: convolutional neural network, BP neural network, logistic regression algorithm, SVM, linear regression algorithm and multi-layer perceptron [6]. The inference engine consists of three servers, which can automatically encrypt user information locally without decrypting it. It only needs to perform cryptographic operations on it and then feedback the results of its operations to the user. The user decrypts it to obtain inferred conclusions [7]. The user has no sense of the above inference. Only the user can encrypt it, ensuring the security of the entire computing process. This paper studies cryptographic intelligence algorithms based on Parlier's cryptography ideas. The algorithm of Parlier homomorphic cipher is:

$$z = \text{Enc}(u, s) = h^u s^m \bmod m^2$$

h and m are the password public keys; $s \in M.s$ and m are mutually prime. h is a random number much smaller than m^2 , and is generally more than 4000 digits, so its operation cost is very huge [8]. The calculation formula of Parlier homomorphic addition is:

$$\begin{aligned} \text{Enc}(u, s) \text{Enc}(v, \varepsilon) &= (h^u s^m \bmod m^2) (h^v \varepsilon^m \bmod m^2) = \\ &h^{(u+v)} (s\varepsilon)^m \bmod m^2 \text{Enc}(u+v, s\varepsilon) \end{aligned}$$

ε is the same random number as s . s is the random number for pairing u , and ε is the random number for pairing v . The formula for Parlier homomorphic multiplication is:

$$\text{Enc}(u, s)^\kappa = (h^u s^m \bmod m^2)^\kappa = h^{u\kappa} (s^\kappa)^m \bmod m^2 = \text{Enc}(u\kappa, s^\kappa)$$

κ is a sub-square number. Information was exchanged based on confidential sharing. The confidential multi-party computation method is used in this paper [9]. This algorithm allows multiple parties to jointly keep their value secret without destroying computing power [10]. This method divides a piece of data into several segments and does not display the original data when sharing. Two operation participants perform the same operation on an encryption key group and then reassemble it. On the user side, the private information u is decomposed into two parts, u_0 and $u_1, u = u_0 + u_1$. Then the two variables u_0 and u_1 are sent to the two servers D_0 and D_1 respectively [11]. Mere possession of u_0 and u_1 does not jeopardize the privacy of data u . The formula for decomposing tensor u is this:

$$u_0 = \text{share}(u, S) = S \bmod N$$

$$u_1 = \text{share} 2(u, S) = u - S \bmod N$$

S and N are both arbitrary numbers. Two servers Q_0 and Q_1 and one secondary server Q_2 are set up, which form a computing cluster. When creating a shared section, you should know how it is distributed [12]. To generate a secret share, you only need to separate the numbers that need to be converted into two values. People Q_0 and Q_1 first exchange half of the shares, and then use the parts they hold to perform calculations and transactions, and finally get the final result. Q_0 will pass α_1 to Q_1 , and Q_1 will pass β_0 to Q_0 . Because Q_0 cannot enter β_1 in Q_1 , it cannot determine the value of β . Adding is the most straightforward operation that can be performed through confidential sharing [13]. It can look like this:

$$\alpha + \beta = (\alpha_0 + \alpha_1) + (\beta_0 + \beta_1)$$

Equation (2.6) is rearranged by adding exchange rules and adding combination rules to:

$$\alpha + \beta = (\alpha_0 + \beta_0) + (\alpha_1 + \beta_1)$$

Q_0 solves for $\alpha_0 + \beta_0$ · Q_1 solves $\alpha_1 + \beta_1$ to ensure that Q_0 gets only part of β . Q_1 gets only part of α . The two parties doing the multiplication need to communicate with each other during the operation [14]. The notation above is used to define multiplication using secret sharing in the following way:

$$\alpha\beta = (\alpha_0 + \alpha_1)(\beta_0 + \beta_1) = \alpha_0\beta_0 + \alpha_0\beta_1 + \alpha_1\beta_0 + \alpha_1\beta_1$$

Q_0 may be responsible for $\alpha_0\beta_0$ and Q_1 may be responsible for $\alpha_1\beta_1$. Giving intermediate project $(\alpha_0\beta_1 + \alpha_1\beta_0)$ to Q_0 or Q_1 will cause certain security risks. This is because either of the two items can be added together, revealing the original α or β . For example, if Q_0 wants to solve $\alpha_0\beta_1$, then Q_0 must have a β_1 . Since Q_0 already contains β_0 , we can find the value of β . Shielding can be used for concealment. When partial concealment is required, new unknowns can be introduced into the parties so that the mask can be eliminated without affecting the final result when all are calculated. The third party Q_2 generates information that it is unwilling to share with the other party for confidentiality purposes [15]. That is, masking $Q_0\beta_1$ and $Q_1\alpha_0$. In this article, the shields are called d and k , and ζ and η are called the values of the shield. Multiplying $\alpha\beta$ by Q_0 is:

$$f_0 = dk_0 + d_0\eta + \zeta k_0 + \zeta\eta$$

The multiplication of Q_1 by $\alpha\beta$ is equal to:

$$f_1 = dk_1 + d_1\eta + \zeta k_1$$

Builds the mask coefficient from Q_2 · Q_2 generates 3 new numbers and divides them into different parts [16]. The first two digits are any number, and the third digit is the product of the first two digits. These values are obtained by subtracting the mask from the original data in the following way:

$$\zeta = (\alpha_0 - d_0) + (\alpha_1 - d_1)$$

$$\eta = (\beta_0 - k_0) + (\beta_1 - k_1)$$

Fig. 3.1: *Key generation time cost.*

Q_2 transmits the values d_0 and k_0 to Q_0 , and d_1 and k_1 to Q_1 . Here the values of d_0 and k_0 take any integer, $d_1 = d - d_0, k_1 = k - k_0 \cdot Q_0$ then produces the $(\alpha_0 - d_0)$ part of ζ and the $(\beta_0 - k_0)$ part of $\eta \cdot Q_1$ produces $(\alpha_1 - d_1)$ regions of ζ and $(\beta_1 - k_1)$ regions of η ; then D and G exchange the ζ and η shares without revealing any information about α or β ; finally, the values are added to the corresponding equations. Combining (2.9) and (2.10) becomes:

$$f_0 + f_1 = \alpha\beta$$

Confidential sharing enables secure interaction with data. All expressions can be simulated using addition and homomorphic multiplication methods. Based on the two primitives of homomorphic addition and homomorphic multiplication, functions such as convolution, pooling, and approximation activation can be implemented, respectively. It can be applied to machine vision and linear or logistic regression fields. In practical applications, it is necessary to rewrite functions such as CNN, BP, MLP, logistic regression, etc., and use Taylor expansion approximation [17]. At the same time, the format of additive and multiplicative operations in homomorphic cryptography is maintained. This method is compatible with various mechanisms such as convolution, ReLU activation function, Maxpool and normalization, and can be combined with different inference methods to form corresponding safe computing solutions.

3. Analysis of experimental results.

3.1. The impact of Blowfish distance preservation on cryptography. The effect on the key is shown in Figure 3.1. The time it takes for a user to generate a key is mainly the time it takes to generate a key. The time when the private key was generated is not taken into account. The generation of a public-private key pair takes approximately eight milliseconds. Find the value of the transformation matrix during initialization keyword processing. Experiments have shown that only 30 fundamental transformations are needed. You can see from Figure 3.2 that encryption takes longer than decryption [18]. This is because generating random numbers that meet the requirements during cryptographic processing takes some time. The average time for each encoding is 0.4 milliseconds. Compared with existing algorithms, the algorithm proposed in this paper has better results. This is mainly because multiple bytes of data can be encrypted or decrypted simultaneously. Figure 3.3 shows that the calculation of 40,000 passwords only takes 67 seconds, and the calculation of 40,000 intermediate points takes only 67 seconds [19]. The amount of encryption required for clustering in a cloud computing environment is acceptable. Since cloud services have higher performance in practice, they can achieve higher privacy mining efficiency in practical applications.

3.2. The performance and accuracy of privacy-based cluster mining algorithms. The research content mainly involves the preprocessing time overhead of some users, part of the time overhead of cloud service providers, and problems compared with existing algorithms [20]. It can be seen from Figure 3.4 that

Fig. 3.2: *Encryption and decryption time.*

Fig. 3.3: *Computing time cost of ciphertext in the cloud.*

the data published by PPCM is more time-consuming than the existing algorithm, but it is still within the allowed range. The fundamental problem is that it is based on the Blowfish problem and increases the time cost required to keep the data confidential.

Figure 3.5 shows that the time complexity of the ciphertext k-means method is $O(n \log(n))$. The computational time complexity of the ciphertext hierarchical clustering algorithm is $O(n^2)$. The calculation time complexity of ciphertext DBSCAN is $O(n)$. Research has found that in a natural environment, the calculation process of k-mean does not fully comply with the theoretical calculation complexity, and due to differences in sample type and initial value selection, The time consumption of the PPk-mean method may deviate from the analytical results to a certain extent. Experiments show that the privacy-based hierarchical mining method performs weakest, while the one based on PPDBscan is the best. This has a lot to do with the selected materials [21]. The other three methods also have advantages and disadvantages when processing various data types. In many situations, users need to perform multiple mining methods to discover potential clusters in a data set.

As shown in Figure 3.6, this method has the same accuracy as the current most correct RBT method but is safer. In exceptional circumstances, k unknown data sets may lead to inconsistent values of k. This project plans to use three methods to compare the k-means analysis results of the original data, and the PPk-means analysis results under the ciphertext to obtain the accuracy rate.

This algorithm can improve its security, accuracy, and mining efficiency. At the expense of this, the accuracy and security of users' private information are guaranteed. The accuracy of mining is very critical for users. If

Fig. 3.4: User preprocessing time overhead.

Fig. 3.5: Time cost of privacy-preserving cluster mining.

there is a problem with the accuracy of discovery, it will likely bring irreparable consequences to the user.

4. Conclusion. The confidentiality of user information in ciphertext advertisements based on intelligent algorithms mainly focuses on the confidentiality of deduction data owned by users. This algorithm can keep the deduced data confidential throughout the entire reasoning process. Because encryption can only be performed by the data holder, confidentiality of the data and instant inference results can be considered simultaneously. And it also avoids the cost of repeated encryption and decryption. A model security method based on Blowfish is proposed. It can effectively store and read advertising mode documents while ensuring ciphertext security.

DESIGN OF 0-DAY VULNERABILITY MONITORING AND DEFENSE ARCHITECTURE BASED ON ARTIFICIAL INTELLIGENCE TECHNOLOGY

JIAN HU*, ZHENHONG ZHANG[†], FEILU HANG[‡] AND LINJIANG XIE[§]

Abstract. In response to the difficulty in detecting attacks caused by the unknown nature of 0-day vulnerabilities, the author proposes a knowledge graph based 0-day attack path prediction method. By extracting concepts and entities related to attacks from existing research on the ontology of network security and network security databases, a network defense knowledge graph is constructed to extract discrete security data such as threats, vulnerabilities, and assets into interrelated security knowledge. Using a knowledge graph reasoning method based on path sorting algorithm to explore possible 0-day attacks in the target system. Experimental results have shown that the proposed method can rely on the knowledge system provided by the knowledge graph to provide comprehensive knowledge support for attack prediction, reduce the dependence of prediction analysis on expert models, and effectively overcome the adverse effects of unknown 0-day vulnerabilities on prediction analysis. It improves the accuracy of 0-day attack prediction and utilizes the path sorting algorithm to infer based on the explicit feature of graph structure, being able to effectively backtrack the reasons behind the formation of reasoning results, this to some extent improves the interpretability of attack prediction analysis results.

Key words: 0day attack, Attack path prediction, Artificial intelligence, Defense architecture

1. Introduction. With the continuous development of computer and communication technologies, network security has increasingly become an important issue affecting network performance and data security. The proliferation of network attacks and viruses poses a serious threat to network and application systems. For enterprise level users, whenever they encounter these threats, they often cause data damage, system abnormalities, network paralysis, information theft, decreased work efficiency, and significant direct or indirect economic losses. Since 2006, the US Security Training and Research Institute (SANS) has included zero day attacks as one of the top 20 global internet security threats annually [1]. Enterprises that have not yet patched zero day vulnerabilities have become the preferred targets for hackers, and such attacks are developing rapidly. Zero day attack refers to an attack launched by malicious software that exploits certain vulnerabilities in the operating system or application software that are not known to developers or have not been patched in a timely manner. Those vulnerabilities that are not known to developers or have not been patched in a timely manner are also known as "zero day vulnerabilities". As a type of attack, the difference between zero day attacks and traditional hacker attacks is that the target of zero day attacks is some potential unknown or publicly disclosed but not patched vulnerabilities. According to authoritative institutions, there may be 4-5 coding vulnerabilities in every 1000 lines of code in operating systems and applications currently in use[2]. With the continuous emergence of various computer vulnerabilities, the situation of zero day attacks is also constantly changing: From a single point to a desktop type, then gradually transitioning to a network type, and even currently there is a trend towards a full network type development. In this complex form, defense against zero day attacks is also constantly evolving. Traditionally, regular updates of system patches, firewalls, intrusion detection systems, and antivirus software are commonly used to protect critical business and IT infrastructure. These systems provide good first level protection, but still cannot avoid zero day vulnerability attacks. Faced with the increasing

[†]Network Security Management Center of Information Center of Yunnan Power Grid Co., LTD., Kunming, Yunnan, China, 650000

[‡]Information Security Operation and Maintenance Center of Information Center of Yunnan Power Grid Co., LTD., Kunming, Yunnan, China, 650000

[§]Information Security Operation and Maintenance Center of Information Center of Yunnan Power Grid Co., LTD., Kunming, Yunnan, China, 650000

zero day threat, both system, network, and security vendors are loudly calling for the importance of real-time updates [3,4]. For manufacturers, the purpose of instant updates is to respond to the increasingly short attack time gap of hackers. However, users often lack manpower, resources, and time to effectively perform the work of instant updates and repairs.

The main reason why many enterprises are unable to immediately complete the repair work of system or software and hardware device vulnerabilities is that they do not have time to discover the vulnerabilities, do not further evaluate and diagnose the vulnerabilities, and are unable to patch and update all computers or endpoint devices. Another more important reason is the inability to conduct compatibility testing on patches, which often leads to system instability and even crashes.

Attack prediction technology is the key to research on 0day attack detection. However, research on 0-day attack prediction generally relies on hypothetical conditions, attack models constructed by expert knowledge, and the pre - and post attack dependencies in the same attack path to address the impact of unknown 0-day vulnerabilities, there are three shortcomings in this process: Firstly, the conditional assumption lacks effective constraints, which can easily lead to a large scale of prediction results for 0-day attacks, reducing the significance of prediction; The second is the attack model constructed by expert knowledge, which is easily constrained by the subjective knowledge of experts; Thirdly, the prediction method is difficult to apply when the known attack path is incomplete. In response to the above shortcomings, the author proposes a 0-day attack path prediction method based on a knowledge graph [5]. By using a network defense knowledge graph, attack related threats, assets, vulnerabilities, and other data are fused into a security knowledge base that is interrelated and covers a wide range of knowledge. Based on the integrated vulnerability data, attack intent, and other knowledge, reasonable constraints are imposed on the assumptions of unknown attributes of 0-day vulnerabilities; Secondly, using path sorting algorithms, the relationship path between the attacker entity and the target entity in the knowledge graph is used as a feature to predict the 0-day attack from a more comprehensive perspective, overcoming the limitations of expert knowledge construction models [6]; Finally, using historical attack data as samples, a logistic binary classifier is designed and trained to implement single step attack prediction, thereby breaking away from dependence on known attack paths. By reusing the single step attack probability output by the logistic binary classifier, the comprehensive utilization rate of the attack path is calculated to predict the 0-day attack path most likely to be exploited by the attacker against the target asset, thereby supporting defense decisions [7,8].

2. Methods.

2.1. Preparatory knowledge. In order to make the expression clear and accurate, the relevant concepts in the text are defined as follows.

Definition of Network Defense Knowledge Graph (CKG). CKG is represented by triplets (CSO, FACT, T), where CSO=(C, R, P) is the network security ontology, C is the class set, R is the relationship type set, P is the attribute type set, FACT is the set of data knowledge represented in RDF (resourcdescriptionframework) triplet format, T is the set of type dependency relationships between classes in CSO and entity objects in FACT [9].

Define a 20day vulnerability. 0day vulnerability refers to a general term for system vulnerabilities that have not been discovered by security vendors but may be mastered by hacker organizations. In order to make the research more targeted, the following 0day vulnerabilities only refer to technical vulnerabilities that have not been discovered by security vendors.

Define a 30 day attack. A 0-day attack refers to a single step attack initiated by an attacker using a known 0-day vulnerability, denoted as a^0 . Relatively, known attack a^k is a single step attack initiated by an attacker exploiting a known vulnerability.

Define 40 day attack path zap. Zap refers to an acyclic attack sequence consisting of a set of single step attacks with 0 day dependencies, represented by (A, E), where A is the set of single step attacks and E is the directed edge set of linked single step attacks [10].

Define 50 day attack graph ZAG. ZAG refers to an attack graph containing 0-day attacks, represented as (A, Priv, L, Prob), among them, $A = \{a^0\} \cup \{a^k\}$ is a single step attack set consisting of 0 day attacks and known attacks. Single step attack a is represented as a binary (host, Vul), where the host is the target device, Vul is the vulnerability exploited, and Priv is the pre - and post permission set for single step attacks,

Table 2.1: Main Symbols and Their Description

symbol	describe	symbol	describe
CKG	Network Defense Knowledge Graph	vul	Vulnerabilities exploited by single step attacks
CSO	Network Security Ontology	rp	Relationship Path
zap	0day attack path	c	Classes in ontology
ZAG	0day attack graph	r	Relationship types in ontology
A	Single Step Attack Set	Domain(r)	Definition domain of relationship types
a	Single step attack	Range(r)	The range of values for relationship types
Priv	Node permission set	s	Source entity
L	Directed Link Set between Single Step Attack and Permissions	d	Target entity
E	Directed Edge Set Between Single Step Attacks in Attack Paths	h	Relationship Path Eigenvalues
Prob	Probability set of single step attack occurrence	H	Relationship path feature vector
host	Devices that have been attacked	θ	Relationship path weight vector

$L=\{AxPriv\}U\{PrivxA\}$ is the link between a single step attack and permissions, representing the pre - and post relationship between them. Prob is the set of probabilities of a single step attack occurring.

Define 6 relationship paths (rp, relationpath). rp refers to a sequence composed of a set of relationship types in a knowledge graph, written as $rp : c_0 \xrightarrow{r_1} c_1 \xrightarrow{r_2} \dots \xrightarrow{r_l} c_l, r \in R$. Among them, $c_l \equiv Range(rp), l = |rp|$ represents the length of the relationship path, which is the total number of relationship types included in the relationship path, $0 \leq i \leq l$.

The relationship between knowledge graph and attack graph is as follows: CKG is the input of attack prediction algorithm, serving as a knowledge base to provide the necessary knowledge for attack prediction; 0day attack graph ZAG is a graphical representation of attack prediction results. The difference between relational paths and attack paths is as follows: rp is used as a feature in the logistic regression model in path sorting algorithms to perform attack prediction; The 0-day attack path zap is a prediction result of the extracted attack path based on the 0-day attack graph, combined with the probability of multi-step attacks occurring. The main symbols that appear are described in Table 2.1 [11,12].

2.2. Network Defense Knowledge Graph. Knowledge graph is an effective technical method that uses graph models to describe knowledge and model the relationships between things. Applying this technology to the field of network security and constructing a network defense knowledge graph can integrate heterogeneous and fragmented network security data into a unified and interrelated security knowledge format, providing support for attack prediction and testing the required knowledge. The 0-day attack graph ZAG is a graphical representation of the attack prediction results. The difference between relational paths and attack paths is as follows: RP is used as a logistic regression model in path sorting algorithms to perform attack prediction, which is beneficial for implementing targeted defense. The following is a detailed introduction to the construction of the network defense knowledge graph architecture and the design of the network security ontology.

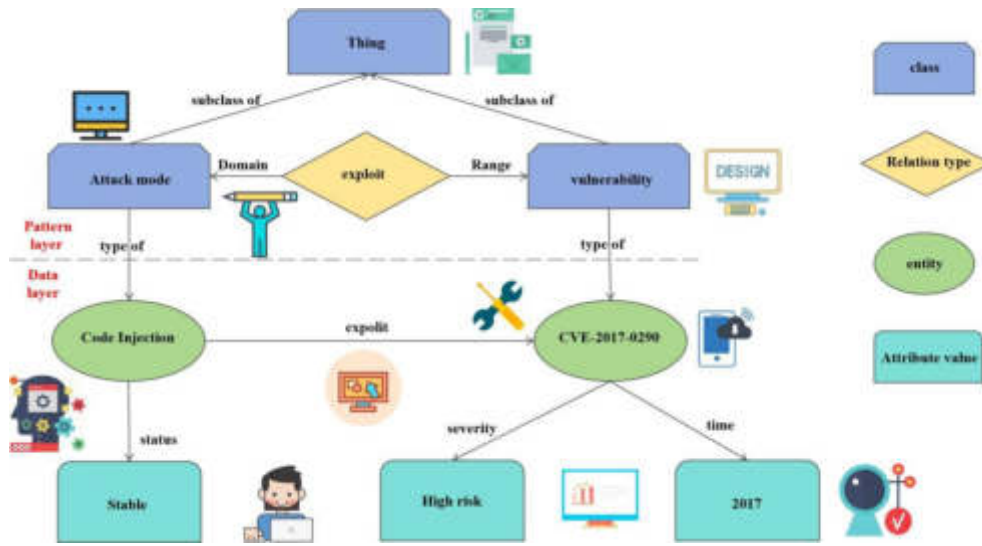

Fig. 2.1: Example of the Relationship between Pattern Layer and Data Layer

(1) *Architecture construction.* According to Definition 1, the network defense knowledge graph can be divided into two parts: The pattern layer and the data layer. Among them, the pattern layer is the core of the knowledge graph, and the basic concept system of network defense is defined by the Cybersecurity ontology (CSO), providing pattern definitions for modeling data layer knowledge[13]. The data layer is the main body of the knowledge graph, which is a collection of data knowledge obtained through knowledge extraction, knowledge fusion, and other steps, modeled under the pattern definition. Data knowledge is represented in the form of RDF triplets as (subject, predicate, object). The example of a two-layer relationship is shown in Figure 2.1. The pattern layer of this example defines attack pattern classes, vulnerability classes, and the relationship type exploit with the two as defined cities and value ranges, respectively. The data layer models data knowledge based on this pattern (CVE-2017-0290, CodeInjection, exploit), indicating that code injection can exploit vulnerability CVE-2017-0290.

According to the hierarchical structure of the knowledge graph, there are mainly two methods for its construction: top-down and bottom-up. Due to the mature research on the conceptual system in the field of network security, the network defense knowledge graph is suitable for a top-down knowledge graph construction method, which first constructs a pattern layer based on the network security ontology, and then integrates multiple knowledge extraction and fusion technologies based on the pattern layer to extract and model data knowledge from heterogeneous data sources and construct a data layer [14,15].

(2) *Ontology design.* From the top-down sequence of knowledge graph construction, it can be seen that CSO is the key to determining the quality of network defense knowledge graph. The author uses ontology integration to construct CSO, integrating existing mature network security ontologies into a unified ontology, drawing on current research achievements in this field, and achieving complementary advantages among different achievements[16]. Due to NSSEKB_0 (ontology of network security situation element knowledge base) systematically sorts out the network security knowledge system from three levels: domain ontology, application ontology, and atomic ontology, and has good knowledge completeness. AFACSDO (asset infrastructure security domain ontology) reuses multiple representative network security ontologies, which is the latest achievement in network security ontology research and has good timeliness. Therefore, the author selected the above two research results as integration objects to implement ontology integration.

2.3. 0-day attack path prediction. The network defense knowledge graph defines the concept of attacks as a type of relationship with attacker classes as the domain and device classes as the value domain. The inference problem of specific attack behaviors is transformed into the prediction problem of attack relationships

between attacker entities and device entities in the data layer of the knowledge graph. The path ranking algorithm (PRA) is an effective method for predicting knowledge graph links. Its prediction results not only have high accuracy, but also strong interpretability, making it easy for defenders to mine knowledge about attack causes and other factors after obtaining the prediction results, therefore, the author chooses the PRA algorithm to perform one-step attack prediction and constructs a 0-day attack graph. On this basis, by analyzing and comparing the comprehensive utilization rates of different attack paths, predict the most likely 0-day attack path that attackers are likely to utilize [17].

(1) Analysis of Unknown Properties of 0day Vulnerability. Before implementing the prediction, the basis of prediction analysis is to make assumptions and implement constraints on the missing 0day vulnerability attributes through unknown attribute analysis. The unknown attributes of the 0day vulnerability mainly include the location of the vulnerability, exploitation conditions, and impact information. Current research mainly supplements unknown 0-day vulnerability information through conditional assumptions. In this process, how to reasonably constrain the assumed vulnerability information is the key to determining the quality of prediction results. Based on the knowledge graph integration, the author proposes hypotheses about the existence, availability, and harm of 0-day vulnerabilities, and uses statistical analysis, sample training, and intention analysis to constrain the relevant hypotheses.

Existence assumption: The 0day vulnerability may exist in any component of the device. The vulnerability data provided by databases such as NVD and CNNVD show significant differences in the number of vulnerabilities exposed by different components, indicating that the existence of vulnerabilities is related to the components that serve as their carriers. Therefore, for this assumption, component features can be used to constrain and consider the 0-day vulnerability as a potential vulnerability that the component may expose in the future. By statistically analyzing the vulnerability exposure history data of different components, the possibility of 0-day vulnerabilities in different components can be quantified[18].

Availability Assumption: The 0day vulnerability may be triggered by arbitrary permissions on the target device. Permissions exist in the form of permission entities in the knowledge graph, and triggering different vulnerabilities requires varying degrees of permission. The higher the permission, the easier it is for attackers to trigger vulnerabilities. Set the attribute "tri_prob" of the relationship "trigger" in the knowledge graph to indicate the probability of permission triggering a 0-day vulnerability, and assign values based on the level of permission. The relationship "trigger" is contained in the relationship path between the attacker entity and the target device entity, so "triprob" can be reflected in the sample features by participating in the calculation of path features. In the process of training a Logistic binary classifier using attack samples, the exploitation conditions of the 0-day vulnerability can be constrained to the scenarios in the samples based on the difference between positive and negative samples. When the classifier determines that the 0-day attack relationship is valid, the permissions used to trigger the 0-day vulnerability can be determined by querying the permission entities that the attacker entity has obtained on the device entity in the knowledge graph.

Harmful assumption: The harm generated by exploiting a 0-day vulnerability can only meet the minimum requirement for attackers to achieve their attack intent on the target device.

The harm caused by vulnerability exploitation is represented in the form of entities in the knowledge graph, and at the same time, the knowledge graph integrates the attacker's attack intent by threatening entities. Due to the fact that attackers exploit vulnerabilities to launch attacks with the aim of achieving the attack intent, if the consequences of exploiting vulnerabilities are not sufficient to support the implementation of the attack intent, then the attacker is not necessary to exploit the vulnerability. When the consequences exceed the need to achieve the attack intent, the excess is not significant to the attacker, therefore, the above assumptions about using attack intent to constrain the harm caused by exploiting 0day vulnerabilities are feasible and reasonable. For example, the attacker entity APT-28 mainly engages in theft activities, and the target device entity stores confidential information. A threat entity "stealing secrets" is constructed in the knowledge graph as APT-28's attack intention against the device. If it is predicted that APT-28 has launched an attack on the device using the 0day vulnerability, the resulting consequences are constrained by the threat entity as "confidentiality damage", without further impact on integrity, availability, and other aspects.

(2) Attack path prediction. Using the historical attack data of a given system to construct attack samples, a classifier LC is trained to predict whether an attack has occurred. Based on this, 0 day attacks and known

attacks are distinguished from the positive attack samples, and 0 day attack samples are constructed. The classifier LCz is trained to determine whether a single step attack occurred as an 0 day attack. After completing the attack prediction, utilize the query function of the graph database to mine the vulnerability and pre - and post conditions of attack exploitation based on the starting and ending entities and relationship paths, construct a single step attack, and generate a 0-day attack graph. Based on the 0-day attack graph, with the attacker's initial permissions as the starting point and the target permissions as the endpoint, extract the 0-day attack path, and calculate the comprehensive utilization rate of different attack paths by reusing the probability of a single step attack output by the LCA classifier. Based on this, predict the most likely 0-day attack path that the attacker is likely to use. The calculation of comprehensive utilization rate is shown in Equation 2.1.

$$Exploit(zap) = \prod_{a \in zap} prob(a) \quad (2.1)$$

3. Results and Analysis. In order to verify the effectiveness of the method, the experimental environment consists of three subnets, with firewalls deployed between the subnets to achieve access control. Among them, the web server and email server deployed in the DMZ region respectively provide external application service interfaces and internal email services: subnet 1 is the office area, where two hosts and one file server are deployed, and the file server stores enterprise confidential files; subnet 2 is the business area, where application servers are deployed to provide application business support for the web server. The distribution of vulnerabilities in the system is divided into 10 training scenarios and 1 experimental scenario, respectively, for training classifiers and implementing predictions. Among them, the classifier was trained using 9 sets of attack samples generated from training scenarios, and the remaining 1 set was used to generate a test set. The performance parameters of the classifier were tested. The experimental scenario was mainly used to generate 0-day attack maps and predict 0-day attack paths. Compared with existing research results, the advantages of this method were tested.

3.1. Sample Training. Based on the attack data of CTF teams simulating attackers on target systems in different training scenarios, relying on knowledge graphs, the successfully attacked devices are used as target entities to calculate path characteristics and construct attack positive samples $\{(H_j, y = 0)\}$. The failed and unselected devices are used as target entities to construct attack negative samples $\{(H_j, y = 0)\}$. Using the model `sklearn.linear_model` in the Python 3.5 environment `_LogisticRegression` constructs a binary classifier and trains LCA using attack samples generated from training scenarios 1-9. On this basis, in the attack positive samples, distinguish between 0 day attacks and known attacks, construct 0 day attack positive samples and negative samples respectively, and train LCz. Use 5-fold cross validation to obtain the learning curve of the classifier, as shown in Figures 3.1 and 3.2[19].

Using the samples generated from training scenario 10 as the test set, the classifier was tested and the predicted results were compared with the actual attack situation. The accuracy of the classifier's LCA was 0.875, the recall was 0.917, and the harmonic mean F1 was 0.883. The classifier LCz's prediction results for the test set are consistent with the actual situation. It can be seen that the classifier has good recognition ability against 0-day attacks.

3.2. Experimental Results. Use the trained classifiers LCA and LCz to predict possible attacks in the target system in the experimental scenario. The predicted attack process is as follows: the attacker first utilizes remote access privileges to access `firewalls_1`. Initiate a 0-day attack, break through access control, and obtain remote access to the `E-MailServer`. Utilize the CVE-2018-18772 vulnerability in its operating system CentOS to launch a cross site request attack, obtain access to `Host_1` and `firewall2`, and launch code injection attacks using the existing CVE-2018-12714 and CVE-2017-17156 vulnerabilities in both, through `Host_1`. Obtain access to `File_server` and access to `Host2` through `firewall2`. At this time, the access permission can be directly used to launch a 0-day attack on `File_server` or `Host2`, obtaining user permissions for `File_Server` and triggering known vulnerabilities such as CVE-2018-8169. The probability of a single step attack occurring in LCA output is shown in Table 3.2.

With the ultimate goal of obtaining `root_File_Server`, the 0-day attack path is extracted, including `zap1: a1 → a2 → a3 → a4` and `zap2: a1 → a2 → a5 → a6 → a7`. The comprehensive utilization rates of the two paths are calculated using Equation 2.1 to be 0.18 and 0.21, respectively. From this, it can be seen that

Fig. 3.1: LCA Learning Curve

Fig. 3.2: LCZ Learning Curve

Table 3.1: Probability of attack occurrence

code	Single step attack	Probability of attack occurrence
a1	(Firewall_1 0day-001)	0.51654178
a2	(Email_Server CVE-2018-18772)	0.77063787
a3	(Host_1 CVE-2018-12714)	0.78201284
a4	(File_Server 0day-003)	0.58126118
a5	(Firewall_2 CVE-2017-17156)	0.76765849
a6	(Host_2 0day-005)	0.77269452
a7	(File_Server CVE-2018-8169)	0.9277652

Table 3.2: Comparative Analysis

method	accuracy	Convenience	Applicability	Comprehensive knowledge	Interpretability
Method A	Lower	Lower	higher	Lower	Not supported
Method B	higher	Lower	Lower	Lower	Not supported
Author's method	higher	higher	higher	higher	support

although the attack path zap2 involves 5 attacks, more than zap1's 4 attacks, its comprehensive utilization rate is higher and more likely to be exploited by the attacker.

3.3. Experimental analysis. Based on the experimental results, by comparing the author with the other two A and B methods, analyze the advantages of this method in terms of accuracy, convenience, applicability, comprehensiveness of relevant knowledge, and interpretability of prediction results, in order to verify its effectiveness. The specific comparative analysis is shown in Table 3.2.

In terms of accuracy, A's simple prediction of attack path zap1 based on the number of 0-day attacks is more likely to become the attack path chosen by the attacker. The author, by constraining the assumption of the existence of 0-day vulnerabilities (the most likely component in Web_Server to have 0-day vulnerabilities is the Apache webserver component, with a probability of 0.05), and using the trained classifier LCA to calculate the probability of an attack on Web_Server (with a probability of 0.3), determined that the attack relationship did not hold, and reasonably excluded the 0-day attack here, reducing the size of the 0-day attack prediction results, at the same time, based on the comprehensive utilization rate, Zap2 can more reasonably predict the attack path chosen by the attacker, improving the accuracy of prediction.

In terms of convenience, A and B not only need to collect relevant knowledge before implementing prediction, but also need to construct specialized 0-day attack rules as the basis for prediction analysis, which causes certain expenses. However, the author relies on network defense knowledge graph and knowledge graph inference methods to implement prediction, without the need for specialized 0-day attack rules, saving expenses and improving the convenience of the method.

In terms of applicability, method B relies on a relatively complete known attack path to implement attack inference. However, in this experimental environment, Web_server does not have a known vulnerability, and firewall_1's known vulnerability, CVE-2019-1934, requires user level permission to trigger. Therefore, it is unable to generate a known attack path under initial permission conditions, and method B is not suitable for such scenarios.

In terms of knowledge comprehensiveness, the author builds a network defense knowledge graph based on the mature conceptual knowledge in the field of network security, from three aspects: threat, asset, and vulnerability, and extracts relationship paths as features to apply to attack prediction. The prediction process not only uses vulnerability knowledge such as the existence, availability, and impact of vulnerabilities involved in A and B, but also combines knowledge of attack intent and asset types, making prediction analysis more comprehensive and improving the rationality of prediction results[20].

4. Conclusion. The author proposes a 0-day attack path prediction method based on network defense knowledge graph to address the difficulty of detecting 0-day attacks caused by the unknown nature of 0-day vulnerabilities, as well as the shortcomings of existing research in using conditional assumptions and correlation before and after attacks to overcome the impact of unknowns. By utilizing the mature knowledge of network security ontology in current research, a comprehensive network defense knowledge graph has been constructed, integrating discrete threat, vulnerability, and asset knowledge into a highly correlated knowledge system, providing comprehensive knowledge support for attack prediction. On this basis, the attack prediction problem is transformed into a link prediction problem. A path sorting algorithm with high prediction accuracy and strong interpretability of prediction results is selected to extract the relationship paths between the attacker entity and the target device entity as features, and more comprehensively predict the attack. This effectively over-

comes the influence of unknown 0-day vulnerabilities and one-sided expert knowledge, and improves prediction accuracy, and provided support for the interpretability of the predicted results. The next step is to expand the knowledge module, improve the accuracy of attack prediction, and explore the traceability problem of network attackers based on knowledge graphs in the presence of multiple attackers simultaneously.

A HYBRID IMAGE FUSION AND DENOISING ALGORITHM BASED ON MULTI-SCALE TRANSFORMATION AND SIGNAL SPARSE REPRESENTATION

DAJUN SHENG*

Abstract. In response to the problem of denoising in image fusion, the author proposes a hybrid image fusion and denoising algorithm based on multi-scale transformation (MLT) and signal sparse representation (SRS). A hybrid model is constructed for shear transformation, and the coefficients after MLT decomposition are thresholded. Sliding window technology and translation invariance are used to form sparse representation for image fusion, and SRS algorithm is used to remove noise from the source image. The experimental results show that the algorithm reduces the contrast and spectral information distortion of the fused image, displays high-quality visual fusion effects, maintains high PSNR values under different noise levels, can provide a more complete description of the features in the image, accurately judge the focus area, maintain the structural correlation of the image, and strengthen the description of fusion edges and details in the fused image. It has been proven that the methods of multi-scale transformation and sparse signal representation can fuse and denoise images.

Key words: Multiscale transformation, Signal sparsity, Image fusion, Denoising algorithm

1. Introduction. In the real world, 20% of human perception information comes from hearing, about 70% of information comes from vision, and about 10% of information comes from taste, smell, touch, and other pathways. From the perspective of biological visual information perception, visual information such as images and videos has become the most important means for humans to perceive and recognize information [1]. In 2015, data showed that the total number of uploaded photos on social networking site Facebook reached 600 billion, with a growth rate of 500 million photos uploaded daily; The average daily video views on the video sharing website YouTube are as high as 8 billion times. With the continuous development of science and technology, the demand for visual information by humans is increasing day by day, and the amount of visual information data is rapidly increasing. The acquisition of multi-source heterogeneous visual information has brought unprecedented development opportunities to visual information processing technology [2]. However, in the process of visual information perception, many factors such as data acquisition, compression, transmission, and storage, as well as hardware device limitations and human operation errors, result in image quality problems such as data loss, noise introduction, and motion blur, which also bring huge challenges to theoretical research and engineering practice.

Natural image quality plays a crucial role in communication and visual perception. High quality images have richer content and information, providing users with a better interactive experience; Poor quality images can lose important information and even cause discomfort to users. Although improving the performance of imaging hardware can improve image quality to a certain extent, equipment costs will significantly increase. The blurring effect caused by the shaking of the shooting equipment, as well as the Gaussian, pulse, and quantization noise introduced during the shooting, storage, and compression processes, cannot be avoided by improving hardware facilities due to the degradation and distortion effects on image quality caused by the computational processing process itself or network packet loss and noise interference [3]. Therefore, utilizing computer theoretical technologies such as image processing, machine vision, and numerical analysis to analyze and process multimodal or noisy images, in order to better understand and perceive target objects, has significant theoretical and practical significance. Image denoising and fusion technology has emerged with the aim of removing or weakening image quality issues during the process of acquiring, transmitting, or storing images. Compared with hardware methods, image denoising and fusion technology has obvious characteristics such as

*College of Big Data and Artificial Intelligence, Xinyang University, Xinyang, Henan 464000, China (Corresponding author, x0376y@163.com)

low cost, high flexibility, and wide applicability. However, it involves the understanding, representation, and modeling of image degradation, noise characteristics, and its own characteristics, and there are many difficult problems and challenges. Image denoising and fusion technology is essentially a fundamental research in the fields of image processing and computer vision, and has received widespread attention [4]. The research in the field of image fusion and denoising began in the 1950s and 1960s. In the practical process, the multi-source images obtained through a large amount of manpower and financial resources often have a certain degree of blurriness. Due to the limited technical conditions at the time, blurred images did not have practical value. Fortunately, through the unremitting efforts of experts and scholars to accurately reconstruct real original images, there is currently a relatively mature and widely used image denoising and fusion technology. A typical successful example is in 1964, NASA's Jet Propulsion Laboratory captured images of the moon on a spacecraft using television cameras, which contained information on noise and interference [5]. Computer processing was used to remove interference and noise, correct geometric distortion and contrast loss, and greatly improve image quality. In recent years, image denoising and fusion techniques based on sparse representation theory have effectively represented and approximated the original image by constructing a dictionary using linear combinations of a few atoms, mining the relationship between representation coefficients and corresponding atoms to reveal the inherent nature of visual information, and obtaining images that conform to human visual perception characteristics. At the same time, due to its superior performance such as simple model, easy implementation, noise resistance, interpretability, and ability to process high-dimensional data, it has sparked a wave of research on image denoising and fusion technology under sparse representation frameworks in the academic and engineering fields. With the continuous development of information technology such as images and videos, image denoising and fusion technology has been widely applied in many scientific and technological fields such as military remote sensing, security monitoring, medical imaging, and consumer electronics.

It can be foreseen that with the comprehensive arrival of social media, the Internet, and the era of big data, the vigorous development of information technology mainly based on images and videos will inevitably give rise to a large number of emerging applications and new demands for image denoising and fusion technology. The large and widespread application demands in the industrial sector will also drive the continuous development of image fusion and denoising research fields. As mentioned earlier, research on image denoising and fusion is also of great significance for the development of theoretical technologies in fields such as image processing and computer vision. On the one hand, image denoising and fusion technology can serve as the underlying technical support for other high-level image processing techniques, thereby improving the efficiency, accuracy, and stability of subsequent image processing tasks; On the other hand, research on image self problems not only involves modeling, representing, and understanding the attributes of images themselves, but also involves interdisciplinary research on human visual mechanisms and psychological perception. It is a fundamental research in the fields of image processing and machine vision, and has great research value for disciplines such as machine vision, pattern recognition, and image understanding[6].

Therefore, in order to solve the noise problem in image fusion, the author proposes a hybrid image fusion and denoising algorithm based on multi-scale transformation (MLT) and signal sparse representation (SRS). The algorithm process is as follows:

- Step 1: Perform shear transformation under the mixed model, thresholding the values of various coefficients after MLT decomposition;
- Step 2: Utilizing sliding window technology and translation invariance to form sparse representations for image fusion;
- Step 3: SRS global processing image denoising algorithm removes noise from the source image.

The experimental results show that the proposed algorithm reduces the contrast and spectral information distortion of the fused image, and has good image fusion and denoising effects.

2. A hybrid image fusion and denoising algorithm based on MLT and SRS. As shown in Figure 2.1, the fusion algorithm proposed by the author consists of the following three steps:

- a) Use cartoon texture decomposition to decompose the original image into cartoon and texture parts. The cartoon part mainly includes the structural and geometric parts of the image, while the texture part mainly includes the oscillation and noise parts of the image.
- b) The cartoon and texture parts of the image are fused separately. The cartoon part is fused using convolu-

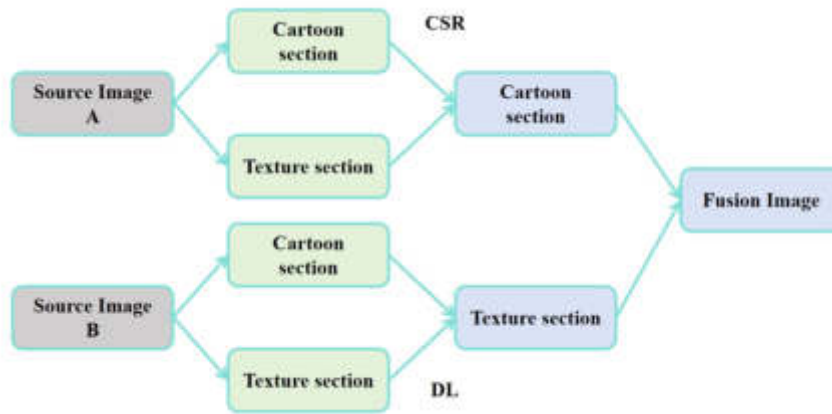

Fig. 2.1: Fusion algorithm framework

tional sparse representation method, while the texture part is fused using dictionary learning method[7].
 c) The fused cartoon and texture parts are fused to obtain a fully focused image.

According to the above algorithm, the high-frequency information in the source image needs to be extracted first[8,9,10]. Based on the MLT algorithm to obtain the required data, and according to the composite wavelet and affine system theory, when the dimension $n=2$, the affine system for composite expansion is defined as follows:

$$A_{AS(\psi)} = \{\psi_{j,l,k}(x) = |\det(A)|^{\frac{1}{2}} \psi(S^l A^j x - k)\}_{j,l \in Z, k \in Z} \quad (2.1)$$

In the formula, A and S are both 2×2 non singular matrices, $\Psi \in l^2(R^2)$ is a composite wavelet, $|\det S| = 1$. Let A be the parabolic scaling matrix, and S represent the shear matrix for $\forall_a > 0, s \in R$. Among them, $\widehat{\psi}_1 \in C^\infty(R)$ is a wavelet.

$$\text{supp} \widehat{\psi}_1 \subset [-\frac{1}{2}, \frac{1}{16}] \cup [-\frac{1}{16}, \frac{1}{2}] \quad (2.2)$$

And $\text{supp} \widehat{\psi}_1 \subset [-1, 1]$, therefore $\widehat{\psi}(0) \in C^\infty(R)$ and $\widehat{\psi}(0) \subset [-\frac{1}{2}, \frac{1}{2}]^2$ assume: $\sum_{j \geq 0} |\widehat{\psi}_1(2^{-2j}\omega)|^2 = 1, |\omega| \geq \frac{1}{8}$, and for $\forall_j \geq 0, \sum_{L=-2^j}^{2^j-1} |\widehat{\psi}_2(2^j\omega - l)|^2 = 1, |\omega| \leq 1$. From this, it can be concluded that:

$$\sum_{j \geq 0} \sum_{L=-2^j}^{2^j-1} |\widehat{\psi}(0)(\xi A_0^{-j} S_0^{-1})|^2 = \sum_{j \geq 0} \sum_{L=-2^j}^{2^j-1} |\widehat{\psi}_1(2^{-2^j} \xi_1)|^2 |\widehat{\psi}_2(2^{-2^j} \frac{\xi_2}{\xi_1} - 1)|^2 = 1 \quad (2.3)$$

For $\xi = R^2$, where x^D is the indicator function of D, $\xi \in [-\frac{1}{8}, \frac{1}{8}]^2, \widehat{\psi} \in [-\frac{1}{8}, \frac{1}{8}]^2$ and $\widehat{\psi} = 1$, set $\{\psi(x - k) : k \in Z^2\}$ is a framework of $L^2([-\frac{1}{16}, \frac{1}{16}]^2)^V$, one attribute of $\psi^d, d=0.1, G(\xi) = (\xi_1, \xi_2)$, changes continuously along the straight line $\xi_2 = \pm \xi_1$, and is used to establish a shear transformation hybrid model.

$F \in R$ is a real value sample signal, SRS is a linear combination of dictionary based prototype signals, forming sparse representation theory based on $D \in R^{n \times m}$ dictionary, among them, there are m prototype signals, and in dictionary D, there is a linear combination of prototype signals indicating $\forall x \in f, \exists s \in R^T$, such as $x \approx Ds$, where s is the sparse coefficient in D. It is usually assumed that the dictionary follows a restricted isometric attribute and is redundant, which solves the problem of reconstructing signals using optimization problems to find the non-zero component with the smallest s:

$$\min_s \|s\|_0 \text{subto} \|D_s - x\| < \varepsilon \quad (2.4)$$

Column based composite system testing solves the problem of the number of non-zero coefficients in sparse matrices, where sparse representation globally processes images, depending on the local information of the source image[11]. The general source image is divided into small blocks with a fixed dictionary D , and the sparse representation of the image is fused using sliding window technology and translation invariance. The source image I is divided into j small blocks of size $n \times n$, represented in dictionary order as vectors $v.V^j$, which can be represented as: $v = \sum_{t=1}^T S^j(t)d_t$, where j is the number of image blocks, d_t is the prototype from D and $D = [d_1 \dots d_t \dots d_T]$, it contains T prototype vectors, and $S^j = [s^1(1) \dots, s^j(t), \dots, s^j(T)]$ is a sparse representation, therefore, the image block of I is used to reconstruct a matrix v , $v=DS$, where S is a sparse matrix.

Due to the impact of noise on image fusion, in order to improve the effectiveness of image fusion, threshold processing is performed on the coefficients after MLT decomposition. The threshold is defined as:

$$\widehat{T}(\widehat{\sigma_I}) = \widehat{\sigma}_n / \widehat{\sigma_I} \quad (2.5)$$

Among them, σ_I and $\widehat{\sigma}_n$ is the standard differentiation and noise of the image source, respectively, assuming that source image I and source noise n are independent of each other, and the noise model of image z is represented as $x = I+n$. Therefore, the average noise and signal source calculations are as follows: $\sigma_x^2 = \sigma_I^2 + \sigma_n^2$. Among them, σ_x^2 is the variance of the observed signal, σ_n^2 is the noise density of the source image, and the output noise power of the source image σ_I^2 is: $\widehat{\sigma_I} = \sqrt{\max((\widehat{\sigma}_s^2 - \widehat{\sigma}_s^2), 0)}$.

The image fusion algorithm based on MLT and SRS proposed by the author can prevent and reduce the contrast and spectral information distortion of the fused image. When some noise is detected in the source image, a given threshold is applied for filtering. The steps are as follows:

1. Perform MLT decomposition on two source images $\langle I_A, I_B \rangle$, and apply MLT to obtain their low pass band $\langle L_A, L_B \rangle$ and high pass band $\langle H_A, H_B \rangle$.
2. Perform threshold processing on low-pass and high pass using the threshold obtained from equation (5) to remove unnecessary coefficients from the decomposition.
3. Perform low-pass fusion by applying sliding window technology to $\langle I_A, I_B \rangle$, dividing image I into image blocks of size $\sqrt{n} \times \sqrt{n}$, and dividing them by step size pixels from top left to bottom right, due to the presence of $\{P_A^i\}_{i=1}^T$ and $\{P_B^i\}_{i=1}^T$ in L_A and L_B respectively, rearrange $\langle P_A^i, P_B^i \rangle$ into column vectors and rearrange $\langle \widehat{V}_A^i, \widehat{V}_B^i \rangle$ in each iteration.
4. Perform high-throughput fusion and filter using the threshold rule of formula (5) to ensure that the fused image contains the source image.
5. Perform image reconstruction and perform corresponding inverse MLT on L_F and H_F to reconstruct the final fused image I_F .

3. Experiments and Results. The experiment randomly assigns values from dictionary D with size 128×512 from image blocks in the training dataset, and then performs sparse encoding to obtain the sparse matrix of the signal. Estimated 160000 training data and 16×16 patches, randomly sampled into images, with a dictionary size set to 128. The experiment uses three commonly used metrics to evaluate the quality of fused images, namely mutual information (MI), standard deviation (SD), and entropy. The proposed algorithm is compared and analyzed with MGA, NST, and CTSR algorithms. As shown in Figure 3.1(a)-(c), the proposed algorithm achieved the best results in SD, MI, and entropy metrics, outperforming MGA, NST, and CTSR algorithms. The proposed algorithm displayed high-quality visual fusion images [12,13,14].

Experimental analysis of different noise levels, that is different standard deviations The application threshold of Equation 2.1 after MLT is used to verify the effect of removing noise and obtaining high-quality denoised images. The proposed algorithm is compared with MGA, NST, and CTSR algorithms, as shown in Figure 3.2. Figure 3.2 shows adding different levels of noise to different images σ the PSNR value shows that the proposed algorithm has higher PSNR values than MGA, NST, and CTSR algorithms in all cases of noise levels[15].

From Figure 3.3, it can be seen that the algorithm proposed by the author has the highest values in desk, Pepsi, and book. Although the comprehensive evaluation criteria in the images of flower, lab, and plane did not reach the maximum value, it can be observed that algorithms such as MGA all exhibit varying degrees of blurring of focus area judgment, block effects, and distortion of fusion boundaries during fusion. The

(a) MI

(b) SD

(c) Entropy

Fig. 3.1: Performance evaluation of the different image fusion algorithms

Fig. 3.2: The performance evaluation at different noise levels

Fig. 3.3: Comparison of algorithm evaluation

emergence of these fusion results is due to the inability of the image decomposition algorithm used to describe all features in the image, inaccurate judgment of the focus area of the source image, and neglect of the structural correlation of the image. Using filtering algorithms to fuse images (as filtering algorithms can ensure that images have relatively smooth edges during fusion, but it is also because of the use of filtering algorithms that the description of fusion boundaries is not accurate enough, such as distortion and Gibbs effect) [16].

In summary, compared to the other three algorithms, the algorithm proposed by the author can provide a more complete description of the features in the image, accurately judge the focus area, maintain the structural correlation of the image, and strengthen the fusion of edge description and detail information in the fused image by fusing images [17,18,19,20].

4. Conclusion. Through the above simulation experiments and analysis, it can be concluded that the proposed hybrid image fusion and denoising algorithm based on MLT and SRS has good applicability. Under appropriate threshold conditions, it can obtain high-quality fused images and achieve the effect of removing noise from the source image, reducing the contrast and spectral information distortion of the fused image. The comparison of this algorithm with MGA, NST, and CTSR algorithms shows that the algorithm can display

high-quality visual fusion effects and maintain high PSNR values under different noise levels. However, there are also cases where there is more noise when dealing with different efficient transformation domains and less appropriate thresholds. Therefore, in the next step of research, the focus should be on improving the model transformation algorithm to address these situations, so as to better grasp the geometric shape changes in the image and graphics fusion process.

DIGITAL MEDIA INTERNET MODELING SYSTEM UNDER COMPUTER ARTIFICIAL INTELLIGENCE TECHNOLOGY

MIAOJUN LI* QI LI† CHANGRONG PENG ‡ AND XIAODONG ZHANG§

Abstract. With the continuous expansion of network scale, the hierarchical and modular characteristics of network structure are becoming increasingly prominent. The traditional single-layer network research paradigm has certain limitations in characterizing the complex relationships between various network systems. Analyzing and constructing models for multi-layer networks has gradually become an important direction in complex network research. The author proposes a multi-layer network model for the Internet and the significance of constructing multi-layer network models in the field of the Internet, based on the characteristics of the multi-layer network structure presented in the application process of the Internet. By analyzing the characteristics of internet data, a multi-layer network model covering three types of networks, namely the internet infrastructure layer, business application layer, and user account layer, was designed. The experimental results show that the average shortest path lengths of the three networks, namely routing relationship network, web hyperchain network, and email address network, are 3.8, 2.9, and 1.7, respectively. Due to the existence of inter layer edges in multi-layer networks, nodes can reach each other across layers in addition to intra layer edges. Experimental results show that the average shortest path length of the three networks has been shortened to some extent, with values of 3.1, 2.7, and 1.6, respectively. On the basis of the single-layer network generation model, a layer correlation method for multi-layer networks was designed, and the model construction of multi-layer networks was achieved.

Key words: Internet, Digital media, Kernel distribution, Multi layer network, model building

1. Introduction. With the continuous development and application of computer artificial intelligence technology, the field of digital media internet has shown enormous development potential. Digital media internet refers to a form of media that utilizes computer networks and digital technology for information dissemination, content exchange, and user interaction [1]. It has become an important way for people to obtain information, entertainment, and socialize in today's society. However, the rapid development of digital media internet has also brought a series of challenges and problems, such as information overload, uneven content quality, and poor user experience. Firstly, with the popularization of the Internet and the rapid development of digital media, people are facing a huge problem of information overload. In the era of digital media and the internet, people can easily access a large amount of information, but at the same time, they also face difficulties in information filtering and screening. Excessive information may lead people to be unable to quickly and accurately find the content they need, and even fall into the dilemma of information overload. In order to solve this problem, digital media internet platforms need to strengthen the research and development of information classification, recommendation algorithms, and other aspects, provide personalized information services, and help users better obtain the required information. Secondly, the uneven content quality of digital media internet is also an urgent issue that needs to be addressed. With the development of the Internet, anyone can easily publish content on digital media platforms, which leads to uneven quality of content. Some information may be misleading, false, or even illegal, causing confusion and distress to users. In order to improve content quality, digital media internet platforms need to strengthen content review and supervision, establish effective information dissemination mechanisms and content management systems [2]. At the same time, users also need to improve their ability to distinguish information and avoid blindly believing and disseminating unreliable information. In addition, the user experience of digital media internet platforms also needs to be further improved. Although the digital media internet provides users with abundant information resources and communication platforms, sometimes

§College of Art, Hebei University of Economics and Business, Shijiazhuang, 050061, China.

users may encounter some problems during the process of using the digital media internet, such as slow page loading speed, excessive advertising, etc. These issues may affect the user experience and even make them lose interest. Digital media internet platforms need to continuously optimize user interface design and improve system performance to provide a smoother, more convenient, and personalized user experience.

In addition, the rapid development of digital media internet has also brought privacy and security issues. In the era of digital media and the internet, the leakage of personal information and network security threats are becoming increasingly serious. In order to protect the personal privacy and information security of users, digital media internet platforms need to strengthen the protection measures of user data, encrypt user data, and establish sound security mechanisms. At the same time, users should also raise their security awareness, strengthen the protection of personal information, and make reasonable use of digital media internet platforms [3].

In short, with the continuous development and application of computer artificial intelligence technology, the field of digital media internet has shown enormous development potential. However, the rapid development of digital media internet has also brought a series of problems and challenges [4,5]. In order to overcome these issues, digital media internet platforms need to strengthen information filtering and filtering, improve content quality, improve user experience, and protect user privacy and information security. Only in this way can digital media and the internet better provide people with high-quality information services, promote social progress and development.

2. Methods.

2.1. Current status of multi-layer network modeling research.

(1) *Multi layer network generation model.* At present, multi-layer network modeling is still in its early stages, and multi-layer network generation models can be divided into two categories. One type is the growing multi-layer network model, in which the number of nodes gradually increases according to a generalized priority connection rule. These models explain the evolution process of multi-layer networks from simple and basic dynamic laws. The process of constructing this type of model is as follows: 1) Growth, adding a new node in each layer of a multi-layer network at each time step, and connecting the new nodes in each layer to other nodes in the same layer through m links; 2) Generalized priority connection, where new nodes select existing nodes in the network to connect based on the probability of intra layer and inter layer connections [6]. Another type is multi-layer network composite models, which consider multi-layer networks as a collection of single-layer networks that satisfy certain structural constraints between layers. These sets can generate multi-layer networks with degree correlation and controllable overlap. The idea of this type of model is to first consider the generation of each network layer and then consider the connections between layers, where each layer is generated according to the static model of traditional single-layer networks: Given the node degree sequence of each layer, a configuration model is used to obtain a specific network implementation for the given connection set [7]. There are two ways to connect layers: One is to add any inter layer connections, and the other is to specify inter layer edges by giving a joint degree distribution. Although the terms "joint degree sequence", "joint degree matrix", and "joint degree distribution" are commonly used in literature to represent the number of degrees related to the end of link nodes in a simple network, they explicitly refer to the connections between layers. In the process of constructing multi-layer networks, the selection of any network model will impose certain constraints on existing research, and each network model corresponds to a set of networks that satisfy the implicit constraints imposed by the model. The computer internet is a typical complex network system, and multi-source data often has multiple types of correlations, making computer network systems have multi-layer network characteristics. Therefore, it is very important to study the generation model of multi-layer network security that conforms to the actual network characteristics.

(2) *Typical network model metrics.* The degree k of node i in a complex network is defined as the number of edges connected to that node, and the average of the total degrees of all nodes is called the average degree. $P(k)$ represents the proportion of nodes with degree k in the network to all nodes, used to represent the distribution of node degrees in the network. If there are N nodes in the network and n_k nodes with degree k , then:

$$p(k) = \frac{n_k}{N} \quad (2.1)$$

The k -kernel of a complex network is defined as the remaining subgraph after sequentially removing nodes

with degree $k-1$ from the network. If a node is in the k -kernel of the network and not in the graph with degree $k-1$, then that node is a k -kernel. $g(k)$ represents the proportion of nodes with kernel number k to all nodes in the network, used to represent the distribution of node kernels in the network[8]. If there are N nodes in the network and n_k nodes with kernel number k , then:

$$g(k) = \frac{n_k}{N} \quad (2.2)$$

The average path length L of a complex network is defined as the average of the shortest path length d_{ij} between any two points i and j in the network. This indicator is usually used to measure the efficiency of the network. The smaller the average path length of the network, the higher the efficiency of the network. Its specific expression is:

$$L = \frac{2}{N(N-1)} \sum_{i \neq j} d_{ij} \quad (2.3)$$

The diameter D of a complex network is defined as the maximum distance between all nodes in the network.

$$D = \max_{i,j \in N} d_{ij} \quad (2.4)$$

2.2. Analysis of multi-layer network structure of the Internet . With the continuous expansion of network scale, various types of networks have formed in the Internet. In addition to the interconnection of underlying network devices, various business system related networks have formed at the application layer, and various network account related networks have formed at the user layer. The entire Internet exhibits characteristics of diversity, heterogeneity, and layering [9]. Traditional single-layer networks cannot characterize the multidimensional characteristics of internet data, so it is necessary to establish a multi-layer network model in the field of the internet. The author proposes a multi-layer network structure for the Internet from three layers: basic device layer, business application layer, and user role layer.

The infrastructure layer is a physical network established by various network devices interconnected through physical links, with nodes mainly including routers, switches, servers, etc; The business application layer is mainly a logical network formed by various application systems during the communication process of various business applications [10]. Its nodes mainly include, as there are many business systems operating in the Internet, different types of business systems may form their own networks. When these application systems are laid out on the same server device, there may be correlation relationships between different business system networks. Virtual entity composition, such as various sites, application systems, and business software, including various types of websites, email addresses, etc [11]. The nodes in the user role layer mainly include various accounts registered and used by people during the process of using the Internet. The entities and attribute elements of each layer are listed in Table 2.1.

In the application process of the entire Internet, each layer can form different types of networks based on different connections. For example, in the basic equipment layer, nodes form communication networks according to the relationship between optical cables and ground cables; In the business application layer, different business relationship networks are formed based on different types of business, such as email address networks, web hyperlink networks, etc; At the user role level, different types of social networks are formed based on different social relationships, such as friendship networks, Weibo account following networks, etc. From a vertical perspective, the lower level network nodes are the foundation for the existence of the upper level network nodes. For example, each application system operates on servers in the lower level network, and each account is registered on application software. There is a strong dependency relationship between layers [12].

This multi-layered network structure representation for the Internet plays an important supporting role in characterizing network spatial trends, analyzing network vulnerabilities, and conducting network tracing and evidence collection.

From the perspective of network situation display, by constructing a multi-layer network in the Internet field, Internet data can be presented to network users in a multi-level and multi-scale form, in order to understand the structural characteristics of the network and provide model support for subsequent network decision-making

Table 2.1: List of the three-tier network model elements

Network hierarchy	Entity	Attribute
Basic equipment layer	Server, computer, router, access device	City, IP address, autonomous domain number, port, manufacturer
Business application layer	Software, various types of data	System software: Windows, Ubuntu, Centos Application software: WeChat, email, website data: account and password, text, video
User Role Layer	Account	Registration time, registration unit, etc

Table 3.1: Statistics of the actual network characteristic parameters

number	project	Routing network
1	Number of nodes	192244
2	Number of edges	609066
3	Average path length	4.61
4	Average degree	6.34
5	Maximum degree	1071
6	Network diameter	12
7	Number of network cores	31

and deployment[13]. From the perspective of analyzing network vulnerability, the analysis of key nodes based on multi-layer network structure will have a significant impact on the analysis process, which may enable cross layer attack paths that were previously unreachable in single-layer networks to be reachable in multi-layer networks. This provides a new research approach for conducting network vulnerability analysis and evaluation. In terms of network traceability, multi-layer network models can more efficiently achieve this function. For example, if a company receives a phishing email and uses a multi-layer network to analyze and trace criminals, the process is as follows: First, match the email with logs to obtain the sender's email address, locate the email sender upwards, and locate the email sender's IP downwards [14]. If the IP is not the attack source, use the association relationship of the email address to find the address that has email exchanges with the email sender, and further locate the user upwards, downward positioning to achieve multi-path traceability of the target.

3. Experiments and Analysis.

3.1. Single layer network modeling experiment. The author used Python and its NetworkX module for network modeling and related feature parameter statistics experiments. In order to better demonstrate the practicality of the CGN model constructed by the author, actual network topology data was first obtained, and then an equally sized network was generated using the CGN model. The relevant statistical parameters of the CGN model generated network and the actual network were compared and analyzed [15].

The model validation data is sourced from the open-source dataset website CAIDA1. In complex network theory, network topology is generally described using statistical characteristics such as the number of nodes, edges, degree and degree distribution, kernel number and kernel distribution. After calculation, the statistical situation of the relevant characteristic parameters of the actual network is listed in Table 3.1.

The author intends to verify the applicability of the model by comparing the relevant parameters of the actual network and the network constructed by the author's proposed model. In order to ensure the reliability of the experimental results, 10 experiments were conducted using the CGN model to generate networks of the same scale. The average of these 10 statistical results was taken as the comparison parameter for each feature parameter.

Table 3.2: The comparison of static statistical characteristics

number	project	Routing network	CGN network
1	Number of nodes	192244	192244
2	Number of edges	609066	614526
3	Average path length	4.61	4.56
4	Average degree	6.34	6.16
5	Maximum degree	1071	1108
6	Network diameter	12	11
7	Number of network cores	31	31

Fig. 3.1: Comparison of Kernel Distribution

From Table 3.2, it can be seen that the actual network and the number of generated network nodes are completely consistent with the number of network cores, the number of node edges is equivalent, the average path length is basically consistent, and the average degree and maximum degree are also similar, indicating that the model has good applicability [16].

The CGN model can achieve complete controllability of the number of cores of nodes in the network, which is reflected in the fact that the network generated by the model is completely consistent with the actual network in terms of the distribution of cores, as shown in Figure 3.1.

3.2. Internet multi-layer network construction experiment . The three layers of the multi-layer network experiment are routing relationship network, web hyperchain network, and email address network. The data sources for the three layers of the network are all from the NetworkData sets network database website [17].

Based on the actual network data obtained, calculate the kernel distribution of the three networks, as shown in Figure 3.2(a-c). The kernel distribution of the three networks follows a power-law distribution, and the function is expressed as:

$$P(K > k) = \alpha \cdot k^\rho + \lambda(5) \quad (3.1)$$

Fit the kernel distributions of three networks using the machine learning library sklearn provided by a third-party in Python, and obtain the corresponding kernel distributions for the three networks α , β , λ , as listed in Table 3.3.

(a) Route network kernel distribution

(b) Core distribution of web page hyperchain network

(c) Core distribution of the email address network

Fig. 3.2: Nuclear distribution fitting

Table 3.3: Network power-law parameters

Network type	α	β	λ
Routing network	0.40	0.79	-0.04
Web hyperlink network	0.64	0.59	-0.19
Email address network	0.32	0.93	-0.01

Based on the obtained kernel distribution functions of the three networks, the sequence of network kernels for a specified network size can be obtained. The node sizes of the three-layer network routing relationship network, webpage hyperlink network, and email address network constructed by the author are $N_1 = 200$, $N_2 = 50$, and $N_3 = 20$, respectively. Next, let's consider inter layer connectivity. In a routing network, both computers and servers are located at terminal nodes, while other nodes are router nodes. As actual business applications run on computers and servers, nodes in the business application layer will only have connectivity with terminal nodes in the basic device layer, that is, nodes with a moderate degree of 1 between the business application layer and the basic device layer will have connectivity. Therefore, the interlayer edge ratio here 1 corresponds to the proportion of connected edges between the terminal nodes in the routing network layer and the upper layer.

Randomly select interlayer node ratio $\alpha_1 = 25\%$, $\alpha_{21} = 55\%$, $\alpha_{23} = 40\%$, $\alpha_3 = 100\%$, corresponding interlayer edge connection parameters $\beta_{12} = \beta_{23} = 50\%$. Associate the three-layer network according to parameters[18].

(2) *Analysis of multi-layer network characteristics.* The average shortest path lengths for the routing relationship network, web hyperlink network, and email address network are 3.8, 2.9, and 1.7, respectively. Due to the existence of inter layer edges in multi-layer networks, nodes can reach each other across layers in addition to intra layer edges. Experimental results show that the average shortest path length of the three networks has been shortened to some extent, with values of 3.1, 2.7, and 1.6, respectively. Due to the small scale of the author's experimental data, it is not reflected clearly enough. But overall, there is a decreasing trend, and experiments have shown that compared to single-layer networks, multi-layer networks achieve multi-path reachability of nodes and reduce the average path length between nodes[19].

4. Conclusion. The author designed a three-layer network model for multi-dimensional data of the Internet based on the characteristics of the multi-layer network architecture, defining the elements, attributes, and the meanings of intra layer and inter layer edges of each single-layer network. Based on the idea of k-kernel decomposition, the author proposes a single-layer network model generation algorithm for digital media, designs a multi-layer network generation model on this basis, and finally proposes the significance of constructing multi-layer network models in the field of interconnection networks. As an emerging research direction in recent years, multi-layer networks have been applied in related fields, but there are still many scientific problems worth exploring. There is still a long way to go in establishing its theoretical framework and enriching databases in related fields. Establishing a multi-layer network model in the field of the Internet is of great significance for network security personnel to correctly assess the network security situation, master key network nodes, and make decisions and deployments. This is an important direction for future research.

E-COMMERCE DATA MINING ANALYSIS BASED ON USER PREFERENCES AND ASSOCIATION RULES

YUN ZHANG*

Abstract. With the development of network technology, online shopping is becoming more and more convenient. But the increasing number of products also makes it difficult for consumers to make the right decision. When there is no apparent market demand, how to recommend products with commercial potential to customers has become an urgent problem for businesses to solve. This paper proposes e-commerce product recommendation based on user preference and association rule algorithm aiming at the problems existing in e-commerce product recommendation. Firstly, this paper constructs a user interest modeling method. Through analyzing users' interests and preferences, to provide users with timely and accurate personalized services. Then, the FP_Growth algorithm is optimized and improved. A more effective CTE-MARM algorithm is designed, and an association rules database based on user benefit items is constructed and analyzed jointly. Analyze products with strong correlations. According to consumers' interest levels, TOP-N is the best product choice. Experiments show that the algorithm has higher prediction accuracy. The research results of this project can not only improve enterprises' ability to analyse data and provide data support for enterprises to carry out effective marketing management.

Key words: Data mining; Association rules; User preference; Electronic commerce; CTE-MARM algorithm

1. Introduction. In modern society, with the rapid development of science and technology, human beings are also faced with the problem of "excess" and the convenience of obtaining science and technology. This phenomenon is no exception in e-commerce. Making customers satisfied with products is a significant issue for e-commerce enterprises. This is how the product recommendation technology in e-commerce emerged [1]. It applies the method of data mining to the actual consumer behavior scenario. Possible business opportunities can be predicted through the correlation mining of historical data. This saves users time finding items they like and increases sales and customer loyalty.

In the same frame, it is of great theoretical value and practical significance to study three different types of customer evaluation: customer perceived value, customer satisfaction, and customer purchase intention. Previous studies have shown that perceived value is the pre-variable of consumer satisfaction. Risk perception, individual innovation, social impact, and perception of usefulness directly and significantly impact user intent. Perceived ease of use and social influence directly impact user availability but cannot play an indirect role through perceived usefulness. Many psychological barriers of consumers to e-commerce, especially the security and reputation problems faced by e-commerce users, will significantly impact consumers' purchase intentions and cause significant obstacles to the rapid development of e-commerce. After a questionnaire survey and analysis of e-commerce users, some researchers found that social factors have the most apparent positive effect on e-commerce intentions, while they have no noticeable effect on e-commerce expected practicability and risk perception. Mobile phone payment intention positively affects users' use, but convenience has no noticeable promoting effect [2]. Some scholars use the integrated technology acceptance model to study electronic transaction intention from six perspectives: perception of usefulness, perception of ease of use, perception of risk, trust, trust and evaluation, and attitude of use. Relevant studies mainly focus on the perception and evaluation of consumer behavior but lack systematic collection and analysis of mobile payment users' characteristics and future consumer behavior [3]. This makes it a complex problem to accurately position the market of its target users in the initial stage of the development of e-commerce.

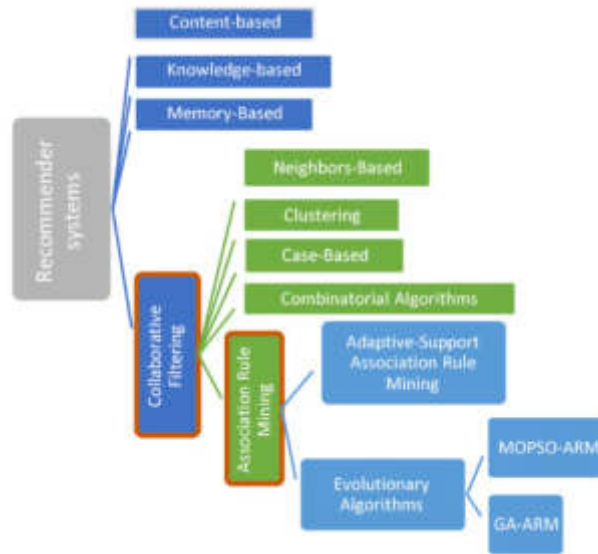

Fig. 2.1: Association rules model flow.

2. Demand analysis.

2.1. Functional Requirements. The key to an e-commerce product recommendation system is to analyze the interests and preferences of users by collecting their shopping habits and shopping records. Then, explore and predict the potential shopping opportunities [4]. The most important thing is to analyze users' personalization and real-time performance. The system implements the following essential functions.

1. Data collection: extracted relevant records and operational data.
2. Preprocess and eliminate unnecessary data to ensure data integrity.
3. The user's interest model is established and classified.
4. Establish the relevant rule database of data mining.
5. Product recommendation for products that are attractive to users.

2.2. Key Parameters.

1. Credibility is introduced to reduce the phenomenon of "rule explosion" and improve the search accuracy;
2. The prescription describes the change in consumption behavior in real life. The closer to the current consumption behavior, the more it can reflect the current demand preferences.
3. The purchase, browsing, collection, rating, and comments of e-commerce consumers can reflect consumers' interests [5]. Users have different levels of interest in different business activities. Use the triplet method to sort the required items in order IR_{ij} . The "user-benefit item chain" comprises the N items with the highest information value by the TOP-N method. The CTE-MARM method is proposed for data association [6]. When good i in the list of customer-benefit items has a strong correlation with good k , good k is added to the tripartite group. The model flow diagram is shown in Figure 2.1.

3. Association rule algorithm model design. This topic focuses on how to quickly find the user group with specific characteristics in the process of commercial marketing of e-commerce enterprises. Discover the characteristics of the target user group. This user group has more complex characteristics [7]. The value of the variable is random and difficult to transform. Each attribute is unrelated, so it is challenging to meet the needs of conventional statistical methods using standard multiple regression analysis, structural equation model, technology acceptance model, technology acceptance model, and integrated technology acceptance model. It is challenging to realize the rapid positioning of specific user groups. In the practical problems, from many incomplete, noisy, fuzzy, random, and other practical problems, we extract the information and knowledge that

people do not know in advance but have potential value [8]. Then, the information in these eigenvalues can be obtained by mining the association rules.

3.1. Principles of Association Rules. Association rules were proposed by R. Agrawal in 1993 to describe the internal relationship between various items in a database. It is one of the essential research contents in data mining [9]. Association rules can directly represent the relationship between a collection of items in a data set. These associations are not based on a specific distribution or depend on a specific pattern. It depends only on the probability of occurrence of the set of items in a pattern. Suppose $Q = \{q_1, q_2, \dots, q_m\}$ is the set of all entries. H represents the transaction database and T represents project subset ($T \subseteq Q$). Each transaction has its unique transaction identifier $TID.B$ is the set of entries. Transaction record T includes item B . Its necessary and sufficient condition is that if the entry B contains k items, it is called the set of k items. The proportion of the number of items B in the transaction database H is called the level of support for the item set. If the support level of an item set exceeds the minimum support threshold set by the user, it is called a frequent item set. The law of association is the logical implication of class $U \Rightarrow V$. Where $U \subset Q, V \subset Q$, and $U \cap V = \emptyset$. If transaction database contains $s\%$ transactions and includes UV , then the support of trading system $U \Rightarrow V$ is $s\%$. The absolute amount of support is the possible number. If $\text{support}(U)$ is used to represent the degree of support for item U , then $\text{support}(UV)/\text{support}(U)$ can be used to represent the degree of confidence of the rule, which is the conditional probability $P(V | U)$.

$$\begin{aligned}\text{support}(U \Rightarrow V) &= P(UV) \\ \text{confidence}(U \Rightarrow V) &= P(V | U)\end{aligned}$$

The related rules conforming to the minimum support and threshold are called strict rules [10]. The maximum is 0 – 100%. That is, whether the item on the right will be selected when the item on the left is purchased or whether the item on the right will be selected in any situation. In the process of selecting target customers, the size of the revenue is the most important. The greater the revenue value, the greater the customer demand for the service. This criterion is the same as the selection criteria for other data exploration modes [11]. To measure how much this criterion improves the prediction accuracy by comparing it with the "original" criterion.

3.2. Evaluate the role of the "promotion" attribute group in association rules. Assume that the mobile user base is constant. It grows at a constant rate over some time. But compared to the number of existing mobile phone users, the number of new mobile phone users is still relatively small [12]. For this reason, the number of users will grow in a particular proportion over some time, so at a certain point in time, the number of mobile phone users can be limited to:

$$\text{total users} = IE$$

I is the invariant growth factor. E is the number of mobile phone users at a given point in time. In association rule $[D, Z, S]$, D is support, Z is credibility, and S is revenue. The number of mobile phone users $\times D$ can be considered to be able to support a certain number of mobile phone users. Under the promotion effect of the previous part, the mobile user number H can promote the latter part. The number of mobile subscribers $\times D \times Z \times S$ can be understood as selling mobile phones to a specific group [13]. The number of mobile users that can make subsequent things happen. Using the number of mobile phones $\times D \times Z \times S$, the "promotion" effect of the former term on the latter term can be evaluated, and the "promotion" effect is more prominent when the effect value is more significant. Since the number of mobile phone users IE is constant at a certain point in time, a "boost" factor is introduced here:

$$\phi = D \times Z \times S$$

D stands for support, Z for credibility, and S for revenue. The "boost" factor is used to measure the strength of the "boost" connection between the first product and the later product [14]. With the increase of ϕ , this "promoting" effect gradually increases. It is targeted at this audience characteristic for marketing publicity, which will receive a good effect.

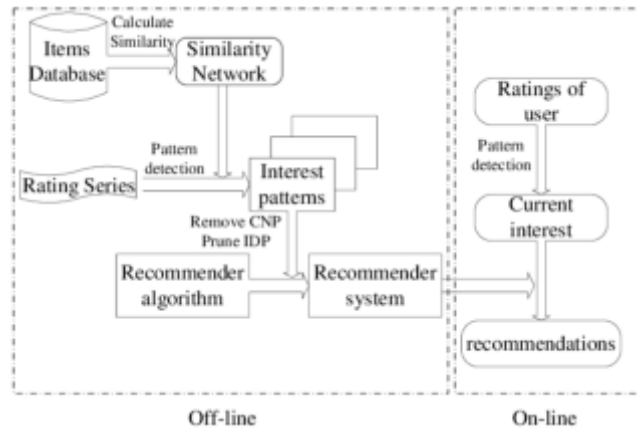

Fig. 4.1: *User interest model framework.*

4. User interest model. Building a user’s interest model can give better feedback on the user’s interest. A person’s hobbies are generally divided into two categories: one is long-term, and the other is short-term. A structural diagram of the user benefit pattern is shown in Figure 4.1.

Long-term interests reflect a person’s preference for one thing over a while. This hobby is not something that will change over some time but a constant state. Most of these are gradually accumulated over a long period of life, and naturally, it is also related to the individual’s educational experience, life background and personality [15]. Short-term interest usually refers to a specific period. People prefer a thing because of some factors and stimuli, but external stimuli will change this preference. Of course, short-term interests can turn into long-term interests. These fleeting interests will gradually dissipate over time. Because the amount of information users is interested in for a long time is considerable, it is necessary to divide it reasonably. If we use the mathematical formula $S = \{(s_1, \varepsilon_1, r_1), (s_2, \varepsilon_2, r_2), \dots, (s_n, \varepsilon_n, r_n)\}$ to describe a person’s long-term interests, then S_i is what we care about. The ε_i stands for the user’s love for the product. r_i indicates that users pay more attention to an event because they prefer it.

Because the short-term interests of users change at any time, it is challenging to transform them into long-term interests, and they are often fleeting, so this paper does not use the method of statistics on the short-term interests of users. The mathematical formula expresses the user’s short-term interest in this paper d. β is for something. ξ stands for the level at which users like a product. Then, the user’s short-term interest can be expressed by $D = (d_1, d_2, \dots, d_m)$. In a shopping system based on consumer preferences, this indicator can reflect in real time the change of consumers’ preferences for fresh items decreasing over time. We define the expression of freshness as: In a shopping system based on consumer preferences, this indicator can reflect in real time the change of consumers’ preferences for fresh items decreasing over time. We define the expression of freshness as:

$$u_t = \begin{cases} 0 & 0 \leq u_{t_0} \leq \varphi \\ \left(\frac{u_{t_0} - \varphi}{u_{t_0}} \right) & u_{t_0} > \varphi \end{cases}$$

t_0 is the past time. t means now. u_{t_0} indicates that the user has previously found the item novel. u_t represents that the user currently finds the item novel. φ stands for a constant number. If freshness is set to 0, then freshness is considered 0. Freshness means that it will gradually decrease over time until it reaches 0. He has lost interest in the item if the novelty drops to zero. According to different user behavior records, different keywords are automatically generated, and the corresponding database is built for personalized search. However, since the value of the freshness decreases over time, it is also necessary to calculate the weight of the freshness. Then, the calculation of novelty weighting for specific keywords can be expressed by expression.

$$(\beta_p, \xi_1, t_1, h_1, u_1), (\beta_p, \xi_2, t_2, h_2, u_2) \cdots (\beta_p, \xi_n, t_n, h_n, u_n) : h_1, \dots, h_n$$

The user's recent preferences on a particular tag can be weighted. u is used to represent the total weight. $\xi_p^t = \xi_1 * u'_1 + \xi_2 * u'_2 \dots + \xi_n * u'_n \cdot u'_1, u'_2, \dots, u'_n$ represents the current freshness value and takes it as the freshness value at t . After weighing each keyword, the interest set can be obtained quickly.

Keywords are weighted according to different user preferences. The detailed calculation method is as follows:

$$S = \{(s_1, \varepsilon_1, r_1), (s_2, \varepsilon_2, r_2), \dots, (s_n, \varepsilon_n, r_n)\}$$

Since each class has keyword glyph, the weight $s_i = ((\beta_1, w_1), (\beta_2, w_2), \dots, (\beta_n, w_n))$ of different classes can be obtained by statistical analysis of text feature vectors of different classes. In addition, using the relevant algorithm, the user's interest category can be accurately displayed.

Input: Important bytes that are currently of interest to the user;

Output: the user's long-term interest choice;

$$S = \{(s_1, \varepsilon_1, r_1), (s_2, \varepsilon_2, r_2), \dots, (s_n, \varepsilon_n, r_n)\}$$

1. Extract all tuples generated on A day t_0 and define them as follows: keyword β , initial weight ξ , creation time t , document containing keyword h , freshness u .
Firstly, $\xi_p^t = \xi_1 * u'_1 + \xi_2 * u'_2 \dots + \xi_n * u'_n$ weighted analysis is carried out for a particular keyword. The corresponding weights of each keyword are obtained after Δt .
2. Repeat step 1 until all tuples have been calculated. Set threshold λ and find a keyword that is larger than this value. Record it in Group ψ . Then, the corresponding text H_0 is determined according to the relationship between the keyword and the tuple.
3. The selection range of the selected associated keywords and text need not be too wide, so according to the threshold value of the initial weight of the keyword, you can find the corresponding collection of files whose original weight exceeds a particular critical value. And as a category according to their level of long-term interest in the category. Use $S_i = (s_1, S_2, \dots, S_m) s_i$ to represent a class.
4. Update keywords when they do not reach a particular range. Re-evaluate it to see if it's of long-term interest.
5. The users' long-term interest set is obtained by calculating steps 3 and 4. Calculate the number of files r_i in each category to get $((s_1, r_1), (s_2, r_2), \dots, (s_n, r_n))$. $\varepsilon_i = r_i / \sum r_i$ represents the extent to which users have different preferences for each category. Generate an end-user long-term interest statement:

$$S = \{(s_1, \varepsilon_1, r_1), (s_2, \varepsilon_2, r_2), \dots, (s_n, \varepsilon_n, r_n)\}$$

5. Design of e-commerce product recommendation system.

5.1. System Architecture. The recommendation of e-commerce products is studied using the calculation method of association rules and user preferences. Figure 5.1 shows the overall architectural design (Picture quoted from Egyptian Informatics Journal, Volume 23, Issue 1, March 2022, Pages 33-45). The system includes data collection and cleaning, user interest analysis, building association rule base, and recommending TOP-N.

- (1) Data collection and cleaning: data collection is divided into two parts: shopping and various business activity information. These two data types provide the basis for discovering and researching users' interests. In addition, many messy, fuzzy, incomplete, and dirty data must be cleaned to improve the mining effect. Through the detection of empty orders, goods in the transaction record are detected, and non-relevant fields are removed. In this way, the data is simplified.
- (2) User interest analysis module: This module is mainly used to model and update the interest model. It is automatically collected by the front end and stored in the corresponding database. A "user-interest item" chain is constructed using the above calculation method. Search for items with high correlation and apply them to the TOP-N model.
- (3) Establishment of association rule database model: the CTE-MARM method proposed above is used to discover the connections between specific levels in specific application scenarios. Set the restriction level k to 2. The rules stored in the transaction table are classified from different perspectives according to credibility.

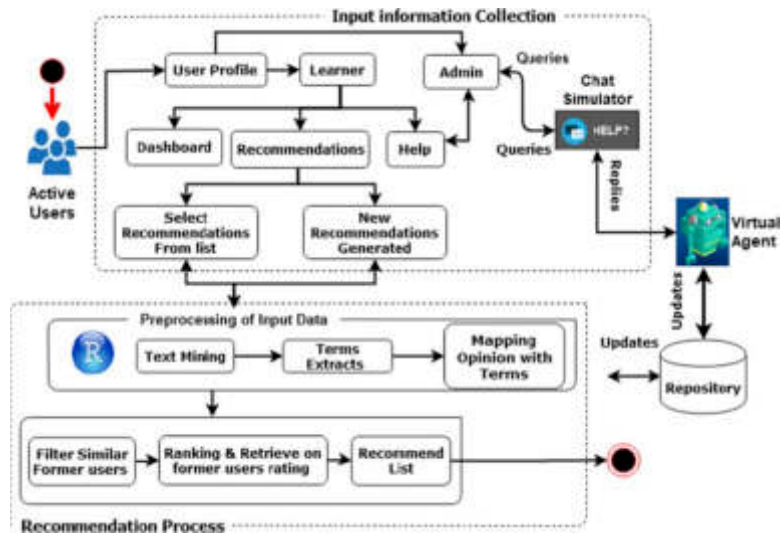

Fig. 5.1: Overall architecture diagram of the system.

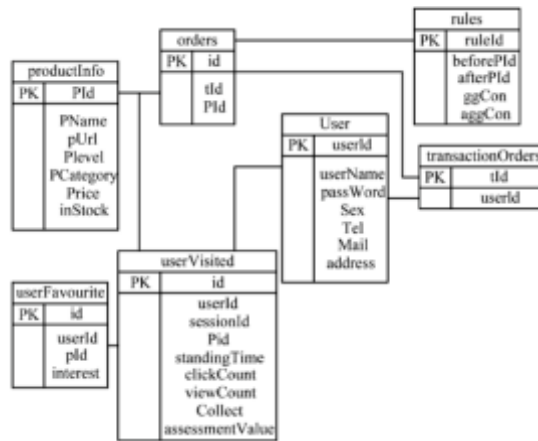

Fig. 5.2: Database E-R diagram.

(4) TOP-N network recommendation mode: The page is visually displayed through the association rules of the products that correlate more with the user’s interest mode.

5.2. Database Design. According to the characteristics of e-commerce product recommendation, a database E-R model based on user behavior and product recommendation is proposed. The database diagram for E-R is shown in Figure 5.2.

Below are the main database tables.

1. The user information form includes user ID, registration name, password, gender, contact information, address, etc.
2. The item information form includes item ID, name, link, grade, classification, price, inventory, etc.
3. The transaction table contains the transaction ID and user ID.
4. The purchase record form contains the unique identification ID, transaction processing ID and item ID.
5. The user behavior table contains unique identifiers, user identifiers, item identifiers, number of clicks,

Fig. 6.1: Hit ratio analysis of manual analysis and system algorithm results.

repeat visits, browsing time, and whether to collect and evaluate scores.

6. The association rule table contains a unique identification, pre-rule component identification, post-rule component identification, inter-item confidence, classification and inter-item confidence.
7. The user interest table contains unique identifiers, user identifiers, product identifiers and interest levels.

6. System testing and verification. The shopping data of 3000 users are used as experimental data to test the accuracy of the established theory and products. The results of manual statistics are compared with user habits and system operation results of manual analysis. Cross-merge was performed after each trial. There were five trials. The result is shown in Figure 6.1. The study found that the accuracy of manual analysis of the best-selling items reached 31.8%. The interest recommendation accuracy of manual analysis reached 51.1%, while the recommendation accuracy of the e-commerce product recommendation system based on association rules reached 55.8%, which is more efficient and accurate than the method. This achieves the original design goal.

7. Conclusion. This paper uses the method based on CTE-MARM to establish an e-commerce data analysis method based on user interests and association rules. In this way, TOP-N products are recommended for users. However, the multi-level association discovery method research needs to be further explored. More influencing factors and technical means must be considered in improving the hit rate of product recommendations.

HIGH-RESOLUTION HOLOGRAPHIC IMAGE RECONSTRUCTION BASED ON DEEP LEARNING

FANGJU LI*

Abstract. Aiming at the shortcomings of existing holographic reconstruction algorithms, which are complex and easily affected by noise, this project proposes a semantic partitioning U-Net for high-resolution reconstruction. Firstly, a method based on the edge-neural network is proposed to obtain more image semantic information and improve the model training effect. Secondly, the effective channel attention mechanism of deep neural networks is introduced to enhance the attention to the detailed information in the holographic image. This further improves the accuracy of the neural network. The convergence rate of the neural network is accelerated by introducing a linear element with leakage correction. Experimental results show that this method can quickly reconstruct phase and brightness images with better detail, better edge texture and flat background. Holographic images of various sizes can be reproduced. The research of this project will lay a foundation for applying holographic image enhancement technology based on deep learning.

Key words: Holography; High-resolution reconstruction; Channel attention mechanism; Terminal neural network; multi-scale reconstruction

1. Introduction. The numerical reconstruction of holograms is a very crucial research work. Firstly, it needs to transform the hologram, filter it +1 times, carry out operations such as unwrapping and phase compensation, and finally realize the reconstruction of the hologram. However, conventional detection technology is more complicated and easily disturbed by noise. So, it is necessary to find a fast and effective reconstruction algorithm. In recent years, with the rapid development of neural networks and corresponding algorithms, it has played a vital role in many industries such as industry, agriculture, medicine and so on with its convenient, fast and efficient characteristics, and it also dramatically promotes the development of three-dimensional image reconstruction. It is imperative to construct an end-to-end coaxial holographic reconstruction network that can resist various optical path aberrations and has no restriction on the wavefront of the reference beam. High-resolution holographic image reconstruction with deep learning is based on deep neural networks, which can reconstruct low-resolution holographic images into high-resolution images. This method takes advantage of the powerful capabilities of convolutional neural networks (CNN) and recurrent neural networks (RNN) in deep learning to learn the features and structure of images, thereby achieving the reconstruction of high-resolution holographic images. Specifically, this approach typically includes the following steps:

1. Data preprocessing: Convert the original low-resolution holographic image into a format suitable for input into the deep learning model and perform necessary preprocessing, such as denoising, normalization, etc.
2. Feature extraction: Use the convolutional neural network (CNN) in the deep learning model to extract features from the preprocessed holographic image to extract high-level features of the image.
3. Super-resolution reconstruction: Use the deep learning model's recurrent neural network (RNN) to perform super-resolution reconstruction on the extracted high-level features to generate high-resolution holographic images.
4. Post-processing: Perform necessary post-processing on the generated high-resolution holographic image, such as denoising, sharpening, etc., to improve the quality and visibility of the image. The high-resolution holographic image reconstruction method of deep learning is a complex technology that requires a large amount of computing resources and training data. It also requires understanding and mastery of deep

learning models and algorithms.

Reference [1] describes a lightweight one-to-two network, which can reproduce both light intensity and bit phase and is applied to digital image reconstruction. In literature [2], U-shaped networks were used to reconstruct three-dimensional images, and the images were not affected by DC, twins and other factors. Reference [3] introduced the attention mechanism into U-Net to achieve high-resolution cell reconstruction. In reference [4], a multi-scale complete convolutional fusion network was constructed to reconstruct the three-dimensional phase diagram of a single cell. Literature has some problems [5], such as low reconstruction rate, complex reconstructed scenes and unclear boundaries. The existing studies only conducted simulation experiments, lacking the real image test. This project will combine the end-to-end neural network with adequate channel attention (ECA) based on U-Net architecture to improve reconstruction efficiency. This project proposes an end-to-end neural network model based on U-Net to improve reconstruction efficiency further. Adequate channel attention is introduced into the feature extraction layer. The method of leakage correction was used to improve the linear cell activation function of the convolutional hidden layer. Then, an efficient and high-quality reconstruction method of multi-scale hologram images based on skeleton structure is proposed.

2. Principles and methods.

2.1. Digital holographic wavefront recording and traditional reconstruction. The reference light is coherently superimposed utilizing object-light wave transmission on the hologram. The interference fringe pattern collected by CCD and a digital hologram are obtained. The principle of digital holographic recording is shown in Figure 2.1 (the picture is quoted in the literature [6]).

Assuming that the density of the object surface is $P(u_0, v_0)$, the complex amplitude of the object wave reaching the holographic recording surface after coherent light irradiation is obtained by the method of angular spectral diffraction.

$$P(u, v) = G^{-1} \left\{ G [P(u_0, v_0)] \exp \left[k \frac{2\pi}{\eta} s \sqrt{1 - (\eta g_{x_0})^2 - (\eta g_{y_0})^2} \right] \right\}$$

G is the Fourier transform. G^{-1} inverse Fourier inversion. s is the distance from the surface of the object to the projection plane of the hologram. $P(u, v) = C(u, v) \exp[k\eta(u, v)]$. It is assumed that $C(u, v)$ represents the light wave amplitude of the object and $\eta(u, v)$ represents the phase of the light wave of the object [7]. The complex amplitude of the reference light on the hologram is called $D(u, v) = C_d(u, v) \exp[k\eta_d(u, v)]$. Where $C_d(u, v)$

Fig. 2.2: Schematic diagram of digital holographic reconstruction.

represents the amplitude of the reference light wave and $\eta_d(u, v)$ represents the phase. Then, the distribution of light intensity on the recording surface of digital holography can be expressed as:

$$\begin{aligned} W(u, v) &= |P(u, v) + D(u, v)|^2 = \\ &|P(u, v)|^2 + |D(u, v)|^2 + \\ &P(u, v)D^*(u, v) + P^*(u, v)D(u, v) \end{aligned}$$

$|P(u, v)|^2$ represents information about the light intensity of the object and $|D(u, v)|^2$ represents information about the intensity of the reference light. The third project is to use conjugated light to regulate matter waves. The fourth project is the study of conjugated optical properties of reference light sources [8]. Therefore, the measured object's amplitude and bit equality information are recorded in the digital hologram. The reproduction principle of traditional digital holography is shown in Figure 2.2. The reconstruction of the image is realized through the steps of illumination and zero-order interference, twin image elimination and phase unwinding using regenerative light. The above processes are not included in reconstructing digital holograms using deep neural networks, so they will not be described here.

Assuming that the copied light wave is A vertically irradiated plane wave $H(u, v)$, then after irradiated digital holography, the diffraction wave generated can be expressed as:

$$\begin{aligned} W'(u, v) &= H(u, v)W(u, v) = H(u, v) [|D(u, v)|^2 + |P(u, v)|^2] + \\ &H(u, v)D^*(u, v)P(u, v) + H(u, v)D(u, v)P^*(u, v) \end{aligned}$$

From the diffraction equation of the angular spectrum, the light field of the reproducing object can be obtained:

$$P(u_i, v_i) = G^{-1} \left\{ G [W'(u, v)] \exp \left[k \frac{2\pi}{\eta} s \sqrt{1 - (\eta g_u)^2 - (\eta g_v)^2} \right] \right\}$$

2.2. Neural network structure. The experiment was divided into two parts. The network structure used in the first experiment is shown in Figure 2.3. Where $U \times Q$ is the proportion of the input image. $U/2 \times Q/2$ represents that the digital holographic image on the $U \times Q$ scale is 1/2 of the original scale after being maximized. The rectangular frame is the characteristic graph obtained after processing each operation module [9]. The number of channels on the current feature map is displayed above the rectangular box. Here, the input and output represented by 1 are two gray images. $Z1$ means that the number of channels in the current characteristic mapping is not fixed and is given according to specific test requirements. $2Z1, 4Z1$, etc., represent the current number of characteristic graph channels is 2 times, 4 times, and $Z1$ so on. The network architecture comprises five operation modules: hierarchical segmentation block, down sampling block, up sampling block, jump link block, output convolutional layer and so on. See Figure 2.3 for a detailed description of each module.

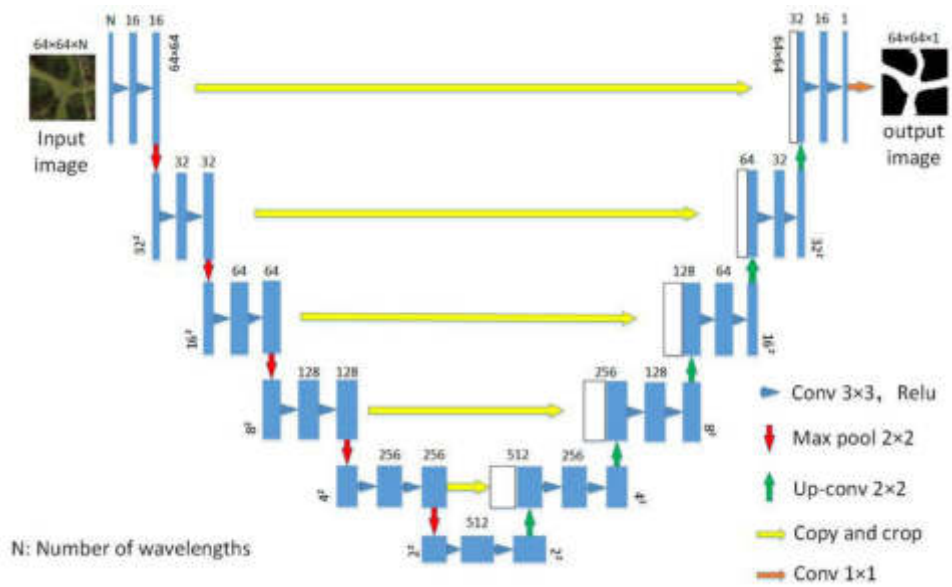

Fig. 2.3: Improved U-Net structure.

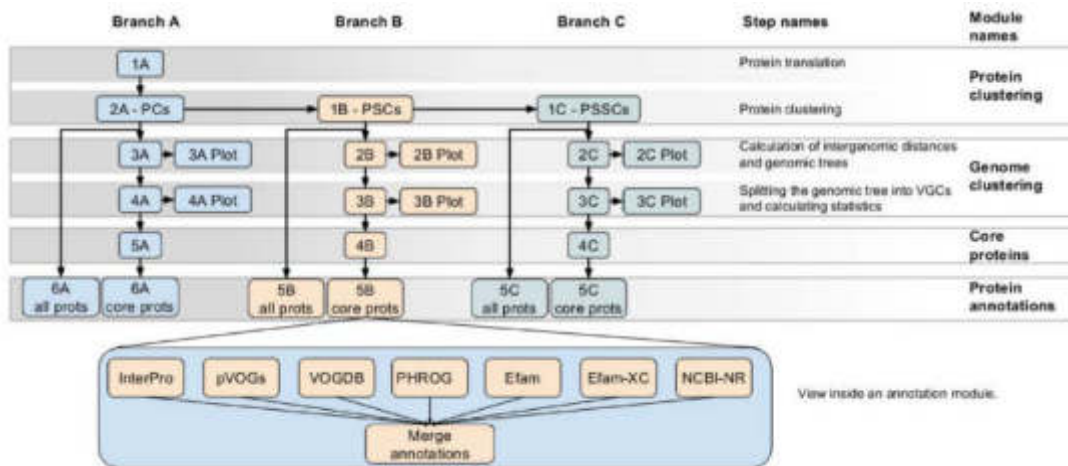

Fig. 2.4: HS-Block structure.

2.2.1. Dividing blocks by layers. This construct is shown in Figure 2.4. The core idea is to use a 3x3 convolution kernel to extract the feature map, perform Batch Norm and ReLU operations, and divide it into five channels. The output of the first set is fed directly to the next level. The second set of images is also extracted by a 3x3 convolutional network with a convolution kernel, and these images are evenly divided into two sub-sequences [10]. The first sub-sequence is connected with the second sub-sequence, and finally, the depth features are further extracted by convolution and the average segmentation is carried out until the fifth set of images is completed. Finally, the output characteristic diagram is integrated and used as the input of the next layer. The advantage of this method is that it reduces the redundant features based on reducing the network structure and improves the operational efficiency and speed of the neural network.

Fig. 2.5: A network of reconfigurable multi-scale digital holograms.

2.2.2. Pooled core subsampling. The lower sampling used the largest pool size, a 2x2 pool. Its primary purpose is to reduce the scale of feature mapping, maintain helpful information, increase the perception field, and, to some extent, prevent overfitting and reduce the difficulty of solving the network structure.

2.2.3. Using Nearest Neighbor Padding. The goal is to decode step by step to restore the original image size. After up-sampling the image, the size of the image will be doubled.

2.2.4. Long Jump Connection. This operation connects the feature graph channels of the output of the shallow network and the deep network together, and the result is used as the input of the next layer so that the deeper network can retain useful shallow information while avoiding gradient disappearance and improving network performance [11].

2.2.5. Output convolution layer. This is simply a combination of convolution and activation layers used to produce a single-channel image.

The network structure used in the second experiment is represented in Figure 2.5. The U-Net in this architecture is represented by the dotted boxes in the Figure 2.3 architecture and otherwise has the same functionality as the corresponding modules in the Figure 2.3 architecture [12]. The numbers above the matrix box represent the channels in the current feature graph. One represents the input and the output as grayscale images, and 40, 20, and 20 represent the number of channels. They also indicate that C1 is 40, 20, and 20 in the modified U-Net architecture. There are three levels from top to bottom [13]. The first level is a 256x256 three-dimensional image. Fix the current model parameters when done. A digital holographic image with a size of 512x512 is passed through the two front and back network structures. Only the second network is learned, and then the parameters of the second network are fixed. The three-level network architecture is added so that every network can pass 640x480 digital holographic, while the three-layer network only needs to learn the network parameters [14]. Since the following layer network can use the local characteristic map extracted from the previous layer network, the number of all network parameters can be reduced. This network structure can effectively solve the problem of multiple extractions of the same image, thus reducing the complexity of modeling and realizing the reconstruction of images of different sizes.

2.3. Generation of data sets and network training. Digital holograms are generated when a computer simulates digital holographic imaging. This project intends to scale up to 18,000 handwritten drawings in the MNIST standard library to obtain amplitude information [15]. The 18,000 images of Chinese characters are normalized and multiplied by 1.9π according to A particular proportion, that is, the wavelength of the illuminated object is $\eta = 632.8$ nm, the distance between the illuminated object and the recording surface of

Table 3.1: Simulation Environment Settings.

Name	Settings

RAM	16G
SDD	500
OS	Win10PersonalEdition

the hologram is $s = 0.3086m$, and the size of the recording surface of the hologram is 5 mm. The reference light is parallel. The Angle of reference light with the x-axis and the Y-axis is set as $\pi/2.02$ and $\pi/2$, and the sampling quantity is 256×256 , 512×512 , 640×480 . The complex amplitude distribution of object wave on the digital holographic plane is obtained by formula (1), and then it coherently overlaps with the reference wave to obtain 6000 digital holograms of different sizes. Five thousand cases were selected as training and 1000 as test samples [16]. The training loss function uses the mean square error loss function, which represents the sum of squares of errors at the corresponding points of the predicted and original data. The expression is

$$\text{lose}_{MSE} = \frac{1}{n} \sum_{i=1}^n (v_i - \bar{v}_i)^2$$

n represents the size of the photo. v_i represents the amplitude information or the i value of the phase information after reconstruction; \bar{v}_i represents i values associated with the initial data [17]. The weights are optimized by the Adam optimization method. Measures were taken to end the training session early when mistakes were made to avoid over-learning. A deep neural network learning framework based on NvidiaRTX2080Ti is constructed by using Pytorch technology.

3. Case analysis.

3.1. Environment Settings. This project intends to use a convolutional neural network and BP neural network for detection [18]. The above algorithms are compared under the experimental conditions given in Table 3.1.

3.2. Experimental object of image reconstruction in laser holography. Five typical three-dimensional images are selected for experiments to verify the universality of the algorithm [19]. Fifty images were selected as simulation tests for different types of laser holograms. The representative image is shown in Figure 3.1.

3.3. Study on image reconstruction in laser holography. The reconstruction results of various stereo images obtained by the three measurement methods are compared, and the results are shown in Figure 3.2. The results show that the accuracy of laser hologram image reconstruction based on deep learning neural networks is better than 95%. The advantages of laser holographic image reconstruction based on deep learning neural network theory are proven.

3.4. Comparison of image reconstruction effects of laser holography. The reconstruction speed in existing large three-dimensional images is also a significant problem. According to the analysis of Figure 3.3, it can be seen that the reconstruction of the 3D stereo image reconstructed by the neural network method based on deep learning takes about 20 milliseconds, the 3D reconstruction based on the BP network takes about 30 milliseconds, and the reconstruction of the convolutional neural network takes about 35 milliseconds.

4. Conclusion. A new idea of three-dimensional image reconstruction using a deep neural network is studied. Its main objective is to improve image reconstruction accuracy in laser holography. The deep neural network model is applied to the reconstruction of laser holographic images, improving the reconstruction effect of laser holographic images. This will help the processing of laser holograms in the future. This project will open up a new way to improve the image quality of laser holographic image reconstruction.

OPTIMIZATION OF E-COMMERCE PRODUCT RECOMMENDATION ALGORITHM BASED ON USER BEHAVIOR

YIFAN JI*, LAN CHEN† AND RUI XIONG‡

Abstract. In order to implement personalized recommendation algorithms for e-commerce, the author proposes a genetic fuzzy algorithm based on user behavior to improve the sales, personalized recommendation, user satisfaction, and purchase matching performance of e-commerce. Collect data based on e-commerce personalized preference recommendation information, extract the associated feature quantities of personalized data for clustering processing, and then combine fuzzy B-means clustering method to achieve e-commerce personalized recommendation. According to the individual preferences of e-commerce, the collected data samples are fitted with differences and restructured, and a genetic evolution method is adopted for global optimization. The experimental results show that the optimized genetic fuzzy algorithm used in this method has improved stability and accuracy compared to the PSO method, with an accuracy increase of 4%. This proves that the algorithm can provide the services needed by users more quickly and is an effective means.

Key words: Genetic algorithm, Personalized recommendations, Fuzzy clustering, User behavior

1. Introduction. The internet generates a massive amount of information every day, some generated during purchases and some generated during page browsing. Behind this complex information lies the unique behavioral characteristics of each internet user. If this information is well utilized, better services can be provided more accurately for specific users [1]. With the skyrocketing amount of information on the Internet, methods for analyzing this information face severe challenges. Therefore, it is of great commercial value to analyze and predict user behavior through data mining and other related technologies, and directly recommend the predicted results to users, providing personalized information recommendation services. In recent years, after successful e-commerce models such as B2B and B2C, the O2O model has for the first time connected online virtual operations with offline physical stores, indicating that internet technology has further spread to people's daily lives. Multiple internet giants are actively participating in the O2O business. In July 2015, Baidu announced an investment of 20 billion yuan in the O2O field within three years, indicating its level of importance. In this context, the daily transaction volume of the Internet will increase, and e-commerce will be the most important market in the future [2].

However, the increasingly serious problem of information overload still troubles internet users. Selecting information that users are interested in from the ocean of data is like finding a needle in a haystack. At the same time, it is difficult to distinguish the accuracy and authenticity of information. Due to limitations in one's own abilities and concerns about expenses, a large amount of information actually brings confusion and confusion to users. In fact, what consumers want is not the amount of information, but the information tailored to their personal interests and hobbies. In recent years, internet companies have shifted their approach from passively providing information to actively guessing what information users need. Nowadays, whether using apps to listen to music or online shopping, there is a "guess what you like" section for personalized recommendations. The rapid development of e-commerce has prompted e-commerce websites to provide higher quality services and more professional information. Personalized services are an important research direction in the field of e-commerce. Currently, e-commerce platforms that only passively provide information services are no longer able to establish themselves. Only by actively attracting users and providing the goods and services they need can

*Sichuan Vocational College of Finance and Economics, Chengdu, Sichuan, 610101, China

†Sichuan Vocational College of Finance and Economics, Chengdu, Sichuan, 610101, China (Corresponding author's e-mail: chenlannncncnc@163.com)

‡Sichuan Vocational College of Finance and Economics, Chengdu, Sichuan, 610101, China

they attract users. Driven by this emerging business model with billions of users, new science and technology have been continuously developed, and recommendation systems have played a crucial role in it [3].

From a research perspective, the massive amount of data brought by the Internet has led to the emergence of a new research model, which has shifted from studying actual experimental objects to analyzing virtual data. In this model, the dependence on theory is not very sensitive, and there are some problems that cannot be accurately explained in theory, but have been proven effective in practical applications. This research method is a breakthrough attempt, it not only prompts the academic community to re-examine research methodology, but more importantly, it itself promotes the progress of current science and technology [4].

From a business perspective, accurate recommendation algorithms can better personalize marketing for users. When placing advertisements on a page, if recommendations are made based on the user's recent browsing data, it can improve the accuracy of advertising placement. On shopping websites, corresponding recommended products can also be provided based on users' recent purchasing behavior to increase sales. It can be seen that high-performance recommendation algorithms can generate significant economic benefits for both advertising and e-commerce businesses.

From the perspective of internet users, with the emergence of recommendation systems, we don't have to waste a lot of time finding things we are interested in from search engines or merchant lists. Instead, data providers can directly push recommendation results to us through recommendation systems on the page. This is not only an efficient way for users to obtain the required information, but also a pleasant user experience.

2. Methods.

2.1. E-commerce personalized recommendation information model and feature extraction.

(1) *Personalized information transmission.* Extract user personalized consumption data based on e-commerce correlation features, obtain fuzzy decision functions, construct non-linear mapping $\varnothing : n \in R^n \rightarrow Q$ to represent user personalized guidance space, combine data information with decision functions, and use intelligent algorithms to map to feature space F [5]. Assuming the e-commerce recommendation sample set is $\{(a_1, m_1), (a_2, m_2), \dots, (a_n, m_n)\}$, the personalized feature quantity $a_i \in R^n$ represents the model input vector, $m_i \in R^n$ represents the target test value, and n represents the quantity, the personalized recommendation objective function is calculated:

$$\begin{aligned} \min \text{imize } & \frac{1}{2} \|w\|^2 + \sum_{i=1}^n B (J_i + J_i^*) \\ \text{subject to } & m_1 - (w' \varnothing(a_i) + b) \leq \varepsilon - J_i \\ & (w' \varnothing(a_i) + b) - m_i \leq \varepsilon - J_i \\ & J_i J_i^* \geq 0, i = 1, 2, \dots, n; B > 0 \end{aligned} \quad (2.1)$$

In Equation 2.1, J_i and J_i^* are ontology attributes and association rule variables, and the cost factor is represented by B . The difference function is obtained by using control optimization method as shown in Equation 2.2.

$$Q(a) = \sum_{i=(e_i - e_i^*)}^n F(a_i, a_j) + b \quad (2.2)$$

In Equation 2.2, e_i and e_i^* represent personalized attribute values and the number of Template categories, while the symmetric kernel function $F(a_i, a_j)$ represents the recommendation threshold. Based on the preference information in the database Web cloud, adaptive optimization is performed to extract the information multipath gradient map and obtain the conduction model a_1, a_2, a_3, a_4 , which is represented as:

$$\begin{cases} a_1 = L_1 - u \\ a_2 = L_2 - u \\ a_3 = L_3 - u \\ a_4 = u \end{cases} \quad (2.3)$$

In Equation 2.3, u represents the genetic fuzzy clustering correlation attribute, and the domain of information subspace dimension is Ω . Extract associated data and feature quantities based on e-commerce information, establish labels, and analyze group interaction relationships.

(2) *Extraction of associated feature quantities.* The personalized preference data is fitted with sample differences and restructured to extract associated feature quantities, $x(s)$, $s = 0, 1, \dots, n-1$, representing the time series of feature quantities in the user area. Under the constraints of relevant rules, the structural distribution function obtained is:

$$E^{bu}(b_1, b_2) = T \cdot \text{Length}(b) + m \cdot \text{Area}(\text{inside}(b)) + P_1 \int \text{inside}(b) |i - b_1|^2 + P_2 \int \text{outside}(b) |i - b_2|^2 \text{dadm} \quad (2.4)$$

In Equation 2.4, b_1 and b_2 are the adaptive feature coefficients, $\text{Length}(b)$ is the length coefficient, and $\text{Area}(\text{inside}(b))$ is the size of the feature region; Construct a feature vector set and control decision function, with a mixed kernel function as shown in Equation 2.5.

$$F_{min} = \mu F_{poly} + (1 - \mu) F_{rbf}, \mu \in (0, 1) \quad (2.5)$$

In Equation 2.5 $F_{poly} = [(a \cdot a_i + 1)]^2$, the preference trust kernel function $F_{RBQ} = \exp(-a||a - a_i||^2)$ is RBQ, and the adaptive clustering process is recommended under the rule, resulting in:

$$Q_{lg-c}(o) = (Q_{lg}(o), Q_{lg-a}(o), Q_{lg-m}(o)) = (Q_{lg}(o), h_a^*(o)) \quad (2.6)$$

In Equation 2.6, $Q_{lg}(o)$ is the user's project rating value, and a quadruple is obtained based on the associated features:

$$\max \left\{ \begin{array}{l} |bh(z) - bh(z) \cap bh(z_2)| + |bh(z) \cap bh(z_2)| \\ |bh(z_2) - bh(z) \cap bh(z_2)| + |bh(z) \cap bh(z_2)| \end{array} \right\} = \max \left\{ \begin{array}{l} bh(z) \\ bh(z_2) \end{array} \right\} \leq \Delta \quad (2.7)$$

In Equation 2.7, $bh(z)$ is a regular coefficient with correlation, which facilitates the extraction of data correlation features.

2.2. Optimization of personalized recommendation algorithms for e-commerce.

(1) *Genetic evolution optimization method.* Personalized data association feature extraction is based on sample difference fitting and structural restructuring. The author uses genetic fuzzy clustering method to extract association features based on kernel function construction. Utilizing the advantages of genetic algorithms, global optimization control is performed on potential user preference variables. The following Equation 2.8 expresses the meaning of the genetic evolutionary control function:

$$m_i = T m_i (1 - m_i) \quad (2.8)$$

In Equation 2.8, T is a personalized recommendation control parameter, and the construction of $m_i \in [0, 1]$ random numbers is completed. Assuming that in a fuzzy clustering space W , u is the mutated individual, $t = \{L_1, L_2, \dots, L_w\}$ is the population, $L_i^d(s) (i = 1, 2, \dots, w)$ represents the user's search for individual i using latent features in the dimension space W , $V_i^w(s) (i = 1, 2, \dots, t)$ is the optimization speed of individual i , $L_{best}^w(s)$ represents the best position of individual i , and $G_{best}^w(s)$ represents the optimal solution, in the process of genetic evolution, the expression for optimizing individual extremum and global extremum at each iteration is:

$$\begin{cases} N_i^w(s+1) = A \cdot N_i^w(s) + B_1 \cdot R_1(L_{best}^w(s)) \\ -L_i^w(s) + B_2 \cdot R_2 \cdot (G_{best}^w(s) - L_i^w(s)) \\ L_i^w(s+1) = L_i^w(s) + N_i^w(s+1) \end{cases} \quad (2.9)$$

In Equation 2.9, the conduction coefficient and correlation eigenvectors of particle i at the current and next time points are $N_i^w(s)$, $N_i^w(s+1)$, and $L_i^w(s)$, $L_i^w(s+1)$; In the formula, B_1 and B_2 represent learning factors,

with values between -25 and 25; The search radius and threshold of genetic fuzzy clustering are represented by R_1 and R_2 , respectively, and are randomly selected[6]. Combining genetic fuzzy clustering optimization with A, a recommended adjustment formula is obtained in interval $[A_{min}, A_{max}]$:

$$A(s + 1) = 4.0w(s)(1 - A(s)) \tag{2.10}$$

$$A(s) = A_{min} + (A_{max} - A_{min})A(s) \tag{2.11}$$

The personal universality analysis of e-commerce users is based on the value of the inertia factor in Equation 2.11 and the convergence control of the pattern neural network recommendation process.

(2) *Data information mining and clustering processing.* Cluster the obtained personalized preference data and combine it with B-means to extract quadruples represented by $\{E_1, E_2, \dots, E_p\}$. Extract the conduction control model under the premise of controlling constraint variables:

$$\gamma'_{desira} = \gamma_1 \cdot \frac{Density_i}{\sum_i Density_i} + \gamma_2 \frac{YL_i}{YL_{init}} \tag{2.12}$$

$$\begin{cases} \gamma_1 + \gamma_2 = 1, \gamma_1, \gamma_2 \in [0, 1] \\ \gamma_2 = \frac{max_i(YL_i) - min_i(YL_i)}{YL_{init}} \end{cases} \tag{2.13}$$

Introducing radii R_1 and R_2 into cluster learning, the recommendation process update Equation 2.14 is obtained, with $R_i(s) \in (0, 1), i = 1, 2$ in Equation 2.14. The phenomenon of using fuzzy clustering method to jump out of the optimal value and merge with user rating measurement is described by Equation 2.15:

$$R_i(s + 1) = 4.0R_i(s)(1 - R_i(s)) \tag{2.14}$$

$$N_i^w(s + 1) = 4.0N_i^w(s)(1 - N_i^w(s)) \tag{2.15}$$

$$N_i^w(s) = N_{min} + (N_{max} - N_{min})N_i^w(s) \tag{2.16}$$

$$\rho_i(f, l) = \frac{\gamma(f)\sigma_{fl}d_l(o_{s+1})\mu_{s+1}(l)}{\sum_{f+1}^V \sum_{l+1}^V \gamma_s(f)\sigma_{fl}d_l(o_{s+1})\mu_{s+1}(l)} \tag{2.17}$$

The range of pheromone values for mutated individuals in Equation 2.16 is represented by $[N_{min} + N_{max}]$. Under the constraint of association rules, Equation 2.17 represents the clustering center of the association feature quantity, where $t + 1(j)$ is the number of nodes, $d_l(o_{s+1})$ is the coefficient point set, and y_{fl} is the score measurement information. The genetic evolution algorithm is used to calculate the variance δ^2 and determine whether $\delta^2 < H$ is valid. In order to achieve personalized recommendation in e-commerce, genetic evolution and optimization processing are combined with clustering algorithms to determine whether the convergence criteria are met [7].

2.3. Introduction to User Group Behavior Analysis Platform. The process of the product recommendation function platform, as shown in Figure 2.1, is mainly to provide users with personalized product recommendation services [8,9]. Users log in to the platform to browse products (the products they browse are basically of interest to the user), and obtain the parameters and prices of the products, at the same time, understanding the type of product, regardless of whether the end user has successfully purchased, the user transaction database will record information such as product number, product type, and matching. The platform is divided into the following three modules to present the user behavior data analysis process:

- 1) User behavior tracking module: By tracking the user's clicking, browsing, bookmarking, storing and other behaviors on the website, the product data and browsing customer data are transformed into user purchasing behavior operation data, and users are grouped for the first time through log data;

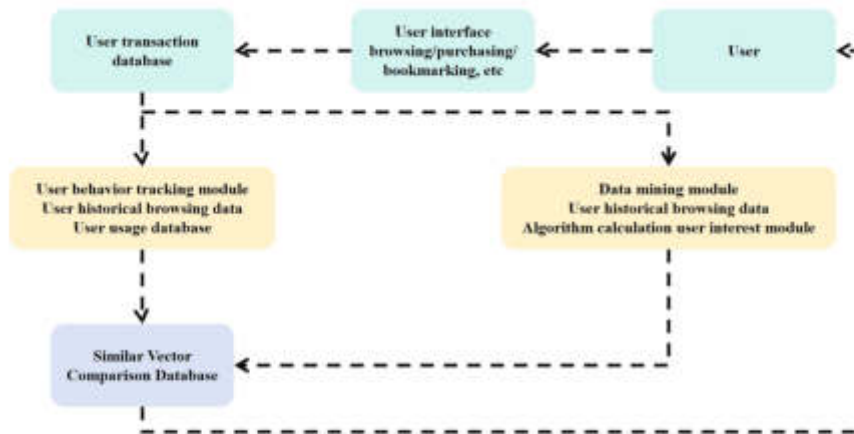

Fig. 2.1: Process of Product Recommendation Function Platform

- 2) Data mining module: Analyze user log data using traditional algorithms and improved fuzzy algorithms based on genetic algorithms, and obtain association rules for frequent items of users respectively. This can uncover the rule habits of users in their recent behavior;
- 3) Result display module: By using the user behavior tracking module to group user data, as well as the association rules of products analyzed by the data mining module, based on similarity vector comparison of user similarity, gather similar rule users, and make Top-N recommendations based on the similarity comparison results [10,11].

3. Experiments and Results. Using Matlab7 to design matrix simulation experiments, the data used in the experiments were all sourced from publicly available online data from JD.com and Alibaba, mainly to verify the accuracy and convergence of personalized e-commerce recommendations[12]. According to the simulation experiment parameters, $Q=41$ is set as the clustering center, the fuzzy control parameters are set to $b_1 = 124, b_2 = 364$, the e-commerce simulation time is 2 minutes (120 seconds), and 3120 iterations are run. In the W individual dimension space, the number is set to 1040, and the population size is 10. The experimental parameters are set to start the simulation analysis.

Test the sample information collected from e-commerce users and compare the convergence of traditional methods with the experimental process to obtain a comparison curve, as shown in Figure 3.1.

The comparison results of Figure 3.1 show that the author's use of e-commerce personalized recommendation has a very good response in terms of user recommendation satisfaction and information accuracy, which fully reflects the good performance of e-commerce personalized recommendation[13]. Analyzing and comparing personalized e-commerce recommendation methods with traditional methods, and comparing PCA algorithm with PSO, the results are shown in Figure 3.2.

The above experimental results indicate that in the personalized dimension space W of e-commerce personalized recommendation, the collection and setting of all experimental data, and the experimental process are compared with traditional methods. E-commerce personalized recommendation provides accurate user information recommendation, promotes transaction completion, and greatly improves efficiency[14]. It is confirmed that genetic evolution method is combined with B-means in global optimization, and preference data is clustered to achieve personalized recommendations for e-commerce. User satisfaction and accuracy are also reflected in Figures 3.1 and 3.2.

By collecting and analyzing a large amount of test data, three constructed methods were used for product recommendation, and the experimental data results shown in Figures 3.3 and 3.4 were obtained.

Fig. 3.1: Comparison of personalized recommendation curves for e-commerce

Fig. 3.2: Comparison of satisfaction with personalized e-commerce recommendations

Figure 3.3 shows the accuracy distribution of some users. It can be seen that in a small number of users, the accuracy difference between the PSO method and this method is not significant. However, as the number of users increases, this method demonstrates its advantages of high efficiency and accuracy [15].

Figure 3.4 shows the distribution of recall rates for some users. Similarly, it can be seen from the figure that when the number of users is relatively low, both accuracy and recall rates do not show the advantages of the algorithm. As the number of users increases, the improvement in system performance after algorithm optimization can gradually be seen. This also fully demonstrates that the results of big data analysis are more accurate and effective.

Finally, the author performed simple average calculations on a large amount of accuracy and recall data, and obtained experimental results as shown in Table 3.1 by calculating the time complexity of the three methods during operation.

Due to the fact that in the PCA model, the entire system does not display the function of product recommendation, but only conducts data analysis on the use and purchase of products, and presents the analysis

Fig. 3.3: Partial user usage accuracy chart

Fig. 3.4: Partial User Function Recall Rate Chart

results to users in the form of bar charts or pie charts, therefore, in the PCA model, users need to rely on these analysis data to determine the products that are suitable for their own configuration, thus unable to provide time complexity [16].

As can be seen, for the PSO method, the author uses traditional incremental mining algorithms to optimize the entire system, and the accuracy and recall of the product recommendation function have greatly increased. However, for the data platform Storm used in the system, traditional algorithms need to be compatible with its segmented data processing method and massive scanning times, which greatly increases the time and space required, the operating cost of the system has also generated tremendous pressure, therefore, the minimum time complexity of the matching algorithm is $O(n)$. For this method, a half search is used, so the time complexity of the matching algorithm is set to $O(1gn)$. Considering the cost, both types of time complexity are acceptable, but the system pursues higher efficiency. Moreover, Table 3.1 shows that the accuracy and recall of this method have also been improved to a certain extent compared to the PSO method. Therefore, considering all indicators comprehensively, this algorithm has indeed played an important role in improving product recommendation effectiveness [17,18,19,20].

From the above data analysis, it can be seen that the PSO method, using traditional incremental mining

Table 3.1: Comparison of evaluation indicators for three experimental methods

	PCA model	The method of this paper	PSO model
Accuracy	0.14	0.68	0.72
Recall	0.19	0.70	0.76
Time complexity	Not have	O(n)	O(lgn)

algorithms, has already achieved very good results in mining user preferences, and can more accurately and efficiently recommend products to users compared to before. And this method utilizes the optimized genetic fuzzy algorithm, which has improved stability and accuracy compared to the PSO method. More importantly, it greatly compresses the system's running time in terms of time cost, and can provide the services needed by users more quickly. It is an effective means.

4. Conclusion. The collection of personalized e-commerce data is sourced from publicly available data from JD.com and Alibaba. The author restructured the data and fitted the sample difference, then optimized and extracted the associated feature quantity, which was processed using the B-means clustering method to achieve personalized e-commerce recommendations. The author confirmed the effectiveness and stability of this recommendation method through experimental results. The effect of using weight increment mining is better than that of general mining, and it is also more efficient and fast. The accuracy of this experiment is as high as 72%, and the recall rate is as high as 76%, which is more accurate than other recommendation methods. Based on the above experimental methods, it can be proven that the algorithm optimized product recommendation method used by the author is an effective product recommendation strategy and has basically achieved the expected results.

APPLICATION OF MULTI-OBJECTIVE OPTIMIZATION ALGORITHM BASED ON ARTIFICIAL FISH SCHOOL ALGORITHM IN FINANCIAL INVESTMENT PORTFOLIO PROBLEMS

HONGXING ZHANG*

Abstract. In order to comprehensively measure these two indicators and make reasonable portfolio investment decisions, the author proposes using swarm intelligence optimization algorithm - artificial fish swarm algorithm to solve multi-objective investment portfolio problems, and has achieved good results. In order to verify the effectiveness and superiority of the artificial fish school algorithm, the author used MATLAB programming to conduct simulation experiments using AFSA algorithm and genetic algorithm (GA), and compared the results obtained. The results show that compared to the GA algorithm, the artificial fish school algorithm can obtain better investment portfolio decision-making solutions for investing in five types of assets, making investment returns as large as possible while minimizing risks, indicating the efficiency and superiority of the algorithm in solving multi-objective investment portfolio problems.

Key words: Artificial fish school algorithm, Multi objective optimization algorithm, Financial investment, Combinatorial problem

1. Introduction. With the continuous development of the market economy in today's society and the increasingly fierce social competition, the competitive field of asset investment has gradually penetrated into various industries and even people's daily financial life. However, when investing, there will inevitably be complex multi-objective investment portfolio problems, which cannot avoid complex calculations, therefore, in the face of the difficulty that existing mathematical programming methods cannot directly solve multi-objective investment portfolio problems, the author considers solving this problem from the perspective of highly efficient swarm intelligence optimization algorithms that have emerged and developed in recent years, which involves handing over a large amount of complex computational work to computers to complete. The so-called optimization algorithm basically describes search or rule based strategy or specific process, and gets the solution which can achieve user expectation by some search rules and channels. The theoretical research and practical application of optimization algorithms have made great progress, and many scholars have attempted to apply them to solve various engineering optimization problems. Many studies have shown that their problem-solving ability is higher than other traditional algorithms, and they have achieved good results, especially in combinatorial optimization problems. Therefore, people insist on innovative research on the theory and application of optimization algorithms. The author chooses a new type of swarm intelligence optimization algorithm - artificial fish swarm algorithm for research and applies it to solve practical problems [1]. The artificial swarm algorithm adopts a new method which is different from other optimization algorithms. There are some differences between the specific implementation of algorithms and the overall design idea, compared to the design method and the solution. However, it can also be combined with other traditional methods. AFSA does not require the initial values, measurement values, or properties of the target function. It has the potential to overcome local weaknesses and globalization. It is precisely because of the excellent characteristics that artificial fish swarm algorithm has attracted great interest and extensive attention from researchers from all walks of life at home and abroad since it has been applied. At present, the research and application of artificial fish swarm algorithms have entered many disciplines and been used to solve practical problems. This conclusion has become a research topic with high research value. So far, although the artificial fish school algorithm has been studied and applied by many scholars in related fields, its application scope and improvement work on the algorithm itself still need further improvement and expansion. Therefore, the author's research on using

*College of Finance, Henan Finance University, Zhengzhou, Henan, 451464, China (18538776139@163.com)

artificial fish school algorithms to solve multi-objective investment portfolio problems has important theoretical significance and practical application value for both the field of economics and computer science [2]. At the same time, it is also a preliminary exploration of the application of artificial fish swarm algorithm in the field of multi-objective investment portfolio.

Artificial Fish Swarm Algorithm (AFSA) is an intelligent swarm algorithm based on the behavior of fish game, which simulates the basic behavior of animals. Since its proposal, AFSA has received widespread attention from domestic and foreign researchers, as well as in-depth research and practical applications. So far, there have been hundreds of relevant references on the research and application of AFSA, indicating the significant influence of this algorithm both domestically and internationally. Related studies have shown that although the artificial fish swarm algorithm has many superior characteristics, it still has some shortcomings, such as low solving accuracy, being trapped in local extremum and low efficiency, and slow convergence speed in the later stage. In response to these shortcomings, scholars have adopted different design methods for exploratory research and improvement, making the algorithm more effective in solving practical problems.

In the process of capital market, rational investors will decide how to allocate some risk factors which they hold in an appropriate way, in order to achieve the goal of increasing risk as much as possible and obtaining the maximum funds. How to comprehensively measure the two main factors that constrain capital investment, namely investment risk and investment return, and make reasonable portfolio investment decisions, this also leads to a multi-objective investment portfolio problem. And this problem belongs to a complex nonlinear programming problem, which is difficult to be effectively solved by traditional algorithms. Therefore, the author proposes to use swarm intelligence optimization algorithm - artificial fish swarm algorithm to solve multi-objective investment portfolio problems, and has achieved good results [3].

2. Methods.

2.1. Multi-objective investment portfolio problem and its model. Assuming there are n assets S_i ($i=1, \dots, n$) available for investors to choose from in the market, with an existing amount of M of funds used for a period of investment. The average return on purchasing S_i during this investment period is r_i , and the expected risk loss rate is q_i . There is a certain level of risk in the investment process. Consider using the largest risk among n assets to measure overall risk. Assuming that a certain transaction fee needs to be paid when purchasing an asset, let the transaction rate paid for purchasing S_i be p_i . When the purchase amount does not exceed the given value u_i , the transaction fee will be calculated based on u_i ; Furthermore, assuming that the deposit interest rate deposited into the bank is fixed [4]. Establish the following multi-objective investment portfolio model, assuming that the proportion of funds for purchasing asset S_i to the total M is x_i , the required transaction cost is:

$$T(x_i) = \begin{cases} 0, & x_i = 0 \\ u_i p_i, & 0 < Mx_i \leq u_i \\ (Mx_i) p_i, & Mx_i > u_i \end{cases} \tag{2.1}$$

The total net income during an investment period is recorded as V :

$$V = \sum_{i=1}^n (Mx_i r_i - T(x_i)) \tag{2.2}$$

For an investment period, the overall risk (taking the maximum risk) is recorded as R :

$$R = \max_{1 \leq i \leq n} \{Mx_i q_i\} \tag{2.3}$$

In order to maximize returns and minimize risks, the mathematical model for the multi-objective investment portfolio problem is:

$$\begin{aligned} \max \quad & v = \max \left\{ \sum_{i=1}^N (Mx_i r_i - T(x_i)) \right\} \\ \min \quad & R = \min \{ 1 \leq i \leq n \{ Mx_i q_i \} \} \end{aligned} \tag{2.4}$$

2.2. The principle of artificial fish school algorithm . The main idea of the Artificial Fish Swarm (AFSA) algorithm is that in the body of water, the area where fish are most abundant is usually the area with the most nutrients. This decision is based on these characteristics to simulate the food, crowd, end-to-end collisions, and behavior of fish schools, in order to achieve global development.

(1) *Individual definitions of artificial fish.* The individual state of artificial fish can be represented as a vector $X = (x_1, x_2, \dots, x_n)$, where x_i ($i=1, 2, n$) is the variable to be optimized; The food concentration at the current location of the artificial fish is expressed as $Y=f(X)$; The distance between artificial fish individuals is expressed as $d_{ij} = ||X_i - X_j||$; The maximum number of attempts per foraging for artificial fish is $trynumber$, the perceived distance for artificial fish is $visual$, the maximum movement step for artificial fish is $step$, and the crowding factor is δ [5,6].

(2) *Description of artificial fish behavior.*

Foraging behavior: Set the current state of the artificial fish to X_i , and randomly select a state X_j within its perceptual range ($visual$), if the food concentration in this state is better than its current state, the artificial fish will move one step forward in that direction; On the contrary, randomly select state X_j again to determine whether the forward condition is met. After repeated attempts at $trynumber$, if the condition is still not met, randomly move one step.

Crowding behavior: Set the current state of artificial fish to X_i , explore the number of ($d_{ij} < visual$) partners nf and their central position X_c in the current field, if $Y_{cnf} < \delta Y_i$, it indicates that the food concentration at the center position is better than the current state and not too crowded, and the artificial fish moves forward towards the X_c position. Otherwise, they perform foraging behavior [7].

Tail chasing behavior: Set the current state of the artificial fish to X_i , and explore the optimal partner X_{max} in the current field, if $Y_{maxmf} < \delta Y_i$, it indicates that the food concentration at the partner's location is better than the current state and the surrounding area is not too crowded. If not, the artificial fish will move forward towards the X_{max} position. Otherwise, they will engage in behavioral activities.

Random behavior: This behavior is easy to execute and is the original behavior for the behavior.

Report board: used to record the status of the best fishermen. During the refining process, each artificial fish compares itself with the status of the reports. If the status of the news report itself is improved, it will be adjusted to its own status so that the news report can record the best events in history.

2.3. Multi-objective investment portfolio problem based on AFSA algorithm.

(1) *Model optimization.* For the solution of the multi-objective investment portfolio problem described by the author, the following method can be used to first transform it into a single objective problem, and then solve it: Set weights ρ for the weight of the total net investment return, then $1 - \rho$ weighting the overall investment risk ($0 \leq \rho \leq 1$), so the above multi-objective investment portfolio model can be transformed into a single objective model as follows:

$$\begin{aligned}
 & \max F(x) = \rho \times V + (1 - \rho)(-R) \\
 & \max F(x) = \rho \times \sum_{i=1}^N (rMx_i - T(x)) + (1 - \rho) \times (\max_{1 \leq i \leq n} \{Mx_i q_i\}) \\
 & \text{s.t.} \begin{cases} \sum_{i=1}^N x_j = 1, 0 \leq x_i \leq 1 (i = 1, 2, \dots, n) \\ 0 \leq \rho \leq 1 \end{cases}
 \end{aligned} \tag{2.5}$$

For the model ρ investors can make appropriate adjustments based on their own situation to obtain appropriate investment portfolio decisions [8].

(2) *Steps for solving the model.* The steps to solve multi-objective investment problems using AFSA algorithm are as follows:

Step 1: Start the size of artificial fish stocks, automatically create N artificial fish stocks, set the requirement for the algorithm, including the quantity of simulation and simulation of artificial fish stocks movement, the detection by artificial fish stocks, the large-scale step artificial fish stocks movement, and the crowds are equal δ the maximum number of iterations to achieve the algorithm.

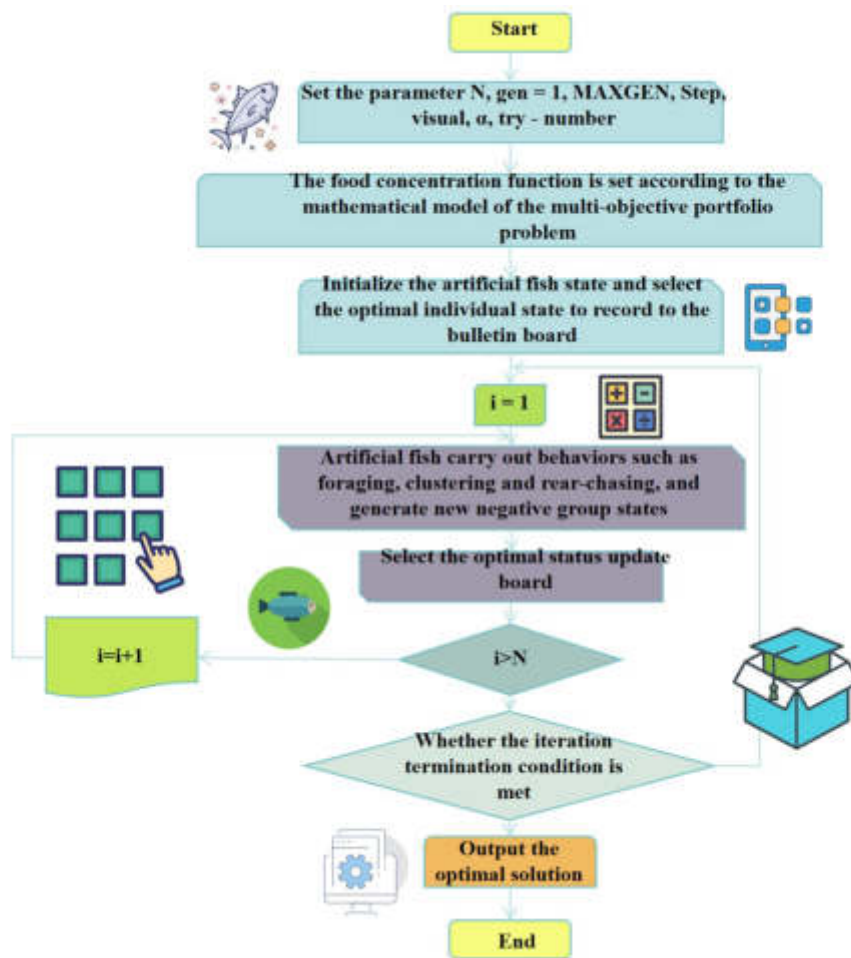

Fig. 2.1: Steps for solving multi-objective investment portfolio problems using AFSA algorithm

- Step 2: According to the mathematical model of multi- objective investment problem, set up the food concentration function of the algorithm.
- Step 3: Sample the current menu of all the fake fishermen and list the status of the best person on the poster.
- Step 4: Each artificial fish acts as a laborer, crowded, and tailor -made, chooses the best practices, and modifies its own state.
- Step 5: After the update, each fake fish will compare its status with the reports. If the effect is greater than the sign, the status of the sign will be adjusted.
- Step 6: Determine the decision for the algorithm. If iteration termination condition is met, output the calculated result; output otherwise, continue with step 4.

Figure 2.1 shows the steps to solve a multi-objective investment portfolio problem using the AFSA algorithm.

3. Simulation experiments. In order to verify the effectiveness and efficiency of the artificial fish school algorithm, the author made a simulation of AFSA algorithm and genetic algorithm (GA) using MATLAB programming, and compared the results. There are five investment assets available for selection, with a total investment amount of M of 1000 yuan. The data on the return rate, risk loss rate, and other factors of each asset are shown in Table 3.1 [9].

The parameters of artificial fish school algorithm were set fish school size of 50%, the quantity of iterations

From Table 3.2, it can be seen that for multi-objective investment portfolio problems, under different risk preferences, the artificial fish school algorithm can obtain better fund investment portfolio schemes. The simulation experiment results show the effectiveness and feasibility of AFSA algorithm to solve such problems. The range of iterations for genetic algorithm used for comparison is $N=100$, with a crossover probability of 0.8, a mutation rate of 0.01%, and a population size of $P=100$; The comparison of investment portfolio schemes based on the calculation results is shown in Table 3.3 and Figure 3.2 (assuming $\rho= 0.5$).

From Table 3.3, it is evident that for investing in five types of assets, compared to the GA algorithm, the

Fig. 3.2: Comparison of Investment Portfolio Plans

artificial fish school algorithm can obtain better investment portfolio decision-making solutions, maximizing investment returns while minimizing risks, indicating the efficiency and superiority of the algorithm in solving multi-objective investment portfolio problems [10].

4. Conclusion. The author proposed to study and apply the artificial fish school algorithm to multi-objective investment portfolio problems, and achieved good results through MATLAB programming. Experimental results show that this algorithm performs very well in solving such problems, but as a new type of optimization algorithm, there are still some shortcomings. Therefore, further research and improvement are needed to improve the performance of solving such problems when there are a large number of assets and investment funds.

OPTIMIZATION ALGORITHM FOR GREEN ENVIRONMENT DESIGN BASED ON ARTIFICIAL INTELLIGENCE

KAI QIAN*

Abstract. In order to build energy-efficient commercial buildings in bustling urban centers and utilize passive means such as natural ventilation and natural lighting as much as possible to improve indoor environmental quality, the author proposes a green environment design optimization algorithm based on artificial intelligence. Taking Building A as an example, simulation technology was used to optimize the performance of the enclosure structure, anti condensation in the glass atrium, and natural ventilation during the transition season. The sunlight and shadow simulation software BSAT was used to simulate the mutual occlusion and self occlusion of the building. It was found that external rolling shutters were not required for shading the facade between axes L2-L5 and 3-9. Using DeST-C, the energy consumption and investment of south facing, east facing, and west facing envelope structures were compared when using different types of glass. Combining economic efficiency and energy-saving effects, the optimal southbound enclosure structure scheme for this building is to use Low-e membrane coated hollow double glass with ten horizontal louvers for external shading; It is recommended to adopt the scheme of hollow double glass (Low-e membrane) or hollow double glass (Lowe membrane)+external roller shutter in the east-west direction. It is worth noting that for east-west oriented glass, the Lowe film should be low permeability, mainly to improve the thermal performance in winter and reduce the radiation heat gain in summer. Using DeST-C for simulation 2 calculation, it was found that when the thermal performance of windows increased from $3.0W/(m^2 \cdot K)$, shading coefficient 0.7 to $2.0W/(m^2 \cdot K)$, and shading coefficient 0.5, the maximum cold and heat load of the building and the cumulative consumption of cold and heat throughout the year were significantly reduced, providing an effective reference for solving problems.

Key words: Artificial intelligence, Green environment, Design optimization algorithms, Energy saving, Enclosure structure

1. Introduction. Due to the high-density agglomeration of urban population and pollution caused by production and daily life, the ecological environment of urban residential areas is increasingly valued by people [1]. Green environment design is an important means of ecological environment design. Green environment design for residential areas can fully improve the climate characteristics of residential areas, and achieve unity and harmony with nature in the living environment of residential areas. Generally speaking, the form of green environment design in residential areas includes grassland greening, tree (tree, shrub) greening, balcony and terrace greening, interior and exterior corridor greening, exterior wall greening, roof platform greening, and indoor greening. It is a three-dimensional and all-round green environment. In residential areas, grasslands not only provide recreation, but also provide a broad view and become the center of public activities, serving as the "breathing space" of residential areas. But in some current residential areas, developers have made the central green space area too large in pursuit of grandeur, and there is a lack of coordination between shrubs and trees. Due to the limitation of the overall plot ratio, residential areas have reduced the green coordination of the adjacent green spaces, on the other hand, there is a lack of trees to shade the sun, resulting in a lack of humanized space in the central green space, which lacks a lot of fun and even becomes purely a decoration. Trees can absorb dust and noise in residential areas, reduce wind speed, preserve soil and water, and block the scorching sun in summer. On the landscape, it can enclose the space and block the view. Meanwhile, the oxygen production of trees is significantly higher than that of grass. When selecting tree species, attention should be paid to selecting trees that are suitable for the local climate, soil, and hydrological conditions, emphasizing the combination of common and precious tree species, the combination of deciduous and evergreen trees, the arrangement of tree clusters and clusters, and the selection of tree size, height, and morphology. The ecological environment of balconies varies greatly due to differences in their enclosed form, orientation, height, and shape. The main way of balcony greening is to place potted flowers inside the balcony and on the concrete handrails

*Shandong University Of Arts, Jinan, Shandong, China, 250300 (18615545701@163.com)

of the railing, and to build various types of planting slots in sync with the civil engineering project. It can be installed around and along the balcony railing, and can also be combined with the solid balcony railing to form a flower hopper groove shape. At the same time, various planting pots can be hung on the hanging board of the railing, which not only enriches the shape of the balcony railing, but also increases the function of planting flowers. At the same time, by setting up greenery on balconies and terraces, the building facade can be enriched, adding a moving and bright color to the building. In architectural design, flower beds and racks can be set up on balconies and terraces, with potted plants as the main greenery, accompanied by climbing plants, which should have strong ornamental value and can generally be floral plants.

Currently, energy conservation and improving indoor environmental quality are receiving increasing attention in architectural design. How to build energy-efficient commercial buildings in bustling urban centers and make the most of passive means (such as natural ventilation, natural lighting, etc.) to improve indoor environmental quality is of great significance for the sustainable development of China's construction industry. In the current development process of large-scale commercial buildings, due to excessive pursuit of aesthetic effects and consideration of eye-catching benefits in the early stage of investment attraction, glass curtain walls are extensively used as facade elements in building design, but the thermal effects and reasonable selection of glass curtain walls are not fully considered, often leading to the deterioration of building thermal performance, increased initial equipment investment, and high energy consumption of air conditioning system operation. At the same time, the summer solar radiation near the glass curtain wall is strong, and the average indoor radiation temperature is high; In winter, when the temperature is low and the radiation is strong, the indoor thermal comfort will significantly decrease. In addition, for the deep interior area, it is also necessary to consider how to effectively organize ventilation and cooling during the transitional season and improve indoor thermal comfort.

In order to avoid the problems that glass curtain wall buildings are prone to in building A, the author fully implemented the concept of energy-saving design in the early design stage, adopted advanced computer simulation technology, optimized the enclosure structure and passive natural ventilation design, and achieved certain results [2,3].

2. Methods. Project A is one of the renovation and construction projects for the commercial area on the west side of Xidan North Street in City A. It is located in the bustling center of the city, with a land area of about $16700m^2$ and a building area of about $200000 m^2$. The design requirements meet various commercial activities such as large-scale commercial, high-end office, catering, entertainment, and hotels. The entire building is lightweight and transparent, using a large number of glass components to enhance the integration between humans and the natural environment; In addition, there is a transparent inverted cone atrium with a unique and prominent design, which can also serve as a natural ventilation channel. For such a super large commercial building, in order to avoid the problems that glass curtain wall buildings are prone to, the concept of energy-saving design was fully implemented in the early design stage. Advanced computer simulation technology was used to optimize the enclosure structure and natural ventilation passive design, and certain results were achieved. Here is a brief introduction.

2.1. Ventilation optimization design. Combining the characteristics of this building, we focus on using natural ventilation or mechanical assisted natural ventilation methods to solve the transitional season ventilation problems in most areas. The layout of various cinema buildings in Building A is relatively dense, making it difficult to organize natural ventilation. Therefore, it is recommended to use a full air system during the transition season to operate under full fresh air and full exhaust conditions [4]. Thermal natural ventilation (or mechanical assisted thermal natural ventilation) mainly relies on the tall inverted cone atrium in the middle of the building and the south side atrium space of the cross. Figure 2.1 shows the indoor natural ventilation node diagram. In order to ensure the effectiveness of thermal ventilation, a certain open external window area is required to construct a calculation program for the thermal fluid network, using meteorological conditions of typical days in the transitional season for calculation [5]. The calculation method is as follows:

- ① Select representative days for the transitional season, calculate the solar heat gain in the atrium and the internal disturbances in various functional areas;
- ② Estimate the appropriate natural ventilation rate to determine the temperature distribution (average air exchange rate) in the atrium; The temperature distribution can be determined according to a linear distribution relationship based on existing research results;

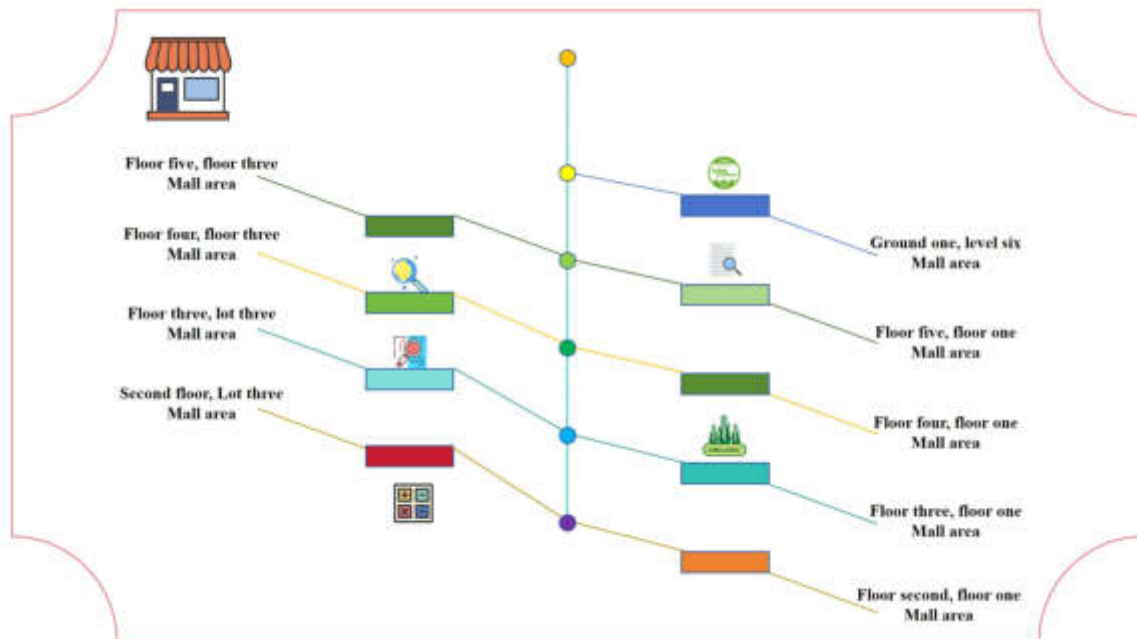

Fig. 2.1: Indoor Natural Ventilation Node Diagram

- ③ Using regional network method to calculate the natural ventilation flow rate of each branch, and guiding and optimizing building design; If there is a discrepancy between the calculated ventilation volume and the estimated value in , the estimated value in should be adjusted, and the above steps should be repeated to solve the calculation until the calculated value and estimated value match.

In this way, the openable window areas for different parts were calculated separately. The result is that the opening area of the north exterior window should not be less than $20m^2$ /floor; The south and west sides of Building D must ensure that the opening area of the external windows on each floor is not less than $30m^2$; The first floor of building B should ensure that the opening area of the external windows is not less than $15m^2$. In addition, on the top of the south facing part of the cross courtyard, an outer window that can be mechanically controlled to open should be installed, and mechanical ventilation equipment should be installed to timely discharge accumulated heat under adverse working conditions. The exhaust equipment can be used in conjunction with the atrium smoke exhaust equipment. Due to the presence of mechanical equipment, the area of the external window that can be opened can be slightly smaller, but should not be less than $20m^2$. For the inverted cone atrium, mechanical control side windows are installed at the top of the twelfth and thirteenth floors, with a total opening area of not less than $50m^2$.

2.2. Energy saving design of exterior facade enclosure structure . Due to the fact that almost all of the peripheral protective structures in the original plan of this building were glass components (K value of about $3.0W/(m^2 \text{ } ^\circ K)$), in the deepening design, according to the original building drawings and the functional and usage requirements of the space, glass curtain walls were minimized as much as possible, and walls (or designed as inner solid walls and outer glass) were added to improve the thermal performance of windows, reducing the drawbacks of operating load and high operating costs caused by the relatively poor thermal performance of too many glass curtain walls. Under this principle, for functional spaces such as shopping malls, elevator rooms, air conditioning rooms, fire centers, garbage stations, storage rooms, bathrooms, etc., the outer enclosure structure will be as solid as possible with some external windows added (some of which are mainly used for ventilation and lighting); Or design according to the combination of inner solid wall and outer glass. In addition, for areas with LCD screens and billboards on the facade, the corresponding exterior walls are also adjusted to solid

Table 3.1: Comparison of energy-saving effects and initial investment increase of different enclosure structure schemes in the south direction

	Hollow double glass +single glass+horizon- -tal shading (double- layer curtain wall)	Hollow double glass (Low-e film)+horizon- -tal shading	Hollow double glass (coated with ten inert gases) +horizontal shading
Annual cumulative energy savings /(kWh/ $m^{2\circ}$ (year))	56.3	75.6	90.7
Annual operating cost savings (yuan/($m^{2\circ}$ year))	39.4	53	63.5
New initial investment/ (yuan/ m^2)	500	300	800

Table 3.2: Comparison of energy-saving effects and initial investment increase of different enclosure structure schemes in the east and west directions

	Hollow double glass +external rolling shutter	Hollow double glass+lou- -ver shading +single glass	Hollow double glass (Low-e membrane)	Hollow double glass (Low-e film)+exter- -nal roller shutter	Hollow double glass (coated with Low-e film)+lou- -ver shading+single glass
Annual cumulative energy savings /(kWh/($m^{2\circ}$ year))	84	92	77	119	119
Annual operating cost savings (yuan/($m^{2\circ}$ year))	59.1	64.7	54.2	83.6	83.6
New initial investment /(yuan/ m^2)	150	500	300	450	800

walls. Using the sunlight and shadow simulation software BSAT for building mutual occlusion and self occlusion simulation, it was found that the facade between L2-L5 and 3-9 axes does not need to be designed with external rolling shutters for shading. However, for the 6th floor and above of Building C (including facades outside the 3-9 axis), it is recommended to design external roller blinds or other sunscreen measures. For Building D (office building), the facade below the seventh floor in the west direction and between the 1/2 axis of the 12-15 axis can be blocked by its adjacent buildings in the west direction between 15:00 and 17:00, and external rolling shutters can be omitted for shading.

3. Results and Analysis.

3.1. Energy saving design results of exterior facade enclosure structure. Using DeST-C, the energy consumption and investment of south facing, east facing, and west facing envelope structures were compared when using different types of glass. The calculation results for the south, east, and west directions are shown in Tables 3.1 and 3.2, respectively. The thermal performance parameters of various glasses are shown in Table 3.3 [6].

Combining economic efficiency and energy-saving effects, the optimal southbound enclosure structure scheme for this building is the combination of Low-e membrane coated hollow double glass and horizontal louver external shading; It is recommended to adopt the scheme of hollow double glass (Low-e membrane) or hollow double glass (Low-e membrane)+external roller shutter in the east-west direction. It is worth noting that for east-west oriented glass, the Low-e film should be low permeability, mainly to improve the thermal performance in winter and reduce the radiation heat gain in summer.

Using DeST-C for simulation 2 calculation, it was found that when the thermal performance of windows

Table 3.3: Thermal performance settings for different glass curtain walls

Glass type	Heat transfer coefficient K value/(W/(m ² °K))	Sunshade coefficient SC
Ordinary hollow	3.1	0.71
Ordinary hollow+single glass (double-layer ventilation curtain wall)	2.1	0.54
Hollow coated with Low-e film	1.9	0.52
Inert gas filling+hollow coating	1.6	0.52
Low e hollow+single glass	1.5	0.41
Inert gas filling +coating hollow+single glass	1.3	0.41

Fig. 3.1: Energy saving effect (load) of glass thermal performance optimization

increased from 3.0W/(m².K), shading coefficient 0.7 to 2.0W/(m² °K), and shading coefficient 0.5, the maximum cold and heat load of the building and the cumulative consumption of cold and heat throughout the year all decreased significantly, as shown in Figures 3.1 and 3.2 [7].

3.2. Analysis of Glass Inverted Cone Atrium Envelope Structure Scheme. The glass inverted cone atrium is located in the middle of this building complex. Due to the use of a full glass curtain wall structure, in winter, the outdoor temperature is very low, and the strong sky radiation at night at the top of the cone will cause a lower surface temperature inside the glass cone, which may lead to large-scale condensation [8-10]. Therefore, it is necessary to analyze the inner surface temperature of the glass cone during the most unfavorable working conditions in winter and make improvements. Using CFD simulation software PHONEICS to simulate and calculate the air temperature distribution inside the cone. The upper diameter of the cone is 28m, the lower diameter is 12.6m, and the height is 25m. The lower part is an opening, and the air entering the cone has a dry bulb temperature of 20 °C, a relative humidity of 40%, a dew point temperature of 6 °C, and an outdoor temperature of -10 °C. The heat transfer coefficients of the inner and outer surfaces of the glass are 8.7W/(m² °K) and 18.6W/(m² °K), respectively. Considering the strong radiation heat transfer between the top of the cone and the sky at night, the heat transfer coefficient of the outer surface of the top glass is set at 30W/(m² °K). For a single glass, the comprehensive heat transfer coefficient is set at 6.0W/(m² °K), while for ordinary hollow double glass, it is set at 3.0W/(m² °K). It can be seen that indoor air at 20 °C rises from below, cools at the top, and then descends along the side and flows out of the cone. The air temperature inside the cone is around 12-15 °C, and in some areas such as the area around the top of the

Fig. 3.2: Energy saving effect (heat) of glass thermal performance optimization

cone, the air temperature can drop to $8\text{ }^{\circ}\text{C}$. When the outdoor air temperature is $-10\text{ }^{\circ}\text{C}$, according to the method of heat transfer resistance difference, the temperature on the inner surface of the glass cone is about $3\text{ }^{\circ}\text{C}$, and the temperature on the inner surface of the glass at the top of the cone is also very low, about $1\text{--}6\text{ }^{\circ}\text{C}$. The temperature on the inner surface of the edge area of the cone is relatively low, about $1\text{ }^{\circ}\text{C}$, and a higher value of $6\text{ }^{\circ}\text{C}$ can be reached at the center. Therefore, if a single-layer glass scheme is adopted, a large area of condensation will inevitably occur on the inner surface of the top of the glass cone. If double-layer glass is used, most of the air temperature can be at $14\text{ }^{\circ}\text{C}$ or above, and even the edge area of the most unfavorable cone top can reach an air temperature of $13\text{ }^{\circ}\text{C}$. On the other hand, the temperature on the inner surface of the conical glass has also increased to a certain extent. According to the difference calculation, the temperature on the inner surface of the conical side can be around $6.3\text{ }^{\circ}\text{C}$, slightly higher than the dew point temperature of the air. The inner surface temperature at the top of the cone is $4.4\text{--}6.3\text{ }^{\circ}\text{C}$, and the surface area below the dew point temperature of $6\text{ }^{\circ}\text{C}$ accounts for about 60% of the total top area. This means that a considerable portion of the inner surface at the top will still experience condensation. According to the above analysis method, it is recommended that the heat transfer coefficient of the inverted atrium glass should not exceed $2.5\text{W}/(\text{m}^2\text{ }^{\circ}\text{K})$.

4. Conclusion. In response to the current pursuit of aesthetic and eye-catching benefits in the development process of commercial buildings, the large-scale adoption of transparent enclosure structures has led to difficulties in meeting indoor thermal comfort and high operating costs. For a large commercial building, analysis and calculation were conducted from several aspects, including optimizing the performance of glass curtain wall enclosure structures, designing anti condensation measures for glass atriums, and designing natural ventilation during the transition season, thus, the energy-saving design of the enclosure structure of the large commercial building and the improvement of indoor environmental quality were achieved. The author has made beneficial explorations on how to build energy-efficient commercial buildings in bustling urban centers, and how to use passive means (such as natural ventilation, natural lighting, etc.) as much as possible to improve indoor environmental quality, which has reference significance for other similar buildings.

IMAGE RECOGNITION TECHNOLOGY BASED ON DEEP LEARNING IN AUTOMATION CONTROL SYSTEMS

JINGJING WANG*

Abstract. In order to solve the problem of recognizing multiple product images, the author proposes the research of image recognition technology based on deep learning in automated control systems. Firstly, the FasterRCNN method is improved by proposing a non class specific FasterRCNN, which can be used for pre annotation of product images by training only on publicly available datasets. Due to the use of position correction networks, the pre annotation effect is more accurate than that of candidate region networks. Then, combining Grabcut with non class specific FasterRCNN, a sample enhancement method was proposed to synthesize a large number of training images containing multiple products and use them for model training. In addition, based on non class specific FasterRCNN, a re identification layer was proposed to improve detection accuracy. In the end, the recognition and positioning of multiple products achieved a recall rate of 93.8% and an accuracy of 96.3%.

Key words: Supermarket product image recognition, Deep learning, Data annotation algorithm, Non class specific FasterRCNN

1. Introduction. In the design process of a product, in order to stimulate consumer purchasing desire while ensuring product recognition, the product image features are very rich. Common image features can be divided into two categories: One is the low-level visual features, which are the global and local features of the product, another type is the intermediate semantic features of the product, which are mainly applied in the process of product recognition based on the underlying visual features. That is to say, the image features of products can be specifically divided into the following types, including color features, shape features, texture features, point features, semantic features, and other aspects [1]. Among these features, color feature is the most direct way. By using color histogram, the color distribution of the product image can be obtained, while shape regions and contour boundaries can be distinguished. Through specific detection algorithms, the feature points of the product can be effectively extracted. Deep learning technology is a perception technique built on neural networks, commonly including neural models, perceptrons, BP algorithms, convolutional neural networks, etc. Taking convolutional neural networks as an example, they are currently the most widely used type of neural network and have been widely used in facial recognition, speech recognition, license plate recognition, object detection, and other fields [2, 3]. Convolutional neural networks and BP neural networks are similar in that they both consist of an input layer, an intermediate layer, and an output layer. However, compared to the former, the intermediate layer is more complex. In practical applications, this neural network has enormous advantages, especially in network depth and massive image data processing. The most important thing is that using this neural network can better complete learning and training. After determining the specific neural network, deep learning can be carried out, utilizing massive data and network models for learning. Feature learning in the data is a very important content, which can ensure the accuracy of model prediction is improved.

In recent years, due to the rapid development of mobile internet, with the support of cloud computing and big data, online shopping like e-commerce has sparked a new wave of people's lifestyles [4]. However, due to the gradual saturation of online users, transaction profits have also gradually decreased. More and more companies are turning their attention to the offline trading platform. The layout of offline transactions by companies such as Alibaba, Meituan, and Ele.me is evident. The retail industry has also become a focus of offline transaction competition. Enterprises are increasingly focusing on how to use artificial intelligence technology to transform product production, circulation, and sales, reshape the industry ecosystem, and integrate online and offline

*Department of Information Engineering, Yangzhou Polytechnic College, Yangzhou, Jiangsu, 225000, China (yzwj2023@163.com)

experiences. That is to say, future innovative retail may be entirely achieved through artificial intelligence technology. In the current era of booming artificial intelligence algorithms, researching retail product recognition technology to improve productivity has become one of the hotspots in the field of artificial intelligence. In the past two years, some automated retail stores have emerged both domestically and internationally, such as AmazonGo, Taobao Coffee, etc. The use of artificial intelligence technology to achieve automation and unmanned retail scenarios has become a trend and is gaining momentum. Nowadays, artificial and intelligent technologies are using algorithms to process information in order to reach the level of humanity. As is well known, humans are best at using vision and hearing to receive, process, and transmit information. In the process of purchasing goods in supermarkets, people have a clear understanding of the products they want to purchase and can visually locate and identify them. In the settlement process, it is still common to use the cashier to scan the code one by one for settlement. With the development of artificial intelligence algorithms in the field of computer vision in recent years, machines can recognize universal objects like humans, such as roads, pedestrians, vehicles, etc. However, in specific tasks, such as the settlement process of supermarket products, how to use image vision to identify items, in order to liberate productivity, improve automation and intelligence, has become a research hotspot in the field of artificial intelligence. For the recognition and localization of multiple products, the author improved the regression layer of FasterRCNN and fully utilized publicly available datasets to learn object bounding box regression knowledge for pre labeling of product images, which is more accurate than the labeling algorithm of RPN. Then, a combination of pre labeling algorithm and Grabcut algorithm, an image synthesis algorithm, is proposed to solve the recognition and localization problem of multiple products, and its working principle is described in detail [5].

2. Methods.

2.1. Problem Description. In recent years, deep learning has been used in many fields. Such as facial recognition, object detection, etc. Deep learning can capture useful information from a large amount of data, and due to the advent of the big data era and the improvement of computing device performance, the application of deep learning has become a reality. FasterRCNN and its extended versions have become one of the most effective methods in recent years. However, if the above methods are transferred to a new task, a large amount of calibration data needs to be used to readjust the model on the new task. However, in practical scenarios, data calibration is a very difficult task that requires significant financial, material, and human resources.

The author proposes a method to solve the data bottleneck problem, which can detect and locate products without the need for border calibration. The dataset constructed by the author contains only a single product in the training images without border calibration, while the test images contain multiple products [6]. The author first improves FasterRCNN by proposing a non class specific FasterRCNN, and combines transfer learning to pre calibrate the training data; Then, combined with the unsupervised Grabcut2l method, the training data is sample enhanced to generate realistic training images of multiple objects; Then train the non class specific FasterRCNN to detect multiple objects; Finally, the author proposes a re identification method based on FasterRCNN, adding a re identification layer to FasterRCNN to improve the accuracy of multiple object detection.

2.2. System Framework Design. The product recognition and localization method proposed by the author can be divided into three modules: The first part is the bounding box calibration module of non class specific FasterRCNN. The second part is a sample enhancement method that combines non-specific FasterRCNN with Grabcut [7]. The third part is a region based re identification method. The first part, the proposal of non-specific FasterRCNN, is aimed at solving data barriers and fully utilizing prior knowledge in public datasets to solve the calibration work of borderless calibration training samples. On the one hand, it removes the impact of complex redundant backgrounds. On the other hand, it provides border interaction input for Grabcut, and at the same time, it can complete border prediction of product areas without training, effectively solving the problem of product positioning. In the second part, by combining Grabcut and non-specific FasterRCNN methods, accurate region extraction is achieved by effectively utilizing the pre calibration information of borders. Based on the extracted regions, fuse the training images of the products to generate a large number of images of multiple products. By using the generated images for overall model training, it is possible to distinguish between cases of product occlusion or overlapping borders, effectively solving the problem of multiple product

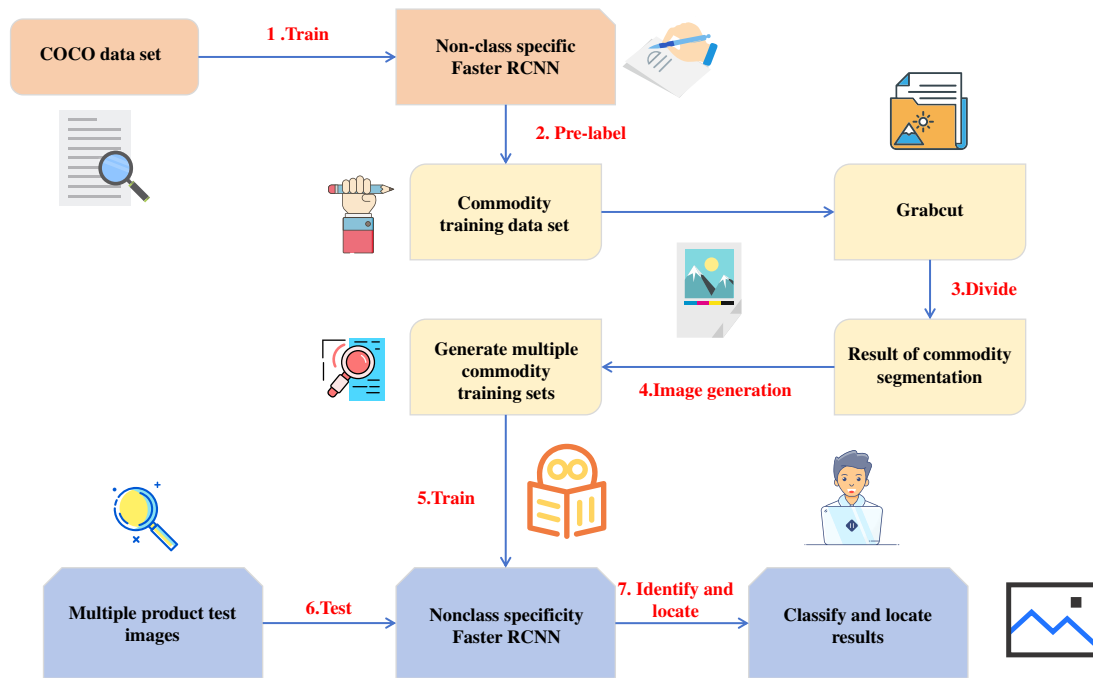

Fig. 2.1: Block diagram of multiple product identification and positioning systems

neighbors or occlusion. Realized the recognition and localization of multiple product images based solely on a single product training image calibrated without borders. In the third part, in order to improve the accuracy of system recognition, a region based re identification method is proposed to solve the problem of misidentifying objects and improve the prediction accuracy of the system. As shown in Figure 2.1.

2.3. Specific System Implementation. Combining Grabcut's sample enhancement method: The non class specific FasterRCNN solves the problem of bounding box regression, making the pre calibration of product positions in training images more accurate. When there is only a single product in the training data, and there are multiple products in the test images, the classification problem still has significant difficulty. Even if a single product can be used to train a classification model, multiple products in the test image may have overlapping or even occluded borders. Due to the lack of product overlap in the training images, training the model will make its classification ability less robust and insufficient to recognize products with overlapping or even occluded borders, increasing the difficulty of classification. Therefore, the author proposes a sample enhancement method to generate training images with multiple products by processing a single product training image. Because using category non-specific FasterRCNN, the borders of individual product images can be obtained. A direct idea is to extract the border part of the product in the image, rotate or translate it, and combine it with other products. However, this method will result in the background area of the product border covering other product areas, and the edge area of the border will differ significantly from the actual image. Therefore, using only the borders of product images is not enough to achieve realistic sample generation. If precise area information of the product can be obtained, such as the product object mask, the background area can be separated to solve the problem of the product being obscured by the background in the generated sample. Therefore, the author uses the Gabcut method to segment the products in the training images.

Both Grabcut and Graphcutsl methods are interactive image segmentation methods. Graphcut needs to provide precise foreground and background pixel seed regions during interaction, calculate the similarity between other pixels and foreground and background, and use graph theory algorithms to calculate the optimal segmentation. The Grabcut algorithm has less user interaction and only needs to provide a rectangular border containing the foreground. Then, the pixels inside the border are used as the foreground, and the pixels outside

the border are used as the background. Gaussian Mixture Model (GMM) is used to model the background, and graph theory algorithm is used for segmentation. The GMM background modeling and graph theory algorithm are repeatedly used until the iteration converges, completing the segmentation.

After utilizing the non class specific FasterRCNN proposed by the author, the rectangular border of a single product in the training image can be obtained. Therefore, it is only necessary to combine the Grabcut algorithm to segment the precise region of the product. Then, the individual product areas in the training set are randomly rotated and translated, and randomly combined to generate training images for multiple products. It is worth noting that, considering the accuracy of the data, products cannot be completely covered between each other, because if the products are excessively covered, it will lead to almost all the real products in the area being covered, and the products occupying a large area will not match the actual labels, which will mislead the training of the recognition model. Therefore, when combining randomly, it is necessary to constrain the overlapping area of the products, assuming that the upper limit of the overlapping area is Sup . Consider three fusion strategies: (1) Perform random rotation and translation, only constraining the upper limit of the overlapping area, that is $sc \leq sup$, which means that during fusion, the product may be far away, at which point $sc=0$. (2) While limiting the upper limit of overlapping area, constrain the lower limit of overlapping area, that is $sc>0$. This approach requires overlap between products, ensuring a close distance between them without extensive coverage. (3) Increase the constraint on the lower limit of overlap area, that is $sc \geq sm$, in order to increase the possibility of overlap between products and differentiate the overlapping situation through model training.

The re identification layer found that the model trained by the above method will have a small number of adjacent bounding boxes predicting two different results, one of which is correct and the other is incorrect. Because FasterRCNN is a two-level (two-stage) method, in the first stage, the RPN (candidate region network) first filters out candidate regions and filters out a portion of the background region; The second level uses the head network to finely classify candidate regions, while correcting the borders of each candidate region, known as border regression. Obviously, the candidate regions extracted by RPN are imprecise, which can affect the accuracy of head network recognition. Because some candidate regions only cover local areas of the object, although bounding box regression can correct them to the correct position, directly using candidate regions for prediction may inevitably lead to misidentification. Therefore, the author proposes a re identification layer to improve the accuracy of FasterRCNN recognition. Because the bounding box position is more accurate after passing through the bounding box regression layer of the head network, the bounding box regression layer here is a non class specific regression method proposed by the author. Moreover, the classification layer of the head network filters out a large portion of the background area. Therefore, the results of bounding box regression can be classified first, and then more accurate bounding box regression results can be used as candidate regions, followed by some re identification. The author will use the precise regions obtained from the head network regression, combined with the ROIAlign method, as inputs to pass through the classification layer of the head network again. Traditional FasterRCNN can be defined as:

$$\begin{cases} c = f_{cls}(roi) \\ reg = f_{reg}(roi) \end{cases} \quad (2.1)$$

Among them, roi represents the candidate regions generated by RPN, f_{cls} represents the classification layer, f_{reg} represents the regression layer, c represents the classification result corresponding to the candidate region, and reg represents the bounding box regression result of the candidate region. The added re identification layer selects the regions classified as non background in the candidate regions, with the background category represented by 0. Then, its regression border is used as the new candidate region for classification and regression, represented as:

$$\begin{cases} c' = f_{cls}(reg_{c \geq 0}) \\ reg' = f_{reg}(reg_{c \geq 0}) \end{cases} \quad (2.2)$$

Among them, c' represents the final classification result after re identification, and reg' represents the final bounding box regression result.

Network Model and Training. The author proposes a non-specific regression layer to improve the class specific regression layer of the original FasterRCNN, forming a non-specific FasterRCNN model. I hope to learn border regression knowledge from public datasets and directly apply it to pre annotation of individual product training images.

Firstly, the original FasterRCNN is trained on COCO, and the Resnet model in its backbone network is pre trained using ImageNet. Then, the classification layer and regression layer are trained, and finally, the overall network model is jointly trained [8]. This is done to enable the model to learn effective feature generalization ability from the COCO dataset. Change the bounding box regression layer in the trained FasterRCNN model to the non class specific regression layer proposed by the author, while keeping the parameters of other parts unchanged, and only train the non class specific regression layer on the COCO dataset. For the new non class specific FasterRCNN, tune the entire network using the COCO dataset. This is to enable the features obtained by ROIAlign to balance the ability of classification and bounding box regression.

The model trained through the above steps can be directly used for annotating product training images. RoiPooling/ROIAlign performs feature extraction in the corresponding area of FeatureMap, and normalized to 7×7 in size, with 256 channels. Then followed by an 7×7 convolutional layer, where an 7×7 convolutional kernel of the same size as the input is used, with an output dimension of 1×1 and a channel count of 1024, the convolutional layer here can be considered as a fully connected layer. Then use the convolutional kernel of 1×1 , with an output dimension of 1×1 and a channel count of 1024. The convolutional layer of this layer is also an alternative to the fully connected layer. Moreover, the output dimension is the same as the output dimension of the previous layer. This is generally done to enhance the non-linear ability of the network model, as each convolutional layer is followed by an activation function, where Relu is used as the activation function. The last layer is the softmax layer, which outputs 4 channels, which is the position parameter for bounding box regression. In addition, the hyperparameters in the model are shown in Table 2.1.

By combining non class specific FasterRCNN with Grabcut, a large number of product image samples can be generated. And used for training the overall model. The training steps are as follows:

- (1) Firstly, based on the parameters of the non class specific FasterRCNN used for pre calibration of training samples, training is carried out while keeping the backbone network and non class specific regression layer parameters unchanged, and only training the classification layer model.
- (2) Then, while keeping the parameters of the non class specific regression layer unchanged, train the classification and regression layers of the RPN network, as well as the classification layer in step (1).
- (3) Train the entire network, including the Resnet parameters in the backbone network, with only fixed non class specific regression layers. This is because the features in the backbone network are trained by COCO, and in order to better extract features from product data, it is necessary to train the backbone network parameters.

Through the above steps, the model trained using the generated samples can be used for the detection task of real product images. Moreover, the non class specific regression layer does not need to be retrained on the target dataset, which further confirms its knowledge transfer ability.

In the experiment, the MaskRCNN method from the FasterRCNN algorithm set was used, which, in addition to the FasterRCNN method, utilized the Feature Pyramid Network (FPN) and Region of Interest Alignment (ROIAlign) methods. During the training process, there was no need for segmentation prediction,

Table 3.1: Comparison of Properties of Different Datasets

Data set	Number of categories	Average training samples for each class	Does the training sample contain multiple targets	Is there a location label
COCO	80	25000	Yes	Yes
VOC	20	1350	Yes	Yes
data set	40	8	No	No

so the segmentation branch in MaskRCNN was removed and only its classification and regression branches were used. The experiment was conducted on two NVIDIA TITAN X GPUs. The initial learning rate is 0.001 and is manually adjusted during training. The momentum parameter Momentum is 0.9. Among them, conv1, conv2, conv3, conv4, and conv5 are components of the Resnet network structure.

3. Experiments and Analysis.

3.1. Dataset Introduction. The author validated the proposed method on the constructed product dataset. The training set consists of training images for a single product. Using the author's method, there is no need to train bounding box regression on the product dataset, so the constructed product dataset training images only contain category information [9]. The training images were captured from four different perspectives using two cameras, with each image containing only one product object. There are a total of 40 product categories, each of which includes 8 training images. The expanded single product image training set contains a total of 3200 training images. The test set consists of multiple product images captured using another camera, and the product positions and angles in the images are diverse. The test set consists of 400 test images, totaling 40 product categories. The proposed non class specific FasterRCNN was trained on the COCO dataset and directly applied to pre labeling of product training image data. The COCO dataset consists of 80 categories, including a large number of images, borders, and category annotations. The main difference between the product dataset constructed by the author and the COCO dataset is that the objects in the product dataset are rotated, and the training data is much less than the COCO dataset. In addition, the dataset constructed by the author only contains a single product in the training images and does not require border calibration.

As shown in Table 3.1, the differences between this dataset and the publicly available dataset were compared. Among them, there are as many as 40 categories of the dataset, and the objects can be rotated, which adds some difficulty to the recognition task. More importantly, the dataset has very few category samples and is a single object sample, without position border labels, greatly increasing the difficulty of localization and recognition tasks.

3.2. Experimental Results.

(1) *Sample Enhancement Strategy Analysis.* After extracting the product border from the training image, the Grabcut algorithm is combined to segment the product area. Because the training image contains a large area of background, if the Grabcut algorithm is directly used to segment the original training image, the segmentation effect is very unsatisfactory. Because there is no border to calibrate the background area of the image, the outermost pixel of the image is generally taken as the background. However, its area is very small, making it difficult to model the entire background. Combining the author's proposed non class specific FasterRCNN pre labeling algorithm with Grabcut algorithm for product image segmentation in the training set. Then use simple image processing methods to generate training images of multiple products for the FasterRNN model training.

When using the Grabcut algorithm for training image data generation, the upper limit of object overlap area sup is set to 10000. The author compared the performance of the trained model on the testing machine for training data generated by different overlapping areas sc. As shown in Figure 3.1, when generating training images, when the overlap area is 0, that is, when the product distance is far, the effect is not good. Because the product distance is far, it is difficult to see folding in the training data, making it difficult for the network to receive training on folding, so the testing effect is relatively poor. When the overlapping area is 6000, the recall and precision of the model reach 93.8% and 96.3%, respectively, and the testing effect is the best. When

Fig. 3.1: Detection results of different fusion strategies

Fig. 3.2: Detection performance of different probability thresholds

the overlap area is too large, the large coverage between products in the training image tends to mislead the network into misidentification and reduce the testing effect.

(2) *Analysis of the effects of each part of the model.* When the model identifies and locates, it will output the probability of its corresponding category for each region. When arranging the model, it is usually necessary to normalize the probability, filter out predictions with low probability, and retain results with high probability. Therefore, the impact of different thresholds on the recall and accuracy of the model was analyzed, as shown in Figure 3.2. In general, the higher the probability threshold, the higher the accuracy, and the lower the recall. The lower the probability threshold, the lower the accuracy, and the higher the recall rate. In Figure 3.2, when the probability threshold is 0.3, the model can achieve high accuracy and recall at the same time. This is because the model has a high probability of predicting categories, and a low threshold has little effect on it. The model has strong predictive ability. In order to balance accuracy and recall, the author determined a probability threshold of 0.7, which is a recall rate of 93.8% and an accuracy of 96.3%.

As shown in Table 3.2, by analyzing various parts of the model, the proposed sample enhancement method combined with Grabcut improved the detection recall by over 40% and accuracy by 30%. In order to improve the accuracy of multiple product detection, the author proposes a re identification layer, which corrects the candidate regions after classification and regression through the bounding box regression layer and inputs them

Table 3.2: Analysis of the effectiveness of the methods proposed by the authors

Method	Recall (%)	Precision (%)
Non class specificity FasterRCNN	58.14	50.96
Non class specificity FasterRCNN +Grabcut	90.43	92.76
Non class specificity FasterRCNN++Grabcut + Re identification	93.81	96.3

Table 3.3: Performance Comparison of Multiple Product Identification Methods

Method	Recall (%)	Precision (%)
SIFT	33.47	20.30
VGG16	41.21	29.38
VGG19	36.50	26.25
Xception	58.50	42.50
Resnet	58.92	43.75
Author's method	93.80	96.29

into the classification layer again. After correction by non-specific bounding box regression layers, classification errors caused by imprecise candidate regions can be effectively avoided. When using the re identification layer, the recall rate is increased by 3% and the precision rate is increased by 4% compared to when not using the re identification layer.

(3) *Comparison of detection models.* Because the proposed non class specific FasterRCNN can detect a single product border, the main problem when applied to the detection of multiple products is that it can interfere with recognition when there are areas of other products within the product border. The bounding box regression of FasterRCNN, which is not specific to category, is not affected by multiple products. Therefore, when using training data from multiple products generated by the author for training, only the parameters of the classification layer are trained while keeping the parameters of the non class specific regression layer unchanged.

Through the proposed image enhancement technology, the detection of multiple products has been achieved, and the non class specific regression layer is only trained on public datasets, and regression knowledge has been learned. Moreover, there is no need for further training when transferring to product image detection. Multiple products can also be well positioned in situations with local occlusion, different perspectives, or across scenes. However, there is no perfect system in the world, and when there is severe occlusion, missed detections can also occur. Among them, the product "Hanshan Pepper and Pickled Vegetable" was not detected due to being partially occluded. The author quantitatively validated the proposed method in the constructed product dataset. Due to the author's intention to address data bottlenecks. The constructed training dataset only has category labels and no border calibration. In this case, traditional image detection methods generally use unsupervised features to calculate local features of the retrieved image and perform similarity matching with the features of the image in the training set. The currently most effective deep learning methods, such as VGG16, VGG9, Xception, and Resnet, are generally regarded as multi label classification tasks for recognition.

The author compared these methods and as shown in Table 3.3, the performance of SIFT and other currently optimal deep learning methods is significantly lower than the method proposed by the author [10]. On the one hand, SIFT does not distinguish background features, which leads to background features affecting the matching effect; On the other hand, it is an unsupervised artificial feature that is not as effective as supervised methods in recognition, and the product packaging will have severe reflection, which also results in lower feature performance. Other deep learning methods can be extended from a single product training image to multiple product training images. Not learning the distinguishing information when multiple products are similar, and also not distinguishing background features, resulting in low recognition rate. Some deep learning models, such as VGG16 and VGG19, have similar performance to SIFT, this is because the cross task recognition task of training images from a single product to identifying and locating multiple products results in low performance

of deep learning models. And this method proposes a sample annotation and sample enhancement method that does not require training on the target dataset. It can use the training image of a single product to learn the distinguishing information of multiple products, serving as a bridge across tasks and greatly improving performance.

4. Conclusion. The author designed and implemented multiple product recognition and localization methods based on improved FasterRCNN and GrabCut. Regarding the above issues. Firstly, the author cleverly improves FasterRCNN by proposing a non class specific bounding box regression layer that can learn prior knowledge of object positions using only public datasets for training, without the need for retraining on the target dataset, and uses it for pre calibration of object positions in commodity training data. Secondly, based on the pre labeled position information of non class specific FasterRCNN products, combined with the GrabCut interactive segmentation method, accurate segmentation can be performed on the training images of individual products. By fusing individual product images from multiple categories, a large number of training images containing multiple products and labels for product positions are generated for model training. At the same time, it solves the problems of limited data volume, no object position annotation, and the expansion of single product image recognition tasks to multiple product recognition tasks.

THE CONSTRUCTION AND APPLICATION OF RESIDENTIAL BUILDING INFORMATION MODEL BASED ON DEEP LEARNING ALGORITHMS

SHUANG ZHAO* AND YU YANG†

Abstract. In order to explore the construction and application of building BIM models, the construction industry is actively exploring a method that can quickly reshape the 3D information model of existing buildings in the wave of digital twins and smart cities. Starting from the perspective of deep learning 3D object detection algorithms, the author starts with the generation of large-scale building datasets and the theory of point cloud deep learning, analyzes the input data types required for point cloud deep learning frameworks, and focuses on the creation process of 3D bounding boxes and 3D point clouds for various building components. The author compares different point cloud datasets with the same data structure and implements an object detection algorithm based on the ScanNet dataset, furthermore, a feasible technology route for automatic generation of BIM models from 3D point clouds based on deep learning is integrated. Through this technology route, the trained neural network can input unknown building 3D point clouds and output BIM model parameters.

Key words: Building dataset, 3D point cloud, Deep learning, BIM

1. Introduction. BIM (Building Information Model), also known as Building Information Model, contains the geometric information, performance, and functionality of all components in the model. It encompasses all information throughout the entire lifecycle of a building project into a single model [1]. In recent years, BIM has gradually been applied to the design and construction of modern buildings. At the same time, due to the development of new technologies, people have begun to study the parameterized information model of ancient buildings and apply it to the design and construction of some antique buildings.

With the transition of urban renewal from the "incremental era" to the "stock era", the relationship between data on built environments and corresponding human behavior data has become increasingly close. Big data demonstrates a people-oriented perspective, timely and real-time information, and fine resolution spatial dynamics. In the face of data research on built environments such as remote sensing images and street view images, after several years of image analysis research in the field of land planning, the semantic labels of high-resolution (VHR) remote sensing images assign a category task to each pixel in the image, including land use planning, infrastructure management, and urban expansion detection. The use of deep learning intervention has been widely adopted. With the deepening of deep learning technology research, street view images have gradually become an important data source for quantitative research on built environments due to their numerical characteristics and the accompanying geographical location information [2]. Spatial quantitative evaluation based on a humanistic perspective has become an important research direction, including the detection of street style features, environmental features, building materials and functions, semantic segmentation of building facade components, and the relationship between street scenery environment.

Illegal construction of structures is one of the important works in the law enforcement and supervision of natural resources. Illegal buildings not only affect urban planning and urban beauty, but also bring trouble to the management of state-owned land. All departments need to monitor and control the illegal construction information, and need a large number of people to obtain first-hand information with human and material resources. The traditional illegal construction information investigation is mostly conducted by relevant departments organizing field investigators to conduct field investigation and field comparison. If newly built or expanded buildings are found, relevant data should be transferred in the land management system in time to

†School of Architecture and Art Design, Hebei Academy of Fine Arts, Shijiazhuang, Hebei, 050800, China (Corresponding author, duoduoduo0620@163.com)

verify whether there is illegal construction. Although this method can obtain illegal construction information, it is time-consuming and laborious, and has low timeliness. With the continuous development of remote sensing technology and application, the use of remote sensing images for land resources and national conditions dynamic remote sensing monitoring has been a part of the annual law enforcement inspection in large and medium-sized cities. Law enforcement inspection based on remote sensing technology has good objectivity, but the manual identification of illegal land use and illegal construction is still the main method. In recent years, with the increasing maturity of artificial intelligence deep learning algorithms, such as using video images to carry out statistical analysis of road traffic flow, target recognition algorithm to carry out cargo ship operation, and semantic segmentation to carry out natural resources survey, etc.

Village building environment with the development of economic construction, the traditional residential buildings are increasingly suffer gradually eating, the style of the village is gradually alienation, fortunately, this problem has gradually get attention, but for the protection of traditional village development, how to evaluate the village residential architectural features, classified statistical management, is indeed a very necessary and difficult work. For the protection of traditional villages, an urgent need to the number of village residential buildings, style, building quality, building height, and other information for quantitative evaluation and analysis, and improve the village planning development management, currently in the practical village planning work, which also put forward specific requirements, but the present for village building information statistics mainly through the way of artificial field investigation, after multi-directional residential photos, artificial interpretation of its architectural characteristics. Such a way, on the one hand, is easy to be limited by the traffic, climate and terrain factors of the local villages, which brings inconvenience to data collection, but also increase a lot of research costs; On the other hand, due to the way of manual interpretation, it is bound to bring some uncertain changes due to the subjective factors such as the subject background, life experience, mood and emotion, and bring certain disturbance to the result of the definition of architectural style. The continuous emergence of new technologies and new data provides a rich data basis for more detailed spatial quality research. At the same time, applying intelligent technologies such as machine learning and edge computing to various industries is a concave solution that conforms to the development of The Times. Such a study first requires a data collection process to collect the required data that collects critical architectural imaging data, often relying on field investigations. Such a high level of labor-intensive and time-consuming work makes a large-scale assessment of architectural features extremely difficult. In this regard, the collection and integration of architectural landscape data in an effective way remains a challenge for current academic research.

Digital twin cities can make forward-looking predictions about people and things in the city to a certain extent, with the premise of reshaping high-precision and multi coupled Building Information Modeling (BIM). However, in the initial digital modeling process of BIM, very few existing buildings have complete and accurate information data. In the field of BIM model generation for existing buildings, current methods focus on preprocessing the 3D point cloud data of existing buildings, extracting point cloud features through prior knowledge and corresponding algorithms (such as Hough transform, RANSAC (RandomSampleConsensus), and then generating BIM models through certain human-computer interaction processing [3,4]. This involves a large amount of manual work, which is time-consuming and subjective and prone to errors, in addition, the generalization performance of 3D reconstruction methods based on prior knowledge is poor, and the point cloud features extracted by traditional algorithms cannot be optimized end-to-end to obtain the global optimal solution. In the process of generating BIM models from 3D point clouds, the segmentation and localization of point cloud data are the most critical steps, and automatic implementation of this step is often difficult. Going deep into the basics, the difficulty lies in the fact that BIM models are composed of various types of components, and point clouds are a whole. In the process of automatically creating BIM models, component identification, localization, and modeling need to be synchronized. With the development of deep learning theory, deep neural networks have been widely adopted in different industries and have achieved good performance in computer vision tasks. The author explores the combination of deep learning and the generation of existing building BIM models. Combining the input data required for training point cloud neural networks, a set of point cloud datasets (SYNBIM) and corresponding creation methods are proposed for conventional building components that can be applied to 3D object detection tasks, by comparing the data storage formats of the SYNBIM dataset and the Scan Net point cloud dataset proposed by the author, the input and output data of the point cloud

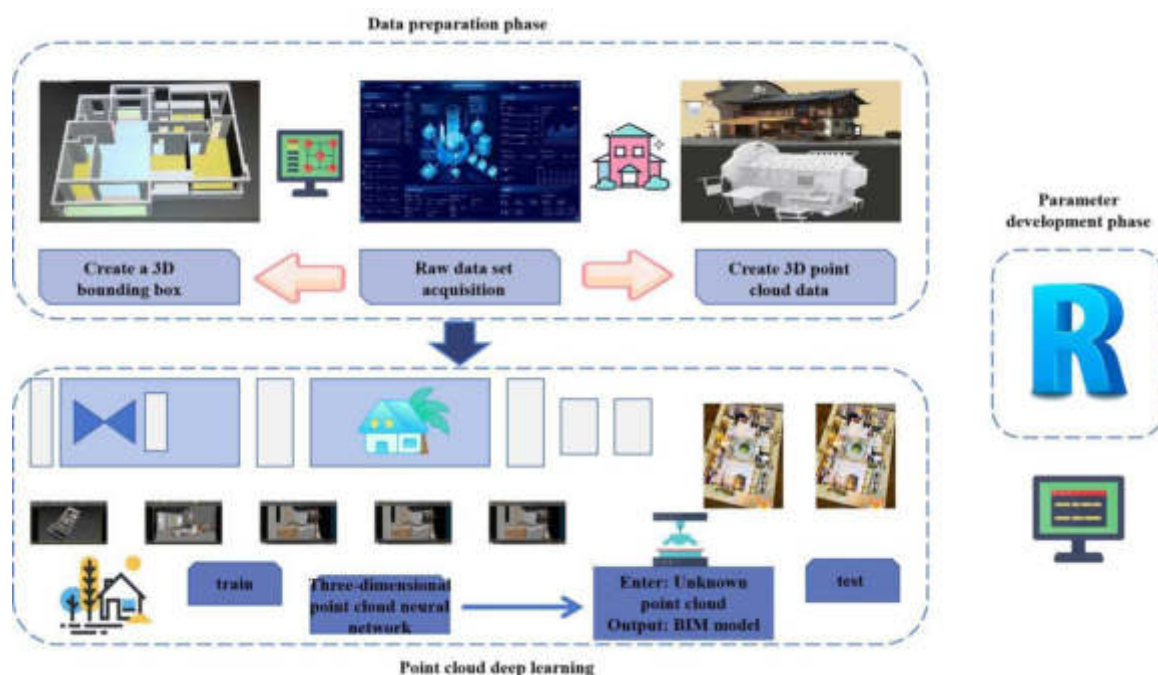

Fig. 2.1: Technical route of BIM model for automatic generation of 3 D point cloud based on deep learning

neural network framework during the testing phase were analyzed, and it was proved that the trained neural network can achieve "input unknown point clouds and output BIM model parameters" [5].

2. Methods.

2.1. Technical roadmap. The artificial intelligence algorithm is the most ideal method for reshaping BIM models in 3D and point clouds, but currently, the theory of point cloud processing and training data resources are not yet mature. The technical roadmap proposed by the author based on these two points is shown in Figure 2.1. In the data preparation stage, the SUNCG dataset 9, released by the Computer Vision and Robotics Research Group at Princeton University in 2017, was selected as the original dataset. This is a manually synthesized large-scale 3D scene virtual dataset with dense volume annotations. However, the original dataset is not mature enough for 3D bounding box annotations of conventional components in the field of civil engineering, such as walls, doors, windows, etc. In order to achieve the task of deep learning 3D object detection, the author selected five types of building components, namely "walls", "doors", "windows", "floors", and "ceilings", as the research objects. With the help of the Open3D 3D semantic library, each type of component was processed separately and corresponding hypotheses were proposed during the processing process. Finally, instance level 3D bounding boxes were generated as the labeled information for supervised learning. Then, combined with the camera pose estimation method, multiple indoor observation points are generated and stereo cameras are placed to capture multiple depth maps and two-dimensional images. These images with depth information are then synthesized into point cloud data, which can be used as input to the neural network. In terms of point cloud deep learning, by combining the input and output data of the point cloud neural network framework Votenet, and analogizing the data storage structures of the SYNBIM dataset and ScanNet dataset, a trained Votenet model is used to test the ScanNet point cloud scene, and the 3D object detection result is the BIM model [6]. For the five types of conventional building components, the data output by neural networks is well-established, and the parameter information of the components can be obtained through relevant geometric operations. In theory, corresponding BIM models can be created through Revit secondary development programming.

2.2. Obtaining the original dataset. The original dataset provides 45622 sets of 3D virtual scenes containing multi story buildings. Each 3D scene is saved in a house.json file. Based on the content of the JSON file, select a hierarchical processing method to generate the target 3D bounding boxes for each scene, and use separate processing for five different objects. With the help of Open3D, an open-source library that supports 3D data processing, and its advantage of customizable operation functions, the original dataset can be read and operated on.

2.3. Deep learning principles.

(1) *The fully convolutional neural network.* Full convolutional neural network (fully convolutional networks, FCN) uses convolutional neural network to realize the transformation from image pixel to pixel category. It can realize the classification of pixel level and solve the problem of semantic level image segmentation. Therefore, it is more suitable for the extraction of building map spots. The traditional convolutional neural network (convolutional neural networks, CNN) usually squashes the original two-dimensional matrix into one-dimensional at the last fully connected layer, losing spatial information, and finally trains to output a label. The building change extraction task is not only to know the types of objects contained in the image, but also to divide the location of different objects. Compared with other CNN, the difference is to remove the original CNN last fully connected layer, using deconvolution layer of the last convolution layer feature map sampling, make it back to the input image of the same size, the last pixel calculation classification loss, so can produce a prediction for each pixel, retain the spatial information in the original input image. Since high-resolution remote sensing images have a lot of detailed information, the underlying low-resolution semantic features directly classify the images, which will produce obvious errors. Therefore, FCN upsamples the results of different pooling layers, forms the optimization output, and then combines them with the downsampling to obtain the final classification results.

(2) *Add deep learning features.* In the sample training, the deep learning algorithm usually carries out a lot of iterative calculation based on the texture and spectral information of the sample, but there will be false identification for the structures with different shapes and different uses. On the basis of the identification and extraction of building information by deep learning algorithm, plus the features of NDVI and SAVI, it can effectively improve the differentiation degree of woodland, bare land, vegetation and building, and then improve the extraction accuracy of building changes. Both indices are calculated as follows:

$$N = \frac{B_{NIR} - B_R}{B_{NIR} + B_R} \quad (2.1)$$

$$S = \frac{B_{NIR} - B_R}{B_{NIR} + B_R + L} (1 + L) \quad (2.2)$$

where N indicates the vegetation index NDVI; BNIR represents the near-infrared band; BR red light band; S is the regulated soil brightness index SAVI; L is the soil regulation coefficient, the value range is 0~1, L=0 means the vegetation coverage is 0, L=1 indicates the soil background effect is 0. The texture features, spectral features and the above two exponential features of the image are combined into multi-source index, and the optimal training accuracy is obtained by the continuous iterative calculation of the image model within the sample range.

CNN can be applied in scene classification and image classification. LeNet is one of the earliest CNN structures, which is mainly used in the character classification problem. Since the convolution operation is used in the program, not only the features of the picture can be extracted, but also the convolution operation maintains the spatial relationship between the pixels. In the CNN, a filter is used as a feature extractor, and the matrix obtained by convolution is called a "feature graph". When selecting a specific CNN, the image characteristics of the target object, such as the difference between rural and urban buildings, and the situation of coarse-grained buildings. Because the real world classification problems are non-linear, and convolution operation is linear operation, so when using CNN to solve, must use a nonlinear function such as ReLU (or other nonlinear functions, such as Tanh and Sigmoid,) to add the results of the nonlinear properties, then adopt the form of downsampling, extract the features after the ReLU processing, or extract the element average or extract the maximum value, so as to reduce the dimension of the feature graph while maintaining the important information

Table 3.1: Part of Wall Ground Truth Data Styles

xc	yc	zc	x_size	y_size	z_size	yaw
7.46×10^{-2}	2.69×10^0	1.4	5.26	7.86×10^{-2}	2.73	$1.58 / \times 10^0$
9.27×10^0	1.38×10^1	1.39	5.04	1.03×10^{-1}	2.73	$1.58 / \times 10^0$

...

of the picture. Finally, the fully connected layer (multilayer perceptron) is combined together and classified through the whole layer using a softmax activation function. To is a vector with a value of 0-1 to judge picture classification by the probability value.

In recent years, deep learning methods, especially CNN performance in various computer vision tasks have gone beyond traditional methods, such as its excellent research results in target detection, semantics and image segmentation. The method of labeling image pixels with labels is based on the semantics in the image, that is, the algorithm will exist in the image, such as cars, trees or buildings as semantics from the extraction of the whole image, and each semantics. Moreover, in the field of computer vision, there is a large amount of research on the various modules used in convolutional neural networks that utilize the concept of "per object classification". These modules, such as convolution and pyramid pooling, improve the algorithmic performance for semantic segmentation tasks. In recent years, with the significant improvement of chip processing power (such as GPU units), the significant reduction of the cost of computing hardware, and the significant progress of machine learning algorithms, deep learning has made rapid progress in the field of image recognition, thus greatly improving the processing power of computers.

3. Results and Analysis.

3.1. Creating 3D bounding box walls. The manifestation of walls in the field of multi story and multi room indoor scene research is very complex. In order to prevent the calibration requirements of model bounding boxes in 3D object detection, a set of paradigms is needed to define the representation of wall objects, therefore, the author proposes the following assumptions when defining wall objects: (1) Shortest wall assumption: When a long wall and a short wall intersect in the same floor space, the long wall is split into two walls at the intersection; (2) One wall corresponds uniquely to a 3D bounding box. The bounding boxes extracted directly from the geometric information of the walls in the original data through programming, where different walls are marked with different colored bounding boxes. However, based on the above assumptions, there are several issues: Firstly, multiple long walls are not broken when encountering short walls; Secondly, there are multiple instances where the same wall is repeatedly calibrated by multiple bounding boxes, resulting in severe box overlap; Finally, there is no height difference between different bounding boxes, which may hide walls with repeated calibration.

By calling the open3d library functions through programming and customizing relevant functions to read and operate on the raw data, a set of bounding boxes is generated. The single-layer building walls are processed to meet the above assumptions.

The data of the wall bounding box is shown in Table 3.1, where a single row of data represents information about a bounding box, and seven parameters represent the coordinates of the three center points of the box in the overall coordinate system, the length, width, height of the box, and the deflection angle along the height direction. These generate the calibration parameters for the wall, and the other four components are processed and have the same data structure as the wall bounding box [7].

3.2. Creating 3D bounding boxes - doors and windows. During the process of processing raw data, doors and windows encountered the problems shown in Table 3.2 and Figure 3.1. Through investigation, it

Table 3.2: Initial Boundary Box Problems and Solutions for Doors and Windows

Initial problem	Initial error rate/%	Solution	Final accuracy rate/%
Thickness greater than wall	23.48	Detect the wall where it is located	99.18
Detaching from the overall building	9.7	Recalibrate the detection&delete it	99.8
Repeated calibration	19.87	Merge	98.18

Fig. 3.1: Error rate and final accuracy rate of initial bounding boxes for doors and windows

was found that some buildings had small doors and partially open windows [8]. According to the minimum bounding box theory, the thickness of the bounding box obtained by directly extracting data from partially open doors and windows exceeded the thickness of the wall.

3.3. Creating 3D bounding boxes - Floors and ceilings. The author defines the following rules when creating board class bounding boxes in the program: (1) Board objects cannot cover two or more rooms; (2) For multi story buildings, the boundary boxes of two floors or two ceilings cannot overlap, but overlapping is allowed between the two types of boxes of floors and ceilings; (3) The edges of at least three edges of the floor and ceiling bounding boxes are in contact with the edges of the wall.

3.4. Creating 3D bounding boxes - entire building . For single story buildings, create 3D bounding boxes for each target instance using the above methods to provide marker information for deep learning 3D object detection training tasks; For multi story buildings, the author first separates the information of each layer separately during the programming process of reading and manipulating the raw data, then sequentially processes and obtains the 3D bounding boxes of each layer's target instances. Finally, the processed multi story data is combined together to complete the processed multi story 3D bounding boxes [9].

3.5. Building Datasets - Creating 3D Point Clouds. In current practical applications, the digital acquisition based on 3D laser point clouds, which uses laser scanners to scan indoor and outdoor buildings in 3D, is a common method to obtain building point cloud data [10]. However, LiDAR has problems such as high cost, mirror black holes, and low lifespan, the method of generating depth images through stereo vision cameras and synthesizing point clouds is the future development direction. Depth images, also known as distance images, refer to images that use the distance values from the image collector to each point in the scene as pixel values. he author takes a long-term perspective and chooses to place a stereo vision camera at the virtual observation

Table 3.3: Dataset generation process and partial result presentation

Classification	subclass	3D Scene	3D Scene	3D Scene
		#1 Layer	#2 Layer	#3 Layer
Input	#Number of Layers/# Number of	1/1596/	2/768/	3 /549 /

	Boundary Box #	28/9/3	11+9	23+23+26
	Wall/# Door/#		/2+1	/4+4+4
	Window		/1+4	/4+4+3
	Boundary Box #	10/9	3+2/2+2	6+6+6
	Floor/# Ceiling			/3+3+3
	Downsampling/Original	29987/	18785/	36429/
	Point Cloud/k	16849.562	12492.263	19443.005
Running time/s	All bounding boxes	12.45	10.6	17.9
	Depth image+	654.76+	445.67+	953.16+
	color rendering	99.46	67.42	137.67
	3D point cloud	1843.13	1403.78	1930.19

points contained inside each building in the SUNCG dataset and generate corresponding depth images. The obtained depth images are 16 bit PNG format files, which can be used to generate 3D point clouds through relevant registration and registration algorithms.

Stereoscopic vision cameras need to capture objects from different observation points, and the depth map information obtained from different stations has their own independent coordinate systems [11]. After unifying the coordinate system, data fusion needs to be carried out. The basic formulas involved are:

$$\begin{cases} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta z \end{bmatrix} + R_z(\alpha)R_z(\beta)R_z(\gamma) \begin{bmatrix} x \\ y \\ z \end{bmatrix} \\ R_z(\alpha)R_z(\beta)R_z(\gamma) = \begin{bmatrix} \cos\alpha, -\sin\alpha, 0 \\ \sin\alpha, \cos\alpha, 0 \\ 1, 1, 1 \end{bmatrix} \\ \begin{bmatrix} \cos\beta, 0, -\sin\beta \\ 0, 1, 0 \\ -\sin\beta, 0, \cos\beta \end{bmatrix} \begin{bmatrix} 1, 0, 0 \\ 0, \cos\gamma, \sin\gamma \\ 0, -\sin\gamma, \cos\gamma \end{bmatrix} \end{cases} \quad (3.1)$$

In the formula: (X, Y, Z) represents the coordinates after point cloud registration; (x, y, z) are the original coordinates of the point cloud; $\Delta x, \Delta y, \Delta z$ is the translation parameter; α, β, γ is the rotation parameter[12]. By creating bounding box marker information and point cloud data, the dataset required for training the point cloud neural network was obtained, consisting of 45622 sets of large-scale 3D scene data. The hardware information and related calculation time used in the data generation process are shown in Table 3.3 [13].

3.6. Point Cloud Neural Network. At present, the application of deep learning to input 3D point cloud data into neural networks is still an open problem, and there are mainly three methods used: (1) Projecting point cloud data onto a 2D plane, which does not directly process 3D point cloud data, but first projects the point cloud to certain specific perspectives before processing, such as MUCNNL; (2) Dividing point cloud data into voxels with spatial dependencies, this approach involves segmenting three-dimensional space, introducing spatial dependencies into point cloud data, and then using methods such as 3D convolution for processing. However, the computational complexity of 3D convolution is relatively high, such as PointCNN; (3) Directly processing the original point cloud, this method generally involves a multi-step 3D object detection algorithm.

Table 3.4: Comparison of Dataset Properties

Data set	Scale	Data sources	Object scope	Data in	Output data	Using Lingcheng
ScanNet	1513	Real scan	Indoor scenes	3D point cloud	3D bounding box	Computer Vision
Hours (recalibration)	45622	synthetic	Indoor scenes	3D point cloud	3D bounding box	Architectural reshaping

Table 3.5: Geometric parameters of target components

Component category	Geometrical parameter
Wall	Wall bottom elevation, wall top elevation, wall centerline starting and ending wall thickness
Doors and windows	Placement coordinates, door bottom elevation, and door top elevation
Floors and ceilings	Outline boundary and plate thickness

In order to deal with the perspective invariance of each target in the point cloud data and obtain accurate 3D box regression, the algorithm needs to perform multiple coordinate transformations, such as Votenet [14]. The reason for the above three input methods is that: (1) Point cloud data is a collection that is not sensitive to the order of data, and the model processing point cloud data needs to maintain invariance to different arrangements of data; (2) The target represented by point cloud data should have invariance to certain rigid transformations, such as rotation and translation. This network does not rely on any RGB information and only relies on simple point cloud geometric information [15,16]. The entire network framework is divided into two parts: The first part uses a point cloud feature extraction network to process the original point cloud data and generate seed points and growth points; The second part aims to achieve classification and localization by training the extracted growth point clusters. It can directly input point cloud data and output target 3D bounding boxes in 3D object detection tasks, achieving good results in the benchmark challenge of the real scanning dataset ScanNet. The comparison of some key parameters between the ScanNet dataset and the SYN BIM dataset created by the author is shown in Table 3.4 [17].

3.7. Parametric modeling. From the perspective of data coherence, parameterized modeling of BIM components only requires extracting model parameters to achieve model creation. Therefore, in response to the author's selection of component categories, the required parameters for creating a BIM model are summarized and listed in Table 3.5 [18].

For these five types of building components, the data output by neural networks is well-established, and the parameter information of the components is obtained through corresponding algorithm operations. Then, through Revit secondary development, corresponding BIM models can be created [19,20].

4. Conclusion. The author explores the combination of deep learning and existing building BIM model generation based on 3D object detection technology, and integrates a feasible technology roadmap for automatic generation of BIM models from 3D point clouds based on deep learning. The following important issues are discussed: Generate target category labeling information from virtual BIM models; Generate a 3D point cloud model from a virtual BIM model; The experimental analysis of the data input and output of the point cloud neural network proves that its output data foundation is complete, and a BIM model can be generated through simple parameter modeling. The implementation method of a deep learning based 3D point cloud generation BIM model proposed by the author unifies the steps of point cloud data preprocessing, component recognition, segmentation, localization, and modeling in traditional methods. Through the deep learning backpropagation mechanism, global optimization can be achieved for the entire process. The core process is the generation of 3D point cloud datasets and the implementation of 3D object detection algorithms.

HUMAN-COMPUTER INTERACTION INTERFACE DESIGN IN THE CAB OF NEW ENERGY VEHICLES

YANXUE ZHANG^{*}; NANMEI ZHANG[†]; HUI YANG[‡] AND YANYU REN[§]

Abstract. A new energy vehicle cab control platform based on human-computer interaction is proposed from control device design and control signal acquisition design. A driving mode conversion algorithm based on the threshold is combined with the existing intelligent vehicle driving mode conversion. The MATLAB and Python hybrid program is used to realize the simulation experiment of the driving control algorithm of new energy vehicles. The system can conduct interactive simulations of various typical driving scenarios. Data acquisition and dynamic display functions can present the operating status of new energy vehicles most directly and efficiently. The system can integrate and intelligently process vehicle driving data, road environment data and external data from multiple dimensions of the "vehicle-road-network". The experimental results show that the system enhances the user experience of new energy vehicles and improves the efficiency of human-computer interaction.

Key words: New energy vehicles; Data accommodation; Autonomous collection; Human-computer interaction; Automatic driving

1. Introduction. In the face of energy shortages in all countries, the development of new energy vehicles has become the future direction. Because its energy supply system is different from conventional vehicles, it belongs to a new stage of transformation from electromechanical equipment to electronic equipment, so the design of human-machine interfaces for electric vehicles will also change. For example, the dashboard occupies less and less area, rather than being limited to the conventional form of multiple dashboards combined [1]. Drive-by-wire technology the instrument display architecture of electric vehicles is more diverse. Electronic LCDS can also be used to replace conventional vehicle dashboards. Therefore, human-computer interaction is a significant work when the vehicle is moving. The instrument panel interface of the electric vehicle contains the speed display, remaining power display, mileage display, and a variety of driving state displays [2]. Reasonable arrangement and design of these information interfaces is the key to the interactive interface experience of the instrument panel of electric vehicles. The instrument panel is the essential carrier and communication window for the communication between people and vehicles while driving electric vehicles, and its use experience directly affects whether the information transmission between people and vehicles is friendly, visible, controllable and operable [3]. To achieve the best user experience is the ultimate goal of human-computer interface design. The user interaction experience is a way to take the user's needs as the key and then translate them into the product image. It needs to meet the following points: the human-machine interface is easy to use, and you can learn to use it without particular research; The interface elements and shape model can intuitively reflect the functional characteristics and operation mode of the system, which can conform to the user's natural usage habits. The graphic logo used in the interface should be consistent with the standardization and beauty of the interface elements. The operation and display of the interactive interface should be coordinated, and the human-machine interaction design can be differentiated for different user types. This provides precise operational instructions to various users. At the same time, it can avoid the wrong operation and ensure the safety of the man-machine interface. This paper first studies the trajectory tracking control algorithm of autonomous driving of new energy vehicles. Construct a new energy vehicle driving simulation experiment

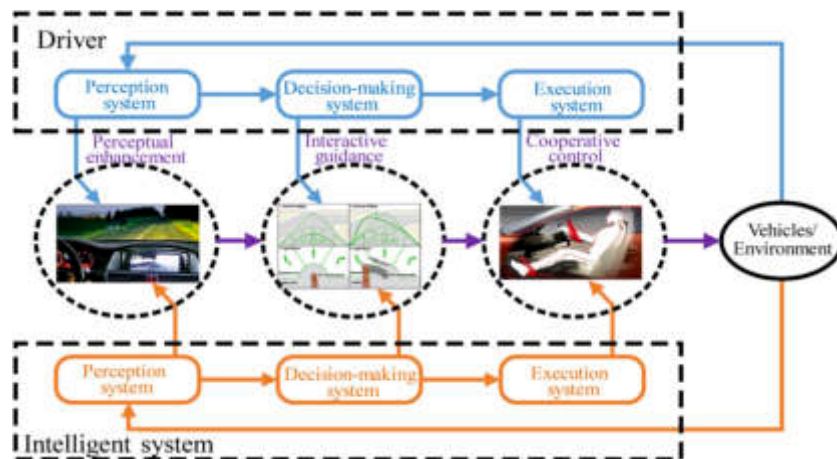

Fig. 2.1: Hardware architecture of human-computer interaction system for autonomous driving of new energy vehicles.

platform based on multi-modal information [4]. Under extreme conditions, it will lay a foundation for vehicle performance analysis and human-vehicle-environment interaction research.

2. Human-machine interaction requirements for driving new energy vehicles.

2.1. Physical Requirements. The human-computer interaction platform for intelligent management and control of new energy vehicles adopts a hierarchical structure composed of three levels: vehicle terminal, road test equipment/edge control unit, and intelligent management and control cloud platform [5]. Build an intelligent network-connected vehicle cloud platform that integrates "human-vehicle-road-network-cloud." Multi-mode communication networks such as 5G are supported on the network to achieve high-speed, low-latency data access and information transfer between vehicles, roadside devices and the cloud. Realize real-time scheduling and network management in specific unmanned driving application scenarios to ensure network security [6]—construction of traffic network architecture system to realize vehicle-road cooperation. Achieve effective vehicle-device-data collaboration. To realize the central scheduling and multi-objective optimal control for all sections and regions.

The comfort problem in the interactive simulation system of driver operation is systematically studied based on the actual vehicle driving situation. While ensuring the accuracy of data signal acquisition as much as possible, people pay more attention to the actual driving experience [7]. The steering wheel and seats are the same material as the vehicle. The clutch, throttle, and brakes are identical to the actual vehicles. In the autonomous driving mode, the design of the autonomous driving mechanism and the transformation of the driving mode are mainly studied [8]. The overall architecture composition of the system is shown in Figure 2.1 (the picture is quoted in IET Intelligent Transport Systems, 2019, 13(6): 960-966).

The platform operating equipment operates the manual driving mode, and the obtained detection information is transmitted to the signal acquisition board [9]. Through the collection and processing of the data, the data is finally transmitted to the computer. In the process of autonomous driving through the operation interface, the vehicle can dynamically adjust the driving path during the driving process. These two driving modes can complete the vehicle's driving simulation, laying a solid foundation for future intelligent research.

2.2. Functional Requirements.

2.2.1. Data integration and intelligence services. Eventually, multiple industry interconnection standards related to the vehicle will be formed, covering all scenarios of the entire intelligent network travel. Standardize information exchange among all links of the travel ecosystem, such as vehicles, traffic, roads, first aid, and meteorology [10]. To create an autonomous and controllable industrial environment for intelligent travel.

Multi-source information is integrated by establishing multi-source information such as road equipment status, road traffic events, and road traffic participants. The vehicle-cloud communication protocol consists of MQTT and TCP channels. Through the way of business reservation, it can realize dynamic lane planning, traffic control information, traffic speed limit information, real-time traffic flow prediction, dangerous road condition reminder, real-time status of signal light, future status of signal light, meteorological reality, conventional weather forecast, catastrophic weather warning, minute level precipitation forecast, parking lot information and other functions.

2.2.2. Real-time monitoring of road network. The lane and lane-level congestion operating conditions on both sides of the road are collected. Collect abnormal conditions such as landslides and large pits on the road surface [11]. Collect traffic lights, speed limits, road hazards, and other information. Browse the car accident list and display the information on the electronic map. The data on road construction and temporary traffic control are collected to realize real-time monitoring of vehicle collisions. The functions of "parking," "right turn," and "acceleration and deceleration" are realized. It can publish traffic events such as road congestion, traffic accidents, construction, temporary road closures and other information [12]. In-depth mining and analysis are carried out to build decision support for driving behavior management, traffic situation monitoring, road network optimization and other aspects combined with the historical data of vehicle-road integration.

3. Overall technical framework of the platform. "Vehicle-road-network" intelligent vehicle control cloud platform for cross-scale real-time monitoring, intelligent decision-making and collaborative control. Intelligent control cloud platform is the center of intelligent road networking cloud computing and the hub of data collection, processing, integration and application [13]. It can capture, convert, process and store advanced information in real-time from driverless vehicles, intelligent connected vehicles, facilities and roadside sensing. The integration of new energy vehicle driving information is achieved through the integration, fusion, and analysis of these data. The human-computer interaction platform combines modern cloud storage, cloud computing, big data, 5G, holographic intelligent perception, data communication transmission, electronic control and computer processing and other technologies into the system [14]. The overall technical architecture of the intelligent management and control cloud platform is shown in Figure 3.1 (the picture is quoted in the Novel ITS based-on Space-Air-Ground collected big-data).

The construction of the human-computer interaction architecture of mobile edge computing centers can reduce the signal delay in the automatic driving mode of new energy vehicles. At the same time, it can give full play to the geographical coverage characteristics of edge computing networks and support the cooperative operation of vehicles and roads with regional characteristics. The Computing architecture of human-computer interaction cloud-edge collaboration for new energy vehicles is shown in Figure 3.2 (the picture is quoted in Vehicular Edge Computing and Networking: A Survey).

3.1. Control signal acquisition. The joystick collects and processes this information in real-time as a critical component linking the platform control equipment to the computer simulation. The selected data acquisition board comprises 16 digital input modules and eight analog input modules and is interfacing with the simulation computer through RS232 serial communication, which can well meet the driving and signal acquisition requirements on the analog platform [15]. The communication module processes the signal received by the control device to realize the connection and data transmission with the vehicle vision. Using serial communication technology and the MSComm control program, the time class of serial communication is set to record and collect data in real time. Its control signal is the throttle, brake, steering, brake, and so on for its input. When the sensor installed on the vehicle body sends out the corresponding change, it will cause a change in the displacement, angle, and other electrical signals connected to it. According to the dynamics model of the vehicle, it is processed, and the environment is monitored in real-time.

3.2. Driverless. The system comprises steering wheel control, throttle control and brake control. The steering system mainly comprises the steering servo motor, the universal joint, and the relevant parts between the universal joint and the steering shaft. To facilitate and accurately control the brake and accelerator and ensure that the driver's brake and accelerator will not be interfered with under manual driving mode, a rolling screw sliding platform is specially selected to pull the brake and accelerator pedals [16]. The ball screw can make the rotation linear. The measured travel of the accelerator pedal and the brake pedal is 80 mm, and the

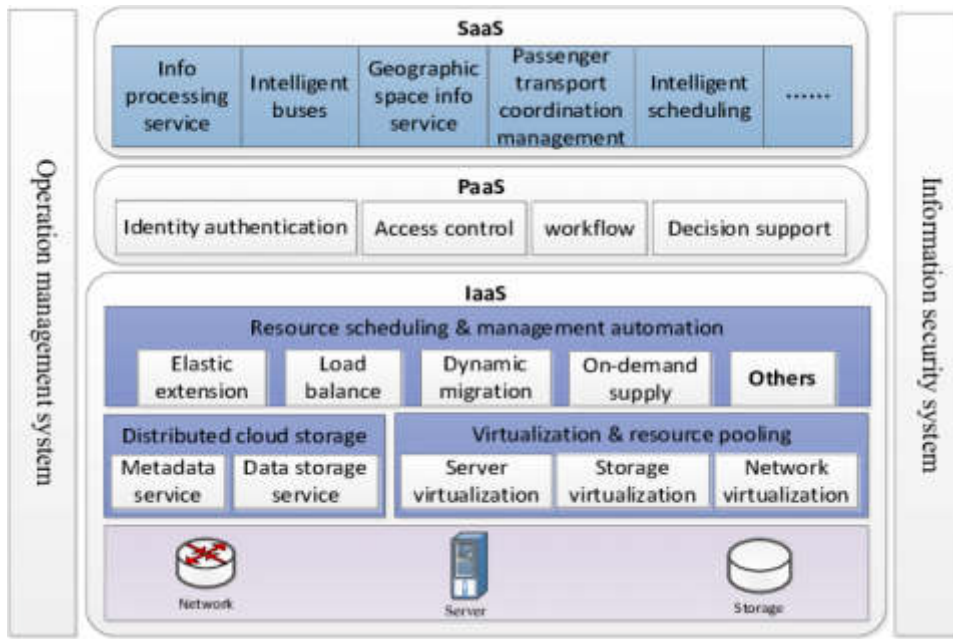

Fig. 3.1: New energy vehicle driving interactive platform system architecture.

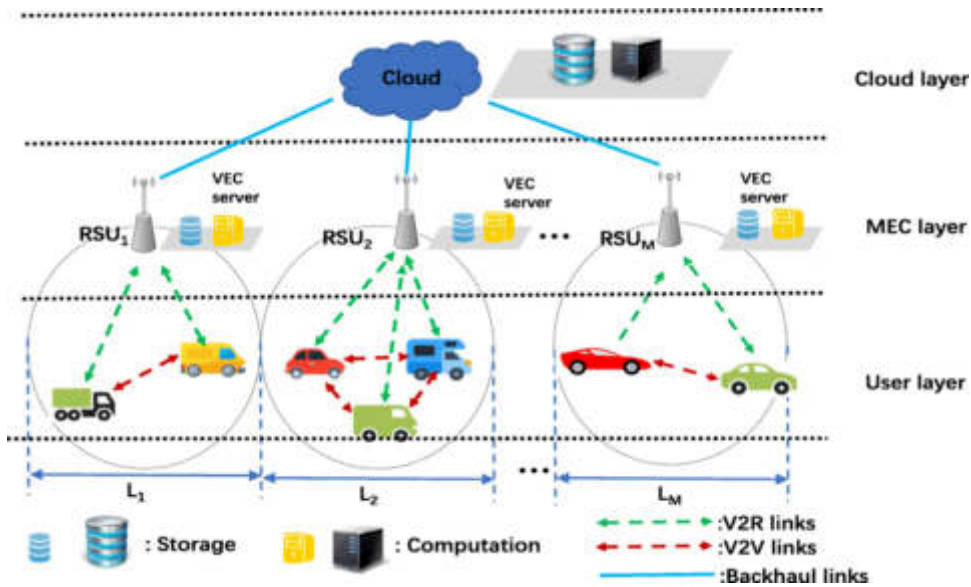

Fig. 3.2: Computing architecture based on cloud edge collaboration.

travel of the brake pedal is 90 mm, where the travel is the length required from the release of the pedal to press the drag chain fully. Through the motion control card to complete the mode of autonomous driving, the motion control card is used to transmit the real-time pulse signal to the servo motor, and then the received pulse signal starts rotating to make the slider rod on the lead screw move. Then, drive the platform for steering, acceleration, deceleration and other actions. In the driverless mode, the user can write the vehicle's trajectory

tracking function into the motion control card for various simulation situations. Let the motion control card perform the corresponding driving action according to the route.

4. Adaptive cruise control algorithm. The combination of PC and low-level hardware is used to collect and process the vehicle distance in front of the vehicle. Pass the desired acceleration command to the underlying device [17]. The onboard sensor at the bottom of the vehicle collects all the information needed when driving, and the motor completes the action, such as an accelerator and brake, to complete the vehicle’s driving. The car must be well-spaced during the journey. Use the front distance to determine the optimal workshop distance:

$$y_{a,y}(x) = \tau_2 u_l(x) + y_{a,0}$$

τ_2 is the distance between cars ahead. $y_{a,0}$ represents the safe distance between parked vehicles. The state quantity $\gamma(x) = [e(x), u_a(x), \delta_l(x), w(x-1)]^T$ of the system is defined. An interference observer that can accurately estimate the system is proposed.

$$\begin{cases} \gamma(x+1) = \lambda\gamma(x) + \eta_w \Delta w(x) + K_\gamma(p(x) - \hat{p}(x)) + \eta_s s(x) \\ p(x) = \mu\gamma(x) \\ \omega(x+1) = Z\omega(x) + K_s(p(x) - \hat{p}(x))s(x) \\ s(x+1) = U\omega(x) \end{cases}$$

$e(x), u_a(x), \delta_l(x), w(x)$ is the distance deviation between vehicles at the time x , the relative speed of vehicles, the acceleration of vehicles, and the acceleration command. The state variables formed by it conform to:

$$\gamma(x) \in \Gamma, \forall x = 0, 1, \dots$$

$$\Gamma = [-\tau_2 u_{l, \max}] \times [u_{a, \min}, u_{a, \max}] \times [\delta_{l, \min}, \delta_{l, \max}] \times [w_{\min}, w_{\max}] . \lambda, \eta, \mu, Z \text{ and}$$

U are constant matrices. K_γ, K_s is the gain of the observatory. $p(\gamma)$ and $\hat{p}(\gamma)$ represent the calculated deviation of workshop spacing and the actual deviation. The acquisition of $\hat{p}(\gamma)$ is detected by sensors on the car to obtain real-time data. s is an input of uncertain bounded interference. Use $\Delta w(x) = w(x) - w(x-1)$ to determine the incremental control input. Through vehicle networking communication and interaction between participants, perception and control of complex scenes are realized. The requirements for traceability and multiple economic objectives required in driving are given.

$$\begin{aligned} K_1(\gamma(x)) &= z_e \gamma_1^2(x) + z_u \gamma_2^2(x) \\ K_2(\gamma(x)) &= z_\delta \gamma_3^2(x) + z_{\delta c} \gamma_4^2(x) \\ K_3(w(x)) &= z_{sw} \Delta w^2(x) \end{aligned}$$

z_e, z_u, z_δ and z_{sw} are the weight factors corresponding to vehicle time error, speed error, acceleration and acceleration instruction in vehicle-road cooperative driving. It indicates the importance of each indicator. The following are sorted out and combined with the proposed performance indicators:

$$H(\gamma, \Delta w) = \sum_{i=0}^{j-1} \{ \gamma^T(i | x) Z_\gamma(x) \gamma(i | x) + z_{sw} \Delta w^2(i | x) \}$$

The state matrix is represented by $Z_\gamma = \text{diag} \{z_e, z_u, z_\delta, z_{sw}\}$. p is the predicted time interval. There exists $[x, x+j](x = 0, 1, L)$ in the control time domain of model predictive control. The vehicle acceleration parameter $\Delta w(i | x)$ is parameterized as follows:

$$\Delta w(i | x) = \varphi^i \Delta w(0 | x), i = 1, 2, L, j - 1$$

$i | x$ refers to the future value predicted for $x + i$ at sampling time x . And the compliance coefficient φ , appropriate to $[0, 1]$, is a parameter used to adjust the smooth output. Due to the high computational complexity

Table 5.1: *Test parameters of simulation test.*

Argument	Default value
Scene size /m x m	3000×3000
Simulation time /h	24
Node communication radius /m	150
Message size /Mb	5
Message generation interval /s	510
MAC layer protocol	IEEE802.11p
Application layer data flow	CBR
Transmission model	Two Ray Groun

of model prediction, its application is restricted, so the control sequence $\Delta w(i | x)$ is parameterized by the current decision variable $\Delta w(0 | x)$. This can be compensated by increasing the step size of the prediction time domain j , because a more significant value of j can lead to better performance. When the control gain of an interval $\Delta \bar{w}_{\min}(x) \leq \Delta w(x) \leq \Delta \bar{w}_{\max}(x)$ is given, the physical properties and driving comfort of the vehicle are considered comprehensively. The constraint is:

$$\left\{ \begin{array}{l} \Delta \bar{w}_{\min}(x) = \max \left\{ \Delta w_{\min}, (w_{\max} - w(x-1)) / \sum_{i=0}^{j-1} \varphi^i \right\} \\ \Delta \bar{w}_{\max}(x) = \min \left\{ \Delta w_{\max}, (w_{\min} - w(x-1)) / \sum_{i=0}^{j-1} \varphi^i \right\} \\ \gamma(i | x) = \lambda^i \gamma(0 | x) + \\ \sum_{j=1}^i \varphi^{i-j} \lambda^{j-1} \eta_w \Delta w(0 | x) \\ + \sum_{j=1}^i \alpha^{i-j} \lambda^{j-1} \Delta \hat{p}(0 | x) \\ + \sum_{j=1}^i \lambda^{j-1} \eta_s \hat{s}(i-j | x) \end{array} \right.$$

Since neither the present nor the future disturbance $s(i-j | x)$ is known, and the values of past disturbances at various times are used as present forecasts, there is $s(j-j | x) = s(x-1)$, $j = 1, 2, \dots, j$.

5. System inspection. The open-source highway traffic simulation programs SUMOSUMOs and NS 3 are tested and studied. The actual mathematical model of vehicle driving is established using the SUMO method. Use NS 3 to simulate packets' transmission success rate and average transmission delay with different nodes and TTL values. The test was conducted on Ubuntu16.04. The test parameters of the simulation test are shown in Table 5.1. The scenario and operation of the simulation test are shown in Figure 5.1 (the picture is quoted in System architecture for installed-performance testing of automotive radars over-the-air).

The simulation of transmission success rate under different node motion rates is shown in Figure 5.2. When the transmission rate is not high, the system's topology will change slowly, and the communication connection is relatively smooth. When the network transmission rate increases, the instability of the link will decrease, and the transmission success rate of various methods will decrease. At the same time, RSSM can dynamically adjust according to the change in network topology caused by fast movement to ensure the transmission channel's maximum connectivity and improve the transmission success rate.

6. Conclusion. Interaction mode selection, information identification, multi-purpose design and beautiful appearance design will all impact the interactive experience of new energy vehicle users. The purpose of this study is to discuss how to overcome the difficulties and satisfaction of the users in the human-machine interaction design of new energy electric vehicles from the theoretical and practical aspects. The acquisition of operation equipment and signals is studied under manual driving of new energy vehicles. The design of the electric control circuit is proposed, and the main parts and electrical components are selected and tested. It has been found that the system can reproduce the whole car process in real-time through human-computer interaction.

APPLICATION OF CLUSTER ANALYSIS ALGORITHM IN SUPPLY CHAIN RISK IDENTIFICATION

QINGPING ZHANG* AND YI HE†

Abstract. The risk control model of the power supply chain system is established. A fault information identification method based on fuzzy clustering is proposed. This method fully considers the power grid's characteristics and uses terrible data. A risk assessment model based on fuzzy set theory is established by the COWA operator weight method and grey cluster evaluation method. The security risk identification model of power grid enterprises uses insufficient data. The security risk identification data are normalized and classified. Empirical analysis determines various risk factors that may appear in power projects. The applicability and feasibility of the index system and evaluation model are verified.

Key words: Fuzzy clustering; Power supply chain; Security risk monitoring; Risk identification

1. Introduction. The rapid development of the electric power industry can benefit the people and greatly promote the development of the national economy. In the early stage of development, because the power industry has a high degree of monopoly, many operating entities such as power generation, electricity sales and transmission are concentrated in one company. This results in an industrial governance model similar to the corporate governance model, which has a high degree of monopoly but also causes a lot of resource waste, low efficiency, and high operating costs. At the same time, there are problems such as rent-seeking, price discrimination and network barriers. China has launched a series of power system reforms and market-oriented plans by introducing market competition to change the monopoly situation of the whole industry. This can reduce the operating cost and realize the rationality of resource allocation. It can not only effectively promote market competition but also reduce the waste of energy. The domestic power grid has separated power plants from the grid and established a perfect quotation model for power generation and other industrial sectors. It has broken through the monopoly model of the past and established a complete power grid supply chain. However, some potential security risks cannot be ruled out in the domestic power supply chain. Against this background, it is an important research direction for power network security risk monitoring.

The FMEA model was analyzed in the literature [1]. A complex diffusion network model of fault mode is established by using a complex network analysis method. The influence of the correlation between fault modes and fault modes is studied. Taking a typical supply chain as the research object, FMEA and complex network methods are studied to test their application value in fault-type evaluation. Literature [2] proposed the generation mechanism of risk factors in the construction stage of hydropower projects based on the perspective of the supply chain. The sub-indexes of 5 categories and 18 categories were established. The final risk assessment value is consistent with the actual risk status of the project. The effectiveness and feasibility of this method are proven. Literature [3] constructs the framework of an inter-provincial power trading system based on RPS. Clarify power supply and demand issues among various market participants. The customer's subjective choice is introduced, and the utility function describes the customer's purchasing behavior. The optimal decision problem of multiple trade participants in the supply chain based on maximum return is constructed. By using the method of reverse derivation, the optimal trade decision problem of each trader is solved [4]. It has particular reference significance to the cross-province power market in our country. However, the power supply in these ways is unstable. Therefore, this paper uses the fuzzy clustering method to monitor the security risks of each

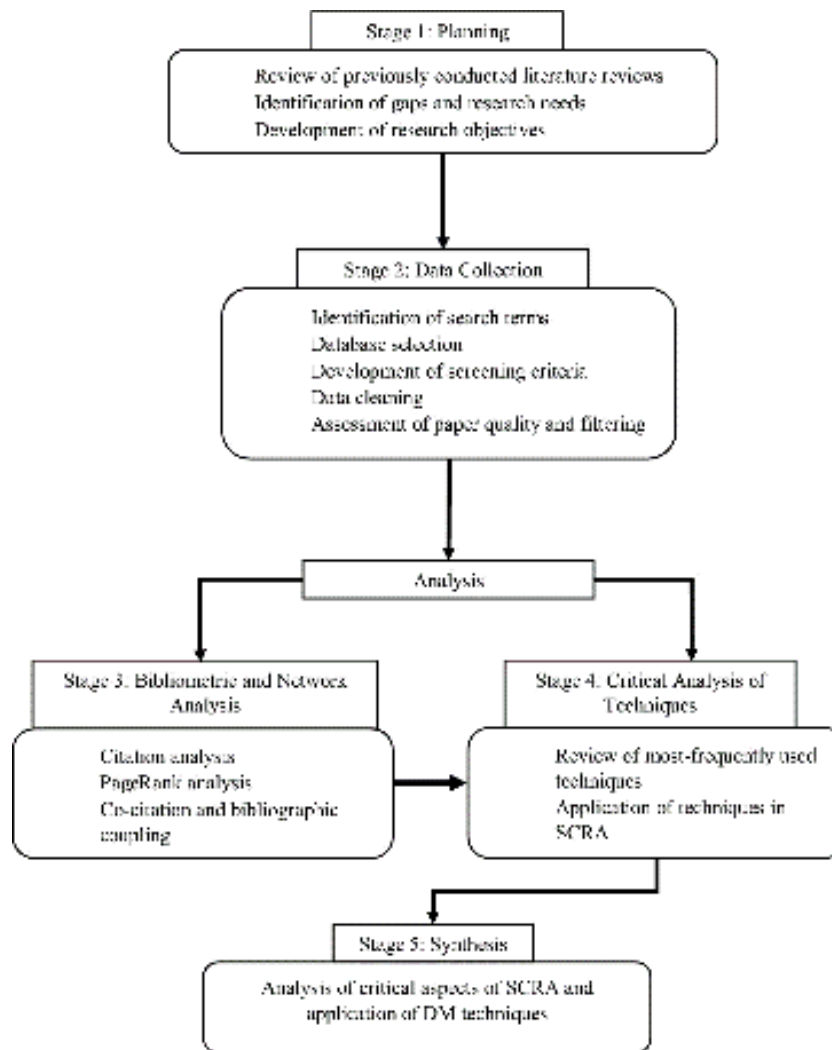

Fig. 2.1: *Specific construction process.*

link enterprise in the power grid to achieve the optimal allocation and supply chain management of each link enterprise in the power grid. The aim is to improve the stability of the power grid.

2. Fuzzy cluster monitoring in the power supply chain.

2.1. Security Risk Identification. The wrong data of the power grid system is analyzed according to the characteristics of the power grid itself based on the identification of power grid fault information. The security risks of power grid enterprises can be effectively identified [5]. The power grid operation's risk identification mechanism is obtained. First, the security of insufficient data must be collected and classified. The security risk index of the power supply chain system based on the network is constructed. Then, a preliminary framework of a fuzzy comprehensive evaluation system is constructed [6]. The detailed construction process is shown in Figure 2.1 (image cited in *Annals of Operations Research*, 2023, 322(2): 565-607). Through the identification of security risks of power grid enterprises, they are divided into internal and external categories. These two risk factors are listed in Table 2.1.

Table 2.1: *Safety risk factors.*

	Evaluation index	Level 1 security risk factor	Secondary security risk factors
Power supply chain security risk factors	Natural hazard index The closeness of national policy Industrial climate index Overall economic condition Customer satisfaction Inventory turnover Profit margin on sales Production cost Research and development phase Product flexibility Order fulfillment rate Qualified rate of finished product Order preparation time	External security risk of the power supply chain Internal security risk of the power supply chain	Ecological environment risk Policy and regulation risk The risk of public security hazards Economic and environmental risks Seller's security risks Manufacturer's safety risk Supplier security risk

2.2. Security risk monitoring. After obtaining the relevant information on the risk factors inside and outside the electricity market, the next step is to process the data [7]. The first step is to limit the scope of the relevant data. Monitoring the power grid security risk is to normalize and classify the collected information. The main contents include daily power threshold security risk monitoring, harmonic limit security risk monitoring, and parameter setting security risk monitoring. The security risk monitoring of the daily load threshold is mainly used to monitor the stability and security risks of the power grid load during the power grid operation. Power grid side security risk monitoring is mainly through the power grid voltage level and change amplitude to monitor the power grid operation [8]. If the voltage level and the range of change cannot meet the electricity demand, it must be modified. A power metering device is designed to measure the running state of the power system. If the parameter of the meter is set to 0.2, then the allowable deviation of the meter must be controlled within 0.2%. If the end indicator of the meter exceeds the control value, it indicates a security risk for the customer's meter in the entire grid. The power data collected during power grid operation is a vital link. It also includes the power meter precision, power rate, and other parameters set by the security risk monitoring function [9]. Prevent users from arbitrarily changing the user's power parameters.

3. A comprehensive risk assessment model of a power supply chain is established by combining C-OWA with grey clustering.

3.1. The COWA algorithm is used to calculate the weights of each evaluation index. The essence of the OWA algorithm is to sort the data incrementally, and the weighting depends only on the space. A ranked, weighted mean C-OWA algorithm is proposed. The detailed process is like this: 1) An expert is invited to evaluate the importance of the evaluation indicators at all levels, and the scores constitute the initial evaluation data set $(\eta_1, \eta_2, \dots, \eta_i, \dots, \eta_n)$ of the evaluation indicator H , and $\theta_0 \geq \theta_1 \geq \theta_2 \geq \dots \theta_j \geq \dots \theta_{n-1}$ is obtained from θ in the order from high to low. 2) The weighting λ_{j+1} of data θ_i is directly determined by the number of combinations Z_{n-1}^j :

$$\lambda_{j+1} = \frac{Z_{n-1}^j}{\sum_{t=0}^{n-1} Z_{n-1}^t} = \frac{Z_{n-1}^j}{2^{n-1}}, j = 0, 1, 2, \dots, n-1$$

Formula: $\sum_{j=0}^{n-1} \lambda_{j+1} = 1$. 3) Weight the evaluation data with weight vector λ to obtain the absolute weight $\bar{\delta}$ of index η_i :

$$\bar{\delta} = \sum_{j=1}^n \lambda_j \cdot \theta_j \in [0, 1], j \in [1, n]$$

4) Calculate the relative weight value δ_i for the exponential factor η_i

$$\delta_i = \frac{\bar{\delta}}{\sum_{i=1}^m \bar{\delta}_i}, i = 1, 2, \dots, m$$

3.2. Grey cluster analysis of the overall risk of the power supply chain. Many factors affect the integration risk of the power supply chain, and most of the existing evaluation methods rely on experts' subjective experience, knowledge level and subjective preferences [10]. So, the grey clustering method is used to study the risk of the power supply chain.

3.2.1. Grey category judgment and whitening weight. The complexity of risk assessment indicators will directly affect the refinement of grey categories [11]. It is assumed that the target to be assessed is divided into s grey categories, and the interval of its secondary index is also divided into s grey categories. It is divided into very low [2,0], low [4,2], average [6,4], high [8,6], and high [10,8]. People can get the point vector $U = (9, 7, 5, 3, 1)$ by applying the traditional grey system theory.

3.2.2. Grey cluster evaluation steps. 1) Construction of evaluation model. This paper classifies the risk degree of the power supply chain based on q class of power industry experts, supply chain research experts, mahagement experts and construction experts [12]. Then the evaluation matrix $S_i = [s_{ijt}]_{s \times q}$ is constructed according to the score of index H_{ij} . s is the number of exponents of the matrix. 2) Construction of grey cluster weight matrix. The clustering factor of Grade H_{ij} and Grade e gray level is grade $U_{ije} = \sum_{n=1}^q g_e [s_{ijt}]$, and the overall level evaluation factor is grade $U_{ij} = \sum_{e=1}^5 U_{ije}$. Then the weight vector of the gray cluster can be calculated as $c_{ije} = \frac{U_{ije}}{U_{ij}}$, and the weight matrix of the gray cluster can be obtained as follows

$$C_i = \begin{bmatrix} c_{i11} & c_{i12} & c_{i13} & c_{i14} & c_{i15} \\ c_{i21} & c_{i22} & c_{i23} & c_{i24} & c_{i25} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ c_{ij1} & c_{ij2} & c_{ij3} & c_{ij4} & c_{ij5} \end{bmatrix}$$

3) Comprehensive cluster evaluation matrix. Evaluate each significant index cluster according to formula (3.5):

$$V_i = \delta \cdot C_i$$

Take $V_0 = [V_1, V_2, \dots, V_n]^T$ as the comprehensive evaluation matrix of the above index, and then use formula (3.6) to conduct a comprehensive cluster evaluation of the index:

$$Y = \delta \cdot V_0 = [Y_1, Y_2, \dots, Y_n]$$

4) Synthesize the evaluation values at all levels. Formula (3.7) is used to integrate weight Y and weight O to obtain the risk level of the power supply chain to prevent secondary losses in the evaluation process.

$$\Lambda = Y \cdot O^T$$

4. Experimental detection.

4.1. System Validity Check. A fault information identification method based on fuzzy clustering is proposed. Data was processed using the Xon (R) Server with Windows Server 2012R2 [13]. The network topology of the power system is established, and the total load is obtained. A risk identification model based on load level is proposed. Different test schemes are compared and analyzed [14]. The 46,890 labeled samples were classified. Among them, 70% are taken as training samples, 10% as confirmation samples and 20% as test samples (Table 4.1).

The correctness of the proposed algorithm is verified by comparing it with fuzzy clustering, k nearest neighbor classification, SVM, convolutional neural network and recurrent neural network. Each class of algorithms is based on a training set. Run ten times in one test set. Finally, the average of 10 samples is the final prediction

Table 4.1: Data set division unit.

Training set	Validation set	Test set
34191	4884	9769

Table 4.2: Accuracy rates of different models.

Model	Accuracy rate / %
Fuzzy clustering method	78.96
KNN	79.48
SVM	85.83
CNN	89.38
LSTM	90.21
CPE	93.54

Fig. 4.1: Test accuracy.

accuracy [15]. Table 4.2 shows that the mathematical model proposed in this paper has good test results. It has advantages over classical machine learning algorithms such as fuzzy clustering, KNN, and support vector machines. Performance is better than CNN LSTM.

The model was trained during the experiment. Each trained model is run ten times on the same data set. The method is predicted ten times, and the final prediction accuracy is obtained [16]. The following conclusions are drawn through the analysis of the experimental data: 1) The accuracy of the fuzzy cluster analysis model in this paper can reach 89.8% by comparing the accuracy of different models. This algorithm exceeds the conventional machine learning algorithm and is better than the widely used deep learning algorithms such as neural networks and LSTM. Because the initial value limits the selection of the KNN initial value, it isn't easy to obtain an ideal initial value. However, support vector machines have substantial limitations in selecting kernel functions and are unsuitable for large-scale data. Although CNN has a good feature extraction function, there is often an aggregation process after extraction. And through pooling, resulting in more significant information loss. The short-term memory method is ineffective in feature extraction [17]. The clustering method has the advantages of better feature extraction, not being easy to lose, not being affected by the initial value, and having a greater demand for data. 2) As seen in Figure 4.1, the variance of the cluster analysis model is the least, while the variance of other models is more significant, indicating that the clustering method is robust. 3) The weights of high-level hazard factors and low-level factors are shown in Figure 4.2. The results show that the factors causing harm are the largest in the distribution system, and the planning links occupy a large proportion.

Fig. 4.2: Risk weight values.

Fig. 4.3: Comparison of power supply chain stability.

4.2. System stability analysis. The supply chain failure mode risk assessment method, EPC mode method, renewable energy quota method and other methods are combined with this method, and the fuzzy cluster analysis method is compared [18]. The results show that the model in this paper can reflect the stability of the power grid well (Figure 4.3).

A risk assessment model based on fault types of supply chain is proposed. The resulting power grid stability is about 72.2% [19]. The simulation results show that the stability of the model is about 42.6%. The results show that the proposed algorithm has good stability. The fundamental reason is that the research idea proposed in this project is based on identifying insufficient data and integrating it with the characteristics of the power grid to identify the security risks of power grid enterprises. It guarantees the stability of the supply chain.

5. Conclusion. The fuzzy clustering model of power supply chain system risk is established to ensure the high stability of the power grid. This research result has important practical significance for developing China's power market. It is also relatively easy to implement. Its implementation process is simple and time-consuming is short, so it has good promotion value.

TRANSFORMER FAULT DIAGNOSIS AND LOCATION METHOD BASED ON FAULT TREE ANALYSIS

ZHIWU WU*, TIANFU HUANG†, CHUNGUANG WANG‡, XIANG WU§ AND YANZHAO TU¶

Abstract. Fiber optical current transformer (FOCT) is widely used in power systems for fault diagnosis and analysis, which can improve its operational reliability. Construct fault modes and fault trees based on fault data of all fiber current transformers, and construct a fault feature space. Constructing a fault diagnosis expert system using fault trees and fault feature space clustering centers to achieve accurate diagnosis of fault types, patterns, and components. The proposed method was validated using fault data and case studies of all fiber current transformers in a regional power grid, and the results showed that: The on-site fault case is closest to the cluster center of drift deviation fault, so it belongs to drift deviation fault. Further extract the on-site maintenance report, which indicates that the operating temperature of the all fiber current transformer is relatively high. The diagnostic results of the fault diagnosis expert system for the faulty all fiber current transformer are consistent with the actual results on site, verifying the accuracy and reliability of this method.

Key words: All fiber current transformer, Fault Mode and Effects Analysis Method, Fault tree, Expert system, fault diagnosis

1. Introduction. Transformer is a very important electrical equipment in the power system, whose main responsibility is to measure and transmit current and voltage information to ensure the safe operation of the power system. However, due to various reasons, transformers may malfunction, such as insulation damage, inter turn short circuits, open circuits, etc. These faults may lead to measurement errors, equipment damage, and even power system accidents.

Firstly, insulation damage is a common occurrence of transformer faults [1]. The insulation layer of the transformer plays a role in protecting the coil and magnetic core. Once the insulation layer is damaged, current may directly enter the coil of the transformer through the insulation layer, causing measurement errors and even equipment damage. Insulation damage may be caused by aging due to prolonged operation, or it may be due to harsh external conditions such as high temperature, humidity, etc. Therefore, it is very important to regularly inspect and maintain the insulation layer of the transformer to ensure its normal operation. Secondly, inter turn short circuit is also a common problem of transformer faults [2]. The coil of a transformer consists of many turns, and when a short circuit occurs between some of these turns, the current will bypass these turns, causing measurement errors. Short circuit between turns may be caused by damaged coil insulation, insufficient insulation distance between coils, and other reasons. In order to avoid inter turn short circuits, it is necessary to ensure that the coil insulation of the transformer is intact and that there is sufficient insulation distance between the coils during installation. In addition, the open circuit of the transformer is also a common fault situation. When the coil of the transformer is interrupted or poorly connected, it will result in the inability of current to flow through the coil and make accurate measurements. An open circuit may be caused by coil damage, loose wiring terminals, and other reasons. In order to avoid open circuit faults, it is necessary to regularly check whether the coils of the transformer are intact and ensure that the connection terminals are firmly and reliably connected [3]. The above mentioned fault situations are only a part of the possible occurrence of transformers, and the actual situation may be more complex. In order to ensure the safe operation of the power system, in addition to regular inspection and maintenance of transformers, other measures should also be

¶Marketing Service Center of State Grid Fujian Electric Power Co., Ltd., Fuzhou, Fujian, 350013, China

taken, such as setting up overcurrent protection devices, installing backup transformers, etc., in order to cope with possible fault situations. In addition, with the development of the power system and the application of intelligent technology, the methods for detecting and preventing transformer faults are also constantly improving [4]. For example, using an infrared thermal imager can detect temperature anomalies in transformers, thereby detecting potential faults in advance. In addition, the emergence of intelligent transformers can achieve real-time monitoring and fault diagnosis of transformers, further improving the reliability and safety of transformers.

In short, as an important electrical equipment in the power system, the failure of transformers may have serious impacts on the power system. Therefore, we need to pay attention to the inspection and maintenance of transformers, timely detect and eliminate transformer faults, in order to ensure the safe operation of the power system. The author's purpose is to study the fault diagnosis and localization method for transformers based on fault tree analysis. By establishing a fault tree model for transformers, analyzing the mechanism and possible fault paths of transformer faults, and determining the probability and importance of faults occurring. Based on the results of fault tree analysis, the author proposes corresponding fault diagnosis and positioning strategies, providing technical support for the rapid diagnosis and accurate positioning of transformer faults. Through this study, the aim is to improve the efficiency and accuracy of transformer fault handling, ensuring the safe operation of the power system.

2. Principle and Fault Mode Analysis of All Fiber Optic Current Transformer.

2.1. Principle of all fiber optic current transformers . When linearly polarized light passes through certain optical materials in a direction parallel to the magnetic field, due to the influence of the magnetic field, the front side rotates. The formula for calculating the rotation angle θ of polarized light is

$$\theta = \mu\nu \int_{L_1}^{L_2} H(L)dL \quad (2.1)$$

In the formula, μ is the magnetic permeability of the material; V is the Verdet parameter of the optical material; L is the distance traveled by light in the material; $H(L)$ is the function of the spatially distributed magnetic field with respect to L [5]. If fiber optic or magneto optic block glass is used to close the optical path around the conductive conductor, then

$$\theta = \mu\nu N \oint H(L)dL = \mu\nu Ni \quad (2.2)$$

In the formula, N is the number of turns of the optical path and current intersection; I is the current flowing through the conductor. Therefore, the current can be calculated by detecting θ .

2.2. Fault mode analysis of all fiber optic current transformers . The process of inferring the form, location, and cause of a fault based on fault knowledge and a certain strategy is called the fault diagnosis process. In the diagnosis process, corresponding fault knowledge should be used as the basis, such as fault symptoms, fault detection methods, degree of fault harm, and maintenance measures. The external manifestation of faults is the fault mode, which can be observed through human senses or measuring instruments and meters [6]. When diagnosing equipment faults, it is necessary to first determine the fault mode through factual data, and then determine its impact on the system through the determined fault mode, and propose targeted maintenance measures and solutions. The Fault Mode and Effect Analysis (FMEA) method is used in multiple fields such as nuclear and aviation industries to eliminate equipment failure hazards. FMEA can provide a comprehensive qualitative analysis of system or equipment failure modes. In the design process of a system or equipment, the FMEA method analyzes the potential failure modes of its constituent units and their impact on the system or equipment, and classifies each potential failure mode according to its severity, proposing possible design, prevention, and improvement measures [7]. Before analyzing the all fiber current transformer using FMEA method, it is necessary to subdivide its various components to establish a reliability diagram of the all fiber current transformer. Existing research indicates that the main factors affecting the reliability of current transformers are as follows.

Fig. 2.1: Reliability Block Diagram of Full Fiber Current Transformer

- (1) The influence of sensor head structure. The optical material of the sensor head undergoes changes in its optical properties under the influence of external electric fields, temperature fields, and stress fields, resulting in various effects that affect the stability of the transformer system.
- (2) The impact of optical system. Due to the difference in surface smoothness and parallelism of optical components, as well as the inevitable small displacement during the bonding process, there will be deviation angles in the optical path system, which will affect the stability of the transformer.
- (3) The impact of signal processing circuits. The differences in component performance in signal processing circuits lead to certain deviations, such as low-pass filters and the dispersion of component parameters, which will affect the amplitude frequency response and cause errors in signal processing [8].
- (4) The influence of insulation structure. The insulation structure not only affects the linear range of system measurement, but also the selection of insulation materials affects the analysis of electric fields. The thermal expansion and contraction of materials cause changes in the distance between electrodes, thereby affecting the stability of transformers.
- (5) The impact of LED characteristics. The output of the sensor is a function of wavelength, and the characteristics of LED determine the stability of the wavelength. With the change of temperature, the wavelength of LED will change, thereby affecting the stability of the transformer. Analyze the various parts of the all fiber current sensor and establish its reliability diagram, as shown in Figure 2.1.

Figure 2.1 is based on a commonly used and effective total reflection fiber optic current transformer. Therefore, the insulation structure and optical path system through which the incident and reflected light pass are the same. Therefore, this reliability block diagram only contains 5 different parts. The above parts will individually or comprehensively affect the stability of the all fiber current transformer, and this impact on stability will be manifested through the output of the transformer [9]. Therefore, based on the abnormal situation of the output of the transformer and the influence of specific parts of the transformer, the following 5 different types of current transformer faults can be determined.

- (1) Fixed deviation fault. A fixed deviation fault occurs when there is always a fixed deviation between the measured value and the true value.
- (2) Drift deviation fault. The sensor head of an all fiber current transformer is easily affected by temperature, leading to a decrease in the performance of optical or electronic components, resulting in drift of measurement values over time. This drift is known as drift deviation fault.
- (3) Variable ratio deviation fault. The ratio of a transformer represents the proportional relationship between the true value and the measured value. In practical applications, sudden changes in the ratio may occur due to changes in the operating environment and an increase in operating time, resulting in distortion of the transformer output signal. This situation is called ratio deviation fault.

Fig. 3.1: Basic Principles of Expert Systems

- (4) Accuracy distortion fault. The failure of the signal processing module and transmission unit of the all fiber current transformer can cause distortion in the accuracy of the measured values. When accuracy distortion occurs, the average measurement value remains unchanged and the measurement variance changes [10].
- (5) Complete failure failure. Due to hardware circuit faults and optical component failures, the measured value of an all fiber current transformer does not change with the true value and always maintains a certain value (zero or maximum range value). This type of fault is called a complete failure fault.

3. Expert System for Fault Diagnosis of All Fiber Current Transformers . Expert system ES (Expert System) enables computer software systems to apply knowledge, facts, and reasoning mechanisms to solve complex problems that typically require human experts to solve. The expert system mainly consists of two parts: An expert knowledge base and an inference machine. Based on the facts provided by the user, the system uses certain inference methods to make inferences and judgments based on the knowledge base, and finally outputs the results [11]. The basic principle is shown in Figure 3.1.

3.1. Knowledge Base. The knowledge base is the fault knowledge base of all fiber current transformers, which is used to store domain expert knowledge and is a key factor in determining the performance of expert systems. The author's knowledge base consists of the following three parts:

1) *FMEA Table.* Using the FMEA table as expert knowledge, there is a certain connection between the component names, fault modes, fault consequences, and fault types in the table. By analyzing the output data of the transformer, the fault type and most of the fault consequence information can be obtained. Combined with a simple analysis of the transformer structure, the fault location can be determined, thus achieving fault diagnosis and providing corresponding response measures [12].

2) *Fault clustering center.* The fault situation of the all fiber current transformer can be reflected through the data obtained from its monitoring. For any all fiber current transformer, obtain the time-domain characteristics of its monitoring data, including rise time, fall time, pulse width, and duration; Frequency domain features refer to spectral peaks in the frequency domain; Shape parameters, namely skewness and kurtosis; And 11 feature quantities, including time center of gravity, equivalent duration, frequency center of gravity, and equivalent frequency width, are used to construct its feature vector for time-frequency joint features. Construct feature vectors for each fault case and classify them according to the fault type to form a feature space for that fault type. Finally, calculate the clustering center of this feature space and use it as a knowledge base.

3) *Fault Tree.* Using the fault tree as a knowledge base, after inferring the fault type of the tested current transformer, the FMEA table and fault tree can be combined to diagnose the fault of the tested current transformer, providing the fault location, fault consequences, and response measures.

3.2. Inference Machine. The inference machine provides results based on user input data, utilizing knowledge from the knowledge base and following certain inference rules. Rules are generally expressed as

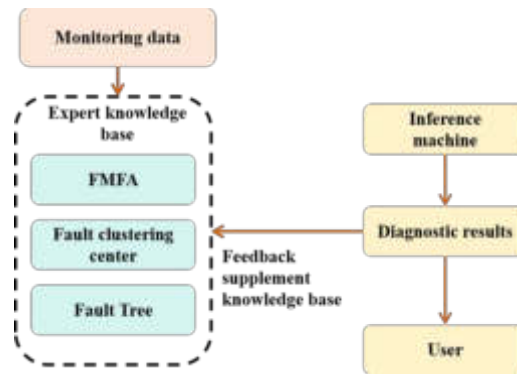

Fig. 3.3: Diagnosis process of expert system

IF-THEN, where IF is the premise and THE is the inference. When diagnosing faults in all fiber current transformers, the real-time monitoring values of the all fiber current transformer are taken as input, and then feature vectors are extracted to calculate the distance between this feature vector and each fault cluster center. The fault type with the smallest distance corresponds to the fault type of the all fiber current transformer [13]. Match the operating conditions (including operating conditions and environmental conditions) of existing all fiber current transformers with the basic events of the fault tree, and provide the final fault diagnosis result in combination with FMEA.

The functional structure and diagnostic process of the fault tree based all fiber current transformer fault diagnosis expert system based on fault mode and impact analysis method are shown in Figure 3.2 and Figure 3.3, respectively.

4. Fault diagnosis examples. Based on simulation data of mathematical models for various fault types and existing fault data of all fiber current transformers, a total of 5569 pieces of data were extracted. From these data, 11 quantities were extracted, including rise time, fall time, pulse width, duration, frequency domain spectral peak, skewness, kurtosis, time center of gravity, equivalent duration, frequency center of gravity, and equivalent frequency width, to construct feature vectors. Normalize the maximum and minimum values for each feature quantity to obtain the clustering centers of each fault type, as shown in Figure 4.1.

Extract the rise time, fall time, pulse width, duration, frequency-domain spectral peak, skewness, kurtosis, time center of gravity, equivalent duration, frequency center of gravity, and equivalent frequency width of all fiber current transformer fault cases obtained on site, and normalize them to obtain their corresponding feature vectors, as shown in Figure 4.2.

Fig. 4.1: Clustering center for each fault type

Fig. 4.2: Characteristic vector of the fault case

Table 4.1: Euclidean distance between the feature vectors of the fault cases and the cluster center of each fault type

Fixed deviation	Drift deviation	Change ratio deviation	Accuracy distortion	Complete failure
0.4914	0.4041	0.6112	0.5408	0.5042

Calculate the Euclidean distance between the feature vectors of the fault cases in Figure 4.2 and the clustering centers in Figure 4.1, as shown in Table 4.1.

According to the calculation results in Table 4.1, it can be seen that the on-site fault case is closest to the cluster center of the drift deviation fault, so it belongs to the drift deviation fault. Further extract the on-site maintenance report, which indicates that the operating temperature of the all fiber current transformer is relatively high[14,15,16,17]. Therefore, a fault diagnosis conclusion can be drawn: The drift deviation fault of the all fiber current transformer may be caused by a decrease in fiber temperature performance or a decrease in sensor unit temperature performance. It is recommended to replace the fiber or conduct performance testing on the sensor unit[18,19,20]. This conclusion is consistent with the conclusion given in the on-site report of the all fiber current transformer that high temperatures lead to a decrease in the performance of the optical

transmission system.

5. Conclusion. The author analyzed the impact of each part of the full fiber current transformer on overall stability, provided a reliability diagram of the full fiber current transformer, and analyzed the types of faults from the perspective of monitoring data, constructing a fault mode and impact analysis Table. A fault tree for all fiber optic current transformers was constructed based on the fault mode and impact analysis table for qualitative analysis of faulty current transformers. A fault diagnosis expert system for all fiber current transformers is proposed, which uses the clustering center, FMEA table, and fault tree of the faulty current transformer as the knowledge base of the expert system. Based on the corresponding inference rules, any all fiber current transformer is diagnosed, and the fault type, fault mode, fault component, and corresponding response measures are provided. The on-site fault case verified the usability of the method proposed by the author.

ETHICAL EVALUATION AND OPTIMIZATION OF ARTIFICIAL INTELLIGENCE ALGORITHMS BASED ON SELF SUPERVISED LEARNING

RUOYU DENG* AND YANG ZHAO†

Abstract. Active learning solves the problem of requiring a large amount of manpower and resources due to the large size of training samples. The core problem is how to select valuable samples to reduce annotation costs. Using neural networks as classifiers, most methods choose samples with large amounts of information without considering the issue of information redundancy between the selected samples. Through the study of redundancy issues, the author proposes a sample selection optimization method to reduce information redundancy. Using uncertainty methods to select samples with high information content to form a candidate sample set, and using latent variable vectors calculated in the network to represent sample information, the cosine distance between candidate samples is calculated using this vector to select subsets with large interval distance and low information redundancy. Compared with several uncertainty methods in the Mnist, Fashion mnist, and Cifar-10 datasets, this method reduces labeled samples by a minimum of 11% with the same sample accuracy. The higher the dimensionality of the feature vector calculated by CNN, the more candidate samples it contains, and the more information it contains. After being improved by self supervised learning algorithms, the effect becomes more significant. The more candidate samples are selected, the stronger the information redundancy. The better the performance of self supervised learning algorithms.

Key words: Artificial intelligence algorithms, Information redundancy, Cosine distance, Uncertainty method

1. Introduction. With the rapid development of artificial intelligence (AI), intelligent algorithms are being applied more and more widely in various fields, such as autonomous driving, medical diagnosis, financial analysis, etc [1]. The introduction of these algorithms has brought great convenience and benefits, but at the same time, it has also raised concerns about ethical issues related to these algorithms. In the decision-making and behavior of AI algorithms, there may be significant impacts on individuals, society, and the environment [2]. For example, in the field of autonomous driving, intelligent algorithms are responsible for determining the trajectory and behavior of vehicles, which is directly related to driving safety and road traffic order. In medical diagnosis, AI algorithms can assist doctors in disease diagnosis and treatment decisions, but their accuracy and safety are also factors that need to be considered. In financial analysis, intelligent algorithms can assist in investment decision-making and risk assessment, but the fairness and transparency of their decisions are also controversial [3].

Therefore, in order to ensure the security, fairness, and trustworthiness of AI algorithms, ethical evaluation and optimization have become crucial. The purpose of ethical evaluation is to examine whether the decisions and behaviors of algorithms comply with ethical and ethical standards, and to predict their potential impacts. This requires consideration of ethical considerations in algorithm design and training, as well as the potential risks and impacts that may arise during algorithm application. Firstly, in the process of algorithm design and training, it is necessary to consider whether the collection and use of data are legal and compliant [4]. For the processing of sensitive information, such as personal identity information, medical records, etc., relevant laws and regulations should be strictly followed to protect the privacy rights of users. At the same time, it is necessary to ensure the quality and reliability of the data, and avoid erroneous decisions made by algorithms due to data bias or incompleteness. In addition, the training process of the algorithm should also follow the principles of fairness and equality to avoid discriminatory results. Secondly, in the process of algorithm application, it is necessary to consider the transparency and interpretability of the algorithm. Intelligent algorithms are usually built based on machine learning and deep learning techniques, and their decision-making process is often black

box like, difficult to explain and understand. This is a challenge for users and relevant stakeholders as they are unable to understand how algorithms make decisions [5]. Therefore, the interpretability of algorithms has become an important ethical issue. In order to address this issue, researchers are working hard to develop interpretable AI algorithms and promoting the development of relevant standards and specifications. In addition, the fairness of algorithms is also an ethical issue that needs to be considered. The decision-making of intelligent algorithms may be affected by data bias and unfairness, such as discriminatory outcomes for certain specific groups. Therefore, it is necessary to review and calibrate the training data of the algorithm to avoid bias and discrimination. At the same time, it is necessary to establish supervision and feedback mechanisms to promptly correct unfair decisions made by algorithms and protect the rights and interests of users [6]. Finally, risk assessment and management of algorithms are also important aspects of ethical assessment. Intelligent algorithms may bring some potential risks, such as privacy breaches, security vulnerabilities, ethical conflicts, etc. Therefore, it is necessary to conduct a comprehensive assessment and management of these risks, take corresponding measures to reduce risks, and establish supervision and monitoring mechanisms to timely identify and solve problems [7].

The sample selection strategy is a core issue in the process of artificial intelligence algorithms. In the pool sample mode, different classifiers have different selection strategies. Under the condition of using SVM as a classifier, the information content of samples is clearly measured by the distance between samples and support vectors, such as SVM's batch pattern artificial intelligence algorithm method. However, considering the distribution problem between samples, Maximum Mean Discrepancy (MMD) is used to measure the distribution difference between sample sets, thereby ensuring the consistency of distribution between unlabeled and labeled sets, for example, the Batch Mode Active Learning (BMAL) method and the Discriminative and Representative Model Active Learning (DRMALS) method [8]. Furthermore, the Similarity based Sparse Modeling Representative Selection (DSMRS) and mutual information method were used to measure the similarity between sample sets, thereby reducing the redundancy between sample sets. For example, adaptive active learning methods, Convex Programming Active Learning (CPAL) methods, etc.

Under the condition of using neural networks as classifiers, similar to SVM, the closer the sample information is to the classification boundary, the greater the amount of information. Currently, most uncertainty methods are used for measurement. Due to the lack of clear explanation from neural networks, some scholars believe that the current method does not select samples close enough to the classification boundary and needs to reselect samples near the classification boundary, such as: The Bayesian Active Learning (DBAL) algorithm calculates the mean of the results after multiple dropouts as the final classification result; Attack the Unmarked Sample (DFAL) algorithm using the Deepool algorithm that generates adversarial samples; Considering the sample distribution relationship, in order to ensure the consistency of distribution between labeled and unlabeled sample sets, a Cost Effective Active Learning (CEAL) method with classifier self labeling is used to transform the sample selection problem into a K-center problem using Euclidean distance, these methods ensure distribution consistency and allow for the selection of samples with large amounts of information, but they do not solve the problem of information redundancy. The author proposes a self supervised learning algorithm to reduce redundancy and achieve better results.

2. Problem Description. This section defines the active learning problem, which indirectly measures the amount of sample information and the redundancy of sample information through latent variables in CNN with MLP. Combining the process of artificial intelligence algorithms, the problem of minimizing redundancy is defined. Assuming there are n samples of m classes [9]. The problem of artificial intelligence algorithm based on pool sample selection sample pattern is as follows:

Question 1. Assuming the number of labeled samples is n_L and $L = \{x_i | i = 1, 2, \dots, n_L\}$; The number of unlabeled samples is n_U , $U = \{x_i | i = 1, 2, \dots, n_U\}$, $x_i \in R^k$ and $n_L + n_U = n$; Sample label set: $Y = \{y_i | i = 1, 2, \dots, n_L\}$ and $y_i \in R^m$. The loss function of the CNN model is $l(L, Y; f(\theta))$, which is mapped to $R^{n_L \times k} \times R^{n_L \times m} \rightarrow R^{n_L}$.

Each time k samples are selected from U to form a S_i set and placed in L . The active learning problem is:

$$\min_L E[l(L, Y; f(\theta))] - E[;(L, Y; f(\theta))] \text{ s.t. } |S_i| = k \quad \text{and} \quad L = \bigcup_{i=1}^T S_i \quad (2.1)$$

The loss function is the information cross entropy function, which is:

$$l(L, Y, \theta) = -\frac{1}{n_L} \sum_{i=1}^{n_L} \sum_{j=1}^m \{y_i = j\} \log p(y_i = j | x_i; \theta) \quad (2.2)$$

In the formula, T is the number of iterations; $1 \{\cdot\}$ is the indicator function, which is 1 when CNN predicts correctly, otherwise $p(y_i = j | x_i; \theta)$ is the output result of class j after the Softmax process.

Due to the lack of clear interpretability of CNN, it is difficult to determine what specific information the sample has about CNN. Given this issue, it is assumed that the CNN is connected to an MLP fully connected layer after passing through a convolutional layer, and the output vector of the hidden layer in MLP is specified as a latent variable, abstracting sample information through latent variables. The modulus of latent variable vectors represents the amount of information, and information redundancy is represented by calculating the distance between samples. The commonly used distance measures include Euclidean distance and cosine distance. The cosine distance is more effective in calculating and yields the same conclusion, so cosine distance is chosen[10]. Furthermore, the inner product measures the redundancy of information between samples, meaning that a larger inner product indicates a higher similarity of latent variables and a higher redundancy of information between the two samples being compared.

Definition 1. For samples x_i and x_j , the latent variables calculated by CNN are x'_i and x'_j , and $x'_i, x'_j \in R^n \in R^n$, the information redundancy matrix R and information quantity I between n samples are:

$$R = \begin{pmatrix} r_{11} & r_{12} & \dots & r_{1k} \\ r_{21} & r_{22} & \dots & r_{2k} \\ \cdot & \cdot & \dots & \cdot \\ \cdot & \cdot & \dots & \cdot \\ \cdot & \cdot & \dots & \cdot \\ r_{k1} & r_{k2} & \dots & r_{kk} \end{pmatrix} \quad (2.3)$$

$$I = (I_1, I_2, \dots, I_n) \quad (2.4)$$

In order to solve problem 1, the goal is achieved by reducing redundancy by selecting a sample set with high information content and low redundancy. Question 1 becomes how to select the sample set S_i to minimize the redundancy between samples[11].

Question 2. Assuming that there is already a redundancy matrix R, select the sample set S_i from U to minimize the mean of R, that is:

$$\min_L \text{average}(R) \text{ s.t. } |S_i| = k \quad \text{and} \quad L = \bigcup_{i=1}^T S_i \quad (2.5)$$

3. Redundancy methods. The redundancy problem mainly occurs between multiple selections of S_i , between sample sets, or between samples in a single selection of S_i . Assuming that after each selection of S_i , the CNN converges on the set L after labeling, there is less information redundancy between the S_i sample sets selected in each iteration, and the redundancy problem mainly lies between the samples in the S_i set [12].

The analysis of the redundancy problem of S_i set is shown in Figure 3.1, where: circle and triangle represent two types of samples m_1 and m_2 ; The dashed line represents the initial classification boundary; The solid line is the classification boundary after selecting samples; Grid points are candidate sample sets; The real point is the selected sample set. The samples are divided into two categories: m_1 and m_2 , where $m_j^{(i)}$ represents the i-th subset of samples belonging to the j-th category. Assuming that some samples have been selected and labeled based on uncertainty methods. As shown in Figure 3.1 (a), several samples were selected from the $m_1^{(1)}, m_2^{(2)}$ sample set near the CNN classification boundary. After iterative training, the original dashed boundary became a solid boundary, and the result did not completely separate the two types of samples. It can be seen that the sample set selected based on uncertainty methods has information redundancy. In response to this issue, the author proposes a self supervised learning algorithm [13].

Fig. 3.1: Analysis of Redundancy Issues in S_i Sets

3.1. Uncertainty methods. The principle of sample selection based on the pooling sample pattern is mainly to select samples with high information content in the unlabeled pool to enable CNN to quickly fit the samples. High information content means that after CNN calculation, the probability of unlabeled samples in each classification is close to $\frac{1}{m}$, or they are uncertain in the most likely classification. Such samples close to the classifier boundary are the selected samples in Figure 3.1 (a). The current methods of uncertainty are as follows:

(1) Low credibility:

$$x^* = \operatorname{argmax}_x [1 - p(y_{max}|x_i; \theta)] \tag{3.1}$$

In the formula: $y_{max} = \max(y_i = j|x_i; \theta)$. Sort the maximum values of samples in various classification probabilities from small to large, and select the top K samples.

(2) Information entropy:

$$x^* = \operatorname{argmax}_x - \sum_i p(y_i = j|x_i; \theta) \log(p(y_i = j|x_i; \theta)) \tag{3.2}$$

Sort the top K samples in descending order of information entropy.

(3) Bayesian estimation:

$$p = \frac{1}{T} \sum_{t=1}^T p(y_i = j|x_i; \theta, dropout_t) \tag{3.3}$$

Average the classification results under multiple dropout values, and then select samples based on Equations 3.1 and 3.2.

3.2. Redundancy algorithm. As shown in Figure 3.1(a), the above uncertainty method only selects some samples as S_i sets based on the given calculation indicators, without considering sample redundancy, thus selecting meaningless samples. A self supervised learning algorithm is proposed based on this problem, as shown in Figure 3.1(b), which constructs a candidate sample set consisting of samples located near the CNN classification boundary, which includes all categories. Finally, select a subset of samples with low redundancy from the candidate sample set.

Select samples located near the CNN classification boundary based on uncertainty methods to form a candidate sample set. Calculate the cosine distance matrix between latent variables for all candidate samples:

$$D = \begin{pmatrix} d_{11} & d_{12} & \dots & d_{1k} \\ d_{21} & d_{22} & \dots & d_{2k} \\ \cdot & \cdot & \dots & \cdot \\ \cdot & \cdot & \dots & \cdot \\ \cdot & \cdot & \dots & \cdot \\ d_{k1} & d_{k2} & \dots & d_{kk} \end{pmatrix} = \frac{R}{2\sqrt{I^T \times I}} \tag{3.4}$$

Using the distance matrix to obtain a sample set with low redundancy, that is, selecting the sample from the candidate set that is least similar to the labeled set each time. If L is an empty set, selecting the sample that is most similar to the candidate set[14].

3.3. Self supervised learning algorithms. From the above algorithms, it can be seen that the purpose of using cosine distance and redundancy algorithms is to select sample sets with category diversity and low redundancy from the candidate sample set.

Assuming that K samples are selected in an unlabeled sample pool in one round, and the LeNet5 network is used as a classifier with S convolutional kernels, with a single convolutional kernel computation time of t_s , the time complexity analysis of self supervised learning algorithms and uncertainty methods is as follows:

Uncertainty methods:

$$T_U = T_s + T_k \quad (3.5)$$

Self supervised learning algorithms:

$$T_D = T_s + T_k + T_R \quad (3.6)$$

In the formula, T_s is the time taken for network training; T_k is the sorting selection sample time; T_R is the redundancy calculation time.

$$T_s = t_s K S = O(t_s S) \quad (3.7)$$

$$T_k = K = O(1) \quad T_R = N K = O(N) \quad (3.8)$$

Obviously, $t_s \gg N > 1$, then $T_s \gg T_R > T_k$, the time is mainly spent on training the neural network. Therefore, Equations 3.1 and 3.2 have the following relationship:

$$T_U \approx T_D \approx O(t_s S) \quad (3.9)$$

From Equation 3.5, it can be concluded that the running time of the two methods is roughly the same[15].

4. Experiments and Result Analysis.

4.1. Datasets and Network Structures. Multiple experiments were conducted on Mnist, Fashion mnist, and Cifar-10 on the Lenet and NIN models. The neural network structure is shown in Tables 4.1 and 4.2, and the description of the dataset is as follows:

- (1) Mnist: 28×28 grayscale images, totaling 10 categories. Used for recognizing handwritten digit datasets, including 50000 for training, 5000 for validation, and 10000 for testing. 10000 samples were used as unlabeled sample pools in the experiment.
- (2) Fashion latest: 28×28 grayscale images, totaling 10 categories. Used to identify fashion clothing datasets, including 50000 training sets and 10000 testing sets. Due to its higher complexity than Mnist, the experiment used 20000 samples as an unlabeled sample pool.
- (3) Cifar-10: $32 \times \text{thirty-two} \times 3$ color images, totaling 10 categories. A small dataset for identifying universal objects, including 50000 training sets and 10000 testing sets. 20000 samples were used as unlabeled sample pools in the experiment[16].

4.2. Experimental parameters. In order to reduce the impact of experimental randomness, each dataset experiment had an average of 5 results. In each experiment, in order to avoid the model being biased during the training process, the validation set selected for each iteration is to randomly and uniformly extract 2% of samples from each class in the existing labeled set, and the CNN initialization network parameters are the same in each dataset experiment[17]. The experiment used the Keras toolkit on the Python platform to compare self supervised learning algorithms with low credibility, information entropy, and Bayesian methods in uncertainty methods multiple times. For the Mnist dataset, $n_0=100$, $T=15$, $N=3$, $K=100$, feature vector length 128, and network structure are shown in Table 4.1. For the Fashion mnist dataset, $n_0=200$, $T=20$, $N=10$, $K=150$, the feature vector length is 256, the network structure is shown in Table 4.1, and the output length of the Fc layer is changed to 256[18]. Considering the complexity of the Cifar-10 dataset and network training issues, in order to reduce overfitting and result stability, the dropout value is reduced, $n_0=1\ 000$ $T = 20$ $N = 30$ $K = 150$ dropout = 0.25 the length of the feature vector is 512.

Table 4.1: Mnist and Fashion mnist experimental network structures

type	Core size/step size	Output Size
convolution	$3 \times 3 / 1$	$28 \times 28 \times 32$

Fc(dropout25%)	—	$1 \times 1 \times 512$
Fc	—	$1 \times 1 \times 10$
Softmax	—	$1 \times 1 \times 10$

4.3. Analysis of experimental results. In order to verify the effectiveness of self supervised learning algorithms, different datasets use different network structures due to their varying complexity. The results are shown in Figure 4.1.

It can be clearly seen that self supervised learning algorithms have significant improvements in the existing uncertainty methods. Compared to the samples required for the highest accuracy of the uncertainty method, in Mnist, when the uncertainty method reaches 98%, the entropy method reduces the maximum number of samples by 28%, while the Bayesian method reduces the minimum number of samples by 16%; In Fashion mnist, when the uncertainty method reaches 85%, the maximum decrease in lead is 30%, and the minimum decrease in entropy is 14%; In Cifar-10, the three methods achieved a maximum lead reduction of 22% and a minimum sample reduction of 11% for Bayesian when achieving an accuracy of 52%. From the above results analysis, it can be seen that the Self supervised learning algorithm (SSL) reduces samples by up to 30% and the lowest by 11% in the three methods.

From these results, it can be found that the information of the samples selected by the original three uncertainty methods is redundant for the classifier. Because self supervised learning algorithms mainly select sample sets with low redundancy through redundancy algorithms. The accuracy in Figure 4.1 increases, and under the same number of samples, the amount of information increases, resulting in a decrease in redundancy. Self supervised learning algorithms can effectively enhance uncertainty methods at the cost of time [19].

In order to reduce the impact of latent variable feature vector length and candidate sample number on sample redundancy research, experiments were conducted on latent variable feature vector length and candidate

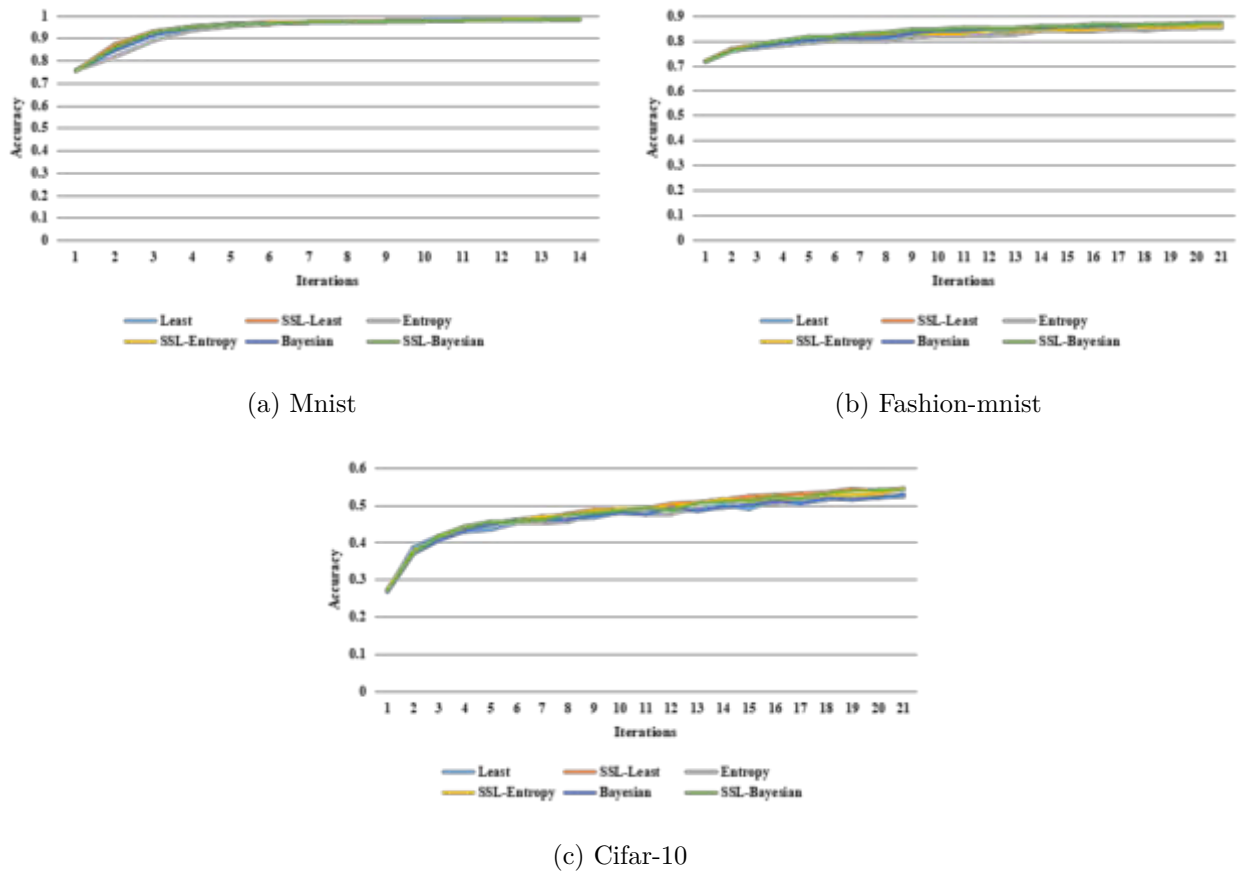

Fig. 4.1: Experimental results of SSL algorithm on different datasets

sample number. Under the conditions of 128 and 256 feature vectors, as well as 300 and 1000 candidate samples, in Fashion minimum, two sets of experiments were conducted using the self supervised learning algorithm - fast method. The experimental results on the relationship between information redundancy and the length of feature vectors and the number of candidate samples are shown in Figures 4.2 and 4.3.

The experiment in Figure 4.2 is conducted on the Fashion mnist dataset, with a candidate sample size of 1000 and feature vector lengths of 128 and 256, respectively. Due to the different widths of CNN in the last layer, the initialization network parameters are inconsistent. To address this issue, this experiment aims to ensure that the initialization network performs equally on the test set as much as possible. It can be seen that when the model accuracy reaches 80%, the former has 100 more labeled samples than the latter. So, the longer the feature vector, the more information it carries. The experiment in Figure 4.3 is conducted on the same dataset, with $n_0=200$, $T=20$, $K=100$, and a feature vector length of 256. The sample size of the candidate set is 300 and 1000, respectively, and the initialization network parameters are the same. Similarly, when the model accuracy reaches 80%, the former uses 100 more labeled samples than the latter. Through this experiment, it can be compared that if the number of candidate samples is small, the information contained in the candidate sample set is insufficient, but the redundancy is small, which will be affected by the number of samples[20]. Through the above experiments, it can be seen that the higher the dimensionality of the feature vectors calculated by CNN, the more candidate samples contain more information, and the more obvious the effect is after being improved by self supervised learning algorithms. The more candidate samples are selected, the stronger the information redundancy. The better the performance of self supervised learning algorithms.

Fig. 4.2: The length of feature vectors in self supervised learning algorithms

Fig. 4.3: Number of candidate samples in self supervised learning algorithms

5. Conclusion. In the sample selection mode of artificial intelligence algorithm pool, the author proposes a self supervised learning algorithm to reduce sample information redundancy. Using uncertainty methods, a large number of candidate samples are selected by CNN to form a candidate set. In the candidate set, the cosine distance relationship of the samples is used for a second screening, resulting in a sample set with large information content and low redundancy. This method can effectively reduce sample data redundancy and further reduce the number of labeled samples required by the model. In the future, uncertainty methods can be further optimized.

MACHINE LEARNING ALGORITHMS IN SUPPLY CHAIN COORDINATION SIMULATION AND OPTIMIZATION

QINGPING ZHANG* AND YI HEI†

Abstract. In response to the current situation of poor adaptive learning performance in Agent production and sales negotiation and dynamic changes in negotiation environment, the author proposes a method based on machine learning algorithms. Consider the impact of conflict level, cooperation possibility, and negotiation remaining time on negotiations in a dynamic negotiation environment, and use the entropy method to determine the weights of three influencing factors and perform linear weighting. Based on the differences in current negotiation topics, a concession amplitude prediction model based on dynamic selective ensemble learning is constructed, and an optimization strategy for supply chain production and sales negotiation is proposed. The experimental results indicate that, in the adaptive negotiation strategy of a regular SVM single learning machine, the joint utility of the most successfully negotiated agents falls within the interval $[0.55, 0.70]$, while the author's ensemble learning strategy mainly focuses on $[0.6, 0.8]$, the author's strategy is relatively superior to ordinary learning strategies in terms of both the number of successfully negotiated agents and the joint utility. Compared with the single learning machine negotiation strategy, this strategy improves the success rate and joint utility of Agent adaptive learning, and ensures the benefits of both production and sales in the supply chain, achieving a mutually beneficial situation for both parties in cooperation.

Key words: Dynamic selective ensemble learning, Dynamic negotiation environment, Agent production and sales negotiation, Adaptive learning, Entropy method

1. Introduction. Supply chain coordination is a key issue in supply chain management, which involves collaboration and coordination among different stakeholders. In the supply chain, due to the different goals and constraints of each participant, problems such as information asymmetry, order lag, and inventory backlog are prone to occur, leading to inefficiency and instability of the supply chain. In order to achieve efficient operation of the supply chain and maximize overall benefits, researchers have proposed various supply chain coordination models and algorithms. The core goal of supply chain coordination is to ensure effective coordination and cooperation among various links in the supply chain through reasonable decision-making and collaboration mechanisms, in order to optimize the efficiency of the entire supply chain system. In actual supply chain management, in order to solve the problem of information asymmetry, some measures can be taken to improve the flow and sharing of information. For example, establishing an information platform to improve the coordination and flexibility of various links in the supply chain through information sharing and transmission [1]. At the same time, adopting appropriate reward and punishment mechanisms to encourage all parties involved to work together and reduce the problems caused by information asymmetry.

In addition, order lag and inventory backlog are common issues in supply chain coordination. In order to address these issues, some supply chain coordination models and algorithms can be adopted. For example, by establishing a supply chain coordination model based on demand forecasting, it is possible to accurately predict demand and make corresponding adjustments according to changes in demand, avoiding the problems of order lag and inventory backlog [2]. In addition, reasonable inventory management strategies such as first in, first out (FIFO) and regular inventory can be adopted to control inventory backlog and improve the operational efficiency of the supply chain.

Supply chain coordination can also be achieved by optimizing logistics transportation and distribution. In the supply chain, logistics transportation and distribution play a crucial role. By optimizing logistics transportation and distribution plans, transportation costs can be reduced, transportation efficiency can be improved,

*Business School, Shunde Polytechnic, Foshan, Guangdong, 528333, China (Corresponding author, 10370@sdpt.edu.cn)

†School of Economics and Management, Guangdong Vocational College of Post and Telecom, Guangzhou, Guangdong Province, 510630, China

and supply chain coordination and optimization can be achieved [3]. For example, centralized distribution can be adopted to reduce the frequency and distance of transportation, and lower transportation costs; At the same time, utilizing logistics technology and information systems to achieve visual management of logistics transportation and distribution, improving the efficiency and service quality of logistics transportation.

In addition to the above methods, supply chain coordination can also be achieved through reasonable partner selection and supplier management. In supply chain management, selecting suitable partners and suppliers is crucial for the coordination and stability of the supply chain. By evaluating and managing suppliers, we can ensure their quality and delivery time, and reduce the risks and problems they bring [4]. At the same time, establish long-term and stable cooperative relationships, strengthen communication and collaboration with suppliers, and improve the efficiency and stability of the supply chain. In short, supply chain coordination is a key issue in supply chain management. Through reasonable decision-making and collaboration mechanisms, problems such as information asymmetry, order lag, and inventory backlog can be solved, improving the efficiency and stability of the supply chain. In actual supply chain management, various means and methods can be adopted to achieve coordination and optimization of the supply chain, including information sharing, demand forecasting, inventory management, logistics transportation and distribution optimization, partner selection, and supplier management. Through continuous research and practice, supply chain coordination models and algorithms can be further improved, promoting the development and progress of supply chain management [5].

The author aims to study the application of machine learning algorithms in supply chain coordination simulation and optimization. By using machine learning algorithms to analyze a large amount of data in the supply chain, we can better understand the operational mechanisms and optimization methods of the supply chain. Specifically, the research objectives include the following aspects:

1. Analyze the characteristics and challenges of supply chain coordination problems: Through in-depth research on supply chain coordination problems, analyze the relationships and interactions between various links in the supply chain, and reveal the essence and challenges of supply chain coordination.
2. Explore the application of machine learning algorithms in supply chain coordination simulation: Using machine learning algorithms, construct a supply chain coordination simulation model, simulate the impact of different coordination strategies on supply chain performance, and further study the behavior and decision-making of all parties involved in the supply chain.
3. Propose a supply chain optimization method based on machine learning algorithms: Based on the analysis results of machine learning algorithms, design a supply chain optimization algorithm to improve the efficiency and stability of the supply chain by coordinating the decisions and actions of all parties involved.

Through the implementation of the above research objectives, the author aims to provide new ideas and methods for supply chain management, promote coordination and optimization of the supply chain, and improve overall operational effectiveness.

2. Agent Supply Chain Production and Sales Negotiation Model.

2.1. Production and sales negotiation framework. In negotiation, the entropy method is used to calculate the weight of the negotiation environment, and the impact factor of the negotiation environment on the concession amplitude of the issue is obtained through linear weighting. Using optimized strategies to predict the concession range of opponents and measuring the impact of other negotiating opponents on the current negotiation based on global utility, the proposal values for each issue in the next round are obtained[6]. After the negotiation, the negotiation agent selects the best partner based on their own wishes, as shown in Figure 2.1.

2.2. Negotiation parameters. The specific steps of a negotiation strategy based on dynamic selection ensemble learning are: 1) Description of the negotiation environment; 2) Define negotiation issues and essential elements; 3) Support adaptive learning, update concession amplitude, and propose counter proposals[7]. Therefore, an octet representation negotiation model is proposed, and the negotiation parameters are explained in Table 2.1.

$$NM = \{A, I, P, w, T, C, Lc, U\} \quad (2.1)$$

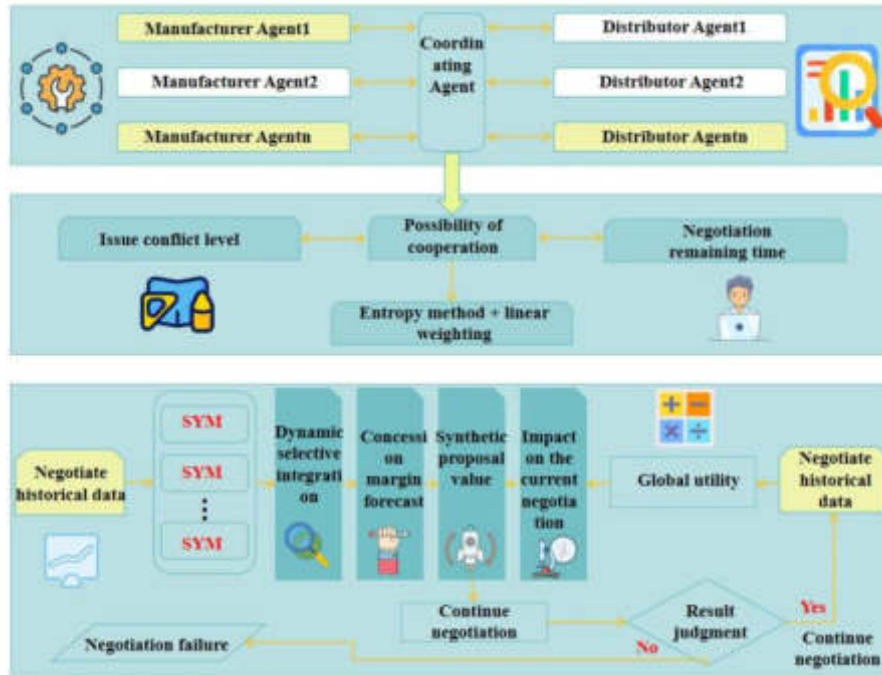

Fig. 2.1: Agent production and marketing negotiation framework

Table 2.1: Description of the negotiation parameters

Parameter	Describe
A	distributor manufacturer coordinator
I	Negotiation topic set
P	The agenda value for each round of negotiation
T	The remaining time for negotiation gradually decreases during the negotiation process
L_c	Conflict level between both parties
w	Participate in negotiating agent's weight vectors for each issue
C	The likelihood of cooperation between manufacturer and distributor agents
U	Evaluation of the proposed value of the opponent in the t-th round of negotiation on issue j

2.3. Negotiation Environment. For the expression of the negotiation environment, the author characterizes it using three factors: the level of issue conflict, remaining negotiation time, and the possibility of the best partner. Among them, the level of issue conflict is a positive indicator; The greater the remaining negotiation time and the possibility of the best partner, the smaller the concession made, which is a negative indicator.

Issue conflict level. The degree of conflict between the negotiating agent and the opponent on issue j, as shown in Equation 2.2.

$$Lc_t = \sum_{j=1}^n ep_j w_j \sqrt{|P_{t,j}^s - p_{t,j}^{opp}|^2} \quad (2.2)$$

Among them, $P_{t,j}^s$ represents the proposal value of our agent for issue j in round t, $P_{t,j}^{opp}$ represents the proposal value of our opponent for issue j in round t; ep_j represents the proportion of the number of opponents who are in conflict with the Agent regarding issue j in the total number of negotiations. Best partner possibility: decreases with the increase of competitors. A_i^t has A_c^t competitors and A_p^t trading parties in round t negotiation, and the possibility of A_i^t being considered as the preferred trading partner of the trading parties is shown in Equation 2.3.

$$c(A_i^t, A_p^t) = 1 - [(A_p^t - 1)/A_p^t]^{A_c^t} \tag{2.3}$$

Remaining negotiation time. The remaining time in the negotiation of round t is calculated as shown in Equation 2.4.

$$T(t, \tau, \lambda) = 1 - (t/\tau)^\lambda \tag{2.4}$$

Among them, τ is the deadline; λ is the optimal time limit for MDA.

2.4. Integration of negotiated environmental factors . The legitimate value method determines the weights of three factors in the negotiation environment, assuming that there are r agents participating in the negotiation, Amd calculates the conflict level of the manufacturer and distributor’s own issues, the possibility of the best partner, and the remaining negotiation time in each round of negotiation[8]. The positive and negative indicators are dimensionless according to Equations 2.5 and 2.6, forming a matrix as shown in Equation 2.7.

$$s_{r,i} = (s_{r,i} - \min\{s_i\})/(\max\{s_i\} - \min\{s_i\}) \tag{2.5}$$

$$s_{r,i} = (\max\{s_i\} - s_{r,i})/(\max\{s_i\} - \min\{s_i\}) \tag{2.6}$$

$$R = \begin{bmatrix} s_{11} & s_{12} & s_{13} \\ s_{21} & s_{22} & s_{23} \\ \dots & & \\ \dots & & \\ \dots & & \\ s_{r1} & s_{r2} & s_{r3} \end{bmatrix} \tag{2.7}$$

The legitimate weight of the jth environmental indicator is shown in Equation 2.8, with a legitimate weight of π_j . The entire negotiation environment should make concessions to the t-round negotiation agent θ_t . As follows:

$$H_j = -(1/\ln r) \sum_{i=1}^r (\frac{s_{ij}}{\sum_{i=1}^r s_{ij}}) \tag{2.8}$$

$$\pi_j = \frac{(1 - H_j)}{r - \sum_{i=1}^r H_j} \tag{2.9}$$

$$\theta_t = \pi_1 l c_t + \pi_2 c_t + \pi_3 T_t \tag{2.10}$$

3. Adaptive negotiation optimization strategy based on multi-agent.

3.1. Concession amplitude learning based on dynamic selective ensemble SVM. The predictive performance of each sub SVM learning machine varies for different data, and it is not advisable to use the same model function to estimate the concession amplitude for different issues. Based on the current issue value in the negotiation, use the nearest neighbor sample set as the evaluation sample to evaluate the performance of each sub model, and retain the sub models with better performance for integration[9]. In the negotiation, the K-means nearest neighbor search algorithm is used for each negotiation topic. The validation dataset is used to find k subsets of samples that are closest to the current value of the topic to be predicted, and the root mean square error is used as the evaluation criterion for the predictive performance of each sub model. Some sub models with poor predictive performance are eliminated, and the combined weights of each sub model are calculated to establish the final dynamic selective ensemble SVM model.

1. Generate an evaluation dataset using K-means. In order to predict the negotiation sequence P_q , let the number of nearest negotiation samples in the validation dataset P_L be k, calculate the distance between P_q and each negotiation data sample point P_i in P_L , and obtain the first k sample sets P_k .

$$P_D(P_q, P_i) = \sqrt{\sum_{i \in L} (P_q - P_i)^2} \quad (3.1)$$

2. SVM sub learning machine filtering. Input P_k sample sets, use root mean square error as the screening criterion, and select the corresponding top \bar{k} sub learning machine as the ensemble sub model of the predicted set P_q . The root mean square error of the i-th sub model is shown in Equation 3.2.

$$E_{ij} = \sqrt{\frac{\sum_{i=1}^k (\widetilde{c}_{ij} - C_{ij})^2}{k}} \quad (3.2)$$

Among them, \widetilde{c}_{ij} represents the predicted concession amplitude of the i-th sub learning machine for the next round of issue j; C_{ij} represents the actual concession amount for the next round of agenda item j.

3. Calculate the combined weights of each sub model. According to the root mean square error E_{ij} of the i-th sub model, the combined weight of this sub model is:

$$a_i = \left(\frac{1}{E_{ij}^2} \right) / \left(\sum_{i=1}^{\bar{k}} \frac{1}{E_{ij}^2} \right) \quad (3.3)$$

When all h sub learning machines are successfully trained, combined with the \bar{k} sub learning model with the smallest selection error for the current issue, four variables are inputted: the average concession amplitude value of the manufacturer and distributor agents in the first t rounds to hedge against the sudden issue j, and the difference in the proposed values of the manufacturer and distributor agents in the t round[10]. The predicted concession amplitude values for A_{fac} and A_{dis} in the t+1 round are obtained. The predicted output for each issue's concession amplitude is:

$$C_{t+1,j}^{fac/dis} = a_1 C_{1j} + a_2 C_{2j} + \dots + a_{\bar{k}} C_{\bar{k}j} \quad (3.4)$$

3.2. Utility Function Optimization. The global utility indicates that for positive issues, the larger the opponent's issue value is, the better, while for negative issues, the opposite is true. The utility evaluation functions for the negotiation object's issue value during t-round negotiation are shown in Equations 3.5 and 3.6, respectively.

$$U_{t,all}^+ = \sum_{j=1}^n w_{t,j} \left(\frac{p_{t,j}^{opp} - p_{t,j}^{min}}{p_{t,j}^{max} - p_{t,j}^{min}} \right) \quad (3.5)$$

$$U_{t,all}^- = \sum_{j=1}^n w_{t,j} \left(\frac{p_{t,j}^{max} - p_{t,j}^{opp}}{p_{t,j}^{max} - p_{t,j}^{min}} \right) \tag{3.6}$$

$$U_{t,all} = U_{t,all}^+ + U_{t,all}^- \tag{3.7}$$

Among them, $p_{t,j}^{opp}$ represents the current proposal value of the other party; $p_{t,j}^{max}$ represents the maximum value of the current proposal. Taking A_{fac} as an example, in the t -round negotiation, the global utility with each A_{dis} is calculated based on Equation 3.6. larger the $U_{t,all}$, the greater the utility obtained from the current A_{dis} negotiation, and the smaller the impact on the concession amplitude, making a larger concession[11].

The difference in local utility between the two rounds of negotiation is used to determine whether to stop the current negotiation process, as shown in Equation 3.8. According to the predicted concession range of A_{fac} on issue j in round $t+1$, the proposal value of distributor BB on issue j in round t of $C_{t+1}^{dis \rightarrow fac}$ negotiation is $p_{t,j}^{dis \rightarrow fac}$. The predicted proposal value of distributor $A_{t+1,j}^{dis \rightarrow fac}$ on issue j in round $t+1$ is shown in Equation 3.9.

$$U_{t,area} = \sum_{j=1}^j w_j^j p_j^{dis \rightarrow fac} \tag{3.8}$$

$$p_{t+1,j}^{dis \rightarrow fac} = p_{t,j}^{dis \rightarrow fac} + C_{t+1,j}^{dis \rightarrow fac} \tag{3.9}$$

Coordinate Amd with Equations 3.8 and 3.9 to calculate the difference between A_{dis} 's predicted utility value in round $t+1$ and the actual utility value in round t . When the difference is $\Delta U_{t+1,t} > 0$, continuing to negotiate A_{fac} 's utility will increase, but the utility has not been maximized yet. Otherwise, end the negotiation[12].

3.3. Topic proposal. Taking A_{fac} as an example, in multilateral adaptive negotiation, not only should the impact of the negotiation environment on the degree of concession be considered, but also the impact of other negotiation objects on the current negotiation. Therefore, the next round of proposal values for topic j are proposed by Equations 3.10 and 3.11.

$$p_{t+1,j}^{fac \rightarrow dis} = p_{t,j}^{dis \rightarrow fac} - p_{t,j}^{fac \rightarrow dis} \times (w_j) \times (a\theta + \beta C_{t+1}^{dir} + \frac{U_{t,all}^i - U_{t,all}^{min}}{U_{t,all}^{max} - U_{t,all}^{min}}) \tag{3.10}$$

$$p_{t+1,j}^{fac \rightarrow dis} = p_{t,j}^{dis \rightarrow fac} + p_{t,j}^{fac \rightarrow dis} \times (w_j) \times (a\theta + \beta C_{t+1}^{dir} + \frac{U_{t,all}^i - U_{t,all}^{min}}{U_{t,all}^{max} - U_{t,all}^{min}}) \tag{3.11}$$

Among them, Equation 3.10 represents cost based issues; Equation 3.11 represents profit oriented issues; θ Indicates the extent of concessions made under the influence of the negotiation environment; C_{t+1}^{fac} represents the concession amount of the opponent in the next round based on the ensemble learning algorithm; $U_{t,all}^i$ represents the global utility obtained from negotiating with the current negotiating party. The larger the value, the greater the concession, and vice versa[13].

3.4. Best Partner Selection. After the negotiation, the A_{fac} manufacturer makes a decision on the negotiation results, selects the appropriate A_{dis} , calculates the similarity of topics based on common neighbors according to the needs of the negotiation, and selects cooperation partners that are more suitable according to the similarity of topics, as shown in Equation 3.12.

$$S_{fac,dis} = (1 + e^{-D_{fac,dis}}) \times ||I_{fac} \cap I_{dis}|| \tag{3.12}$$

Among them, $D_{fac,dis}$ represents the issue gap between A_{fac} and A_{dis} ; $I_{fac} \cap I_{dis}$ represents the number of topics that A_{fac} and A_{dis} are satisfied with after successful negotiations, and selects the best partner based on similarity.

Table 4.1: Issue range and corresponding weights of manufacturers and distributors

Parameter type	Manufacturer Issue Range	Distributor Issue Range	Manufacturer weight	Distributor weight
Price/yuan	[3 000,3 800]	[3 000,3 300]	0 25	0 25
Quantity	[800,1 000]	[850,1 200]	0 25	0 25
Delivery time/month	[2 5,3]	[1,3]	0 25	0 25
Warranty period/month	[12,24]	[15,48]	0 15	0 10
Defective rate/%	[80,95]	[0,95]	0 10	0 15

4. Adaptive negotiation steps and examples.

4.1. Negotiation Steps.

- The specific steps for adaptive negotiation are as follows:
- Step 1: Negotiate initialization. Based on the negotiation targets of A_{fac} and A_{dis} , determine issue I, initialize issue weight W, maximum negotiation time T, and acceptable range of the issue, and normalize the issue.
- Step 2: A_{md} determines if the remaining negotiation time T has been exceeded. If it has been exceeded, the negotiation will be concluded; On the contrary, proceed to step 3.
- Step 3: A_{md} evaluates the negotiation environment and calculates according to Equation 2.10 θ and provide feedback to A_{fac} and A_{dis} who are currently negotiating [14].
- Step 4: A_{md} adds the new proposal to the negotiation history database. A_{fac} and A_{dis} divide the negotiation data into multiple samples, adjust the parameters of each sub learning model, and calculate the root mean square error E_{ij} of each model according to equation (12).
- Step 5: A_{fac} , A_{dis} calculates the weight of each sub learning model according to Equation 3.3 α , output the final strong combination learner, combined with the current proposal, to determine the next round of concession amplitude and measure $C_{t+1}^{fac/dis}$.
- Step 6: A_{md} calculates the current global utility based on Equation 3.7 and provides feedback to A_{fac} and A_{dis} who are currently negotiating.
- Step 7: Calculate the impact of the negotiation environment on the concession level of A_{fac} and A_{dis} being negotiated θ , based on the predicted concession amplitude in step 5, derive the counter proposal for each issue according to Equations 3.10 and 3.11, update the current utility value, negotiate the environmental conditions, and provide feedback to A_{md} .
- Step 8: A_{fac} , A_{dis} proposes a counter proposal. If the negotiating opponent accepts it, proceed to Step 9; Otherwise, proceed to step 3.
- Step 9: A_{md} will write the successfully negotiated agent to the database. After the quick negotiation activity, A_{fac} and A_{dis} determine their partners based on Equation 3.11.

4.2. Example analysis. In order to demonstrate the differences between the two algorithms, simulation experiments were conducted. Assuming that there are conflicts between multiple manufacturers and distributors in the mobile phone production and sales chain when formulating collaborative plans, negotiations should be conducted according to common learning strategies and integrated optimization strategies. Consider the price, quantity, delivery time, warranty time, and defect rate of the plan as negotiation topics [15]. According to expert experience, manufacturers are most concerned about price, quantity, and delivery time, followed by warranty time and defect rate; Distributors are most concerned about price, quantity, and delivery time, followed by defect rate and warranty time. Therefore, the issue range and weight of manufacturers and distributors are shown in Table 4.1.

Generate 50 manufacturers and 50 distributors for the two adaptive negotiation strategies proposed by the author, and simulate the conflict resolution of collaborative plans. Based on existing experience, it is assumed that the maximum negotiation time τ_{fac} is 25 and τ_{dis} is 20.

In Figures 4.1(a)-(b), the x-axis and x-axis represent respectively α, β . The y-axis represents the average joint utility value of manufacturers and distributors at the time of successful negotiation, with different combinations of values [16]. It can be seen that as Increase in size The difference between the average joint utility

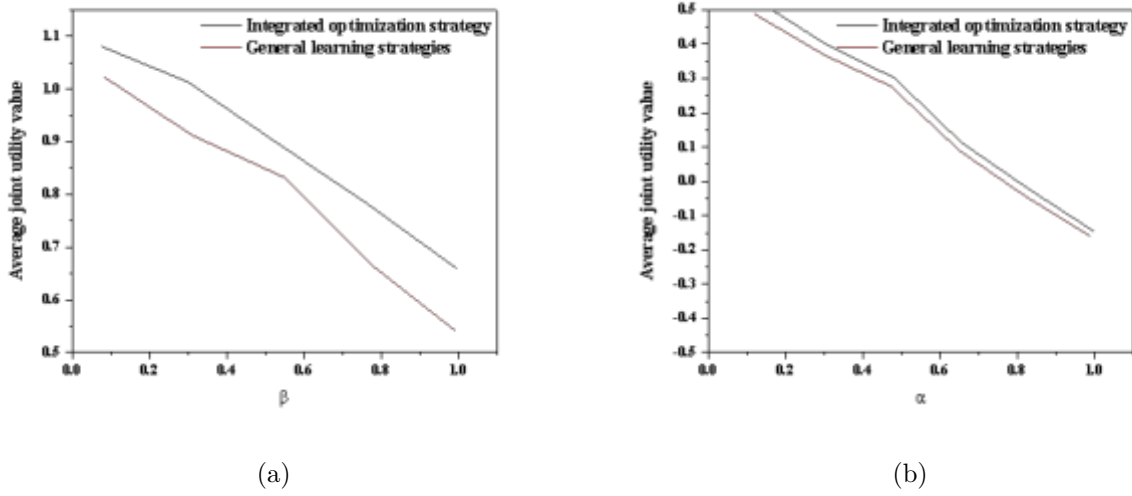

Fig. 4.1: Meverage joint utility simulation results for 2 strategies

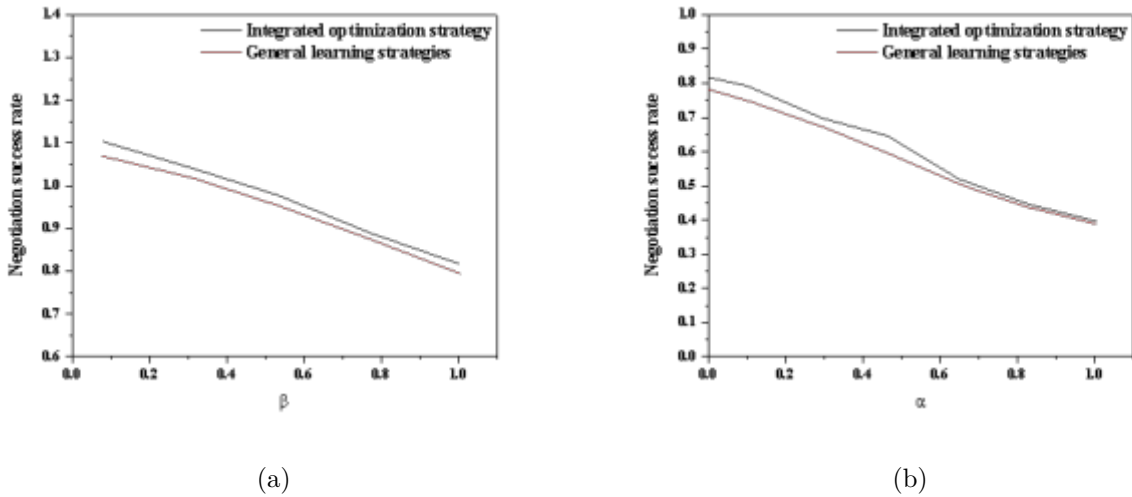

Fig. 4.2: Negotiated success rate simulation results for 2 strategies

of the two negotiation strategies is increasing as the decrease in β . When it is 0.6, the average combined utility of the two reaches its maximum. Therefore, the ensemble learning optimization strategy proposed in this article has better negotiation effectiveness than ordinary single learning machine adaptive strategies.

In Figures 4.2(a)-(b), the x-axis and y-axis represent respectively β and α . The y-axis represents the negotiation success rate of manufacturers and distributors with different value combinations. It can be seen that in general, the integrated learning optimization strategy proposed in this paper has a higher negotiation success rate than the ordinary single learning machine adaptive strategy. Therefore, the integrated learning optimization strategy can improve the success rate of production and sales negotiations to a certain extent [17].

Fig. 4.3: Meverage error rate simulation results for 2 strategies

Fig. 4.4: Relationship between joint utility and successfully negotiated Agent

Figure 4.3 selects 50 manufacturers in the experiment to predict the average error rate of the opponent's concession amplitude on the same issue. Comparing the performance of the two strategies, it can be seen that in most cases, the author's ensemble learning strategy has lower error rates than the ordinary SVM single learning machine adaptive strategy [18].

From Figure 4.4, it can be seen that in the adaptive negotiation strategy of a regular SVM single learning machine, when the most successful agents are negotiated, their joint utility falls within the interval $[0.55, 0.70]$, while the author's ensemble learning strategy mainly focuses on $[0.6, 0.8]$, the author's strategy is relatively

superior to ordinary learning strategies in terms of both the number of successfully negotiated agents and the joint utility [19,20]. The conclusion drawn from the above is that the negotiation strategy based on dynamic selective ensemble learning performs relatively better than ordinary single learning machine adaptive negotiation strategies in terms of joint utility, negotiation success rate, average error rate, etc.

5. Conclusion. Resolving conflicts in supply chain production and sales collaboration is beneficial for improving the operational efficiency of the supply chain. On the basis of considering the impact of the environment on negotiation, the author proposes an adaptive negotiation strategy based on dynamic selective ensemble SVM, which can reduce the error of opponent prediction information and also consider the impact of other negotiation processes in multilateral negotiation. The experimental results show that compared with the adaptive negotiation strategy of ordinary single learning machines, this strategy can to some extent improve the negotiation success rate, conflict resolution efficiency, and the joint utility of manufacturers and distributors. The next step will be to study adaptive negotiation methods for resolving conflicts in supply chain production and sales collaboration based on multilateral negotiations, in order to improve the intelligence level of the supply chain.

SIMULATION OF SEGMENTED CLUSTERING OF CLOUD STORAGE DATA BASED ON NEURAL NETWORK MODELS AND PYTHON

GUOQING XIA* AND HUAZHEN CHEN[†]

Abstract. In order to improve the operational efficiency of traditional cloud storage data segmentation clustering methods, the author proposes a machine learning based cloud storage data segmentation clustering method. Reasonably extract multiple small datasets from the cloud storage database, which contain all natural clusters in the cloud storage database. Construct a similarity matrix based on the definition of similarity. Using nonlinear kernel principal component algorithm to measure the similarity of data in the similarity matrix, data with the same features are grouped together through similarity measurement, and a mixed Gaussian distribution probability density model is used to calculate the posterior probability of different categories of data, implement segmented clustering of cloud storage data by comparing probability sizes. The experimental results show that the proposed method can shorten the clustering running time, reduce the clustering variation to 29%, and effectively improve the smoothness of the clustering results.

Key words: Neural network models, Cloud storage, Segmented clustering of data, A mixed Gaussian distribution probability density model

1. Introduction. Neural networks are widely used in nonlinear system identification and control due to their strong learning ability. However, practical objects are full of uncertain factors, and many problems cannot be described with accurate mathematical models. Fuzzy systems utilize the knowledge and experience of experts to solve mathematical problems through natural language. Since the proposal of Adaptive Network Based Fuzzy Reference System (ANFIS), the research and application of this theory have made significant progress [1]. For a long time, fuzzy design networks were based on traditional Type 1 fuzzy logic systems. With the development of fuzzy set theory and the shortcomings of Type 1 fuzzy logic systems in describing the uncertainty of the objective world, the theory and application of Type 2 fuzzy logic systems have become a research hotspot in fuzzy theory in recent years. With the deepening of research on the identification and control of type 2 fuzzy logic systems in nonlinear systems, research on the identification and control of type 2 fuzzy neural networks in nonlinear systems is gradually increasing. At present, the structure of type-2 fuzzy neural networks mainly includes fixed network structure, self adjusting type-2 fuzzy neural network, self evolving type-2 fuzzy neural network, self-organizing interval type-2 fuzzy neural network, etc. Once the structure of interval type-2 fuzzy neural networks is determined, the next step is to learn the network parameters. Currently, the most commonly used parameter learning algorithm is the backpropagation (BP) algorithm. However, the BP algorithm is sensitive to initial values, and inappropriate initial values can cause the algorithm to diverge or converge to non optimal solutions. The structure of interval type-2 fuzzy logic systems is similar to that of traditional fuzzy logic systems, but it requires a key step, which is order reduction. The order reduction process first reduces the type-2 fuzzy set to a type-1 fuzzy set, and then obtains the precise output of the final interval type-2 fuzzy system using the conventional method of defuzzification of type-1 fuzzy sets. Currently, most interval type-2 fuzzy neural network systems use the Karnik Mendel (KM) reduction algorithm, which is an iterative optimization algorithm, firstly, it is necessary to sort the discrete points by size, so that the corresponding membership degree needs to be modified accordingly. The order can be reduced to obtain two switching points, and each switching point may not be the same. Therefore, when using the BP algorithm to learn parameters, the process is relatively cumbersome and there is no unified learning formula.

Clustering is the process of distinguishing and classifying things according to certain requirements and rules. In this process, there is no guidance from teachers or any prior cognitive information about classification, but only the similarity between things is used as the standard for their classification. Therefore, it belongs to the research content of unsupervised learning. Cluster analysis is the use of mathematical methods to process and study things that need to be classified [2-3]. Birds of a feather flock together. Clustering method is the process of grouping a collection of physical or abstract objects into multiple classes composed of similar objects, and clustering is an ancient problem. Since the emergence of human society, with the continuous development of human society, research on clustering has also been deepening. The continuous exploration of the world by humans requires distinguishing things that belong to different categories and recognizing the similarities of things in the same category. Multivariate statistical analysis, as a branch developed from classical statistics, is also an important branch of mathematical statistics, and cluster analysis belongs to multivariate statistical analysis. As one of the important research directions in statistics, cluster analysis has a profound theoretical foundation and has formed a systematic methodological system. In the field of pattern recognition, cluster analysis is also an important research direction for unsupervised pattern recognition.

Unlike classification, clustering does not rely on pre-defined classes and signed training practices, so clustering analysis is observational learning rather than example based learning. Through cluster analysis, a sample set without any prior knowledge is divided into several subsets based on specific classification rules. The samples within these subsets maintain high similarity, while the samples between subsets maintain low similarity as much as possible. In other words, samples in the same cluster should be as close as possible, while the distance between different cluster centers should be as far as possible. In many applications, data objects in certain classes can be treated as a whole. There are many clustering methods, and their principle is to divide the sample set that needs to be classified into several different categories based on similarity to represent the different characteristics of the system.

The minimum overlap between categories should be used to avoid repetition, which means that each category should contain as many similar samples as possible and have significant differences from each other. The purpose of clustering algorithms is to find several least similar sample centers that contain a set of similar samples, in order to maximize the representation of different features of the system. At the same time, each cluster center should contain a sufficient number of samples to ensure that it uses as few cluster centers as possible to represent the system. Clustering is a technique that studies the logical or physical interrelationships between data. Its analysis results not only reveal the inherent connections and differences between data, but also provide important basis for further data analysis and knowledge discovery. The purpose of clustering is to discover the essential clustering properties between samples, and it is an important component of data mining techniques. Data clustering is flourishing, and contributing fields include data mining, statistics, machine learning, spatial database technology, biology, and marketing. Nowadays, data clustering analysis has become a very active research topic [4]. Traditional clustering analysis is a hard division that strictly divides the objects to be analyzed into certain categories, with the property of either this or that. Therefore, the boundaries of this type of classification are clear. However, in reality, most objects do not have strict attributes, and they have intermediary properties in terms of form and category, with the nature of "this is also that". For example, people are classified according to their height as "tall people", "short people", and "not tall but not short people". However, as tall as possible, and as short as possible, this classification discrimination is a problem that classical classification cannot solve, so it is suitable for soft partitioning. The proposal of fuzzy set theory provides a powerful analytical tool for this soft partitioning, and people have begun to use fuzzy methods to handle clustering problems, namely fuzzy clustering analysis. Fuzzy clustering analysis extends the values of membership relationships from binary logic of 0,1 to the interval of [0,1], thereby more reasonably representing the mediating nature between things. Due to the uncertainty level of the sample belonging to each category obtained by fuzzy clustering, which expresses the "this is also that" property of the sample belonging to different categories, that is, the fuzziness of the sample's membership relationship to different categories, the description and expression of the real world are more reasonable, and have made significant progress in the theory of clustering analysis. The implementation process of data clustering is shown in Figure 1.1.

Fuzzy clustering theory has been widely used in the real world, promoting the improvement of social productivity. With the continuous development of practice, fuzzy clustering theory is also constantly improving

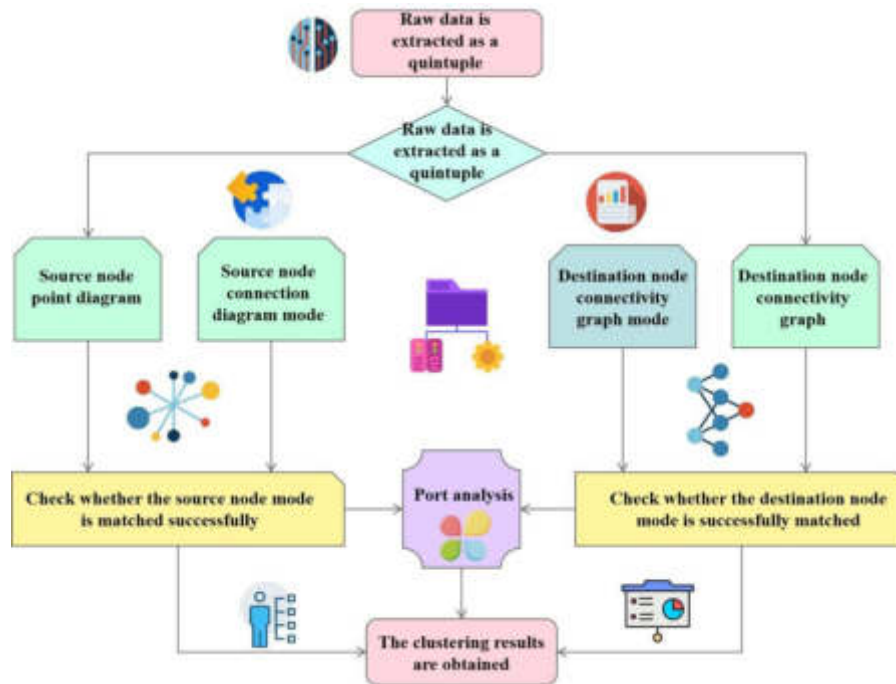

Fig. 1.1: Implementation process of data clustering

and enriching in practice. With the development of practice and the improvement of theory, fuzzy clustering has been widely applied in many fields, and has achieved satisfactory results and objective benefits. Its application scope involves many fields such as channel equalization in communication systems, codebook design in vectorized coding, time series prediction, neural network training, nonlinear system identification, parameter estimation, medical diagnosis, weather forecasting, food classification, water quality analysis, etc, the author mainly studies its application in nonlinear system identification. In nonlinear system identification, fuzzy clustering algorithms can be used for feature space partitioning and fuzzy rule extraction to construct fuzzy classifiers based on fuzzy if then rules.

The amount of data on the internet is showing an explosive growth trend with the rapid development of computers, leading to increased data storage costs, reduced reliability of data storage, and difficulties in managing large amounts of data, which have long plagued users. Users hope to obtain useful information from complex and diverse data, therefore, cloud storage data segmentation and clustering technology has emerged. However, in traditional cloud storage data segmentation and clustering methods, the use of Ethernet and TCP/IP network communication protocols improves and simplifies network protocols to reduce clustering delays, however, neglecting the diversity of data types can lead to problems such as long clustering time and large errors. In this context, researching accurate and efficient cloud storage data segmentation clustering methods has become a widely concerned focus in the current data clustering field, receiving widespread attention from industry insiders. At the same time, many good methods have also emerged. In response to the above issues, the author proposes a machine learning based segmented clustering method for cloud storage data. The experimental results show that the proposed method can shorten the running time of data segmentation clustering and improve the smoothness of clustering results.

2. Methods.

2.1. Overview of Spatial Data Cloud Storage. Space cloud storage mainly refers to the distributed storage and read/write of spatial data based on cloud computing technology. Currently, most of its research focuses on raster data storage and management, while there is relatively little research in the field of vector

data cloud storage. At the same time, research on spatial database systems and spatial databases as services (SDBaaS) in cloud environments based on cloud storage of spatial data is also in its early stages. We will elaborate on the theoretical research of spatial data cloud storage from two aspects: Raster and vector [5].

(1) *Overview of Cloud Computing.* Cloud computing, as a new type of distributed parallel computing model, can integrate computing power, storage space, and network resources from different regions, allowing any terminal (PC, Web, iOS, Android) user to access the cloud platform at any time and effectively use any resources on the platform. It fully utilizes the good scalability, powerful computing power, and cross regional information resource sharing function of distributed computing systems, by establishing a virtual and single system image for applications and data, users can easily and easily access all shared resources on the entire cloud platform, which is an excellent strategy to solve the deep sharing of current geospatial data and data processing services. Large cloud computing providers (Amazon, Google, Microsoft) encapsulate their infrastructure, platforms, frameworks, software, applications, and even data into network services, providing users and developers with standardized interfaces and on-demand billing models. Google's cloud computing platform provides basic technical support for applications such as Google App Engine, Google Map, and Google Trend. Google Cloud Platform was founded in 1996, when the founder of Google began attempting to combine multiple inexpensive PCs into a powerful computing platform to index billions of web pages; Nowadays, Google has a cloud computing platform consisting of over one million servers, providing different levels of services including IaaS, PaaS, and more.

Finally, Amazon created an elastic computing cloud EC2 based on this platform, providing users with on-demand online rental services for computing resources with surplus hardware resources. Microsoft also released its cloud computing platform product Azure in November 2009, which is a cloud application platform built on top of Microsoft's data center. It can manage and hook cloud application systems and provide a set of tools to facilitate developers to develop and debug cloud applications locally. So far, few have conducted research and development on cloud computing platforms as an integrated platform for spatial cloud storage and third-party service release and deployment. In order to achieve the goals of cloud computing and its high performance, low cost, and strong universality, cloud computing has developed a series of key technologies that support its functions such as data storage, data management, parallel computing, and concurrency control, including computer system virtualization technology, massive distributed storage technology, parallel programming mode, large-scale data management technology, distributed resource management technology, etc.

Virtualization technology is the underlying key to building an IaaS cloud platform. It quickly integrates and decomposes physical resources in a specific way, can dynamically organize multiple heterogeneous hardware, and achieve isolation between underlying physical hardware and other virtual machines on specific computers, achieving loose coupling between computing cluster hardware and software, and relieving severe dependencies between these architectures, thus meeting the scalability and scalability requirements of cloud computing for clusters. Its basic strategy is to build independent virtual machines, flexibly respond to the sudden increase or decrease in resource demands of cloud users, and improve the efficiency of platform resource utilization. Simulation is a process of continuously extracting dependencies, and its guest virtual machines will be managed and operated by virtual machine administrators (Hypervisors), providing personalized and diverse computing environments.

(2) *Spatial database.* Spatial databases optimize the storage and querying of spatial objects, including points, lines, and surfaces, based on traditional relational databases. A typical relational database typically only includes various numbers and characters, while a spatial database adds spatial data types and adds database functionality to handle these types of data [6-7]. OGC (OpenGeospatial Consortium) has developed the Simple Features Specification for geospatial data and corresponding standards to standardize the functionality of spatial databases in data processing. Due to the fact that the indexes of relational databases are not optimized for spatial queries, spatial databases need to develop their own spatial indexes to improve the efficiency of spatial database operations. Universal spatial databases typically support spatial operations such as spatial metrics, spatial functional functions, spatial predicates, constructors, and more. However, currently many NoSQL databases such as MongoDB and CouchDB, although they support spatial data types, do not fully support the aforementioned spatial operation functions.

Table 2.1: Comparison of NoSQL Database Types

Type	Product	Characteristic
Key value	Redis	Simple and easy to use, with direct values
Column Family	Bigtable, HBase	Flexible mode, allowing for arbitrary addition or deletion of column families
Document	MongoDB, CouchDB	Arbitrary pattern query, nested documents
Chart	Neo4, GraphLab	Suitable for complex data structures

(3) *NoSQL database*. Popular Web 2.0 applications typically have hundreds of millions of users, and these applications generate massive amounts of user data in a short period of time (ranging from a few months to a year), causing server loads to grow exponentially, resulting in extremely high demands for data storage scalability. In order to meet the requirements of data storage and management for such applications, web data must be partitioned and stored on thousands of processors. These new storage systems aim to provide distributed data storage, good horizontal scalability, and high-performance read and write operations. At the same time, traditional relational databases severely lack horizontal scalability, which limits the performance of single machines to handle data of such scale. NoSQL is a thriving non relational database technology in this context, which is usually classified into various types such as key values, column families, documents, and graphs based on different data models, as shown in Table 2.1.

The NoSQL database adopts a looser consistency model to provide a simple, lightweight, and efficient storage and retrieval mechanism to support better scalability and availability than traditional relational databases. The key technology for NoSQL to handle massive data is that it pre-set partitioning functions for the data. NoSQL typically automatically divides data into relatively small table units (MB level), stored on multiple different physical servers, and user programs access the servers where these table blocks are located through indexes or metadata. All updates generated by the user program will be aggregated to the main server, and then the updates to the data will be propagated to each replica server storing the table block through synchronization services.

Due to the high cost of the two-stage commit protocol used in traditional distributed databases, it may also fail during commit, leading to cluster congestion. NoSQL databases follow the CAP theorem and mostly provide a BASE concurrent transaction model that is looser than ACID, achieving basic availability, flexible state, and final consistency of the database in specific application areas. Therefore, NoSQL basically includes the following characteristics:

The ability to expand horizontally. NoSQL database can dynamically expand to multiple servers as business and data grow; Copy distribution capability. NoSQL database easily, effectively, and accurately replicates and propagates data to child node servers; Simple query interface and protocol. Compared to the complete SQL syntax of relational databases, NoSQL databases only provide lower level data query interfaces; Data storage can effectively utilize distributed indexes and memory; Ability to dynamically add new attributes to data records.

(4) *Figure Database*. In many fields including semantic analysis, geographic information systems, image processing, social networks, and biochemical informatics, graphs are a natural and suitable data model for domain data features. Semantic web information can be viewed as a collection of graphs that represent entities and explicit relationships; The transportation network in GIS is a typical graph; In chemical informatics, graphs can be used to represent the atoms and chemical bonds of compounds. The data in these fields are highly complex and large-scale, and existing data models, query languages, and database systems are difficult to support the modeling, querying, and management of these data. A graph database is a database system that represents and stores data in a graph structure with vertices, edges, and attributes, providing adjacency operations without indexing. The existing graph databases mainly use PropertyGraph as the data model, and some graph databases support HyperGraphModel. A property graph is a multigraph in which both vertices and edges have attributes stored in key value pairs, and all edges of the property graph are directed and asymmetric, as shown in Figure 2.1. A hypergraph is a superset of a graph, whose edges can be associated with any number

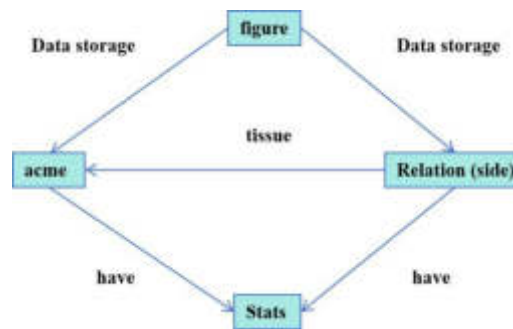

Fig. 2.1: Attribute Graph Data Model

of vertices.

Due to the fact that graph databases typically use attribute graphs as data models, native graph based data management systems have natural advantages in data management in the aforementioned fields. They can be used to store highly complex and large-scale non relational data in many fields, including semantic web, GIS, social network, bioinformatics, chemical informatics, and more. The author will map vector data that follows the OGC Simple Feature Specification (SFS) to an attribute graph model, where the objects and relationships of the vector data correspond to the vertices and edges of the graph data, respectively. Due to the fact that both the item points and edges in the attribute graph have attributes, there will be some storage redundancy. The spanning tree of the attribute graph model itself can serve as a natural database index, but it is not entirely applicable to spatial data. Spatial indexing can effectively improve the efficiency of spatial data queries, and in-depth research is needed on the theory of spatial indexing in order to select the appropriate spatial index.

(5) *Spatial index*. Spatial index is a spatial data structure that can be used in spatial databases to optimize spatial query indexing techniques by preserving the position, shape, and positional relationships of spatial entities. The components of spatial indexing include pointer objects pointing to spatial entities, bounding polygons of spatial entities, and object identifiers of spatial entities, which have very similar implementation principles. The spatial index will divide the spatial query area based on the principle of spatial segmentation by dividing the query dimension of the target. The spatial dimension will identify these partitioned subspaces with a tree structure and ensure index uniqueness through hash identification. The principle of spatial segmentation mainly includes two methods: Rule-based segmentation and object based segmentation. The former is based on the idea of computational geometry, while the latter is based on the independence of spatial objects. Rule based segmentation method, viewing a geographic plane as a multi-dimensional geometric body, segmentation is achieved through regular rectangles or irregular concave polygons. The integrity of a single spatial feature entity is ignored, and it will be divided into multiple parts of different units. However, this method of segmentation does not disrupt the logical consistency of spatial entities, but only changes the pointer object of the spatial index. The object segmentation method first determines the minimum bounding rectangle of the spatial entity, and then separates it according to the degree of entity independence, while ensuring the spatial and attribute consistency of the entity. However, this method has a high time complexity and produces a large number of spatial entities, resulting in significant storage and computational consumption. Therefore, it can be seen that spatial indexing, through preprocessing, can exclude objects unrelated to user query targets and quickly locate spatial entities that meet query syntax requirements.

2.2. Machine learning based segmented clustering method for cloud storage data.

(1) *Building a similarity matrix for cloud storage datasets*. Reasonably extract multiple small datasets from the cloud storage database, which should contain all natural clusters in the database. Divide the numerical data in the small-scale dataset into other types of data, extract them separately, and obtain independent datasets. Based on the data in each column, construct numerical and symbolic matrices, and combine them to obtain similarity matrices. Various types of data are mixed and stored in the database, and the dataset forms multiple natural clusters in the database. Extracting small-scale datasets from the database and performing segmented

clustering on the selected dataset can effectively reduce the computational error of numerical data clustering algorithms and simplify the algorithm steps. When extracting small-scale datasets, it is important to ensure the validity of the dataset and determine the number of selected natural clusters. Assuming that there are a total of n natural clusters in the selected dataset, in order to effectively simplify the complexity of mixed large-scale databases, a small-scale dataset sampling method is adopted to cluster the selected dataset, and a sample estimation method is designed to obtain the ideal sampling sample. Use S to represent the sampling sample, and let $\xi, \xi \in [0, 1]$ be the data extraction ratio of the dataset, due to the presence of n natural clusters in the dataset, the size of the extracted natural clusters is n . T represents the probability of extracting $\xi \times n$ data from the natural clusters in the dataset, and the resulting data samples are represented as:

$$S = \xi \times n + \frac{n}{n_i} \times \log \frac{1}{\tau} + \frac{n}{n_i} \sqrt{\log\left(\frac{1}{\tau}\right)^2 + 2\xi \times n \times \log \frac{1}{\tau}} \tag{2.1}$$

If the size and number of categories of the natural cluster are small or equal, it indicates that the size of the natural cluster is more than one layer, and the size of the natural cluster meets the requirements for extracting the dataset [8]. Set the extraction ratio of the dataset to ξ in such cases where the natural cluster size and number of categories are small, the extracted dataset size will also be smaller. Adopting equal scale sampling for mixed large-scale dataset A can enhance the convenience of dataset sampling in cloud storage databases and ensure the rationality of sampling. Set the small-scale dataset size as A_i , undergo m sampling, and meet the sampling control conditions as follows:

$$\begin{cases} A_i \cap A_j = \emptyset \\ m_i = m_j \end{cases} \tag{2.2}$$

Because the size of the sampled dataset is relatively small, when clustering the dataset, the aggregation level will quickly complete the clustering, which greatly improves the clustering speed. Moreover, due to the small size, the clustering accuracy is also improved. Further cluster the numerical data extracted from the dataset, strip out other types of data, and in order to simplify the algorithm steps, all other types of data are uniformly recorded as symbolic data. Extract numerical and symbolic data separately, construct two independent datasets, and construct the approximation matrix of the dataset as follows:

$$W_i = \frac{C_i}{\sum_{i=1}^n C_i} \tag{2.3}$$

In the formula, W represents an independent dataset.

Calculate the similarity between numerical and symbolic data separately, and construct a matrix of numerical data using a Gaussian function, assuming AA represents a numerical data matrix, and d represents the euclidean distance between data points, λ represents the characteristic parameter of the Gaussian function, then T_{ij} can be expressed as:

$$T_{ij} = \exp\left(-\frac{d}{2\lambda^2}\right), i, j = 1, 2, \dots, n \tag{2.4}$$

Symbolic data attributes can be set to:

$$T'(x_i, x_j) = \begin{cases} 0, & x_i \neq x_j \\ 1, & x_i = x_j \end{cases}, i, j = 1, 2, \dots, n \tag{2.5}$$

The numerical matrix $T_{i,j}$ and symbolic data $T'_{i,j}$ can be represented as follows:

$$T_{i,j} = \begin{bmatrix} 1, 0.331, 0.475, 0.358 \\ 0.331, 1, 0.331, 0.135 \\ 0.475, 0.331, 1, 0.216 \end{bmatrix} \tag{2.6}$$

$$T'_{i,j} = \begin{bmatrix} -1, 0, 0, 1, 0, 1 \\ 0, 1, 1, 0, 1, 0 \\ 0, 1, 1, 0, 1, 0 \\ 1, 0, 0, 1, 0, 1 \\ 0, 1, 1, 0, 1, 1 \end{bmatrix} \quad (2.7)$$

The similarity matrix constructed by combining numerical matrix $T_{i,j}$ with symbolic data $T'_{i,j}$ is:

$$T' = T_{i,j} + \sum_{i=1}^n P_i \times T'_{i,j}, j = 1, 2, \dots, n \quad (2.8)$$

In the formula, P represents the similarity weight.

(2) *Segmented clustering of cloud storage data based on machine learning.* Based on the similarity matrix provided in (1), a nonlinear kernel principal component algorithm is used to measure the similarity of data in the similarity matrix. A mixed Gaussian distribution probability density model is used, combined with the comparison of similarity measurement probabilities, to achieve segmented clustering of cloud storage data.

Based on the similarity matrix, a non-linear kernel principal component algorithm is used to obtain the matrix similarity measure, taking into account a set of variables with non-linear correlation in the cloud storage database $X_{i,j}(t), i = 1, 2, \dots, N, j = 1, 2, \dots, m, t = 1, 2, \dots, T$, N represents the data capacity in the cloud storage database, n represents the number of variables, and T represents the length of the time series. Assuming that the $N \times m$ sample data in cloud storage is represented as $X(t)(x_1(t), x_2(t), \dots, x_n(t))$, a nonlinear mapping function ω is used to project the sample data $X_i(t)$ from the input space R^N to the high-dimensional feature space F^N :

$$\omega : R^N \rightarrow F^N \quad (2.9)$$

The sample data projected onto the high-dimensional and high-dimensional feature space F^N is represented by $\omega(x_i(t), i = 1, 2, \dots, N)$, and the mapping process needs to satisfy the centralization condition of the feature space as follows:

$$\sum_{i=1}^N \omega(x_i(t)) = 0 \quad (2.10)$$

After projection, the covariance matrix of the sample data that meets the centralization condition is set as:

$$C = \frac{1}{n} \sum_{i=1}^n \omega(x_i(t)) \omega^T(x_i(t)) \quad (2.11)$$

In the formula, C represents the covariance matrix.

Assuming that the eigenvalues of C satisfy $0 \leq \lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_N$, the corresponding feature data is $V(\nu_1, \nu_2, \dots, \nu_N)$. Due to the fact that the non-zero feature data V and the projection data $\omega(X(t))$ belong to the high-dimensional feature space F^N , there exists a set of coefficients $\alpha = [\alpha_1, \alpha_2, \dots, \alpha_N]^T$ that enable V to be represented by a linear combination of $\omega(X(t))$ as:

$$V = \sum_{i=1}^N \alpha_i \omega(x_i(t)) \quad (2.12)$$

Set a kernel matrix K for $N \times N$, the specific process is as follows:

$$K_{i,j} = k(x_i, x_j) = \omega^T(x_i(t)) \omega(x_j(t)) \quad (2.13)$$

The vector form of its sum matrix is:

$$K\alpha = N\lambda\alpha \quad (2.14)$$

In the above equation, K is the kernel function matrix of $N \times N$; N is the data characteristic value of K ; $\alpha_1, \alpha_2, \dots, \alpha_N$ is the eigenvector corresponding to the eigenvalues of each data. The projection $P(x_j(t))$ of sample data $x_j(t)$ in the direction of feature vector $V_r (r = 1, 2, \dots, k)$:

$$P(x_j(t)) = V_r^T \omega(x_i(t)) \quad (2.15)$$

In the formula, the vector $(x_i(t))$ represents the j -th sample data.

After setting the non-linear kernel function $k(x_i, x_j)$, it is possible to perform non-linear projection of data in cloud storage databases based on mapping rules, reduce data dimensions, and extract data feature information according to non-linear related indicators. The weight of the extracted features is:

$$p_i = \frac{\lambda_i}{\sum_{i=1}^k \lambda_i} \quad (2.16)$$

In the formula, p_i represents the weight of the eigenvalues [9].

Based on similarity measurement, a mixed Gaussian distribution model is used to segment and cluster cloud storage data. The mixed Gaussian distribution model is a weighted linear combination of a finite number of multivariate Gaussian distributions. The probability density function $g(x)$ of the mixed Gaussian distribution is calculated as:

$$g(x) = \sum_{i=1}^k \alpha_i f_i(x; \mu_i) \quad (2.17)$$

In the formula, K represents the number of multivariate Gaussian distributions; $f_i(x; \mu_i)$, α_i is the probability density function and weight of the i -th multivariate Gaussian distribution. In the parameter estimation of the model, due to the large number of parameters to be estimated, the moment estimation method is obviously difficult to implement. Therefore, consider maximum likelihood estimation and construct the corresponding likelihood function L ;

$$L = \prod_{j=1}^N g(x_j; \theta) \quad (2.18)$$

According to the above equation, when there is a large amount of data, maximum likelihood estimation is more difficult.

Assuming the number of clusters k is a known exogenous variable, initialize all parameters of the mixed Gaussian model, assuming $\theta_0 = (\alpha_{i0}, \mu_{i0})$, among them, the mean vectors and covariance matrices of K multivariate Gaussian distributions can be obtained through other statistical algorithms, and the weights are initially set to $\frac{1}{k}$.

In the first step of updating weights, for any sample x_j , the probability $\omega_{j1}(k)$ of the k -th class is used, and the $\omega_{j1}(k) \times x_j$ part of its value is treated as generated by the k -th multivariate gaussian model, the k -th multivariate gaussian model produces $\omega_{j1}(k) \times x_j, (j = 1, 2, \dots, N)$, with a total of N data points, and the parameters belonging to this multivariate gaussian distribution replace the initial parameters. After the first iteration, the parameters of the k -th single Gaussian model are:

$$N_{k1} = \sum_{j=1}^N \omega_{j1}(k) \quad (2.19)$$

After a complete EM calculation, the updated value $\theta_1 = (\alpha_{i1}, \mu_{i1})$ of all cloud storage segment data can be obtained. Using θ_1 as the cloud storage segmentation data for the mixed Gaussian model, a second EM iteration can be performed. Given a sufficiently small threshold, after multiple iterations, when $|\ln(L)^{[n-1]} - \ln(L)^{[n]}| < \text{threshold}$, the EM loop iteration can be exited. Obtain convergent model parameters.

After achieving global convergence of model parameters, clustering of cloud storage segmented data samples x_j can be achieved by comparing the probability value $\omega_j(k), \omega_j(k)$ of any sample x_j belonging to different categories.

Fig. 3.1: Comparison of runtime (s) of different methods

Table 3.1: Clustering variation of different methods (%)

SJ/s	W7	W8	ST
2	59	66	43
4	63	69	47
6	57	70	39
8	62	73	32
10	60	83	30

3. Results and Analysis. In order to verify the comprehensive effectiveness of the proposed machine learning based cloud storage data segmentation clustering method, a simulation is required, and the simulation environment is: Intel (R) Core (TM) 2i5-3210M, CPU main frequency 2.3GHz, 2GB of memory, operating system Windows 7, software environment Anaconda3 (64 bit), simulation program using Python language. Cluster the proposed method with method A for cloud storage data, and compare the operational efficiency (%) of the two methods. The comparison results are shown in Figure 3.1. (Method A: Segmented clustering method for cloud storage data based on trend function space).

As shown in Figure 3.1, as the number of samples increases, the running time of the two methods also changes. Overall, the proposed method has a shorter running time than method A [10]; Specific analysis shows that when the number of data in the dataset is 30, the clustering time of method A is 11 seconds, which is 1 second shorter than the proposed method. However, when the number of data in the dataset is higher than 30, the running time of method A increases linearly, which is 8 seconds longer than the proposed method. The main reason is that method A needs to calculate the integrated spatial distance between a large number of data points, the proposed method effectively reduces the calculation of integrated spatial distance and shortens the clustering running time by dividing the data in the cloud storage database into multiple small datasets. Compare the clustering changes (%) at different times on the same dataset using the proposed clustering method, A clustering method, and B clustering method, respectively. The comparison results are shown in Table 3.1: In Table 3.1, SJ represents different time points in seconds, represented by (s); JL represents the degree of clustering change, in%; ST represents the method proposed; W7 represents method A; W8 represents method B. (Method A: Segmented clustering method for cloud storage data based on trend function space, Method B: Segmented clustering method for cloud storage data based on principal component analysis).

Compare the experimental data in Table 3.1 in the form of experimental graphs, as shown in Figure 3.2.

Fig. 3.2: Clustering variation of different methods

From Table 3.1 and Figure 3.2, it can be seen that the clustering degree of the three methods is not the same at different times. At 2 seconds, the clustering degree of the B clustering method is 65%, which is 23% higher than the proposed clustering method and 7% higher than the A clustering method; As the clustering time increases, the clustering degree of A and B clustering methods also increases. At 10 seconds, the clustering degree of A method is 30% higher than that of the proposed method, and the clustering degree of B method is 53% higher than that of the proposed method; Throughout the clustering process, only the proposed method showed a decreasing degree of clustering variation with increasing clustering time, decreasing from 42% to 29%. Overall, the proposed method effectively improved the smoothness of clustering results.

4. Conclusion. In response to the problems of low efficiency and insufficiently smooth clustering results of traditional cloud storage data segmentation clustering methods, the author proposes a machine learning based cloud storage data segmentation clustering method. The experimental results indicate that, the method proposed by the author has significantly improved the clustering variation compared to traditional methods. The proposed method reduces the clustering variation from 42% to 29%, effectively improving the smoothness of the clustering results. There are still many problems in using the proposed cloud storage data segmentation and clustering method in practical applications, and the network environment is becoming increasingly complex, with the types of data becoming more diverse, after the emergence of complex and diverse data, the proposed method cannot effectively cluster all types of data. In the face of a wide variety of data, it is necessary to improve the ability of segmented clustering.

PLATEAU ALTITUDE DISASTER PREVENTION AND REDUCTION PLATFORM BASED ON BEIDOU SYSTEM

TONGWEI ZHANG*, YONGQI LIU† AND LINGYING LI‡

Abstract. This project is based on the Beidou satellite navigation and positioning technology developed by China. The integrated analysis method is used to obtain the monitoring data of high-precision power cables in high-altitude areas with high-precision millimeters to realize the whole process of monitoring various disasters. An early warning system for power line swing and tower bottom geological hazards is established. The track data of cable swing is obtained by using single-frequency dynamic data post-processing (PPK) based on synchronous power grid monitoring. The applicability and trajectory accuracy of the scheme are evaluated by combining theory with practical engineering. This provides essential technical support for the mechanism and prevention of cable sloshing. The experimental simulation shows that the monitoring efficiency of the system is high.

Key words: Beidou satellite; Transmission lines; Cable sloshing; Foundation strengthening system

1. Introduction. In recent years, the frequent occurrence of power line swaying events has seriously affected the regular operation of the power system. In January 2020, due to continuous low-temperature rainfall, the power systems of five provinces and cities, Anhui, Hubei, Hunan, and Jiangxi, appeared to have a wide range of swings. Among them, more than 20 high-voltage transmission lines of 220 kV and above appeared to have different degrees of oscillation. The oscillation period is more than 40 hours, and the oscillation amplitude can reach 5 meters. Transmission line oscillation is a kind of mechanical vibration caused by wind force, ice-covered wing lift and wire tension under particular weather conditions. It is determined by three factors: ice covering, wind excitation, line structure and parameters, and the whole process includes starting, maintenance, attenuation and other stages.

The power network monitoring and management system must monitor the transmission lines in the swing area online and measure the swing influence factors in real-time. Currently, there are two kinds of real-time monitoring methods for power line swaying at home and abroad: video image and accelerometer. The existing monitoring method based on video images has some problems, such as limited transmission of transmission lines, low resolution, low accuracy of swing detection, and inability to realize real-time monitoring. The monitoring mode of the acceleration sensor is to measure a single conductor's acceleration and then obtain its oscillation's velocity and displacement through mathematical integration. However, this method can only reflect the swing amplitude locally, and it is easy to produce cumulative errors and cannot reflect the direction characteristics of the swing. Literature [1] uses a novel FBG sensing mode to design a method for measuring the shaking of objects. Literature [2] established a new idea of regional sloshing monitoring and early forecasting based on measured data by combining sloshing sampling with weather data. Literature [3] proposes using independent differential GPS technology to monitor and forecast the swing of transmission lines in real time and dynamics. But the above methods have some defects. Therefore, a method of wide-area transmission line shaking monitoring based on the Beidou foundation strengthening system and Beidou high precision positioning technology is proposed in this paper. A new method of swing detection for a "wide area transmission line" is studied [4], and at the same time, related equipment development is studied. This lays a foundation for the application research of "swing" monitoring and "active early warning" in China's power system.

2. Design a power disaster prevention Beidou system in high-altitude areas.

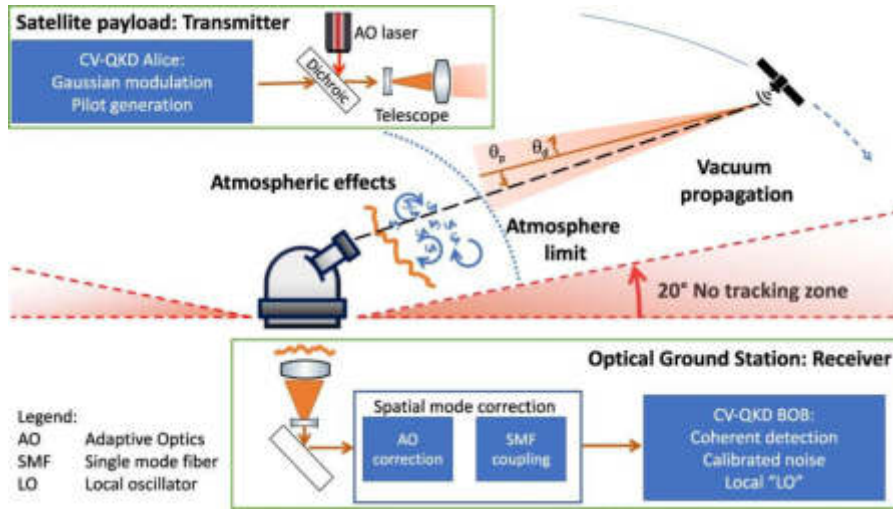

Fig. 2.1: Schematic diagram of satellite single point positioning.

2.1. Basic Theory of Satellite GPS. In practical application, the Beidou system (BDS) is complicated to achieve accurate distance measurement because of the uncertainty of inter-satellite and receiver clock differences. Therefore, in measuring the distance between the satellite and the receiver, the Beidou system includes multiple navigation satellites, user receiver equipment and ground measurement and control network [5]. They are both spatial position reference points and communication relay stations. In engineering practice, the receiver synchronously receives signals from multiple satellites and obtains more accurate navigation and position through corresponding algorithms [6]. The receiver then obtains a pseudo-range formula containing the unknowns. Since the unknowns include the user’s space coordinates (X, Y, Z) and the receiver’s time difference, the pseudo-range positioning is essentially to obtain the receiver’s geodetic coordinate system and receiver clock difference by using the pseudo-range measurements of multiple satellites [7]. Figure 2.1 shows the schematic diagram of satellite single point positioning (the picture is quoted in Feasibility of satellite-to-ground continuous-variable quantum key distribution).

Suppose the user’s position is (X, Y, Z) , the satellite coordinates on BDS are (X_r, Y_r, Z_x) , and the distance between the user and the i satellite is S_{ri} .

$$S_{ri} = \sqrt{(X_r - X)^2 + (Y_r - Y)^2 + (Z_r - Z)^2}$$

It is determined that there is an error between the pseudo distance of GPS and the actual distance. The pseudo-distance is represented by Q_{ri} ,

$$Q_{ri} = S_{ri} + v\Delta t_d$$

v is the speed of light. Δt_d represents the time error of the receiver. There are four unknowns X, Y, Z and Δt_d in equation (2.1) and (2.2). The receiver must receive at least four satellite position signals to find the uncertainty [8]. When more than four satellites are received, the least square method is used to determine the coordinates and clock differences of the receiver. The equation composed of $n(n \geq 4)$ satellite position formulas is shown in formula (2.3):

$$\begin{cases} Q_{r1} = \sqrt{(X_{r1} - X)^2 + (Y_{r1} - Y)^2 + (Z_{r1} - Z)^2} + \sigma W \\ Q_{r2} = \sqrt{(X_{r2} - X)^2 + (Y_{r2} - Y)^2 + (Z_{r2} - Z)^2} + \sigma W \\ Q_m = \sqrt{(X_m - X)^2 + (Y_m - Y)^2 + (Z_{rn} - Z)^2} + \sigma W \end{cases}$$

There is $\sigma W = v\Delta t_d$ in the formula. Because the prerequisite for calculating by the least square method is that the equation is linear, while the satellite navigation is non-linear, the term (2.3) should be linearized [9]. The above expression is malleable using the Taylor series.

$$Q_{rn} = Q_{rn} + \frac{X_m - X}{S_{rn}} \Delta X + \frac{Y_m - Y}{S_m} \Delta Y + \frac{Z_m - Z}{S_m} \Delta Z - \Delta \sigma W$$

Q_{rn} is the approximate distance between the receiver and the second n satellite. $(\hat{X}, \hat{Y}, \hat{Z})$ are the approximate azimuth coordinates of the receiver for each solution. $\Delta X, \Delta Y, \Delta Z, \Delta \sigma W$ is the displacement concerning the four unknowns. Convert all (2.3) to (2.4) and represent it with a matrix table

$$Q_r = \varphi H$$

$Q_r = [Q_{r1} \quad Q_{r2} \quad \cdots \quad Q_m]^T$ $H = [\Delta X \quad \Delta Y \quad \Delta Z \quad \Delta \sigma W]^T$, φ is the coefficient matrix, specifically

$$\varphi = \begin{bmatrix} \frac{X_{r1}-X}{S_{r1}} & \frac{Y_{r1}-Y}{S_{r1}} & \frac{Z_{r1}-Z}{S_{r1}} & -1 \\ \frac{X_{r2}-X}{S_{r2}} & \frac{Y_{r2}-Y}{S_{r2}} & \frac{Z_{r2}-Z}{S_{r2}} & -1 \\ \vdots & \vdots & \vdots & \vdots \\ \frac{X_{rn}-X}{S_m} & \frac{Y_m-Y}{S_{rn}} & \frac{Z_{rn}-Z}{S_m} & -1 \end{bmatrix}$$

Due to the interference of atmospheric transmission time delay and multipath effect, the position accuracy of pseudo distance positioning will decrease when the least square algorithm fixes the measured value.

2.2. System Design. This project relies on the national "Beidou" navigation and ground combined navigation technology to carry out high-precision differential positioning of multiple wobbler points in an extensive range (Figure 2.2 quoted in Journal of Revisualization and Spatial Analysis, 2020, 4:1-12.). Grasp the real-time information on wire swaying waveform, swaying amplitude, swaying ellipse Angle, and swaying frequency. The position information of each wobbly satellite is transmitted in real-time [10]. At the same time, combined with the field environment, it is dynamically adjusted in real-time to achieve the purpose of real-time detection and alarm of the security risk of the power grid. The obtained results will be pushed to the monitoring and early warning application center and related monitoring terminals.

The oscillating monitoring equipment based on Beidou is adopted. At the same time, it is integrated with the sensing equipment installed in the equipment to realize the online monitoring of multiple signal sources [11]. Through the public network communication module in the equipment, the obtained information is uploaded to the solution business platform of the "Beidou" ground enhancement system. Using the PPK solution, each observation point's X, Y and Z coordinates in vertical coordinates are dynamically post-processed. The corresponding road map is given, combined with the historical data of each monitoring point [12]. The heave curve's response equations of X, Y and Z coordinates are established, and spectral analysis is carried out.

2.3. System Communication. With the support of the Beidou application terminal, SMS transceiver, mobile communication terminal, emergency communication server and emergency communication service platform software, each component realizes the sending and receiving of Beidou short messages and mobile short messages under the support of the system network of Beidou Communication and mobile communication. The system architecture is shown in Figure 2.3 (image cited in Satellite Navigation, 2020, 1:1-23).

Beidou handheld/vehicle terminal equipment is used for people/vehicles to move in and out of specific areas. The "Beidou" system is used as the command terminal to provide support for communication support in emergencies. The RDSS link is used to realize short message communication between Beidou mobile phone/car users and Beidou command clients. Short message sending and receiving is a communication device with mobile phone short message sending and receiving, which can send and receive short messages to the mobile communication terminal through the communication base station. In an emergency, the mobile phone short message sending and receiving device is configured in the emergency communication support center [13]. The system is mainly used to manage the user terminal and short message-receiving device in the Beidou system and realize the system's data transmission and address transmission.

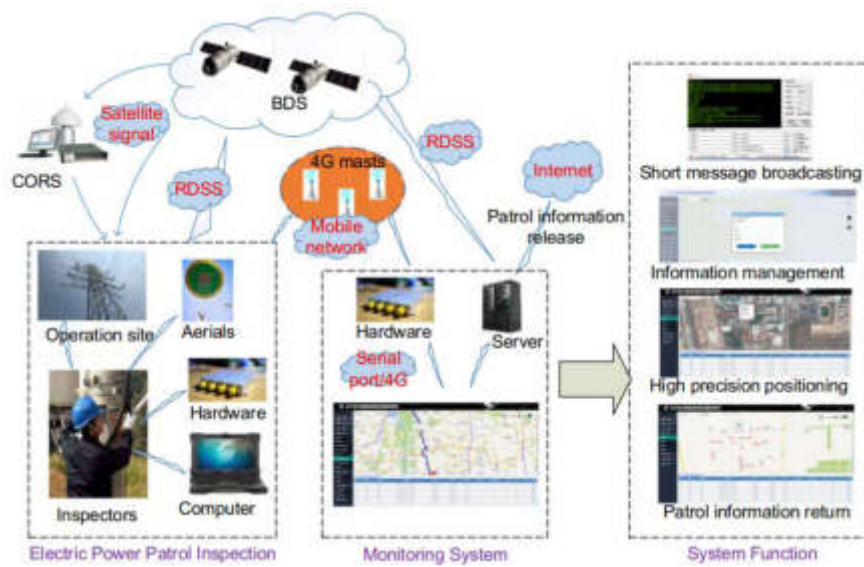

Fig. 2.2: Structure of BDS swing monitoring system.

Fig. 2.3: Structure of the Beidou communication system.

3. Data processing methods. When the wire is affected by ice or wind force, the wire will have a sizeable self-excited vibration at low frequency. A small swing from the equilibrium position will eventually produce an increasingly sizeable elliptical orbit dominated by lateral and longitudinal orbits. When the wire does not shake the phenomenon, the system will use the position, acceleration and other related data statistics to determine whether the system is balanced. The "Beidou" system and the sensing system are used to collect the position information of each measuring point in real-time and convert it into discrete values. By comparing the change values of Beidou high-precision coordinates in continuous periods, the change difference values of each observation point on the corresponding axis are obtained [14]. Plot the sway trajectories of the monitoring points. The sloshing rate of the wire can be obtained by differentiating the displacement data by the first

Fig. 4.1: ENU coordinate change curve of simulation test.

difference method. Further, the pendulum acceleration of each measuring point is obtained. Set the horizontal movement direction of the wire to the x direction and the vertical movement direction to the y direction [15]. Then, based on the change of the coordinates before and after each direction, the displacement along the direction is obtained, and the calculation method of the velocity and acceleration in each direction is obtained:

$$C_{x(t)} = \frac{s(X_t - X_0)}{dt}$$

$$\gamma_{x(t)} = \frac{\frac{s(X_t - X_0)}{dt} - C_{x_0}}{dt}$$

$$C_{y(t)} = \frac{s(Y_t - Y_0)}{dt}$$

$$\gamma_{y(t)} = \frac{\frac{s(Y_t - Y_0)}{dt} - C_{y_0}}{dt}$$

where X_0, Y_0 is the coordinates of each monitoring point in the x direction and Y direction at the previous time. X_t, Y_t is the coordinate of the measuring point in the X and Y coordinates after time t . Where C_{x_0}, C_{y_0} is the velocity of the time before the monitoring point. Under the initial conditions, its speed is zero. $\gamma_{x(t)}, \gamma_{y(t)}$ is the value of the acceleration of the measuring point in both directions X and Y. Then, based on the high-precision differential positioning of the Beidou satellite, this paper obtains parameters such as the trajectory, amplitude, vertical amplitude and horizontal frequency of sway through the simulation analysis of sway.

4. Application testing. A 500 kV power line tower simulation test system is established. The research results show that using Beidou navigation technology for transmission line sway detection has high accuracy and practicability. Install the swing monitoring device on the top of the tower. The observation data of Beidou have been accepted by the shaking detector in the field test site, and the condition is good. In this project, the initial observation data of the wobbly monitoring equipment were established on board, 1-second sampling was adopted, and Beidou B1 was used as the receiver frequency. In this way, the measured data at every moment are transmitted in real-time to the fixed platform of the Beidou ground-enhanced positioning system. Through the data exchange with the ground data server, the "Beidou" observation data near the reference station of the swing monitoring network are verified. The Beidou satellite navigation positioning and solving platform monitors the real-time ground sway. After dynamic post-processing under the PPK model, each measurement's X, Y and Z coordinates are obtained. The velocity and acceleration curves of each measuring point are obtained after testing. Figures 4.1, 4.2, and 4.3 show the values of the coordinates, velocity, and acceleration differences over different periods.

A total of 357 pieces were tested. After systematic processing, the definite number of dynamic post-processing was obtained for 355 pieces, and the ratio of the definite number of dynamic post-processing to the

Fig. 4.2: Speed change curve of simulation test.

Fig. 4.3: Acceleration change rule in simulation test.

number of outputs was 99.44%. The internal consistency accuracy error (Table 4.1) is calculated for data with coordinate change values, velocity and acceleration $\sigma_i = \sqrt{\frac{\sum \Delta_i^2}{n-1}}$. Where σ_i is the internal consistency of each component, and Δ_i is the calculated value and average difference of each component. n is the actual observed quantity of each component.

At the same time, the system can also quickly obtain high-precision motion speed, acceleration and other parameters to meet the needs of transmission line sloshing detection. The calendar has a total of 2511 elements. By analyzing the system, 2511 definite solution values were obtained after dynamic post-processing, among which the ratio of the number of definite solutions after dynamic post-processing to the total number of iterations reached 99.47%. Several monitoring points were sampled. The MATLAB software was used to analyze the horizontal and vertical displacement data of each measuring point measured at each time, and the corresponding dance traces were fitted. The fitting results show that the vibration amplitude is 0.66 meters.

5. Conclusion. This paper introduces a new idea of real-time monitoring of power line swing by using Beidou satellite positioning technology. This method can improve swing detection and monitoring of transmission lines. The research results of this project will lay the foundation for the realization of real-time monitoring and intelligent analysis of big data of the whole network under space reference. The threshold of the power cable is adjusted individually using the existing history data. The research scheme proposed in this project can adapt to the safety monitoring requirements of power systems for transmission lines. This system has a high reference significance.

STATE MONITORING AND ANOMALY DETECTION ALGORITHMS FOR ELECTRICITY METERS BASED ON IOT TECHNOLOGY

CHUNGUANG WANG*, TIANFU HUANG†, ZHIWU WU‡, YING ZHANG§ AND HANBIN HUANG¶

Abstract. In response to the practical application of the electricity consumption information collection system in the online monitoring business of measuring equipment, the author introduces a method for analyzing the abnormal flying away of electricity meters based on the IoT technology LOF local anomaly detection algorithm. This method can effectively determine whether the abnormal energy representation value belongs to accidental or trend anomalies by calculating the abnormal factor of the energy representation value. After excluding the influence of accidental data, perform a secondary judgment on the abnormal flight of the energy meter. The experimental results show that when calculating the LOF factor of the electricity meter, it can be found that the LOF curve data range is mainly concentrated in the range of 0.8 to 1.3, and there is no significant change in the LOF factor near the mutation point. This proves that this method can effectively improve the accuracy of anomaly detection, avoid misjudgment of faults, and improve the efficiency of on-site fault handling.

Key words: Smart energy meters, Electricity information collection system, LOF, Outliers

1. Introduction. The electricity settlement of power enterprises is mainly completed through energy metering devices. Electricity metering management is an important link in the production and operation management of power enterprises and the safe operation of the power grid. Its technology and management level not only affect the development and corporate image of power enterprises, but also affect the accuracy and fairness of trade settlement, involving the interests of a large number of power customers [1]. Therefore, in order to ensure the accuracy and reliability of the energy meter, it is necessary to reduce the error of the energy meter and make direct payment. fair and reasonable. In order to ensure the accuracy and reliability of the electricity meter, it is necessary to ensure the accuracy and reliability of the standard electricity measurement equipment first [2]. Electrical measuring instruments are distributed only to various state electrical testing centers and power plant states, and currently, the measurements of measuring instruments in various modes are monitored in the laboratory by directly connected computers by the measuring staff in electronic measuring instruments. Since the power meter cannot be monitored remotely, if any abnormality or problem is detected during the measurement, the calibration staff can only remind the management to go to the laboratory for maintenance immediately, which will delay the detection. problems, long-term solutions, low performance, high cost, and difficulty adapting to the growing demand for energy metering. For example, a three-phase energy meter standard device in the metering center of a certain power supply bureau has a total of 16 calibration meter positions [3]. From the surface analysis, it can be judged that the crimping of positions 3, 4, and 11 is damaged and cannot properly calibrate three-phase energy meters, the remaining meter positions are working normally, and the calibration data also meets the requirements of the electric energy meter calibration regulations. There is a special case where the calibration data of the 16 meter positions is better than that of other normally working meter positions. It took three working days for maintenance personnel to check and find that the compression joint of the 16 meter positions was severely damaged, resulting in abnormal data. Due to the large workload of calibration, calibration personnel can only pay attention to whether the calibration data is out of tolerance and whether the voltage connection of the energy meter is normal for most of the time during the calibration

process. Such problems require a long period of time to be discovered, which can have a long-term impact on the accuracy of energy measurement.

As the core infrastructure equipment of ubiquitous power Internet of Things, the demand for smart energy meters is constantly increasing. In terms of electricity metering, the accuracy of smart energy meters is the core element of fairness in electricity trade; In the field of big data research, accurate and qualified smart energy meters are one of the foundations for building ubiquitous power Internet of Things [4]. As of the end of 2020, more than 300 million electricity meters have been put into operation in China, and this number will continue to grow in the future. Traditional manual calibration methods cannot meet the growing demand for calibration, and the transformation from manual calibration to automated systems is imperative. As a result, intelligent electricity meter automated calibration assembly lines have emerged. During the long-term operation of automated calibration assembly lines, frequent connection of smart energy meters to meter positions can cause deformation of the mechanical crimping terminals at the meter positions; Long term live operation can accelerate the oxidation rate of the surface material of mechanical crimping terminals, leading to terminal corrosion [5]. The deformation and corrosion of the mechanical crimping process of the meter will directly affect the reliability of the error test results, thereby affecting the calibration quality of the smart energy meter. At present, the provincial metrology centers under the State Grid Corporation of China generally adopt the method of regular verification to inspect and repair the meter positions on the calibration assembly line. This method cannot detect meter position faults in a timely manner and relies on manual troubleshooting. Its reliability is insufficient and labor costs are high. Therefore, achieving online anomaly detection of calibration assembly line meter positions is of great significance [6].

The abnormal occurrence of the meter flying away is relatively accidental, and generally it will not occur repeatedly on the same meter; Due to external factors such as communication interference, there is a certain amount of data noise in the electricity consumption data. Therefore, using the general analysis method of threshold judgment can cause a large number of misjudgments of runaway anomalies, which affects the discovery and handling of actual meter runaway faults. The LOF algorithm is a classic density based time series anomaly diagnosis algorithm. The author used this algorithm to establish an intelligent diagnostic analysis method for the flying away of electric energy meters, which can effectively remove the influence of outliers, improve the accuracy and timeliness of detecting and judging the flying away anomalies of electric energy meters.

2. Construction of an accuracy analysis platform for electricity metering.

2.1. System Design. The author uses Hadoop distributed technology to build a massive data storage and high-performance parallel computing cluster that covers various power supply bureaus in the province to cope with large-scale data parallel processing. The author also uses Nigera load balancing technology and Redis as a caching component to improve throughput and system availability, meeting the needs of high concurrency requests [7]. Due to the need to process real-time collection of massive power grid measurement data, the system adopts a distributed architecture based on Hadoop and applies the HDFS distributed file system, from the monitoring terminal of measurement standard devices, laboratory calibration control system, measurement automation system, marketing system, on-site inspection business system, semi-structured or unstructured data, then it is stored in the non relational database HbaSe, and some of the data is cleaned and analyzed offline through the Hive data warehouse. The overall architecture of the accuracy analysis platform for electricity metering is shown in Figure 2.1.

2.2. System Software Architecture. In order to meet the requirements of high concurrency, high reliability, and system scalability for data collection, the system is planned to be constructed in MVC mode. The data collection part adopts Nginx+Tomcat cluster to achieve high concurrency and high reliability of web servers, and the backend uses queues+process pools to achieve multi-channel processing of various protocols and concurrent links; The system adopts a B/S architecture based on J2EE for construction. The core technology framework of the platform adopts JAVA as the development language, based on mainstream open-source J2EE frameworks, including Struts, Spring, Hibernate, JQuery, JBOSSOA, JBPM, Druid, and other frameworks. Capable of supporting multiple heterogeneous databases and compatible with mainstream web containers. The technical structure is divided into four layers: basic environment, DAO layer, logic layer, and presentation layer [8].

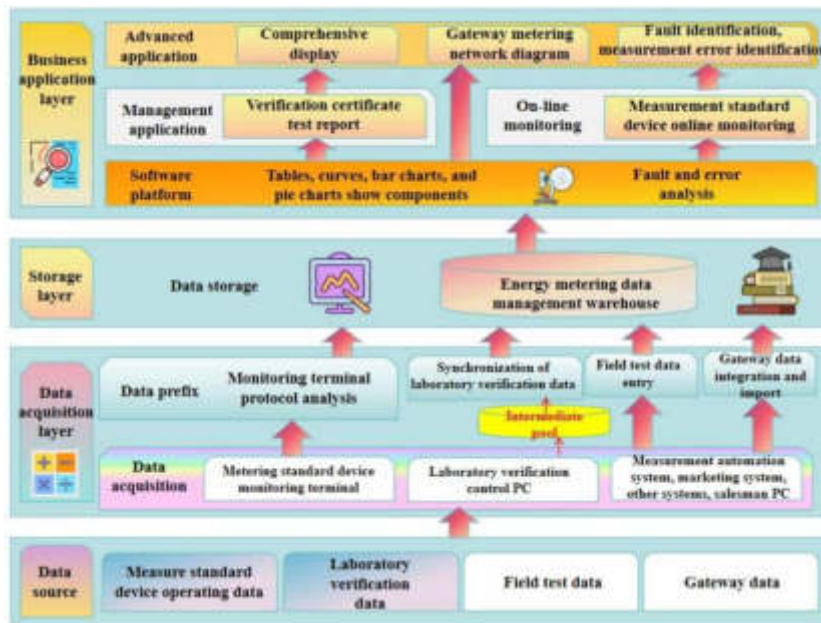

Fig. 2.1: Overall architecture of the accuracy analysis platform for electric energy metering

2.3. System Hardware Architecture. Establish a dedicated network for the metering center on the internal power network and install encrypted communication. VPN gateway achieves remote access by encrypting data packets and converting the target address of the data packets. Implement VPN proxy servers through various methods such as servers, hardware, and software. By using virtual private networks, the measurement center network is made more humanized, software oriented, and intelligent, providing secure, controllable, and flexible resource scheduling capabilities to meet the dynamic restructuring needs of power metering data communication. Addressing network security and monitoring, MAC address tracking, and security vulnerabilities in virtual machine management programs [9].

3. LOF anomaly detection algorithm.

3.1. Abnormal point detection. Outlier detection (also known as outlier detection) is an important part of data mining and refers to the process of identifying objects whose behavior is significantly different from what is expected. These items are called outliers. Vulnerability detection is critical to many applications, including healthcare, public safety, fault detection, image processing, sensor/video networks, and testing see. Misdiagnosis can be divided into controlled and uncontrolled [10]. If the analyst can find registered original and unusual items, they can be used to create an abnormality detection sample before using control methods to detect them. In some applications, unsupervised learning techniques are used when there are no objects labeled as "normal" or "abnormal". Undoubtedly detection assumes that the product contains some kind of impurity.

3.2. Method Comparison. Due to the different electricity consumption patterns of different users, it is not possible to use a unified method for state labeling of energy representation values, and it is not possible to provide a learning set of supervised methods. Therefore, unsupervised anomaly detection algorithms are more suitable for the analysis of energy representation value anomalies. In unsupervised methods, statistical, distance, and density based methods are currently the main methods for anomaly detection [11].

The statistical anomaly detection method mainly analyzes the dispersion of data, analyzes the distribution of data, extracts the variation indicators of data, commonly used include standard deviation, interquartile spacing, etc., and extracts outliers through the variation indicators. This type of algorithm requires prior knowledge of the distribution characteristics of the data, as well as parameter determination of mutation

indicators. The algorithm has poor universality and is mainly used in scientific research fields.

The distance based anomaly detection method considers the neighborhood of an object with a given radius. If it is an anomaly, there are not enough other points in its neighborhood. Compared to statistical algorithms, it does not require users to have any domain knowledge and is more intuitive in concept. However, due to the algorithm detecting outliers from a global perspective by calculating the distance between objects, the detection effect is not good when there are multiple distributions or subsets with different densities in the dataset [12]. Density based detection methods mainly examine the density of the object and its neighbors. If its density is much lower than its neighbors, it is considered an outlier. In this type of algorithm, each point will calculate an outlier degree, overcoming detection errors caused by mixing different density subsets, and the detection accuracy is relatively high. The author mainly adopts density based anomaly detection methods.

3.3. LOF algorithm. The key of density detection is to compare the density around an object with the surrounding density. There is a significant difference between the density of non-outlier objects and the surrounding neighborhood, and there is a significant difference between them and their surroundings. In this paper, a Local Outlier Factor (LOF) is proposed based on the combination of density and anomaly detection. The algorithm is defined as follows:

For a given set of objects D , the objects contained in D are denoted as o . The k -distance of object o is denoted as $dist_k(o)$, which is the distance $dist(o, p)$ between o and another object $p \in D$, such that:

*At least k objects $o \in D - \{o\}$, such that $dist(o, o) \geq dist(o, p)$

*At least $k-1$ objects $o \in D - \{o\}$, such that $dist(o, o) < dist(o, p)$

$dist_k(o)$ is the distance between o and its k -th nearest neighbor. Therefore, the k -distance neighborhood of o includes all objects whose distance to o is not greater than $dist_k(o)$, denoted as:

$$N_o = \{o' | dist(o, o') \leq dist_k(o)\} \quad (3.1)$$

If the average distance between objects in $N_k(o)$ and o is used as the local density measure of o , a problem arises. When a very close neighbor o' is encountered in o , causing $dist(o, o')$ to be very small, the statistical fluctuation of the distance measure will be unexpectedly high. In order to solve this problem, a smoothing effect can be added to convert it into the following reachable distance [13].

$$reach-dist(o, o') = MAX\{k - distance(o), d(o, o')\} \quad (3.2)$$

The local reachable density of object o is the reciprocal of the average reachable distance between object o and its MinPts neighborhood.

$$lrd_{MinPts}(o) = \frac{1}{\frac{\sum_{o' \in N_{MinPts}(o)} reach-dist(o, o')}{|N_{MinPts}(o)|}} \quad (3.3)$$

The local anomaly factor of object o is defined as:

$$LOF_{MinPts}(o) = \frac{\sum_{o' \in N_{MinPts}(o)} lrd_{MinPts}(o')}{|N_{MinPts}(o)|} \quad (3.4)$$

The degree of anomaly in object o can be evaluated through its local anomaly factors; The anomaly factor is directly proportional to the degree of anomaly of the object. If the factor value is larger, the likelihood of anomaly increases; If the factor value is smaller, the likelihood of anomalies decreases, and the LOF factor level of normal values is generally within 1.

4. Example Analysis.

4.1. Calculation steps. In the analysis of electricity meter runaway, we can use the LOF algorithm to filter the original data, effectively identify abnormal points in electricity meter readings, and eliminate the impact of abnormal points in electricity meter readings on the judgment of electricity meter runaway. At the same time, due to the introduction of table readings before and after abnormal points in the judgment, it is necessary to improve the threshold judgment. The author mainly judges based on the daily maximum electricity consumption and daily average electricity consumption [14].

Fig. 4.1: Daily freezing curve of electric energy representation (accidental mutation)

Table 4.1: Daily freezing readings and corresponding LOF factors (accidental mutation) for the three days before & after the electricity meter trip

Date	July 18th	July 20th	July 21st	July 22nd	July 23rd	July 25th	July 26th
Indicating value	40647	39908	39908	72300	39908	39908	39908
LOF	1.501447	0.984361	0.984361	6041.262	0.984361	0.984361	0.984361

- (1) Preliminary judgment of abnormal flight according to the flight formula of the electric energy meter;
- (2) Extract suspected daily data of the flight, generally including at least 7 days before and after the flight date;
- (3) Extract daily data from one of the meters, organize the data and sort the dates;
- (4) Calculate the LOF factor and count the number of abnormal factors;
- (5) Remove the daily data corresponding to LOF abnormal factors;
- (6) Calculate daily electricity consumption;
- (7) Calculate the improvement N value.

$$N = \frac{\text{Maximum daily electricity consumption}}{\text{Average daily electricity consumption}} \tag{4.1}$$

4.2. Calculation results. Perform LOF factor calculation on the energy meter in Figure 4.1, and the calculation result is shown in Figure 4.2. It can be observed that the position of the mutation point on the electric energy representation curve is the same as that on the LOF curve [15,16]. We extracted the daily data of the mutation point and the three days before and after, as shown in Table 4.1. It can be found that the LOF of the mutation point is 6041.262, while the LOF of the other points is basically around 1. The outlier can be filtered out. After elimination, calculate the daily electricity consumption and calculate the N value for flight judgment.

The LOF factor calculation was performed on the electricity meter, and the results are shown in Figure 4.3. It can be found that the LOF curve data range is mainly concentrated in the range of 0.8 to 1.3, and there is no significant change in the LOF factor near the mutation point, as shown in Table 4.2 [17,18,19,20].

Fig. 4.2: Comparison of Daily Freezing Curve and LOF Curve for Energy Representation (Accidental Sudden Change)

Table 4.2: Daily freezing indication and corresponding LOF factor (indication flying away) for the three days before and after the jump of the electric energy meter

date	June 9th	June 10th	June 11th	June 12th	June 13th	June 14th	June 15th
indicating value	1913	1919	119614	119619	119627	119632	119638
LOF	1.0772	1.1393	1.1476	1.1077	1.0639	1.0495	1.0411

5. Conclusion. Through the above algorithms, it is possible to achieve a secondary judgment of the abnormal flight of the electric energy meter detected by the monitoring of the electricity consumption information collection system, which greatly improves the quality and efficiency of the judgment of the electric energy meter flight. It can timely detect the abnormal flight of the electric energy meter, effectively avoid fault misjudgment, and improve the efficiency of on-site fault handling; This method can be further extended to the analysis of other topics related to electricity consumption information collection, improving the accuracy of diagnosis and analysis of the operating conditions of measuring equipment, and further supporting the marketing business decision-making and implementation of power supply enterprises.

Meanwhile, the above is only a practical method for handling data outliers. With the deepening application of electricity information collection system data, how to handle anomalies in data will be the first problem that needs to be solved in future business applications. The rapid development of technologies such as statistical analysis, data mining, and machine learning has laid a solid theoretical foundation for solving the above problems. We need to further increase the introduction, understanding, and practice of data science in the power business.

OPTIMIZATION OF LOGISTICS DISTRIBUTION NETWORK BASED ON ANT COLONY OPTIMIZATION NEURAL NETWORK ALGORITHM

JING YANG*

Abstract. In order to improve the timeliness of logistics distribution, based on the theory of road network smoothness and reliability, the author conducted a study on the optimization of urban logistics distribution and transportation networks based on smoothness and reliability. The concept of logistics distribution and transportation network smoothness and reliability was proposed, and a logistics distribution and transportation network optimization model was established. The solving process of ant colony algorithm was given, and finally, a comparative analysis of a case was conducted. The results showed that: With a 6% increase in total delivery distance, the reliability of the delivery network has increased by 30%. This indicates that when using the model built by the author for distribution network optimization, effective optimization of network smoothness and reliability can be achieved, while only increasing the distance by a small amount. The optimal reliability of a smooth distribution network means that the probability of delivery delays is minimized, which is the most powerful guarantee for the effective accessibility of delivery. Verified the practicality of the constructed model. The proposed logistics distribution network optimization model has practical significance in guiding decision-making for optimizing urban logistics distribution transportation networks and reducing uncertainty in the process of urban logistics distribution.

Key words: Logistics distribution, Network optimization, Smooth reliability, Ant colony

1. Introduction. In the process of globalization, the level of modernization of logistics has become an important indicator of a country's modernization and strength. It is the fundamental driving force for the sustained development of the national economy at a high starting point and an effective way for enterprises to seize competitive advantages in fierce market competition [1]. China is increasingly valuing the development and application of logistics technology to reduce logistics costs and bring considerable economic benefits to enterprises and society. The logistics distribution path optimization problem is a typical combinatorial optimization problem that involves multiple disciplines. Many practical problems can be classified into this category, with broad application prospects. Therefore, it has always been a hot research topic in the fields of operations research and combinatorial optimization. In recent years, significant achievements have been made in the research of vehicle optimization scheduling problems, which have been widely used in various aspects of production and life, such as newspaper or cargo delivery, taxi scheduling, and parcel express delivery.

The logistics network is specifically composed of various logistics nodes and routes connecting each point. Among them, nodes include distribution centers, warehouses, etc., while routes refer to the routes and routes for logistics distribution operations in accordance with regulations. The purpose of optimizing the distribution network path is to optimize the movement (transportation) path of goods during the spatial transfer process from the production area to the consumption area. The purpose of studying it is to find the most reasonable vehicle transportation path, overcome spatial barriers, and achieve cost savings. Due to the fact that solving the distribution path problem is an NP hard problem with high complexity. The traditional methods for solving such problems include precise algorithms and heuristic algorithms. The optimal solution to a problem can be obtained using precise algorithms, but its solving time often increases exponentially with the size of the problem. When there are a large number of nodes to be processed, it takes a considerable amount of time to solve, so its practical application scope is limited. Heuristic methods usually simplify problems into several small problems or modules based on their characteristics, and solve them in a more intuitive way. Therefore, most researchers are committed to the development and improvement of heuristic algorithms. Research on previous research has found that although heuristic algorithms can obtain satisfactory solutions to VRP problems, it is difficult to

* School of Finance and Economics, Hainan Vocational University of Science and Technology, Haikou, Hainan, 570000, China (yjkytg2023@126.com)

obtain the optimal solution within a reasonable computational time using existing algorithms as the problem size increases.

At present, logistics distribution logistics in a general sense refers to the establishment of distribution centers according to the frequency and size of goods order the needs of different customers, as well as the use of 7R (for products, quality, time, time, location, conditions, customers, and costs). Because of the complexity of the transportation system in distribution, especially in urban distribution system, not only the multi-points transportation system, multi-products, and the traffic network, but the distribution of the transportation content in the transportation service area is also incompatible. Therefore, reasonable and efficient road design to reduce the number of vehicles and transportation costs has become an important and practical problem. The goal of logistics distribution center will be how to make good use of the vehicles, determine the cheapest driving way, to deliver the products to the customers in the shortest possible time. Specifically, it means using multiple vehicles from the distribution center to deliver goods to multiple demand points (users), with a fixed location and demand volume for each demand point, a fixed load capacity for each vehicle, and a reasonable arrangement of vehicle routes to achieve predetermined goals (such as shortest distance, least cost, least time, and least number of vehicles used). The interesting situation during this process is that the total number of points needed on each delivery path is within the carriage; The length of each road shall not exceed the maximum distance that a car can deliver at one time; All requests must and only be sent by one vehicle. This is a special topic of vehicle problem detection (VRP).

According to statistics, the annual logistics costs in the US industry reach \$400 billion. As long as it is reduced by 10%, it can save 40 billion US dollars in a year, so the logistics industry is vividly likened to "a gold mine worth 40 billion US dollars yet to be mined." In 2004, the demand for logistics in society continued to grow rapidly, with a total logistics volume of 3.84 billion yuan, a year-on-year increase of 29.9%, an increase of 2.9 percentage points compared to the same period last year. The logistics industry showed a rapid development trend. However, as a rapidly developing industry, the logistics industry has become a bottleneck that must be effectively managed in the process of national economic development. The proportion of logistics costs to GDP continues to be high, far higher than that of developed countries. At present, the logistics cost in developed countries accounts for about 10% of GDP, while in moderately developed countries (such as South Korea) it accounts for about 16%, while in China it is as high as around 20%. Transportation is the key to logistics decision-making, and in general, transportation costs account for a higher proportion than other logistics costs, except for procurement costs. Therefore, optimizing transportation logistics and reducing transportation costs is one of the effective ways to enhance the core competitiveness of logistics enterprises and reduce logistics costs.

Meanwhile, with the accelerated development of urban economy in recent years, various problems in cities have become increasingly prominent. Transportation and distribution have not only become important factors affecting the cost of goods, but also the level of urban development. The problems caused by distribution transportation, such as traffic congestion, traffic accidents, and exhaust pollution from transportation vehicles, have become major problems that hinder urban economic development and affect the normal life of residents. The traditional delivery method of goods involves retailers receiving goods directly from factories, forming a spider web cross transportation route, resulting in chaotic transportation and low efficiency; With the rapid increase of private vehicles in cities, especially in large cities, although cities have built three-dimensional transportation networks on the ground, above ground, and underground, they still cannot meet the transportation needs of population and vehicles, and urban traffic is becoming increasingly congested; In addition, due to the severe reduction of petroleum energy, fuel prices have risen rapidly, posing challenges to improving vehicle operating efficiency and reducing transportation costs. Therefore, as the volume of logistics and distribution business in cities gradually increases, if the previous logistics methods are still used to organize distribution, a series of problems will arise, such as a decline in service quality and inability to meet customer requirements; The emergence of a large number of unreasonable distribution plans will make it difficult to control logistics costs; Unreasonable vehicle path planning can increase the number of trips and routes for logistics delivery vehicles, leading to an increase in urban transportation burden. In order to solve the above problems, the urban logistics distribution network should be optimized to achieve goals such as on-time delivery, lowest total cost, and shortest total driving path. The advantage of distribution is that it eliminates cross transportation,

saves transportation costs, increases the loading rate of transportation vehicles, reduces empty driving rates, timely delivery, improves service quality, and eliminates the need for users to place orders everywhere, while also reducing consumer inventory. With the development of urban transportation and economy, the demand in the market is gradually diversifying, and in such an environment, a new distribution center - a distribution center - has emerged. In this logistics distribution and transportation method, the distribution center organizes delivery according to the high-frequency and small batch ordering requirements of different customers, generating activities such as physical distribution, commercial flow, information flow, and capital flow. Physical distribution refers to the process of delivering products to customers during the production and sales process. In this process, transportation costs often account for the majority of the total transportation and sales costs. Therefore, in recent years, many enterprises have been committed to reducing transportation costs to improve their core competitiveness. In terms of transportation costs, the cost of moving goods in the sales channel is the highest. Therefore, it is of great practical significance to study how to allocate vehicles and generate distribution routes based on the determined amount of goods, in order to reduce the total transportation cost.

With the rapid development of the economy and the continuous acceleration of urbanization, urban spatial structure, transportation layout, and infrastructure construction are constantly undergoing changes [2]. However, it is not optimistic that the problems that may arise during the urbanization process are increasingly exposed, among which urban traffic congestion is particularly prominent, which directly affects the efficiency of logistics distribution based on urban road networks. Therefore, in order to meet market needs, the logistics distribution and transportation network system should be optimized in a timely and reasonable manner [3,4]. From the perspective of traffic flow, the smoothness of logistics distribution networks is closely related to the random changes in road network traffic status. Therefore, while improving the operational efficiency of logistics distribution systems themselves, we must consider the impact of road network traffic status on logistics distribution networks. In reality, there are many random factors that affect the effectiveness of road network traffic, such as natural disasters, traffic accidents, or frequent traffic congestion. The reliability index is an important indicator for measuring the performance of road networks under the influence of random factors. The existing research results on road network traffic reliability can be divided into two categories: One focuses on the physical stability of the road network, only studying its reliability from the perspective of network topology structure, and basically not considering traffic flow; Another type focuses on the comprehensive performance of network functions, rather than just the evaluation of the road network structure itself [5]. In practical situations, the road network often maintains connectivity, but due to random changes in traffic flow, it may not always be smooth, which may cause logistics delivery vehicles to be unable to arrive at customer points in a timely manner. Based on the characteristics of urban logistics delivery itself, the author analyzes from the perspective of smoothness and reliability, and makes reasonable choices for distribution routes to improve logistics delivery efficiency and achieve the goal of optimizing the logistics distribution transportation network [6].

2. Methods.

2.1. Logistics Network Optimization Issues.

(1) *Logistics Network Definition.* From the micro perspective of enterprises, the definition of logistics network can be summarized as: the circulation channels through which goods move from the place of supply to the place of sale. By abstracting the social logistics system, a network consisting of logistics nodes and transportation routes has been formed, as shown in Figure 2.1 [7]. The transportation routes in the network represent the movement routes of goods between different inventory storage points, while logistics nodes refer to the storage or demand points of goods, such as warehouses, distribution centers, logistics centers, factories, suppliers, etc. There may be multiple transportation routes connected between any pair of logistics nodes, representing different transportation modes, routes, or products. Logistics nodes also represent temporary stopping points during the inventory flow process, such as logistics centers.

(2) *Mathematical model of logistics distribution.* The general distribution vehicle routing problem can be described as follows: Linear programming can effectively solve balanced transportation problems, as it can be summarized into the following linear programming model. Assuming the unit freight rate from place of origin i to place of sale j is c_{ij} , $i=1, 2, \dots, m$; $J=1, 2, \dots, n$. X is the optimal shipping volume from origin i to destination j ,

Fig. 2.1: Logistics Network Structure

and z is the optimal total shipping cost, the mathematical model is:

$$\min z = \sum_{i=1}^m \sum_{j=1}^m c_{ij} x_{ij} \tag{2.1}$$

Constraints:

$$\sum_{i=1}^m x_{i,j} = b_j, j = 1, \dots, n \tag{2.2}$$

$$\sum_{i=1}^n x_{i,j} = a_j, i = 1, \dots, n, x_{i,j} \geq 0$$

Therefore, equation 2.1 and its constraints precisely constitute the mathematical model of the linear programming problem. By using the linear programming method to solve it, the optimal solution can be obtained, which is to minimize the total freight cost while satisfying the possible supply and demand of the place of origin [8].

2.2. Optimization modeling of logistics distribution and transportation network based on smooth reliability. The main purpose of optimizing logistics distribution and transportation network is to improve the efficiency of reliability and accessibility of distribution network. Therefore, the purpose of the modeling is to achieve the reliability and reliability of shipping and transportation systems. According to the characteristics of multi-city, multi-variety, small-scale, multi-package, and short cycle logistics distribution, the following parameters are mainly determined:

1. The total amount of goods on each distribution route shall not exceed the limits of vehicle capacity and load capacity [9,10];
2. Within the allowable range of existing transportation capacity in the logistics center;
3. During the delivery process, each delivery point can only be accessed once and must be accessed once;

4. Each vehicle can only serve one route, and each delivery vehicle must depart from the distribution center and finally return to the distribution center;
5. Delivery costs should be controlled at a certain level.

Following the above constraints, establish an optimization model as follows:

$$\begin{aligned}
 \max Z &= \max \Psi = \sum_{n=1}^N \xi_n \Psi_n \\
 \text{s.t.} & \begin{cases} \Psi_n = \prod \Psi_{ij} \\ q_n \leq Q_n \\ N \leq M \\ \sum_{i=0}^n x_{ij} = 1 (j = 1, 2, \dots, n) \\ \sum_{i=0}^n x_{ij} = 1 (i = 1, 2, \dots, n) \\ \sum_{i=0}^n x_{i0} = \sum_{i=0}^n x_{i0} = N \\ \sum_{i=0}^n \sum_{j=0}^n C_{ij} X_{ij} \leq A \end{cases} \quad (2.3)
 \end{aligned}$$

In the formula, Ψ_n represents the smoothness and reliability of the nth distribution line in the network; Q_n is the load capacity of the vehicles arranged on the nth route; Q_n is the total amount of goods at all distribution points on the nth route [11]; N is the overall number of distribution routes; M is the number of delivery vehicles in the logistics center; C_{ij} is the cost from node i to node j , $x_{ij} = \begin{cases} 1, & \text{The vehicle line passes the arc}(i,j) \\ 0, & \text{The vehicle line does not pass through the arc}(i,j) \end{cases}$ A is the cost quota at a certain level of certainty, which is a constant and can be determined based on empirical values.

2.3. Implementation Algorithm of Logistics Distribution and Transportation Network Optimization Model Based on Smooth Reliability. Due to the large number of units in large-scale logistics distribution network systems, traditional algorithms for solving nonlinear programming may encounter "curse of dimensionality" or combinatorial explosion problems; Meanwhile, the design or improvement of the actual distribution network is often selected from several feasible solutions. Therefore, based on the specific situation of the logistics distribution network system, the author chooses ant colony algorithm for system optimization and solution.

(1) *Introduction to Ant Colony Algorithm.* The principle of the ant colony algorithm is to first create an ant colony with a certain number of ants, and let each ant create a solution or part of the solution [12]. Then, each ant starts from the first node of the problem and selects the next node to switch according to the concentration of pheromones along the path until the solution is reached. Each ant releases pheromones that are proportional to the quality of the solution in the state it passes through based on the quality of the solution found; Afterwards, each ant begins a new solving process until a satisfactory solution is found. Ant colony algorithm needs to follow the following rules in computing loops:

State transition rule: The probability calculation method for the h-th ant at location r to choose to transition to location s is:

$$P_{rs}^k = \begin{cases} \frac{[\tau(r,s)] \cdot [\eta(r,s)]^\beta}{\sum_{u \in J_k} [\tau(r,u)] \cdot [\eta(r,u)]^\beta} & s \in J_k \\ 0, & \text{other} \end{cases} \quad (2.4)$$

In the formula, P_{rs}^k represents the probability of ant k transferring from the current location r to the location, $\eta(r, s) = 1/d(r, s)$, $d(r, s)$ represents the distance between location r and location s , the expected degree of $\eta(r, s)$ from location r to location s [13]. $\tau(r, s)$ represents the residual information between location r and location s , J_k represents a location that the k -th ant has not yet visited, parameter β is a parameter used to adjust the relationship between $\tau(r, s)$ and $\eta(r, s)$, it represents the different roles played by the information accumulated by ants during their movement and heuristic factors in ant path selection. Specifically, it represents

the concentration of pheromones on a path and the reciprocal of its length, which person has the greater importance in probability calculation.

Ant's next path selection rule:

$$s = \begin{cases} \arg \max_{u \in J_k(r)} [\tau(r, s) \cdot \eta(r, s)]^\beta \\ S, q \leq q_0(\textit{exploitation}), \textit{otherwise}(\textit{exploitation}) \end{cases} \quad (2.5)$$

In the formula, q is a random variable uniformly distributed on $[0, 1]$, q_0 is a parameter on $[0, 1]$, and S is a probability distribution calculated based on the state transition rule for selection.

Local update rule: During the process of establishing a solution, each ant also undergoes a local update of pheromones. The information intensity of each arc on its path is adjusted according to the following formula:

$$\tau(r, s) = (1 - p) \cdot \tau(r, s) + p \cdot \Delta\tau(r, s) \quad (2.6)$$

In the formula, p represents the volatility factor of local pheromones, and $1-p$ represents the retention rate of pheromones. In order to prevent infinite accumulation of information, the value range of p is limited to $(0, 1)$. $\Delta\tau(r, s)$ is the amount of information increase, which refers to the concentration of pheromones that Ant k increases along the path from City r to City s during the time period t to $(t+n)$.

Global update rule: After all ants have completed one cycle, only the ants that have generated the global optimal solution (i.e. the ants that have constructed the shortest path from the beginning to the present) have the opportunity to perform global updates. The pheromones on all paths passed by the optimal ant are globally updated according to the following formula. The pheromones on paths that do not belong to the optimal ant are updated to 0.

$$\tau(r, s) = \begin{cases} (1 - \alpha) \cdot \tau(r, s) + \alpha \cdot \Delta\tau \\ 0 \end{cases} \quad (2.7)$$

In the formula, α represents the volatility factor of global pheromones, $1-\alpha$ represents the retention rate of global pheromones, and the value range of α is between $(0, 1)$. $\Delta\tau = 1/L_b$, L_b is the shortest path length calculated by the algorithm (the shortest path here only refers to the shortest path obtained in this cycle).

(2) *Model Ant Colony Algorithm Solving*. Using ants instead of vehicles, the next delivery point to be served will cause the total carrying capacity to exceed the vehicle's capacity, and then return to the distribution center, indicating that the vehicle has completed the transportation. Then change to another car and continue to serve the other delivery points until all delivery points receive a service, which represents the completion of an ant tour. When all ants patrol once, it is recorded as a cycle. After one cycle, calculate the pheromone increment and update the pheromones on the relevant paths based on the quality of each ant's patrol history (objective function value). The specific implementation steps are as follows:

Step 1: Initialize each basic parameter and set $nc=Q$;

Step 2: Calculate the transition probability;

Step 3: Based on the calculated transition probability and randomly generated q value, select the next path for each ant to move;

Step 4: When each ant passes through an edge and reaches the next delivery point, a local update of pheromones is performed on this edge according to local update rules;

Step 5: Repeat steps 2 to 4 for each ant in step 5 until all distribution points have ants passing by and the needs of the distribution points are met [14];

Step 6: Find the path that matches the optimal goal of the model among all generated paths, and the ant that passes through that path is the optimal ant;

Step 7: Perform a global pheromone update on each edge passed by the optimal ant according to the global update rule for this path;

Step 8: Repeat steps 2 to 7 until the nc reaches the specified maximum number of iterations or no better solution appears for several consecutive generations.

In this article, Matlab programming is used to implement the ant colony algorithm and solve practical problems.

Table 3.1: Customer demand at delivery points

Delivery point	Demand/t	Delivery point	Demand/t

②	0.96	3	0.91
③	0.96	4	0.8
④	0.86	5	0.91
1	0.96		

3. Results and Analysis. A certain distribution center P₀ needs to deliver goods to 9 distribution points P_j (j=1, 2, 3,..., 9). The demand for each distribution point is q_j, and the specific values are shown in Table 3.1. There are 2, 4, and 6 ton trucks available for allocation in the distribution center. The distances between distribution centers and distribution points, as well as between distribution points, are shown in Table 3.2. The unit distance cost is 2Q, and the cost quota A is 2000. Given the smoothness and reliability of the road sections and intersections between various distribution nodes, we will try to develop a reasonable distribution route.

3.1. Smooth reliability between distribution centers and distribution points, as well as between distribution points. Based on the smoothness and reliability of the road sections and intersections between various distribution nodes, the OD formula for calculating the smoothness and reliability of the inter transportation system is used to calculate the smoothness and reliability between distribution centers and distribution points, as well as between distribution points and distribution points. Taking the road network between distribution center P₀ and distribution point P₉ as an example for calculation, the smoothness reliability and road network of the road units between the nodes are shown in Table 3.3 [15,16].

According to the OD formula for calculating the smoothness reliability of the transportation system, the smoothness reliability between distribution center P and distribution point P is 0.79. Similarly, calculate the smoothness reliability between other distribution nodes, as shown in Table 3.4 and Figure 3.1 [17].

3.2. Develop delivery routes. Apply optimization models and use ant colony algorithm for solving. When initializing the data, the maximum number of ants taken is 5Q, and the maximum number of executions

Table 3.4: Reliability of smoothness between distribution points

Delivery point pairs	Unblocked Reliability	Delivery point pairs	Unblocked Reliability
P01	0.76	P19	0.66
P02	0.62	P23	0.8
P03	0.72	P34	0.63

P12	0.73	P79	0.68
P18	0.76	P89	0.73

Fig. 3.1: Reliability of smooth delivery between different distribution points

is 200Q. After iterative calculation, the following three reasonable delivery routes are finally obtained.

Route I: P0-P3-P2-P1-P0. Using a 4-ton vehicle with a delivery distance of 28.5 [18]

Route II: P0-P4-P5-P6-P7-P0 uses a 6t vehicle with a delivery distance of 30;

Route III: P0-p8-P9-P0. Using a 2T vehicle with a delivery distance of 29, the optimal smoothness and reliability of the logistics distribution network under various constraints reached 0.297.

3.3. Comparative analysis. Using the mileage saving method, solve this example and obtain three delivery routes. Route i: P0-P2-P1-P9, P8-P0 uses a 4t vehicle with a delivery distance of 41; Route ii: P0-P3-P4-P0 uses a 2-ton vehicle with a delivery distance of 21.5; Route iii: P0-P5-P6-P7-P0 uses a 6t vehicle with a delivery distance of 20, and the reliability of the delivery network under this delivery plan is 0.229. Through calculation and analysis, it can be concluded that with a 6% increase in total delivery distance, the reliability of the delivery network has increased by 30%. This indicates that when using the model built by the author for distribution network optimization, effective optimization of network smoothness and reliability can be achieved, while only increasing the distance by a small amount. The optimal reliability of a smooth distribution network means that the probability of delivery delays is minimized, which is the most powerful guarantee for the effective accessibility of delivery. In today's fast-paced society, where the value of time is increasingly valued by people, the distribution model built by the author undoubtedly has certain practical significance [19,20].

4. Conclusion. Due to the fact that the optimization of logistics distribution and transportation networks only fully utilizes the existing road network and cannot transform it, further analysis of the reliability of logistics distribution and transportation networks can only be conducted based on the analysis of the existing road network's smoothness and reliability. The research conducted by the author aims to maximize the smoothness and reliability of logistics distribution networks at a certain cost level, thereby ensuring the effective accessibility of logistics distribution. However, in practical applications, if the improvement of the smoothness and reliability of logistics distribution networks requires a significant cost, it is necessary to consider whether the distribution center is in a reasonable transportation location or whether the division of distribution areas is reasonable. This is a direction that needs further research in the future.

REVIEW OF AUTOMATED TEST CASE GENERATION, OPTIMIZATION, AND PRIORITIZATION USING UML DIAGRAMS: TRENDS, LIMITATIONS, AND FUTURE DIRECTIONS

SRINIVASA RAO KONGARANA * A ANANDA RAO † AND P RADHIKA RAJU ‡

Abstract. This systematic literature review examines the effectiveness of automated test case generation, optimization, and prioritization methods based on Unified Modeling Language (UML) diagrams. The review summarizes the methods, main contributions, and limitations, and suggests areas for future research. This paper examines various optimization algorithms, model-based testing methods, and UML diagram validation methods to determine how well they perform. The review highlights some issues with the current situation, such as the fact that it only examines a few types of UML diagrams and does not go into great detail about how they work or compare to other diagrams. However, it also suggests ways in which these issues could be addressed in future research. Some of the suggested directions include researching different modeling languages and devising solutions to handle the complexity of system models. Model-based testing should also be combined with optimization and prioritization methods to increase the flexibility and usefulness of research in this field. This article makes no direct comparisons to UML diagrams, but it does provide a thorough discussion of the current state of the art and a list of strategic priorities to advance the field of automated test case generation, optimization, and prioritization. These reviews are useful for both researchers and practitioners because they demonstrate how things are currently done and how they should be done in the future.

Key words: UML, Optimization, Prioritization, Test Case Generation, Sequence Diagram, SLR

1. Introduction. Software testing finds and fixes system bugs, which is a critical part of the software development lifecycle. Creating inputs and expected outputs to assess the software’s functionality and behavior is known as test case generation, and it is an essential part of software testing [1]. The ability of automated test case generation techniques to increase software testing effectiveness, decrease human labor, and increase efficiency has drawn attention in recent years [1]. Test case generation using Unified Modeling Language (UML) diagrams shows promise for automated testing. Software systems can be visually represented with UML diagrams, which depict interactions, behavior, and structure [2]. These diagrams are appropriate for automated test case generation because they standardize and simplify software system modeling. From 2010 to 2022, a thorough overview of research on creating test case diagrams from UML diagrams is intended to be provided by this systematic literature review. This systematic review outlined the field’s present methods, results, research trends, shortcomings, and potential future directions. The use of UML diagrams in test case generation has several advantages. Between test cases and system requirements or design specifications, UML diagrams provide a clear mapping [3]. Making it simpler to track test coverage and ensure system behavior matches design, traceability enhances understanding and documentation of the testing process.

Because UML diagrams automatically generate test cases and model system behavior, they also enhance model-based testing [4]. Automated test case generation is minimized, dynamic behavior is managed, and system complexity is captured through model-based capturing. Efficient system functionality coverage is another advantage of UML diagrams. A comprehensive view of the system is provided by UML diagrams, which enable testers to pinpoint crucial paths, significant interactions, and test scenarios [5]. With the aid of this data, automated test case generation techniques are able to produce an exhaustive collection of test cases that encompass every facet of the system, guaranteeing a comprehensive assessment of its functionality.]

UML diagrams have limitations when it comes to test case generation. One drawback is the emphasis on state machine, activity, and sequence UML diagrams. These diagrams show important system behavior,

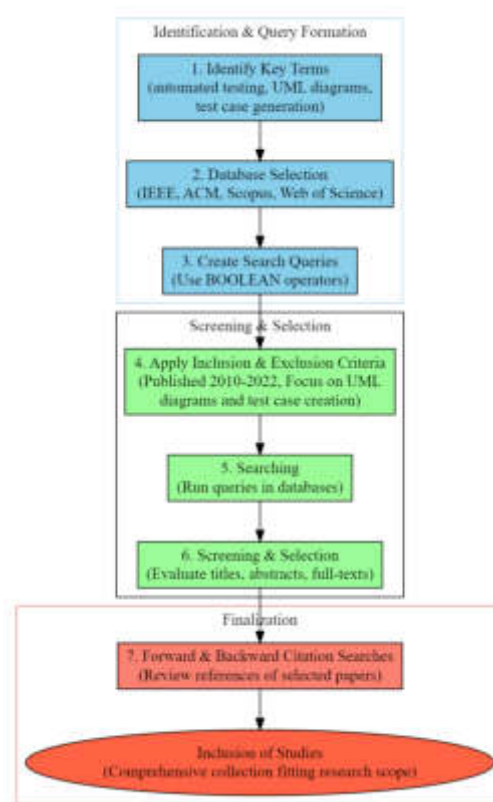

Fig. 2.1: Architecture of the systematic literature review (SLR)

but they may not cover all software details, resulting in test coverage gaps. Evaluate whether UML-based test case generation is applicable to complex systems as well. UML diagrams might not adequately depict the complex behavior, interdependencies, and edge cases of complex software systems. Assessing the effectiveness and scalability of these techniques is essential before applying them to large, complex systems.

Empirical evaluations and comparative analyses of the suggested approaches are crucial to assess their effectiveness, efficiency, and practicality. The lack of thorough empirical evaluations in many of the current studies limits their understanding of adoption and performance in practice. Consolidating knowledge and identifying gaps and limitations in automated test case generation using UML diagrams are the goals of this systematic literature review. Insights into new trends will be provided by this review, which will also help to clarify the current research landscape. By addressing limitations, investigating new avenues for research and development, and promoting the adoption of successful and efficient test case generation methods in software testing practices, the objective is to advance the field of automated test case generation.

2. Search Strategy. Figure 2.1 depicts the systematic literature review (SLR), which used a thorough and methodical search strategy to uncover relevant literature on creating test cases from UML diagrams. The method was carefully planned to ensure that a comprehensive set of research papers were assembled that met the specific criteria for inclusion and covered the entire scope of the research question. With this focused and organized approach, the review sought to compile a body of work that demonstrates the current state and recent progress in creating test cases from UML diagrams.

The following steps were used to create an efficient search strategy:

1. Finding the key terms and concepts associated with the research topic: "automated testing," "UML diagrams," "test case generation," and other related terms.

2. Database selection: Digital libraries and pertinent scholarly databases were looked through. In computer science, software engineering, and testing, common databases include IEEE Xplore, ACM Digital Library, Scopus, and Web of Science.
3. Creating search queries: The key terms and concepts were combined to create search queries. The search space was widened and terms were connected using BOOLEAN operators (AND, OR). UML diagrams were used in the search queries to locate studies on test case generation.
4. Application of inclusion and exclusion criteria: Clearly defined inclusion and exclusion criteria were created in order to weed out studies that did not fit the intended research scope. Published in English between 2010 and 2022, with a focus on UML diagrams and test case creation.
5. Searching: Queries were run in a few databases to get the desired results. Consistency and accuracy were sought after by several researchers working independently.
6. Methods of screening and selection: The titles and abstracts of the retrieved studies were evaluated for their applicability to the research question. The full-text eligibility of the chosen studies was subsequently assessed for systematic literature reviews.
7. Forward and backward citation searches: To increase the search's rigor, we looked through the reference lists of a few chosen papers and carried out forward and backward citation searches to locate more pertinent studies that the first search had overlooked.

In order to reduce bias, incorporate pertinent studies, and offer a thorough and representative sample of UML diagram test case literature, this systematic search approach was employed. The method found and chose studies that supported the systematic literature review and the research goals.

2.1. Search Queries. Compatible search queries are terms or keywords that align with the objectives and topic of a study. In databases and other sources, these queries discover relevant and compatible literature.

Creating compatible search queries requires researchers to take into account the key concepts, terms, and relationships related to their research topic. While excluding irrelevant studies, the queries should cover a wide range of relevant research. Additionally, they should consider variations in terminology or synonyms used in the literature.

Here are some search queries related to perform suggested review:

1. Automated test case generation techniques using UML diagrams
2. Trends in test case generation, optimization, and prioritization with UML diagrams
3. Limitations of automated test case generation with UML diagrams
4. Future directions in test case generation, optimization, and prioritization using UML diagrams
5. Model-based testing and UML diagrams for automated test case generation
6. Optimization algorithms for test case generation with UML diagrams
7. Validation techniques for automated test case generation using UML diagrams
8. Comparative analysis of automated test case generation approaches with UML diagrams
9. Handling complexities in system models for test case generation with UML diagrams
10. Integration of optimization methods, prioritization techniques, and model-based testing for test case generation with UML diagrams

These search queries can assist researchers and practitioners in exploring pertinent literature, trends, limitations, and future directions in the field of automated test case generation, optimization, and prioritization using UML diagrams.

2.2. Search Statistics. Table 2.1, Figure 2.2 categorizes scholarly articles based on the frequency of keywords related to test case development techniques using Unified Modeling Language (UML) diagrams. It shows that "UML" is the most prevalent keyword, appearing in 36 articles, which constitutes 69% of the literature. This is followed by "Test Case Generation" with 30 articles (58%), suggesting a strong academic focus on these areas. Less prevalent, though still significant, are articles on "Sequence Diagram" and "Activity Diagram," with 8 (15%) and 14 (27%) articles respectively, indicating a moderate research interest. "Test Case Optimization" and "Test Case Prioritization" are covered in 11 (21%) and 9 (17%) articles, pointing towards an interest in enhancing the efficacy of testing procedures.

Finally, "UML Diagrams" as a collective category feature in 23 articles, making up 44% of the distribution, highlighting the central importance of UML in the discourse of test case methodologies. This tabulation

Table 2.1: Distribution of Articles According to Keywords

S.No	Number of Articles	Keywords	Ratio of Articles
1	36	UML	69.00%
2	30	Test Case Generation	58.00%
3	8	Sequence Diagram	15.00%
4	14	Activity Diagram	27.00%
5	11	Test case optimization	21.00%
6	9	Test Case Prioritization	17.00%
7	23	UML Diagrams	44.00%

Fig. 2.2: The distribution of articles according to keywords

underscores the varied levels of academic engagement across different facets of test case methodologies within the realm of UML.

A filter was also applied to the publication type of the articles, resulting in the removal of 5 articles. The selected articles' type distribution is displayed in Table 2.2, Figure 2.3. The publisher reviewed the 52 remaining articles, discarding none. By publisher, Table 2.2 lists the articles.

The Figure 2.4, Table 2.3 resulting in the removal of two articles, articles were filtered in the final stage based on their year of publication. After applying qualitative synthesis factors to the remaining 52 articles, two more were discarded. Table 2.3 displays the articles' publication years.

2.3. Research Questions.

Research Question 1: What is the most effective and efficient approach for automated test case generation in object-oriented software development, considering the use of UML behavioral models and diagrams?

Research Question 2: What are the most effective and efficient approaches for automated test case generation in software development, considering the utilization of optimization techniques and UML diagrams?

Research Question 3: How can automated test case generation techniques using UML diagrams be effectively

Table 2.2: Distribution of Articles by Publisher

S.No	Publisher	Ratio of articles
1	Elsevier	8%
2	Springer	6%
3	IEEE	2%
4	Conference	23%
5	Other Journals	62%

Fig. 2.3: The distribution of articles by publisher

utilized to improve software development processes, considering optimization methods, soft computing techniques, and the automation of test case generation?

Research Question 4: How can automated test case generation techniques utilizing UML diagrams be improved to address limitations such as applicability to specific diagram types, complexity limitations, and lack of comparative analysis, while considering factors like model-based testing, optimization, and validation approaches?

Research Question 5: How can the limitations of existing approaches for test case generation and optimization in model-driven software development using UML diagrams be overcome to improve their applicability, effectiveness, and efficiency?

Research Question 6: How can test case prioritization techniques be enhanced to address the limitations identified in the reviewed papers?

3. Literature Review. This review on "Test Case Generation and Optimization" presented in section 3.1 provides valuable insights into the state of software testing today by examining the intricate processes and state-of-the-art methodologies. The architecture diagram shown in figure 3.1 that serves as a visual guide for the plethora of studies, methodologies, and findings that make up this field is used to describe our systematic literature review strategy in detail. These images not only demonstrate the meticulous manner in which data was gathered and examined, but they also demonstrate the connections between various research topics,

Table 2.3: Fraction of articles by year of publication

Article Count	Publish Year
15	2019
7	2020
12	2021
5	2022

ranging from the most recent optimization algorithms to the use of UML diagrams to create test cases. By assembling an extensive array of contemporary models and methodologies, this review seeks to provide readers with a comprehensive understanding of test case generation and optimization. It also emphasizes how crucial systematic reviews are to expanding the realm of software testing possibilities.

The review presented in section 3.2 underscores the significance of prioritizing test cases to boost the effectiveness of software testing procedures. The central component of our study is a meticulously constructed architecture diagram that shown in figure 3.2. It demonstrates the sequential and iterative processes involved in prioritizing test cases, from locating them and grouping them according to their importance to applying various prioritization criteria and algorithms and ultimately executing the tests in an orderly fashion. The iterative refinement inherent in test case prioritization criteria is highlighted by the feedback loop for modifying test case prioritization based on empirical results. We aim to provide you with a comprehensive understanding of the approaches, issues, and advancements in test case prioritization by based our review on this architectural framework. Researchers and practitioners who are attempting to enhance software testing outcomes will benefit from this.

3.1. Test case Generation and Optimization. The use of UML diagrams to streamline test cases in software development was covered by Tiwari, R. G., et al. [1]. Contribution includes recommending the usage of UML diagrams (activity, state, and sequence) and outlining their benefits for streamlining test cases. The technique lacks any actual data or experiments and is based solely on a survey of the literature. The goal is to educate software engineers about the usage of UML diagrams for test case simplification. The absence of empirical data, unresolved difficulties or constraints, and the narrow focus on just three categories of UML diagrams are all drawbacks. To establish efficacy and resolve any difficulties, more study is required.

J. Cvetkovi and M. Cvetkovi., [3] provided a research on the creation of test cases with UML diagrams that concentrated on modelling depression brought on by internet addiction. By recommending a technique for creating test cases using UML diagrams and offering a case study to illustrate its use, the paper makes a contribution to the subject. The process comprises categorising test case creation based on unit diagrams or combinations of UML diagrams and employing a variety of UML diagrams. The objective is to advance the area of software testing by offering a fresh method for creating test cases. The case study's specificity

Fig. 3.1: The process of Test Case Generation and Optimization

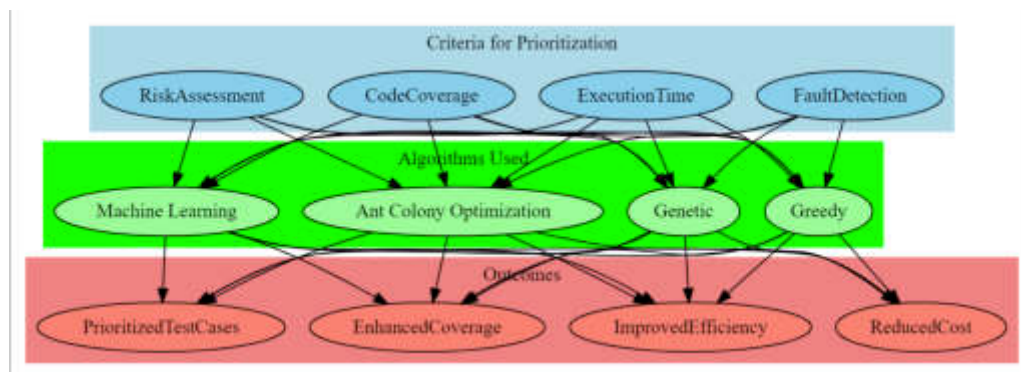

Fig. 3.2: Process model of the Test case Prioritization

and the absence of comparison with other approaches are also drawbacks. An approach for creating test cases from UML sequence diagrams combining MDE (“model-driven engineering”) and MBT (“model-based testing”) methodologies was given by Rocha, M., et al. in [5]. Modifying transformation rules, using real software models in a case study, and using the ModelJUnit and JUnit libraries are all part of the process. The contribution consists of a methodical process for automatically creating test cases from UML models, which raises the productivity and calibre of software development. The inability to use nested combined fragments in sequence diagrams, the manual creation of stubs, and the limited usage of one case study for demonstration are some limitations.

B. N. Biswal. Using UML behavioural models, [6] suggested a technique for creating and refining test cases of object-oriented software. It offers a technique for creating test cases that uses UML activity diagrams, sequence diagrams, as well as class diagrams. An error minimization method for test case optimisation is also presented in the study. Its application to particular categories of object-oriented software as well as reliance on the excellence of UML behavioural models are limitations.

Meena, D.K. [7] A technique for creating test cases using UML diagrams, notably Interaction Overview diagrams as well as Sequence diagrams, was presented by [7]. The difficulty of test case selection in object-oriented programmes is what this aims to address. Building UML diagrams, creating intermediate graphs, and creating test cases that reflect various scenarios are all part of the technique. The paper’s contribution is the message route coverage. Limitations include the fact that it only applies to object-oriented programmes and the absence of actual data contrasting the suggested strategy with other ones.

Jiang, L., and Li, Y. A technique for creating test cases using UML sequence diagrams was covered in [8]. By examining the sequence diagram as well as assessing the message sequence, it gives instructions for creating test cases. The idea is to provide a useful method for testing object-oriented applications. The study does not, however, present a prototype system for autonomous test case generation, and it does not discuss the drawbacks or viability of the suggested approach in practical contexts.

A. Herrmann, M. Felderer, and M. [9] looked at mistakes occurring while manually deriving test cases from state machines and activity diagrams using UML. The goal is to offer instructions for methodically generating test cases while avoiding mistakes. Participants in the methodology's controlled student experiment create test cases from state machines and UML activity diagrams. The study offers a taxonomy of faults, evidence that activity diagrams are more error-prone than state machines, and recommendations for minimising errors. The utilisation of student participation and the emphasis on UML activity diagrams as well as state machines are limitations.

An approach for creating test cases using UML sequence diagrams as well as interaction overview diagrams was proposed by Jena, A. K., et al. in [10]. As part of the technique, produced graphs from various UML components are combined to create test cases and find errors early in the design process. The goal of the study is to identify various error types and raise software quality. The emphasis on a single case study and the lack of a comparison with alternative techniques for creating test cases are both drawbacks.

A. Herrmann, M. Felderer, and M. [11] findings of a controlled experiment [11] examining mistakes caused during manual test case derivation from state machines and UML activity diagrams were provided. The study offers a taxonomy of faults, evidence that activity diagrams are more error-prone than state machines, and recommendations for minimizing errors. The concentration on certain diagram kinds without comparison to other types or automated test case derivation techniques, as well as the sample size's relative smallness, are limitations.

A technique for creating test cases using state chart diagrams and UML use case diagrams was put out by Jagtap, S., et al. [12]. Utilizing testing criteria that address the diagrams' state and transition is part of the technique. The goal is to aid software engineers in the early phases of software development in the creation of efficient test cases. Limitations include the emphasis on use case diagrams as well as state chart diagrams in UML 2.0 and the potential need for manual testing to ensure thorough coverage.

An automated test case creation method for unstructured SysML "Activity Diagrams" (Ads) was provided by Yin, Y., et al. [13]. The process entails converting the ADs into an IBM ("Intermediate Black Box Model"), which is used to generate test cases. The objective is to offer industry practitioners employing SysML ADs an efficient testing methodology. The concentration on the AD model alone, without taking into account other SysML models, is the restriction.

In order to create test cases from UML state chart diagrams, Salman, Y. D., et al. [14] concentrated on finding the most efficient combination of coverage requirements, notably in handling loops. The study suggests appropriate coverage criteria and offers formulas to calculate coverage percentages. The goal is to increase test data generation's efficiency during software testing. The emphasis on UML state chart diagrams and the requirement for context adaption are limitations.

A method for automated test case development utilising UML Statechart as well as Sequence diagrams was proposed by Efendi, N. B. M., et al. [15]. The approach includes using UML diagrams to create test cases automatically. The aim is to keep the price of software development as low as possible. The drawback is the emphasis on UML Statechart and Sequence diagrams at the expense of other UML diagram types.

PSO ("Particle Swarm Optimization") was described by Prakash, V. C., et al. [16] as a tool for automated test case development in combinatorial testing. In order to address the optimisation issue in test case generation, the study offers a comprehensive assessment of PSO and its variations. The goal is to demonstrate how PSO-based algorithms may be used to reduce test suite sizes and boost programme dependability. The emphasis on PSO and its comparison to other optimisation methods is one limitation.

Using a dynamic programming technique and tester specification, Kamonsantiroj, S., et al. [17] suggested a memorising strategy for producing test cases in concurrent UML activity diagrams. The route explosion challenge in testing concurrent systems is the key contribution. The goal is to prevent the development of all feasible concurrent activity routes in order to reduce the explosion of test cases. The application to other diagram types or concurrent systems, as well as the emphasis on concurrency testing in activity diagrams, are limitations.

Mokhati, F.; Dehimi, N. E. H. A novel method for evaluating multi-agent systems using AUML sequence diagrams was put out by [18]. The method addresses interactions between actors and potential scenarios in a parallel, exclusive, or inclusive manner. To make sure that faults found in one interaction or scenario are not

connected to others that are occurring simultaneously or in parallel, it provides plugs utilising OCL restrictions. The goal is to offer a testing strategy that guarantees mistake independence. Only applying to holonic agents and the absence of empirical proof of the efficacy of the suggested strategy are drawbacks.

Dawood, Y. S., and Hashim, N. L. [19] evaluated the prior research on the creation of test cases using UML statechart diagrams. It investigates the domain's algorithms, coverage standards, and assessment techniques. The goal is to highlight discrepancies and give a better knowledge of the test case generating procedures. A content analysis of 24 books in the topic is part of the technique. The emphasis on UML statechart diagrams and the little treatment of prior works are limitations.

A method to produce test cases from software requirements at the use case description level was put out by Alrawashed, T. A., et al. [20]. The method fine-tunes use cases, transforms them into control flow diagrams, and then use a tool to produce test cases. Regression testing is made more effective while test complexity is reduced and test coverage is improved. Limitations include the absence of comparison with current methods and a thorough evaluation of the case study findings.

Using machine learning, Khalifa, E. M., et al. [21] demonstrated a method for creating test cases from use case diagrams. The technique tries to automate the difficult and laborious process of test case generation. In order to increase precision and effectiveness, it employs a metaheuristic method. Information extraction, preprocessing, the use of the metaheuristic approach, and performance evaluation make up the methodology. The application to certain software systems and the reliance on the calibre of use case diagrams are limitations.

A method for creating optimised test cases from UML sequence diagrams using the Firefly algorithm was put forth by Runal, G., et al. [22]. The process of creating test cases will be automated, and the quality and dependability of software systems will be increased. Model-based testing and the structural test selection concept are used in the technique. The emphasis on UML sequence diagrams and possible drawbacks in big and complicated systems are constraints.

A technique for automatically creating executable test scripts for an IoT system using UML state machine diagrams was provided by Swain, R., et al. [23]. The goal is to make testing simpler and require less manual labour. The process entails the creation of mappings between actions and assertions as well as between transition events and functions. The algorithm creates transition pathways together with the corresponding assertions and actions. The contribution is a unique strategy that is shown by a case study on a diabetic monitoring and control system. Limitations include the absence of transition guard evaluation and the potential for method improvement through symbolic evaluation.

ALI, H. M. B. M. [24] addressed looping and iteration issues in order to improve the production of test cases from UML sequence diagrams. The contribution is an enhanced method that gives software testers a quick and easy approach to create test cases. A case study is used in the approach to show how the suggested strategy is used and how it compares to other strategies. The objective is to address the problem of producing test cases from UML sequence diagrams. The emphasis on looping and iteration issues as well as the need for knowledge of UML sequence diagrams are limitations. In their discussion of the automation of software development processes in telecom carrier networks, Kikuma, K., et al. [25] emphasised cost savings while upholding dependability and safety. The method's creation, which uses mathematical principles to boost learning effectiveness in software testing, is the contribution. The methodology makes use of the preparation of test cases and the use of mathematical techniques by qualified engineers. The report emphasises the significance of using the preparation procedure to its full potential. Data creation from already-existing design documentation is one limitation.

A methodical process for creating test cases from a UML model, especially from UML Sequence Diagrams, was provided by Rocha, M., et al. [26]. The contributions include the usage of the ModelJUnit and JUnit libraries for automated test case generation as well as the design of transformation rules using ATL. The goal is to provide UML Sequence Diagrams a defined meaning and make them appropriate for automated testing. ModelJUnit and JUnit libraries are used in the process, which entails translating UML Sequence Diagrams into Extended Finite State Machines. The emphasis on UML Sequence Diagrams and the efficacy relying on the calibre of the UML model are limitations.

Tiwari, H. Swathi, B. [27] investigates soft computing approaches like genetic algorithms and artificial bee colonies while focusing on test case creation in software testing. The contributions also explore soft computing approaches, provide an assessment criterion, and examine the value of code coverage in addition to underlining

the significance of test case production. The methodology uses soft computing techniques to generate test cases and analyse code coverage to determine efficacy. To give a thorough grasp of test case generation and its importance is the goal. The emphasis on soft computing methods and the empirical study's constrained scope are both drawbacks.

Soni, D. Jain, P. [28] gave a survey on several methods for prioritising and generating test cases using UML diagrams. A thorough analysis of relevant work, a comparison of methods, and the identification of knowledge gaps are all included in the contributions. The process entails gathering data and comparing algorithms according to their efficacy. The goal is to outline test case creation techniques using UML diagrams and identify potential directions for further study. The emphasis on UML diagrams as well as the absence of a thorough analysis and useful implementation are limitations.

Using UML interaction diagrams, Minhas, N. M., et al. [29] developed a methodical mapping of test case generating approaches. The objective is to contrast various methods based on their strengths and weaknesses. The study evaluates the original studies' reporting quality and identifies any potential errors. An overview of the possibilities and constraints of test case generating methods utilising UML interaction diagrams is provided in this work. The report demonstrates that the examined studies lacked empirical evaluation in industry contexts and conformity to research principles. It implies that the industry needs stronger tool support for test case creation methods based on UML interaction diagrams.

Using class and activity diagrams, Mburu, J. M., et al. [30] suggested an improved multiview test case generating approach for object-oriented software. The creation and use of the MUTCAS Generator technology constitute the contribution. Utilising UML models, the technique creates test cases automatically that include both structural and behavioural aspects of the system. The aim is to allow early identification of software flaws and to solve the issues of time, money, and effort necessary for manual test case development. Limitations include the fact that they only apply to UML models, the possibility of problems in complicated systems, and reliance on the calibre of the UML models.

Dash and Panda, M. [31] An overview of the model-based and search-based testing strategies used to create test cases and test data for object-oriented programmes can be found in [31]. One aspect of the contribution is the framework for search-based testing that uses hybrid metaheuristics algorithms. The process includes a literature research to compile data on testing procedures and approaches. A framework for search-based testing of object-oriented programmes is proposed together with insights into the various testing methodologies. The suggested paradigm has limitations, such as the lack of a comparative analysis and empirical backing.

S. B. Tatale, V. C. Prakash, & Co. [32] concentrated on leveraging UML Sequence and Activity diagrams to automatically generate test cases. The contribution is a feasibility study on producing test cases focused on combinatorial logic using UML diagrams. The process entails employing dynamic slicing techniques and converting UML diagrams into tree or graph representations. The goal is to present a fresh method for creating test cases automatically from a system's design specification. The only emphasis on UML Sequence and Activity diagrams without taking into account other UML diagrams is one limitation.

K. Jin, K. Lano, and K. A systematic literature review (SLR) on creating test cases from UML diagrams was published in [33]. The contribution consists of identifying methods, results, research trends, gaps, and suggestions for future study. The approach entails running an SLR and using predetermined criteria to choose pertinent documents. The goal is to give a summary of the research on creating test cases from UML diagrams. The concentration on UML diagrams alone without taking other modelling languages into account is the restriction.

For the purpose of load testing mobile apps, Ali, A., et al. [34] suggested an autonomous model-based test case creation technique. An technique that minimises testing time while validating requirements, including both performance and functional elements, is the contribution. The process includes model-based testing, UML model creation, test case generation, and performance evaluation. The goal is to solve time-to-market restrictions and load testing of mobile applications. The absence of a thorough review and the choice of workload are limitations.

A technique for automatically creating test cases for flight control systems using UML state diagrams was developed by Fan, C., and Zou, P. [35]. A real-time extension strategy, a time domain equivalence partition method, and a feasibility check of the approach are the contributions. Modelling flight control systems, ex-

panding UML state diagrams, creating equivalence classes, creating test pathways, and automating test case creation are all part of the technique. The goal is to increase the efficacy and efficiency of flight control system testing. Only being applicable to UML state diagrams, having a cap on complexity, and not taking component interactions into account are some of the restrictions.

Using a Basic Genetic Algorithm (BGA), Sahoo, R. K., et al. [36] suggested a method for improving test data generated from UML activity and state chart diagrams. To produce test data that validates system requirements is the goal. The automated creation of specification-centered test data from UML models is the contribution. The process entails integrating diagrams into intermediate graphical representations, then optimising them using BGA. The paper examines findings and offers a case study. The application to particular diagram kinds, reliance on input quality and BGA settings, and absence of comparison analysis are some limitations.

J. Mburu, J. G. Ndia, & Co. [37] provided a comprehensive mapping research on approaches for creating and optimising test cases based on UML models. Finding trends and gaps in the study is the goal. A comprehensive literature review of publications published between 2010 and 2022 is part of the process. Contributions include an overview of trends and gaps, a list of often used search strategies, a need for greater study on combinational UML diagrams and optimisation, and a list of frequently used validation strategies. The focus on test case optimisation, automation, and combinational UML diagrams is restricted, and the assessment of research is also limited.

Prakash, V. C., Tatala, S. A method for automatically creating combinatorial test cases from UML Activity Diagrams was proposed in [38]. The key contribution is the creation of a programme that takes input parameters from UML Activity Diagrams and use the Particle Swarm Optimisation technique to produce the optimal number of test cases. To show how well the method works in practise, a case study of the Indian Railway Reservation System is presented. The technique uses the Particle Swarm Optimisation algorithm for test case generation, constraint detection, and parameter extraction. To reduce time and effort, test case generation is automated. Application to UML Activity Diagrams only, possible efficacy restrictions in large systems, and appropriateness for certain testing situations are some limits.

A technique for producing scenario-based test cases from UML-ADs (“UML activity diagrams”) was put out by Hettab, A., et al. in [39]. The primary contribution enables early testing in the software development life cycle by automatically generating test cases from UML-ADs. According to the technique, test scenarios are derived from EADG models by creating an EADG (“extended activity dependency graph”) from UML-ADs. By employing graphical simulation to apply the test scenarios to UML-ADs, testers may verify the test scenarios. Through mutation analysis, the method’s capacity to discover faults is assessed. Application to UML-ADs alone, possible drawbacks in big and complicated systems, and reliance on the correctness of UML-ADs are some constraints.

At the beginning of software development, Tamizharasi, A., and Ezhumalai, P. [40] presented a technique for producing optimised test data from UML models using the Hybrid GBCSA (“Genetic and Crow Search Algorithm”). The contribution consists of using GBCSA to streamline the test suite by eliminating unnecessary test data and focusing the search on global optima. Comparing experimental results to conventional crow search and genetic optimisation methods, they show 100% route coverage and time efficiency. To assess the suggested technique, UML models are used, along with experimentation. The goal is to show the method’s efficacy and tackle the problem of producing test data for intricate software systems. The absence of a thorough examination of constraints, comparison with alternative approaches, and scalability for big systems are among the drawbacks.

Based on various coverage requirements, Pradhan, S., et al. [41] suggested methods for creating test cases from a state chart diagram. By addressing an object’s states and transitions, the aim is to spot state-based defects. In order to build test cases based on various coverage requirements, the process entails converting the state chart diagram into a SCIG (“State Chart Intermediate Graph”). In this study, efficient state-based criterion algorithms like RTP (“Round Trip Path”) and ATP (“All Transition Pair”) are introduced. There includes discussion of the two case studies, stack operation and vending machine automation system. The algorithmic suggestions for creating test cases based on coverage requirements constitute the contribution. The restriction is ATP’s inability to provide complete transition coverage.

Hammad, M., and Hamza, Z. A. [42] gave a case study on the creation of test sequences, concentrating on

the usage of a previously suggested method based on use case model analysis. The process entails dissecting the UML use case diagram, transforming it into activity diagrams, simplification, and information extraction. The purpose of the study is to show how well this method works at producing test sequences for software testing. The method's shortcomings, however, include its restricted application to UML use case models, reliance on a single case study, and lack of a comparison with other methodologies already in use.

Sumalatha, V., & Raju, G. S. V. P. [43] used UML activity diagrams to solve the problem of test case creation in model-driven software development. For the purposes of test case creation, reduction, and prioritisation, the authors suggest using Evolutionary and Greedy Heuristic algorithms. The authors of the study compare their methodology to current practises and use UML activity diagrams in an effort to increase the efficacy of software testing. The examination of a single case study, the absence of in-depth comparisons with other methodologies, and algorithm constraints are some of the shortcomings, though.

An innovative method for creating and refining test cases from UML design diagrams was put forth by Khurana, N., et al. [44]. The SYTG ("system graph"), which is explored using a Genetic Algorithm, is created by combining use case, activity, and sequence diagrams. Its limitations include the fact that it only applies to UML design diagrams, how dependent it is on the quality of the input diagrams, and how well suited it is for big and complicated systems.

Using a hybrid bee colony approach, Sahoo, R. K., et al. [45] described a method for creating and refining test cases from combinational UML diagrams. The contribution is an automated test case generation method that aims to make software testing more effective and affordable. Although the technique is model-driven testing-based, it has several drawbacks, such as its emphasis on combinatorial UML diagrams and possible customisation needs for particular software systems.

Chandra and Meiliana, L. C. D. [46] A approach for automatically creating and improving test cases in software testing was put out by [46]. The goal is to use resources more efficiently, especially in the field of mobile technology. Utilising a genetic algorithm, the process entails creating test cases from combinational UML diagrams. Despite offering a beneficial technique, the study has certain drawbacks, such as a small population size and few genetic algorithm operators.

Tiwari, H. Swathi, B. [47] A method for creating test cases for web applications utilising input values and data dependencies was put forth in [47]. Pairwise testing, a genetic algorithm, and a system graph are all components of the process. The contribution of the research is the suggested approach for online applications, which addresses the challenging task of test case creation. The emphasis on functional testing and the absence of other testing kinds, such as security testing, are drawbacks, though.

S. S. Panigrahi. [48] suggested a technique for automatically creating test cases that makes use of a hybrid firefly algorithm and UML Activity diagrams. The strategy focuses on choosing the best test cases in terms of cost and coverage. The case study of an ATM withdrawal strategy is presented in the paper to illustrate the viability of the suggested approach. The objective is to lessen the amount of effort and time needed for software testing. However, drawbacks include the lack of a comparison with alternative approaches and the evaluation's constrained scope, which was only the ATM withdrawal system case study. The contribution. Methodology, merits and limits of these contemporary models have been listed in table 3.1 for quick view.

In table 3.1 there are some research gaps in the use of UML diagrams for test case generation, optimization, and prioritization across multiple domains. One recurring theme is that people tend to focus on specific UML diagrams, such as sequence and activity diagrams, rather than exploring other types of diagrams. An important issue is that there are few empirical studies comparing the proposed methods to existing methods. This lack of comparative data makes it more difficult to demonstrate the effectiveness of new methods and determine how they can be applied in various software development scenarios.

In future research, it may be beneficial to look beyond simple UML diagrams and include modeling languages that are more diverse and complex. This could result in deeper insights and stronger testing frameworks. Furthermore, future research should focus on developing real-world studies that not only compare different test case generation methods, but also assess their effectiveness and scalability. Filling in these gaps can aid in the development of more complex and useful test case strategies, resulting in improvements in automated testing that can keep up with changing software system requirements.

Table 3.1: Summary of contemporary models on test case generation, optimization, and prioritization.

Author	Contribution	Methodology	Merits	Limits
B. N. Biswal [6]	Technique for creating and refining test cases of object-oriented software	UML activity diagrams, sequence diagrams, class diagrams	Error minimization method for test case optimization	Application limited to particular categories of object-oriented software, reliance on the excellence of UML behavioural models
Meena, D.K. [7]	Technique for creating test cases using UML diagrams	Interaction Overview diagrams, Sequence diagrams	Message route coverage	Limited to object-oriented programmes, absence of actual data contrasting the suggested strategy with other ones
Jiang, L., and Li, Y. [8]	Technique for creating test cases using UML sequence diagrams	Examination of sequence diagram, message sequence assessment	Useful method for testing object-oriented applications	No prototype system for autonomous test case generation, no discussion of drawbacks or viability of the suggested approach in practical contexts
A. Herrmann, M. Felderer, and M. [9]	Instructions for methodically generating test cases from state machines and activity diagrams	Student experiment, controlled methodology	Taxonomy of faults, evidence of activity diagrams being more error-prone, error minimization	Utilization of student participation, emphasis on UML activity diagrams and state machines
Jena, A. K., et al. [10]	Approach for creating test cases using UML sequence diagrams and interaction overview diagrams	Combination of produced graphs from UML components, error identification	Early error detection, software quality improvement	Emphasis on a single case study, lack of comparison with alternative techniques for creating test cases
A. Herrmann, M. Felderer, and M. [11]	Controlled experiment examining mistakes in manual test case derivation	Student experiment, taxonomy of faults, evidence of activity diagrams being error-prone	Error minimization, recommendations for minimizing errors	Concentration on certain diagram kinds without comparison to other types or automated test case derivation techniques, relative smallness of sample size
Jagtap, S., et al. [12]	Technique for creating test cases using state chart diagrams and use case diagrams	Testing criteria addressing state and transition in the diagrams	Creation of efficient test cases during early phases of software development	Emphasis on use case diagrams and state chart diagrams in UML 2.0, potential need for manual testing to ensure thorough coverage
Yin, Y., et al. [13]	Automated test case creation method using unstructured SysML ADs	Conversion of ADs into Intermediate Black Box Model, test case generation	Efficient testing methodology for industry practitioners employing SysML Ads	Concentration on the AD model alone, without considering other SysML models
Salman, Y. D., et al. [14]	Efficient combination of coverage requirements in test case generation	Emphasis on UML state chart diagrams, handling loops	Increased efficiency in test data generation during software testing	Emphasis on UML state chart diagrams, requirement for context adaptation
Efendi, N. B. M., et al. [15]	Automated test case development using UML Statechart and Sequence diagrams	Utilization of UML diagrams for automatic test case creation	Cost reduction in software development	Emphasis on UML Statechart and Sequence diagrams at the expense of other
Prakash, V. C., et al. [16]	Tool for automated test case development using Particle Swarm Optimization (PSO)	Comprehensive assessment of PSO and its variations	Reduction of test suite sizes, boost in program dependability	Emphasis on PSO and its comparison to other optimization methods

Table 3.1 – continued from previous page.

Author	Contribution	Methodology	Merits	Limits
Hettab, A., et al. [39]	Technique for producing scenario-based test cases from UML activity diagrams	EADG, graphical simulation	Early testing in software development, automatic generation of test cases from UML activity diagrams	Application limited to UML activity diagrams, possible drawbacks in big and complicated systems, reliance on the correctness of UML activity diagrams
Tamizharasi, A., and Ezhumalai, P. [40]	Producing optimised test data from UML models using the Hybrid (“GBCSA”)	Hybrid GBCSA (“Genetic and Crow Search Algorithm”)	Streamlining the test suite, elimination of unnecessary test data	Absence of thorough examination of constraints, comparison with alternative approaches, scalability for big systems
Pradhan, S., et al. [41]	Methods for creating test cases from a state chart diagram	Conversion of state chart diagram into SCIG (“State Chart Intermediate Graph”)	Spotting state-based defects, algorithmic suggestions for test case creation	Inability of ATP to provide complete transition coverage
Hammad, M., and Hamza, Z. A. [42]	Case study on the creation of test sequences using use case model analysis	UML use case diagram analysis, transformation into activity diagrams	Production of test sequences for software testing	Restricted application to UML use case models, reliance on a single case study, lack of comparison with other methodologies
Sumalatha, V., & Raju, G. S. V. P. [43]	Test case creation, reduction, and prioritisation using UML activity diagrams	Evolutionary and Greedy Heuristic algorithms	Increased efficacy of software testing using UML activity diagrams	Examination limited to a single case study, absence of in-depth comparisons with other methodologies, algorithm constraints
Khurana, N., et al. [44]	Creating and refining test cases from UML design diagrams	Genetic Algorithm, creation of (“SYTG”)	Combination of different UML design diagrams, refinement of test cases	Application limited to UML design diagrams, dependence on input diagram quality, suitability for big and complex systems
Sahoo, R. K., et al. [45]	Creating and refining test cases from combinational UML diagrams	Hybrid bee colony approach, model-driven testing	Automated test case generation, improved software testing	Emphasis on combinational UML diagrams, customization needs for specific software systems
Chandra and Meiliana, L. C. D. [46]	Automatic creation and improvement of test cases in software testing	Genetic Algorithm, creation of test cases from combinational UML diagrams	Efficient resource utilization, application in the mobile technology field	Small population size, limited genetic algorithm operators
Tiwari, H. Swathi, B. [47]	Creation of test cases for web applications using input values and data dependencies	Pairwise testing, genetic algorithm, system graph	Approach for online applications, addressing the challenge of test case creation	Emphasis on functional testing, absence of other testing types
S. S. Panigrahi [48]	Automatic creation of test cases using a hybrid firefly algorithm and UML Activity diagrams	Hybrid firefly algorithm, UML Activity diagrams	Reduction in effort and time for software testing	Lack of comparison with alternative approaches, evaluation limited to a specific case study

3.2. Test Case Prioritization. Regression testing test case prioritisation method employing sequence diagrams and labelled transition systems was suggested by As’ Sahra, N. F., & Komputeran, F. [49]. The method use Bayesian Networks to incorporate source code modifications, software fault-proneness, as well as test coverage data into a single model. However, the research makes an assumption about test case independence that could not hold true in actual circumstances.

A novel method of test case prioritisation for model-based mutation testing in the automotive sector was introduced by Shin, K. W., and Lim, D. J. [50]. They use the UML statechart to create a software model, use

mutation operators to generate mutations, and suggest a TCP technique based on the ("alternating variable method") AVM. The study covers actual research in the automobile sector, however its application outside the sector and the quantity of investigated problems are also limits.

The use of machine learning approaches in "test case prioritization" (TCP) for regression testing was examined by Meçe, E. K., Paci, and Binjaku [51]. They review current research that employs machine learning in TCP and provide details on methods, measurements, data, benefits, and drawbacks. There are drawbacks, such as the potential rejection of important test cases via selection approaches and the requirement for a significant quantity of data for efficient machine learning methods.

An autonomous test route generating method and prioritisation model for software testing were suggested by Fan, L., Wang, Y., and Liu [52]. They build a priority model to order the test pathways, design the activity flow graph, and specify the mapping rules from UML activity diagram to the graph. The article does not, however, compare new algorithms to old ones or evaluate large-scale software systems. It also presupposes that UML activity diagrams are accessible.

For user interface testing, Nguyen, V., & Le, B. [53] introduced a unique test prioritisation technique called RLTCP. The technique uses the coverage graph and reinforcement learning (RL) to prioritise test cases. With an experimental assessment contrasting it with other approaches, the research builds on a past work on prioritising UI automated test cases using RL. The drawback is that it ignores alternative testing methods in favour of a narrow emphasis on user interface testing.

A test route prioritisation approach based on the testers' interests, as well as the altered area in UML activity diagrams, was proposed by Sornkliang, W., and Phetkaew, T. [54]. They use various techniques to give weights to symbols and then order test pathways accordingly. The technique tries to aid testers in swiftly identifying critical issues. The dependence on testers' preferences and the work involved in weight assignment are limitations.

The contribution of the Methodology, merits and limits of these contemporary models have been listed as a table for quick view table 3.2.

Table 3.2 a thorough examination of the most recent models for test case prioritization, several research gaps were identified that could be addressed in future studies. Sahra, N. F., and Komputeran, F. [49] use Bayesian Networks for prioritization, assuming test case independence, which may not be true in practice. Future research could look into models that account for interdependence among test cases. Shin, K. W., and Lim, D. J. [50] use model-based mutation testing exclusively in the automotive industry. This demonstrates the need for mutation testing to be applied in more areas and studied in greater depth. The machine learning approach proposed by Meçe, E. K., Paci, and Binjaku [51] shows promise in terms of efficiency, but it may miss important test cases and need a large amount of data. This suggests that we need more reliable machine learning models that do not require as much data.

Fan, L., Wang, Y., and Liu [52] propose an autonomous test route generation method that needs to be compared to traditional algorithms and tested in large-scale systems. This opens the door for future research to confirm its usefulness and potential for expansion. The RL-based method developed by Nguyen, V., and Le, B. [53] for testing user interfaces is novel and intriguing, but it only tests a few things. This demonstrates that reinforcement learning could be applied in a broader range of testing scenarios. Finally, Sornkliang, W., and Phetkaew, T. [54] interest-based route prioritization heavily relies on tester input to assign weights. This demonstrates the need for more automated, objective prioritization frameworks with less human bias and effort. Filling these identified gaps would significantly improve the development of test case prioritization methods, making regression testing more useful.

4. Observations. The review of the articles [6–15] highlights various techniques and approaches for automated test case generation using UML behavioral models and diagrams in object-oriented software development. Each article focuses on specific UML models or diagrams and has some limitations. The most effective and efficient automated test case generation method that makes use of UML behavioral models and diagrams needs to be determined in order to address these limitations and provide guidance to practitioners. The identification of best practices for automated test case generation in object-oriented software development will be made possible by this research question, which will also allow for a thorough examination of current approaches, comparison of their effectiveness and efficiency.

Table 3.2: Summary of contemporary models on test case prioritization

Author	Contribution	Methodology	Merits	Limits
As' Sahra, N. F., & Komputeran, F. [49]	Regression testing test case prioritisation method employing sequence diagrams and labelled transition systems	Bayesian Networks	Incorporation of source code modifications, fault-proneness, and test coverage	Assumption of test case independence that may not hold true in actual circumstances
Shin, K. W., and Lim, D. J. [50]	Test case prioritisation for model-based mutation testing in the automotive sector	UML statechart, mutation operators, TCP technique based on AVM	Application in the automotive sector, software model creation	Limited application outside the automotive sector, limited investigation of problems
Meçe, E. K., Paci, and Binjaku [51]	Use of machine learning approaches in test case prioritization for regression testing	Review of existing research, analysis of methods, measurements, data	Potential for efficient machine learning methods, insights into benefits	Potential rejection of important test cases, requirement for a significant amount of data
Fan, L., Wang, Y., and Liu [52]	Autonomous test route generating method and prioritisation model for software testing	Priority model, activity flow graph, mapping rules from UML activity diagram	Autonomous test route generation, prioritisation of test pathways	Lack of comparison with old algorithms, lack of evaluation on large-scale software systems, assumption of accessibility of UML activity diagrams
Nguyen, V., & Le, B. [53]	Test prioritisation technique called RLTCP for user interface testing	Coverage graph, RL ("reinforcement learning")	Prioritisation of test cases in user interface testing	Narrow emphasis on user interface testing, ignoring alternative testing methods
Sornklang, W., and Phetkaew, T. [54]	Test route prioritisation approach based on testers' interests and altered area in UML activity diagrams	Weight assignment techniques, ordering of test pathways based on weights	Aid in quickly identifying critical issues, prioritisation based on interests	Dependence on testers' preferences, effort required for weight assignment

The review of the articles [16–24] highlights different approaches for automated test case generation that use optimization techniques and UML diagrams. The article focuses on specific optimization techniques or UML diagram types and has some limitations. In order to address these limitations and offer guidance for practitioners, identify the most effective and efficient approaches for automated test case generation that combine optimization techniques with different kinds of UML diagrams. This research question will enable a thorough examination of current approaches, comparison of their effectiveness, and identification of best practices for automated test case generation in software development.

The review of the articles [25–32], [1], and [5] highlights different approaches and methodologies for automated test case generation using UML diagrams. Each article focuses on specific optimization techniques, soft computing, or UML diagrams and has its own limitations. In order to address these limitations and offer thorough recommendations for software development, it is important to investigate how various methodologies and techniques can be effectively combined to improve test case generation using UML diagrams. In order to enhance the effectiveness and efficiency of test case generation and software development, this research question will enable an exploration of optimization methods, soft computing techniques, and automation approaches.

Reasoning the review of the articles [33–41] reveals limitations and opportunities for automated test case generation using UML diagrams. Limitations include a lack of comparative analysis or thorough evaluation, a focus on specific diagram types, and applicability to complex systems. To overcome these limitations and enhance the effectiveness of test case generation, look into how automated techniques can be improved to address the identified challenges. This research question will examine the exploration of factors such as model-based testing, optimization techniques, and validation approaches to enhance the applicability, efficiency, and effectiveness of automated test case generation using UML diagrams. By addressing these limitations, software developers can enhance test case generation to support more complex systems, stronger comparative analysis, and evaluation.

The review of the articles [42–46] highlights common limitations in current approaches, including a focus on specific diagram types, reliance on input diagram quality, customization demands, and limitations in algorithm design. The applicability and effectiveness of the suggested methods are restricted by these limitations. More research is needed to address these limitations, create better approaches that can be used more broadly, improve software testing effectiveness, and maximize test case generation and prioritization. By looking into and addressing these limitations, researchers can promote model-driven software development and test methodologies.

The review of the papers [47–54] highlights several limitations in the current test case prioritization techniques. These limitations include limited applicability outside of case domains, omission of crucial test cases, lack of comparison with current algorithms, reliance on a specific type of testing, and reliance on testers' interests. It is important to investigate and suggest improvements to current techniques in order to address these limitations and enhance the effectiveness and efficiency of test case prioritization. Considering the limitations of the reviewed papers, this research question allows for the exploration of potential solutions and advancements in test case prioritization.

5. Implications and possible future research. Software testing researchers and practitioners can benefit from a thorough literature review on the topic of creating test cases from UML diagrams in a number of ways. These ramifications point to potential directions for future investigation.

1. **Research Gaps and Deficiencies:** The review points out research gaps and deficiencies in the literature. By highlighting areas that haven't been addressed, these gaps can guide future research efforts. Filling these gaps can be the focus of empirical studies, novel methodologies, and alternative approaches to test case generation from UML diagrams.
2. **Comparative Evaluation:** The review demonstrates the dearth of empirical support and thorough comparative evaluations in many studies. Future research may highlight the necessity of conducting thorough comparative analyses to assess the effectiveness, efficiency, and applicability of different test case generation techniques. Comparative studies assist researchers and practitioners in selecting the most appropriate methodology for their specific requirements.
3. **Generalizability and Applicability:** Identify and discuss the applicability and generalizability limitations of the suggested approaches. Research should focus on creating techniques that can handle various types of UML diagrams rather than just specific diagram types like activity and design diagrams. In different software development contexts, look into ways to scale and make the approaches effective.
4. **Algorithmic Improvements:** Deal with the algorithmic elements' limitations of the suggested approaches. Future research should improve the methods' heuristic and evolutionary algorithms. Investigate advanced optimization techniques, optimize algorithm parameters, or develop hybrid approaches to improve the effectiveness and efficiency of test case generation and optimization.
5. **Quality Assurance of UML Diagrams:** Examine techniques to enhance the accuracy and coherence of UML diagrams used for test case generation and optimization. To ensure that diagrams are accurate and complete, develop automated validation and verification techniques. Investigate techniques to improve UML diagram clarity and interpretability to facilitate test case generation, as well as approaches to handle incomplete or inconsistent diagrams.
6. **Integration of Testing Types:** Go beyond functional tests and incorporate other test types using the recommended approaches. Security, performance, usability, and other testing types should be considered in test case generation and optimization. This ensures that various quality-related issues are addressed during software testing.
7. **Automation and Tool Support:** The review highlights the importance of automation and tool support in test case generation from UML diagrams. Future research can focus on automated frameworks and tools that provide effective test case generation and integrate with UML modeling tools. These tools can facilitate UML-based test practices, reduce manual labor, and enhance productivity.
8. **Scalability and Complexity:** For large and complex software systems, many studies overlook the scalability of test case generation techniques. Future research can address these issues because modern software systems are larger and more complex than ever. In order to address scalability concerns, system complexity, and resource efficiency during test case generation, this includes looking into techniques.

9. **Criteria for Coverage and Optimization:** Review highlights the importance of coverage criteria and optimization techniques in test case generation: In order to produce optimized test cases with high coverage and low redundancy, future research can create sophisticated optimization algorithms, hybrid approaches, and intelligent techniques. Another important area of research is the investigation of novel coverage criteria and the assessment of their effectiveness in detecting different types of faults.
10. **Other Languages for Modeling and Integration:** While other software engineering modeling languages are explored, UML diagrams are the main focus of the review. Future research can examine test case generation techniques for these alternative modeling languages in an effort to enhance the effectiveness and efficiency of test case modeling.
11. **Real-world Evaluation:** Several reviewed studies lacked adequate validation and assessment. In real-world software development projects, test case generation techniques can be applied and evaluated as a research topic. The proposed methods may be assessed for effectiveness and applicability by incorporating realistic software systems, industry partnerships, and case studies from diverse fields.

5.1. Test case Generation and Optimization.

- Utilizing evolutionary and heuristic algorithms, along with UML diagrams, can improve test case generation and prioritization.
- Comprehensive models, like System Graphs, offer a holistic approach to test case generation and optimization.
- Hybrid optimization algorithms and model-driven testing methodologies show promise for automated and cost-effective software testing.
- Evaluating and comparing the performance of different algorithms and approaches for test case generation and prioritization.
- Investigating the applicability of proposed techniques to various types of UML diagrams and software systems.
- Addressing limitations related to input diagram quality, scalability, customization requirements, and the need for flexible solutions.
- Assessing the effectiveness and efficiency of hybrid optimization algorithms in real-world scenarios and comparing them to alternative approaches.
- Exploring the impact of population size, operators, and optimization techniques on test case generation and optimization.
- Extending solutions to address various testing scenarios, assessing their effectiveness across various applications, and managing the growing complexity of software systems.
- For test case prioritization techniques to be effective in practical settings, test case dependencies and relationships must be taken into account.
- Integrating multiple factors, such as source code changes, fault-proneness, and test coverage data, into unified models shows potential for enhancing test case prioritization.
- Machine learning techniques offer improved efficiency but require careful consideration of data availability and the potential exclusion of critical test cases.
- To develop test case prioritization techniques that are capable of handling dependencies and inter-test case relationships, more research is needed.
- Investigate ways to incorporate metrics and factors into prioritization models to increase their thoroughness and accuracy.
- Look into alternative data sources that can offer trustworthy information for prioritization based on machine learning, or investigate ways to lessen the reliance on large amounts of data.
- Evaluate the suggested techniques' generalizability and scalability on complex software systems.
- To develop versatile techniques, broaden your research beyond particular domains or testing types.
- Consider ways to enhance or automate weight assignment for more effective test case prioritization. By addressing these implications and exploring the suggested future research directions, researchers can advance the field of test case generation from UML diagrams, improve the efficiency and effectiveness of software testing practices, and contribute to the development of reliable and high-quality software systems.

6. Conclusion. The current state of research in this field is clarified by the systematic literature review on creating, optimizing, and prioritizing test cases from UML diagrams. Along with implications and future research directions, we review research trends, approaches, limitations, and gaps. Several important areas for additional research are highlighted in the review. The development of automated tools and frameworks for seamless integration with UML modeling tools, scalability and complexity challenges in large and complex software systems, advanced optimization algorithms and coverage criteria to generate optimized test cases, and investigation of test case generation techniques for alternative modeling languages are a few examples. The field of test case generation from UML diagrams can progress by addressing these implications and following recommended future case research directions. The effectiveness and efficiency of software test case generation techniques can be improved, and researchers can offer testers useful solutions. To aid in the development of dependable and superior software systems, they can decrease manual labor, increase automation, and enhance test procedures. The researchers and practitioners in the field of software testing gain from this systematic review of the literature. It discusses current methods, makes recommendations for advancements, and establishes the foundation for future research. The software development industry will benefit from researchers' use of the insights from this review to enhance test case generation from UML diagrams.

HIGH SPEED LOW POWER ANALYSIS OF 12 TRANSISTORS 2×4 LINE DECODER USING 45GPDK TECHNOLOGY

SRUTHI PAVANI JAVVADI* C R S HANUMAN† SIVADURGARAO PARASA‡ AND SANNAJAJI NARAGANENI§

Abstract. This paper proposes the high speed low power analysis of 12 transistors 2×4 Low Power (LP) and Low Power Inverting (LPI) Decoders by using Dual Value Logic (DVL) and Complementary Metal Oxide Semiconductor (CMOS) Logic. A huge challenge faced by this era of developing is power reduction. The LP circuit design is a requesting issue in high performance digital frameworks, for example, microchips, DSPs and other different applications. Power and speed are the main highlights considered while comparing any design. Diminishing chip area is additionally truly impressive factor, designers need to recall when suggesting any novel design. 2×4 LP and LPI Decoders using 12T (Transistor) is used for conversion of binary inputs to associated output bits in a pattern. A novel design (CMOS logic and DVL logic) of 2×4 LP and LPI Decoders using 12T is proposed with area optimization, LP and high speed in this paper. Delay and power is evaluated between the novel design and CMOS logic. The novel design of 12T LP and LPI 2×4 Decoders is 60.72% optimized for power in contrast to CMOS logic design at a typical value of 1.8V. The proposed method has been validated using Cadence 45 GPDK (Generic Product Design Key) Virtuoso Tool.

Key words: CMOS and DVL, LP Decoder, LPI Decoder and 12T.

1. Introduction. The bulk integrated circuits consist primarily of logic gates created utilizing static CMOS circuits [1]. The pullup PMOS and NMOS pulldown network are the two main components of a CMOS circuit. Display resilience in the face of background noise and device fluctuations, consistent performance at low voltages and small transistor sizes are two advantages of CMOS circuitry [2]. Since CMOS circuits can only accept inputs at the transistor's gate terminals, fewer building blocks are available when synthesizing cell-based logic. To compete with CMOS logic, the 1990s saw the development of Pass Transistor Logic (PTL) [3]. When compared to CMOS logic [4], pass transistor logic has advantages in terms of speed, power, and area. No matter which diffusion terminals of the transistors the inputs are tied to the either source/drain or gate, determines The primary design difference between pass transistor circuits. The two most popular techniques for building pass transistor circuits are, at first the PMOS and NMOS transistors are used. while in the second, a transmission gate is used to combine the two types of transistors in parallel [5].

The requirement for miniaturization and voltage scaling are two examples of how advances in VLSI technology have imposed new requirements on the design of swift, space- saving, and low-power logic systems. For high-performance computing devices like microprocessors and digital signal processors, LP design is a significant challenge. In computing, A straightforward combinational circuit called a decoder that transforms series of input signals into another code. Seven-segment displays, address decoding with in arrays of memory, data de-multiplexing and microchip/microcontroller personal based architectures are just a few of the many uses for line Decoders. Address Decoders are critical components because their design heavily influences consumption of power and access time of the SRAM [6] memory cell. For the sake of lowering the electrical bill, delay, and transistor count when constructing Decoders, a novel mixed logic approach is presented in this study [7].

2. Literature. Binary codes in digital systems are used to represent discrete amounts of information. An n-bit binary code can represent up to n distinct pieces of encoded data. Combining many circuits, a decoder converts binary data from n input lines to a maximum of $2 \times n$ different output lines or fewer if the n-bit coded data contains any unused combinations [8]. The circuits were looked at. These decoders are n-to-m line and produce the $m = 2 \times n$ input variable minterms.

A decoder with 2×4 lines produces four outputs from two inputs. Depending on the corresponding input combinations, there will only one active output at any given time. Table 2.1 summarizes the non-inverting 2×4 decoder's truth table [9], inputs A and B produces D_0, D_1, D_2 & D_3 as outputs. The complimentary outputs I_0, I_1, I_2 & I_3 produced by inverted 2×4 Decoder are always set to logic 0 for the selected output and logic 1 for the other three outputs as shown in 2.2[10].

Transmission gates are most frequently utilized in circuits using XOR logic, such as complete adders and multiplexers, as the main switching portion. In any event, as demonstrated in, we consider the possibility of utility in line decoders when AND/OR logic is applied. Figure display the TGL AND/OR gates with two possible inputs. Even if they are completely swinging, not every combination of inputs produces a restoration. The two most prevalent types of circuits in pass-transistor logic are those that employ only NMOS pass transistors, such as CPL, as well as DPL and DVL, which use both PMOS and NMOS pass transistors. With this study, we focus on the DVL approach, in which full swing operation is preserved while DPL is improved fewer transistors. Figure display two input DVL AND/OR gates [11]. Similar to the TGL gates, They can swing but not restore. CMOS NAND/NOR gates require four transistors, but TGL/DVL gates only require three. presuming the presence of complementing inputs. High-fan-out circuits called decoders allow multiple gates to share a limited number of inverters. Using TGL/DVL gates facilitates transistor count reduction [12].

One significant similarity trait of these gates' asymmetry is one of their characteristics, are the reality that their input loads are not balanced. We identified the two The X and Y inputs to the gate are displayed in Figure 2.1 [2]. In TGL gates, input X controls the gate terminals of three transistors. while input Y is sent from the input to the output node through the transmission gate.

However, only one gate terminal is controlled by input Y in DVL gates, and it is routed to the output. The X and Y inputs of the gate will receive both the control signal and the propagation signal. This asymmetric characteristic allows a designer to arrange signals by deciding which input acts as the control and which one acts as the signal propagation of gate in each situation. When the propagating signal is a complimentary input, there is a considerable increase in latency since an inverter needs to be added to the propagation channel. It is greater effectiveness to use the Inverse variable as the control signal when using the inhibition ($A'B$) or implication ($A'+B$) function. The AND (AB) and OR ($A+B$) operations have the same power. Finally, regardless of whether you're working with $A'+B'$ in NAND or $A'B'$ in NOR any picking to make will unavoidably result in a complementing propagation signal [12].

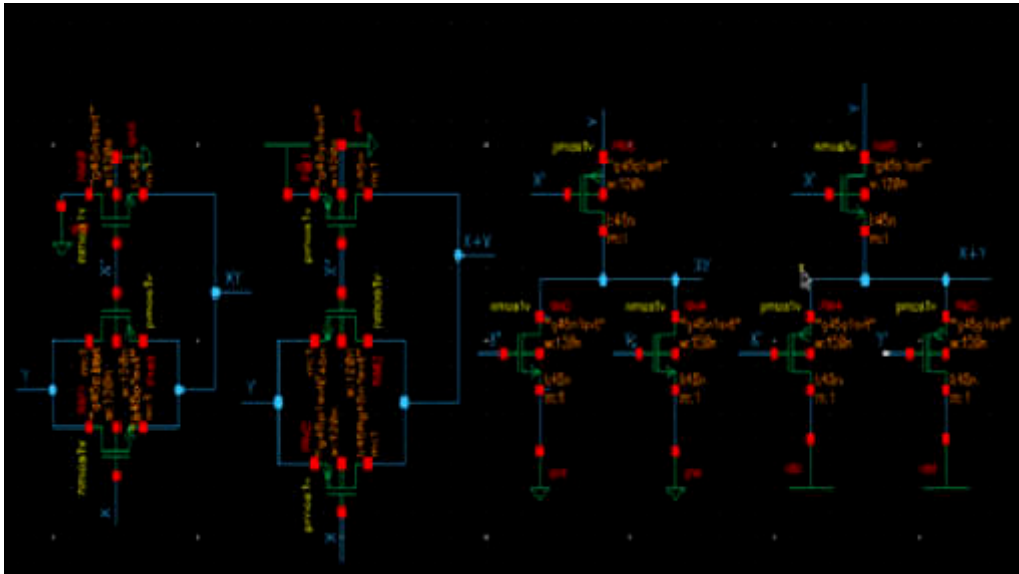

Fig. 2.1: (a) TGL AND gate , (b)TGL OR gate , (c) DVL AND gate ,(d) DVL OR gate

NAND and NOR gates have an advantage over AND and OR in typical CMOS architecture because they can express logic operations more efficiently with 4 transistors as compared to 6 transistors. It is possible to construct a 2×4 decoder using two inverters and four NOR gates. In contrast, an inverting decoder needs four NAND gates and two inverters which together produce “20” transistors.

Similarly the 16 min terms $D_0 D_{15}$ of the four input variables A, B, C, and D are produced by a Decoder with 4×16 lines, while the corresponding min terms $I_0 I_{15}$ are produced by inverted 4×16 line decoder. A predecoding approach, which divides blocks of n address bits into 1-of-2n pre decoded lines [12] that act as inputs to the final stage decoder, can be used to create such circuits. Pre decoding may be used to create such circuits [14]-[15]. As a result, two 2-four inverting decoders and sixteen 2-input NOR gates can be used to build a 4×16 decoder and two 2-four decoders and sixteen 2-input NAND gates can be used to implement an inverting one. These designs require eight inverters and twenty-four 2-input gates in CMOS logic, which adds up to “104” transistors per design [10].

2.1. 14T LP Topology for 2×4 Decoder (Non-Inverting). Developing a plan based on multiple logics A 2×4 decoder would require sixteen transistors altogether, two inverters, four TGL or DVL AND/OR gates, and two inverters. A 14 transistor decoder architecture is created by merging TGL and DVL AND gates in this design, which eliminates one of the two inverters, by carefully utilizing control and propagation signals.

In Figure 2.2 [1], the Decoder has two inputs A and B which produces the 4 min terms D_0, D_1, D_2 & D_3 , with the intention of removing inverter B. DVL AND gates are utilized to put into practice the min terms D_0 means $(A'B')$ and D_2 means (AB') , where Signals A and B are transmitted. The TGL AND gate is employed to realize the min terms [12]. D_1 means $(A'B)$ and D_3 means (AB) , with B functioning as the propagate signal for D_1 means $(A'B)$ and D_3 means (AB) each. The elimination of the B inverter is made possible by the choice of inputs and gates, resulting in a topology with 14T for the Decoder.

Figure 2.3, demonstrates the simulation of 14T LP Topology 2×4 Decoder. When $A=B=0$, D_0 will be enabled [14], when $A=0$ and $B=1$, D_1 will be enabled, when $A=1$ and $B=0$, D_2 will be enabled, when $A=1$ and $B=1$, D_3 will be enabled.

2.2. 14T LPI Topology for 2×4 Decoder (Inverting). Similarly, a 14T architecture with inverting 2 inputs 4 outputs Decoder can be built out of an inverter and four TGL/DVL OR gates. TGL /OR gates are utilized for min terms I_0 and I_2 , while DVL OR gates are utilized to put into practice for min terms I_1 and I_3

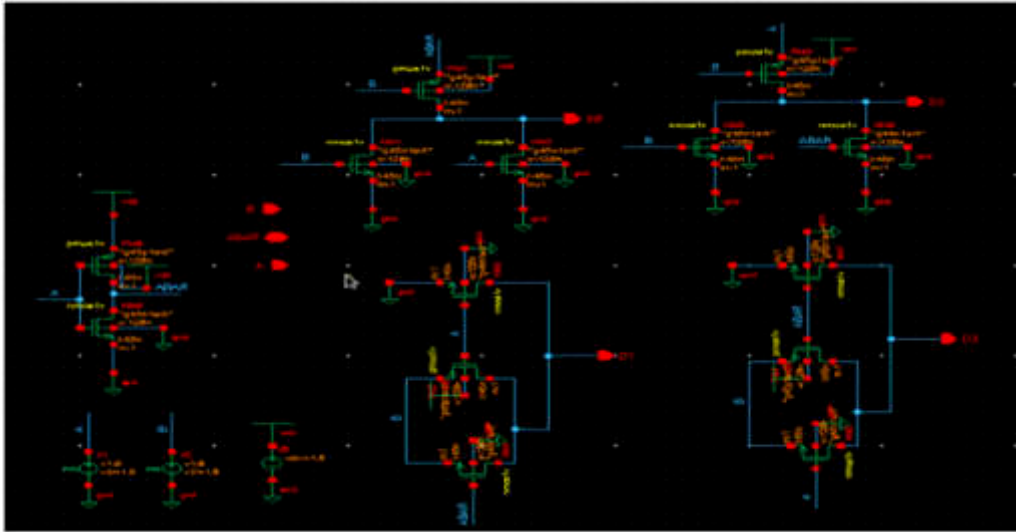

Fig. 2.2: 14T LP Topology for 2×4 Decoder (Non-Inverting)

Fig. 2.3: Simulation result of 14T LP 2×4 Decoder (Non- Inverting)

are the output signal [16].The terms "2×4 LP" and "2×4 LPI," which "2×4 LP" stand for "Low power" and "2×4 LPI, stand for" Low Power Inverting" respectively, describe two LP Decoder architectures are used. These are shown Figure 2.2 and Figure 2.4.

Figure 2.5[1], demonstrates the simulation of 14T LPI Topology for 2×4 Decoder (Inverting). When A=B=0, I_0 will be enabled, when A=0 and B=1, I_1 will be enabled, when A=1 and B=0, I_2 will be enabled, when A=1 and B=1, I_3 will be enabled.

2.3. 15T HP Topology for 2×4 Decoder (Non-Inverting). Due to the complimentary propagate signal utilized in minterms D_0 and I_3 , One drawback of the above-discussed 14 transistor low power decoder topologies is their maximum latency. Due to their lack of requirement for complementary inputs, these minterms may be implemented using normal CMOS logic gates, which overcomes this disadvantage. minterm D_0 is

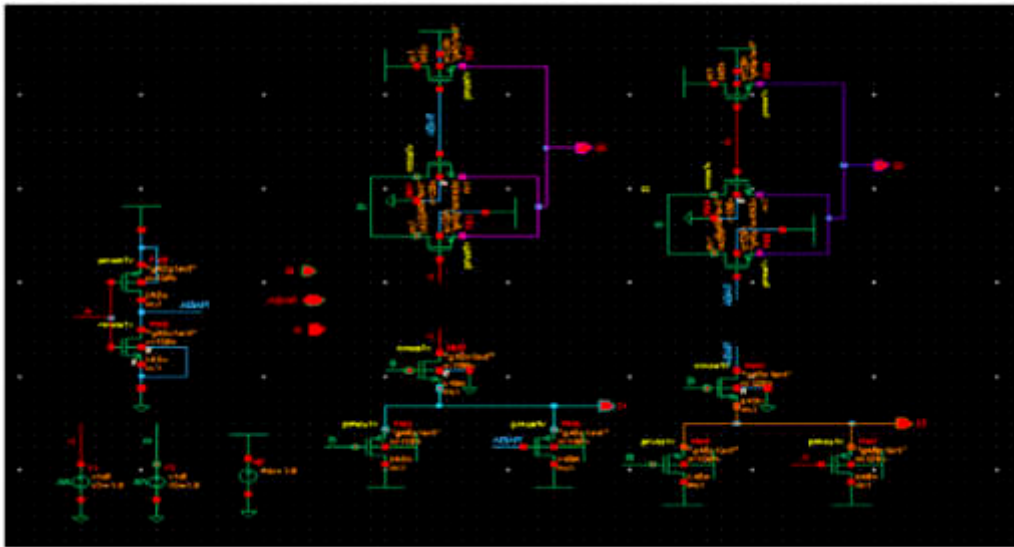

Fig. 2.4: 14T LPI Topology for 2x4 Decoder (Inverting)

Fig. 2.5: Simulation result of 14T LPI 2x4 Decoder (Inverting)

put into practice using a CMOS NOR gate, while I_3 is constructed using a CMOS NAND gate. One more transistor is added to each structure. The resultant decoder structure, known as High Performance (HP) topology, comprises three distinct logic types in a single circuit (CMOS, TGL, and DVL) [17], improving power and delay performance are both excellent. The schematics of 2x4 HP decoder is as illustrated in Figure 2.6. This modification resulted in a Decoder architecture that has three distinct logic types in a single circuit (CMOS, TGL, and DVL) into a single circuit that improves power and timing efficiency. The HP topology describes

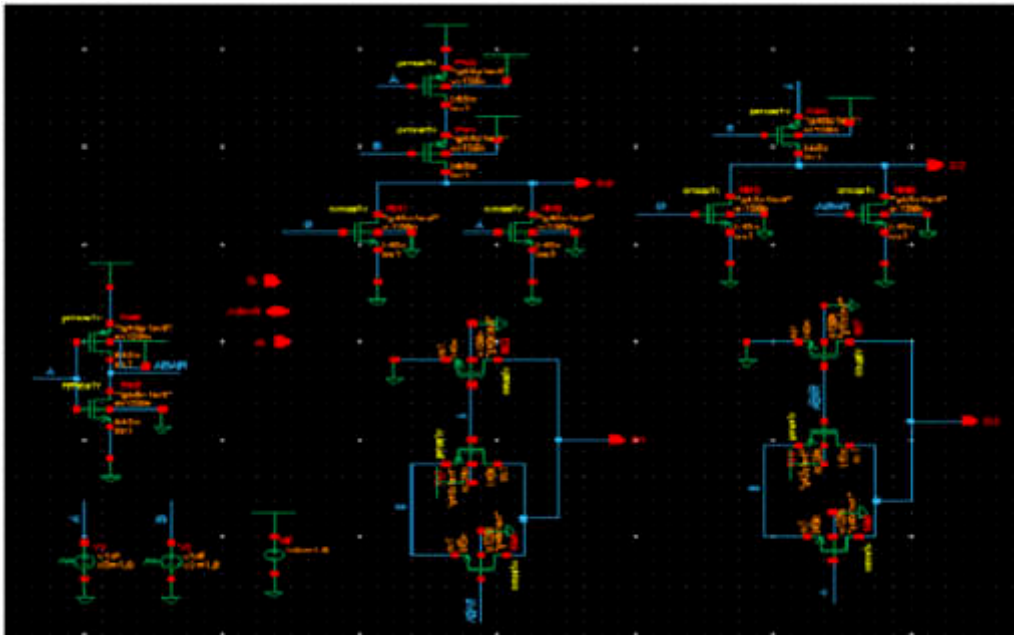

Fig. 2.6: 15T HP Topology for 2×4 Decoder (Non-Inverting)

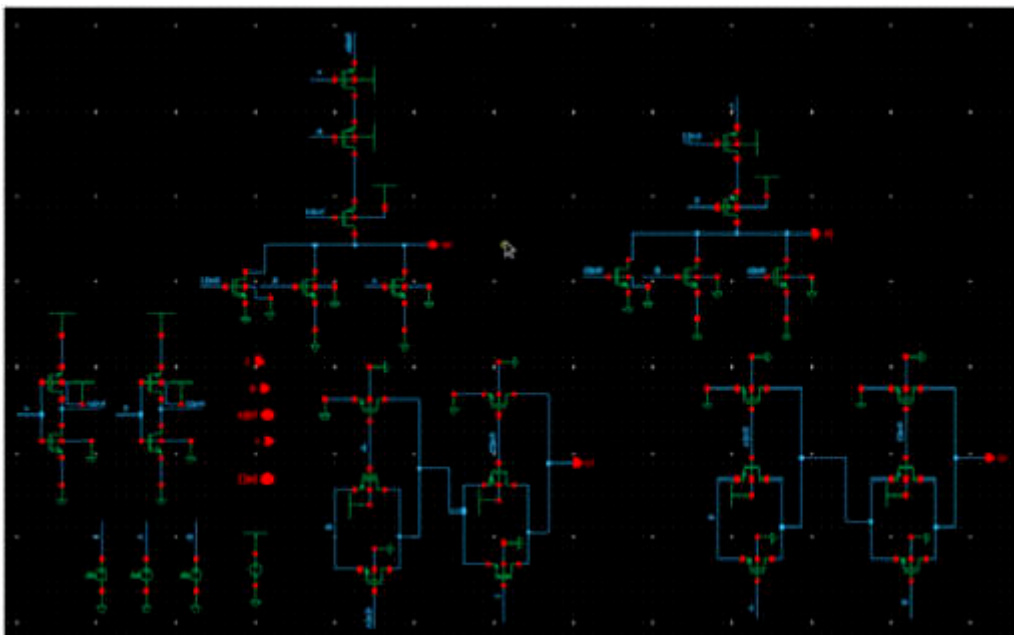

Fig. 2.7: Simulation result of 15T HP 2×4 Decoder (Non-Inverting)

this configuration specifically for its high throughput [9].

Figure 2.7[1], Shows the simulation of 15T HP Topology for 2×4 Decoder (Non-Inverting). When $A=B=0$, D_0 will be enabled, when $A=0$ and $B=1$, D_1 will be enabled, when $A=1$ and $B=0$, D_2 will be enabled, when $A=1$ and $B=1$, D_3 will be enabled.

Fig. 2.8: 2×4 HP Mixed Logic Decoder with Enable (Non-Inverting)

2.4. 2×4 HP Mixed Logic Decoder with Enable (Non-Inverting). This section covers the design of decoders with enable input. The use of 2×4 decoder blocks can reduce the number of transistors in a $n: 2n$ decoder. Since they don't need any extra logic gates, 2×4 decoders can be used to build higher stage decoders, which reduces design complexity. There are a number of benefits to logic gates are used in the post-decoder phases [18]– [22], including a reduction in wire delays and cross-talk caused by connections. However, the area overhead increases linearly with the number of logic gates needed. Only decoders without enable input are designed in every previous decoder study utilizing method of mixed logic design. This work uses the method of mixed logic design to construct decoders with enable input. The regulated functioning of decoder circuits is achieved with the addition of an enable input. In other words, only when the enable input is set to "on" does the decoder function, which also lowers dynamic power dissipation. Furthermore, instead of implementing at the transistor or gate level, it is always advised in contemporary techniques for chip design to construct macros or minor circuits that can be reused based on requirements.

A total of 30 transistors are needed for the non-reversing standard CMOS 2×4 decoder which includes enable, which also needs three NOR gates with three inputs and three inverters. DVL AND gates can be used to implement D_0 and D_2 in the 2×4 LP decoder which includes enable. A is used as the propagation signal, while EN and B are the signs of control; EN is the enable input. TGL AND gates are used to implement the minterms D_1 and D_3 , with B serving as the propagation signal and A and EN serving as the signs of control. 2×4 LP decoder which includes enable input requires 26 transistors. Similarly for 2×4 HP decoder which includes enable input requires "27" transistors use a CMOS NOR gate with three inputs to replace D_0 minterm as shown In Figure 2.8

Figure 2.8 [1], Shows the mixed logic line Decoder with enable. Inputs A and B produces D_0, D_1, D_2 & D_3 as outputs. Figure 2.9, Shows the simulation of Mixed Logic 2×4 HP Decoder with Enable (Non- Inverting). When $A=B=0$, D_0 will be enabled, when $A=0$ and $B=1$, D_1 will be enabled, when $A=1$ and $B=0$, D_2 will be enabled, when $A=1$ and $B=1$, D_3 will be enabled.

3. Proposed Methodology. A novel 2×4 Decoder with only 12T Transistor is proposed with area optimization in this research. CMOS logic is additionally used for execution of 2×4 Decoder. Delay and power is used for evaluation between the novel design and CMOS logic. The novel design of 2×4 Decoder [1] is Less

1	1	0	0	0	1

optimized for power in contrast to CMOS logic design at a typical value of 1.8V.

The LP circuit designs is a requesting issue in high performance digital frameworks, for example, microchips, DSPs and other different applications. Power and speed are the main high lights considered while comparing any circuit or design. Diminishing chip area is additionally truly impressive factor, creators need to recall when suggesting any novel design. Decoder is used for conversion of binary inputs to associated output bits in a pattern. There are wide range of applications of Decoder such as seven-segment display, data de-multiplexing, etc. Numerous studies using sequential and combinational circuits are currently being conducted different logics.

3.1. 12T LP Topology for 2×4 Decoder (Non-Inverting). Decoders are crucial circuits, for the most part utilized in the hardware involving collections of RAM [19]. In this study, we propose an innovative approach to putting them into practice, which rapidly decreases the amount of transistors in 2×4 Decoder circuit. Power and area efficient Decoders with less number of transistors plays a very significant role in circuit designing and act as elementary units. Figure 3.1 Shows proposed non inverting 2×4 Decoder generates 4 min terms D_1, D_2, D_3 & D_4 with two inputs A and B and its truth table is shown in below Table 3.1.

The proposed circuit for implementation of 12T LP 2×4 Decoder designed using CMOS and Dual Value Technique is shown in Figure 3.6. One of the four outputs is chosen and set to 1 depending on the input

Fig. 3.1: Proposed 2x4 Decoder with 12T

Fig. 3.2: 12T LP Topology for 2x4 Decoder with "D₁" data output

combination, while the other three are set to 0 [7].

3.1.1. 12T LP Topology for 2x4 Decoder with "D₁" data output. The proposed circuit for implementation of 12T LP 2x4 Decoder designed using CMOS and Dual Value Technique is shown in Figure 3.6. First term "D₁" using proposed design as shown in Figure 3.2 is both PMOS and NMOS gates has been connected with input A, PMOS drain has connected with one of the input complement of B. "D₁". will be formed by the combination of the PMOS and NMOS linked to the output

3.1.2. 12T LP Topology for 2x4 Decoder with "D₂" data output. The proposed circuit for implementation of 12T LP 2x4 Decoder designed using CMOS and Dual Value Technique is shown in Figure 3.6. Second term "D₂" using proposed design as shown in Figure 3.3 is both PMOS and NMOS gates has been connected with input complement of B, PMOS drain has connected with one of the input complement of A. PMOS and NMOS combined with their connections to the output will result in a "D₂".

3.1.3. 12T LP Topology for 2x4 Decoder with "D₃" data output. The proposed circuit for implementation of 12T LP 2x4 Decoder designed using CMOS and Dual Value Technique is shown in Figure 3.6. Third term "D₃" using proposed design as shown in Figure 3.4 is both PMOS and NMOS gates has been connected with input B, PMOS drain has connected with one of the input A. A "D₃" will be produced by connecting PMOS and NMOS.

Fig. 3.3: 12T LP Topology for 2x4 Decoder with "D₂" data output

Fig. 3.4: 12T LP Topology for 2x4 Decoder with "D₃" data output

3.1.4. 12T LP Topology for 2x4 Decoder with "D₄" data output. The proposed circuit for implementation of 2x4 Decoder designed using CMOS and Dual Value Technique is shown in Figure 3.6. Fourth term "D₄" using proposed design as shown in Figure 3.5 is both PMOS and NMOS gates has been connected with input complement of A, PMOS drain has connected with one of the input B. The combination of the both PMOS and NMOS linked to the output will produce data "D₄".

The proposed circuit 12T LP Topology for 2x4 Decoder has been validated with Cadence Virtuoso with 45GPDK Technology. The entire technology designed with CMOS and Dual Value Methodology shown in Figure 3.6.

Figure 3.7 Shows the simulation of Non-Inverting 12T LP Topology for 2x4 Decoder with CMOS and DVL topology. When A=B=0, D₁ will be enabled, when A=0 and B=1, D₂ will be enabled, when A=1 and B=0, D₃ will be enabled, when A=1 and B=1, D₄ will be enabled.

3.2. 12T LPI Topology for 2x4 Decoder (Inverting). Figure 3.8 shows 12T 2x4 Decoder in inversion mode. It contains two inverters that will produce complement of A and complement of B. i.e A' and B'. A 2x4

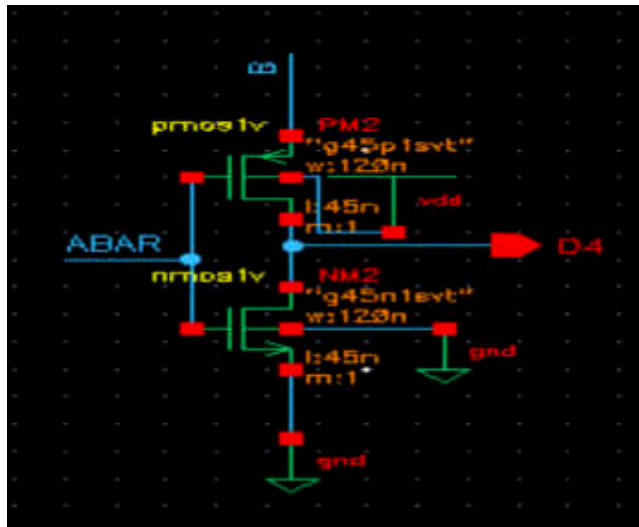

Fig. 3.5: 12T LP Topology for 2x4 Decoder with "D₄" data output

transistors, they are suitable for scenarios where size and power loss are the main design issues. The two innovative topologies (CMOS and DVL) used in the design of the proposed decoders are low power and low power inverting, respectively. The propagation delay, the circuit's static and dynamic powers, and the overall average power are computed in each scenario. For simulation, an operating voltage of 1.8V is utilized. When compared to their typical CMOS predecessors, All of the Applied decoders can swing freely and have fewer transistors. The suggested 12T 2×4 LP decoder consumes average power of 1.129 μ w, static power of 105.28 pw, dynamic power of 5.36 μ w and delay of 631.2 ps and 12T 2×4 LPI decoder consumes average power of 651.9 nw, static power of 1.053 nw, dynamic power of 37.51 μ w and delay of 50.34 ns. The results for 12T LP 2×4 and 12T LPI 2×4 Decoders are tabulated in Table 4.1

5. Conclusion. The design in this research was validated using Cadence Virtuoso 45GPDK Technology. An efficient Decoders designed by blending DVL Topology with static CMOS. Simulation results prove that, when comparison with the proposed 12T LP, LPI Decoders with existing 2×4 LP, LPI Decoders provides the upgrade in power with an upward on delay with diminished quantity of transistors and are acceptable for operations in area and power dissipation are the crucial device consideration. The 2×4 Decoders implemented has essentially less number of transistors so it will inhabit less on chip area as compared to CMOS logic which can be observed from 4.1. The novel design is 60.72% optimized for power as compared to CMOS Logic design at a typical value of 1.8V which can also be observed from the Table 4.1. these Implemented Decoders have full swing capacity and diminished quantity of transistors count in contrast to usual CMOS counterparts.

MULTI OBJECTIVE DATA TRANSFORMATION IN HYBRID CLOUDS NETWORKS FOR OFFLOADING DATA

V SRIDHAR REDDY*, N. JAYANTHI†, SHARON ROSE VICTOR JUVVANAPUDI‡, SRINIVAS BACHU§ AND MADIPALLI SUMALATHA¶

Abstract. Recently hybrid cloud solutions integrating public and private cloud is proposed to address the privacy and security concerns faced by Enterprises in their data offloading decisions. In these solutions, the transformed data is kept in public cloud while transformation keys are kept in private cloud. The existing works for data transformation used in hybrid clouds does not address multiple objectives of privacy, security, fine grained access control, utility preservation for mining and data retrieval efficiency. This work proposes a multi objective data transformation technique for hybrid cloud to address all these objectives. The proposed solution is built on attribute based hierarchical data access control with hierarchy selection based on joint consideration of security, utility preservation and retrieval efficiency. The proposed solution is able to provide 5% higher security strength, 1.34% higher clustering accuracy over perturbed data and 29.95 % higher data retrieval efficiency over perturbed data compared to existing works.

Key words: Multi objective data transformation, Hybrid cloud, Hierarchical data access control, Generalization control .

1. Introduction. Enterprises are adopting cloud for offloading both storage and computations. The adoption is triggered due to various benefits like CAPEX and OPEX reduction, high availability and mobility etc. With increasing cloud adoption rate, there is also increasing cloud security breaches. The recent security survey by IDC and Ermetic [1] reports that almost 98% of enterprises suffer atleast one security breach. The average total cost of data breach globally is estimated about 4.24 million USD. Data breaches and leakage can create huge financial loss for the Enterprise, lose to competitors and sometimes wipe out from market. Thus ensuring security and privacy of data has become a important requirement for enterprises in their cloud offloading and vendor selection decisions. Though there are various data protection mechanisms, enterprises are adopting multi cloud and hybrid clouds to reduce the risk. Flexera's 2021 State of the Cloud Report [2] found that almost nine out of ten enterprises are adopted multi cloud approach and eight in that nine enterprises are adopting hybrid cloud to reduce security risks. Hybrid cloud solutions are also not full proof. Though they have reduced risks and breach cost compared to public and private cloud, they could not completely eliminate the data breach cost as evident from the IBM and the Ponemon Institute's 2021 Cost of a Data Breach Report Figure 1.1

This data breach cost could be avoided in hybrid cloud with more effective security and privacy enforcement. The data must be prevented from compromise either directly or through inference. Many works have been proposed in category of anonymization, randomization, cryptography, diversification and aggregation to address the security and privacy concerns. In addition to security and privacy, the data transformation techniques must also address other requirements like differential access control, utility preservation and retrieval efficiency. Most solutions as discussed in Section II do not address all these requirements. This work proposes a multi objective data transformation technique which jointly addresses all the five requirements of privacy, security, differential

Fig. 1.1: Data breach report (Courtesy: IBM and Ponemon Report 2021)

access control, utility preservation and retrieval efficiency. Attribute based hierarchical data transformation with mix of anonymization, aggregation and diversification is adopted in this work with hierarchy selection fine tuned to address the five requirements.

The rest of paper is organized as follows. Section II provides the survey of data transformation techniques used in cloud and their shortcomings. Section III details the proposed multi objective data transformation technique. Section IV provides the results of the solution and its comparison to existing works. Section V provides the concluding remarks and the scope for future work.

2. Related Work. A survey of data transformation techniques for cloud is presented in this section. Yang et al [3] proposed a data transformation technique addressing security and privacy for data in cloud. The data is partitioned vertically and transformed using cryptographic primitives. The keys for transformation are kept at the private cloud and transformed data at public cloud. The transformation is not distance preserving and the method is not able to provide differential privacy to users. Kao et al [4] proposed a reversible privacy contrast mapping (RPCM) algorithm for data transformation.

Data is transformed by replacing two adjacent values by a new value. The mapping between adjacent values to new value is kept separately in private cloud. By grouping the values, anonymity is created among the records. But without consideration for distance preservation in transformation, the utility of data for data mining becomes infeasible. Yun et al [5] proposed a faster data perturbation algorithm using tree travel strategy.

A multi tier tree structure is built, which is able to transform a numeric attribute to another attribute. Though the retrieval efficiency is ensured, the differential privacy is not considered in this work. Zhang et [6] proposed a data transformation technique called as Cocktail.

This technique applied quasi identified partitioning with differential privacy strategy. The data transformation is lossless. But the retrieval efficiency is low in this approach. Zhou et al [7] proposed a data partition strategy. The strategy is application independent. The sensitive attributes are detected based on entropy with the identifier. The sensitive columns are kept in private cloud. The insensitive columns are moved to public cloud. Though retrieval efficiency is high in this approach, it distorts the data mining utilization. Lyu et al [8] transformed the data using repeated Gompertz (RP) followed by random projection (RP). The data is transformed to less dimension space with distance preserving property so that utility is not affected. But the retrieval efficiency is poor and it is not possible to execute any query operations on transformed data. Security is strong this approach. The transformed data is secure against estimation and component analysis attacks. Chen et al [9] proposed geometric data perturbation scheme. The geometric perturbation has three steps of rotation, translation and noise addition.

The mechanism has tighter security and privacy, bit retrieval efficiency is low for higher dimensional datasets. The same author in [10] proposed a random projection perturbation extension to geometric perturbation. The method is able to achieve faster geometric perturbation for multi dimensional datasets. Yuan et al [11] used

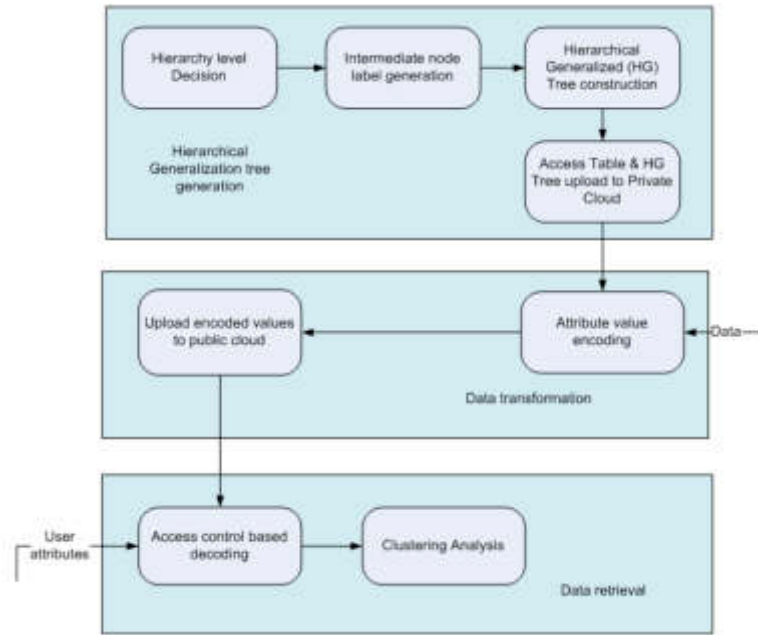

Fig. 2.1: Multi objective data transformation

compressive sensing based data transformation and fast indexing to improve retrieval efficiency. Due to violation of distance preservation, the transformed data becomes unsuitable for data mining operations like clustering and classification. Majeed et al [12] proposed a data transformation technique based on data anonymization. The attribute values in fixed interval are replaced with their averages. This method affects the original data and suitable only for certain data publishing requirements. Li et al [13] proposed two K-anonymity algorithm for data transformation. The data is transformed in way not to affect the classification capability. It is done by checking the entropy after transformation and choosing the level of transformation based on entropy. Begum et al [14] proposed data transformation scheme by removing sensitive items based on support and confidence values. The minimum number of items is removed in such a way to remove sensitivity.

Though the method is able to reduce the security leakages, it reduces the utility of data for data mining operations. Sridhar et al [15] clustered the data and passed the clustered data to geometric data perturbation. The solution considered security, privacy and utility preservation but did not consider retrieval efficiency. The solution did not consider differential privacy and query matching. Kodhai et al [19] proposed a secure fuzzy keyword search technique for data stored in cloud. But the technique cannot be used for the case of differential privacy and fine grained access controlled search problem considered in this paper work. Gheisari et al [20] used four different techniques of data micro aggregation, sampling, swapping and random noise to perturb data. But these schemes do not consider fine grained access control and differential privacy. Jafar et al [21] used public key cryptosystem for providing security to data but the scheme does not support differential privacy, fine grained access control and search over perturbed data. From the survey, it can be seen that most of the data transformation techniques focused on privacy and security, but they have not considered multi objectives of providing differential privacy, fine grained access control over data, retrieval over perturbed data and preservation of utility mining etc. In addition, the existing works have not considered efficiency in data transformation on hybrid cloud platform. This work considers this problem of multi objective data transformation and efficiency in data transformation for hybrid cloud environment.

3. Multi objective data transformation. The architecture of the proposed multi objective data transformation is given in Figure 2.1. As seen from figure, the proposed solution has three important functionalities: generation of hierarchical generalization tree, data transformation and retrieval. Each of the functionalities is

Fig. 2.2: Generalization tree for categorical variable

detailed below.

3.1. Generation of hierarchical generation tree. The data uploaded by data owner is in table format in which each column is an attribute. The attributes are marked as sensitive or in-sensitive by the data owner. For each of the sensitive attributes, a hierarchical generalization tree is constructed. This generalization tree is constructed to transform the data values of the corresponding attribute. The transformation using the generalization tree provides a differential view on the data after retrieval as desired by owner. Generalization is the key to the differential view. A sample generalization tree is shown in Figure 2.2. The attribute values are at the leaf nodes. The intermediate nodes in the tree are the generalization labels. It is not possible to construct a semantically correct generalization label for categorical variables as it requires domain knowledge. Thus data owner must provide the translation for each of the categorical variable in terms of numbers. The number must be provided in such way that if two categorical variables a and b are semantically close by degree d_1 , then the distance between their corresponding numerical variables must be in proportion to d_1 .

$$|N(a) - N(b)| \propto d_1 \tag{3.1}$$

Also if there is order in categorical variable, then if

$$a < b \text{ then } N(a) < N(b) \tag{3.2}$$

The generalization tree for attributes is constructed automatically by normalized the attribute values and repeated binary split till the maximum level allowed by data owner is achieved. The generalization tree is constructed in way to maximize the data mining utilization. The attribute value is first normalized in range of 0 to 1 from their actual value to decide the hierarchy. The normalization is done as

$$NV = \frac{AV}{(MaxV - Minv + 1)} \tag{3.3}$$

where NV is the normalized value, AV is the actual value, MaxV is the maximum value of the attribute and Minv is the minimum value of the attribute.

A Gaussian kernel density function is plotted with the normalized values. The minima of kernel density estimation for normalized values are taken the partitions as shown in Figure 3.2. In the Figure 3.2, minima of kernel is at $\langle 0, 0.4, 0.5, 0.9, 1 \rangle$. Thus 4 clusters need to created with values from (0 to 0.4), (0.4 to 0.5), (0.5 to 0.9), (0.9 to 1).

Once the normalized ranges are identified, they can again brought back to actual value.

$$AV = NV \times (MaxV - Minv + 1) \tag{3.4}$$

Fig. 3.1: Gaussian Kernel Density

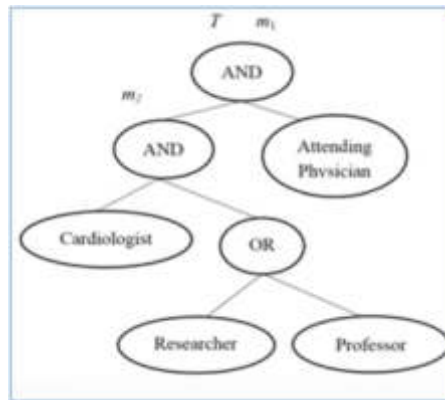

Fig. 3.2: Access tree

The cluster ranges are now in actual values. The mean of the values in those cluster is taken as next level generalization label. The generalization label is calculated for next level in same way till the maximum level specified by the owner is achieved. Once the generalization trees for the attributes are constructed, access control tree is provided by data owner for each level. A sample access tree for each generalization label is given in Figure 4.1.

The access tree is generated for each level based on the user attributes by data owner and access tree is uploaded to private cloud.

3.2. Data transformation. Each attribute value (V) is encoded into all its level generalization as $E_n = V, L_1(V), L_2(V), \dots, L_n(V)$ where $L_x(V)$ is the level x generalization of V and n is the number of levels. A homomorphic encryption (HE) key (k) is generated for each data owner. The encoding E_n is then homomorphically encrypted using the k, the encrypted E_n is given as

$$E(E_n) = HE(V, k), (HE(L_1)(V), k), \dots, (HE(L_n)(V), k) \tag{3.5}$$

The control to the particular level in the $E(E_n)$ is enforced using AHAC (Attribute based Hierarchical Access Control) CP-ABE (Cipher policy Attribute Based Encryption) [16]. The access tree for each level and $E(E_n)$ is passed as input to the AHAC CP-ABE encryption algorithm. The encryption algorithm provides a transformed $E(E_n)$ as output. The algorithm for transformation of attribute value is given in Algorithm 1.

Algorithm 1: Encoding

Input: attribute value (V) , HG tree of Attribute, HE key k, access control tree(T)

1. $E_n = V$

Table 4.1: Clustering accuracy

K	RG+RP [8]	GP [15]	SFAC-SHC [17]	Proposed
2	66.23	65.89	68.52	70.12
3	66.56	71.25	75.62	77.14
4	73.33	74.59	78.85	79.89
5	67.22	79.58	82.34	83.56

2. for $x=1$: num of level(HG)

$$En = En \cup HE(L_x(V), k)$$

3. EV AH ACCP-ABE. *Encrypt*(En,T) [16]

4. upload EV to public cloud

5. upload HG, k,T to private cloud

Each of the attribute value in the data is transformed using Algorithm 1. The transformed data is then uploaded to private cloud.

3.3. Data retrieval. When user requests the data for data mining utilities like clustering, the transformed must be decoded at first stage. The user attributes and transformed attribute value as input and provides the value at index of $E(En)$ corresponding the access provided for the user. Since the value is homomorphically encrypted, distance preservation is maintained and the data is suitable for data mining operations like clustering without any need for decryption. Since the $HE(L_x(V), k)$ is provided only for the level x matching the user access control credentials, it is difficult for user to learn any data characteristics beyond his access rights. The decoding algorithm for de-transformation of each attribute value in transformed data is given as Algorithm 2.

Algorithm 2: Decoding

Input: Query User (U).

Ouput: Decoded Value (DV).

1. $EV \leftarrow \text{downloadfromprivatecloud}$
2. $QV \leftarrow \text{Download user attributes from public cloud}(U)$
3. $DV \leftarrow AHACCP - ABE.Decrypt(EV, QV)$ [16]
4. return DV

Each of the attribute value in transformed data is decoded using Algorithm 2. This de-transformed data is then used for data mining utilities like clustering analysis.

4. Result. The performance of the proposed solution is tested against Arrhythmia dataset [18] in UCI machine learning repository. The performance is measured in terms of: (i) clustering accuracy (ii) data storage overhead (iii) retrieval efficiency and (iv) security against attacks. The performance of proposed solution is compared against geometric data perturbation (GP) [15], RG+RP [8] and searchable fine access control on secure hybrid clouds (SFAC-SHC) [17].

The clustering accuracy is calculated by measuring the differences between clusters of original and perturbed data. K-means algorithm is used for clustering the original and perturbed dataset.

The clustering accuracy is calculated as

$$ACC = \frac{1}{N} \sum_{i=1}^N | - Cluster_i(P) | - | Cluster_i(P') | \quad (4.1)$$

where P is the original data, is the transformed data, k is the number of clusters and N is the number of items in the dataset. The value of ACC is measured for different values of K and result is given in Table 4.1.

The value of ACC in proposed multi objective transformation is 9.3% higher compared to RG+RP, 4.87% higher compared to GP and 1.34% higher compared to SFAC-SHC. With the increase in K value, the ACC

Fig. 4.1: Comparison of clustering accuracy

Table 4.2: Data upload time

Size (MB)	Upload time (sec)			
	Proposed	SFAC-SHC[17]	GP [20]	RG+RP [8]
20	13	14	19	22
40	18	24	35	38
60	24	43	61	64
80	30	78	112	122
Average	21.25	39.75	56.75	61.5

increases in the proposed solution. ACC value increases by 13.82 % for K value increase from 2 to 5. Distance preservation is ensured using Homomorphic encryption in proposed solution. This has increased the accuracy in the proposed solution.

The data storage time is measured as the time taken for transformation of data and uploading of transformed data to cloud. The data storage time is measured for various volumes of data and result is given in Table 4.2.

The storage time in proposed multi objective transformation is atleast 20.36% lower compared to GP and 36.93% lower compared to RG+RP. While storage time increases exponentially with increase in data volume in existing works, it is linear in proposed solution. This is because generalization tree construction and data transformation are linear operation in proposed solution.

The data retrieval efficiency is measured by varying the volume of data and the result is given in Table 4.3. The data retrieval efficiency is on average 29.95% lower compared to GP and 35.36% lower compared to RG+RP. Like storage time, retrieval time also increases exponentially with increase in data volume in existing works, but it is linear in proposed solution. The data de transformation using AHAC CP-ABE is linear in proposed solution and due to this retrieval time increases linearly with increase in data volume.

The security strength is measured in terms of difficulty in predicting the original data from perturbed data, provided the attacker has access to the perturbed data. The difficulty level is estimated in terms of measure called Variance of difference (VoD).

Let X_i be a random variable representing the column i , X'_i be the estimated result of X_i and difference $D_i = X'_i - X_i$. Let mean of D be $E(D_i)$ and variance be $Var(D_i)$. VOD for column i is $Var(D_i)$. VOD is measured for each column and average VOD is given as privacy measure(pm)

$$pm = \sum_{i=1}^N \frac{VOD_i}{N} \quad (4.2)$$

A guess is launched for 5 hours on the perturbed data and the privacy measure (pm) is measured for every 1-hour interval and plotted in Figure 4.4.

Higher the value of VoD, the effort to predict the original data is difficult. VoD in proposed solution is very high in proposed solution. It is almost twice compared to GP and RG+RP and it is on average 5% higher

Fig. 4.2: Storage time

Table 4.3: Data retrieval time

Size (MB)	Upload time (sec)			
	Proposed	SFAC-SHC[17]	GP [20]	RG+RP [19]
20	14	15	18	21
40	20	26	34	37
60	27	48	59	63
80	33	87	110	120
Average	23.5	44	55.25	60.25

Fig. 4.3: Comparison of retrieval time

Fig. 4.4: VOD over time

compared to SFAC-SHC. Two level of encryption – first with Homomorphic encryption, followed by AHAC CP-ABE has made it difficult to predict the original data in the proposed solution.

5. Discussion. The data transformation technique proposed in this work addressed multiple objectives of privacy, security, differential access control, utility preservation and retrieval efficiency. The private data were perturbed using homomorphic encryption (HE) with access control over the keys for HE. The privacy and security was measured in terms of VOD and it is found that it is harder to infer any private information by launching brute force attacks. The security is higher by 5% compared to existing works. The higher security is due to differential privacy provided over data. Existing works used same keys without considering differential privacy. The proposed solution preserved distance based statistics in data even after perturbation. This has increased the accuracy for clustering operations on perturbed data by atleast 1.34% compared to existing works. Distance preservation in proposed solution is due to HE based transformation. The data retrieval efficiency is also higher in proposed solution as the transformation is light weight and easy to reverse the data. But existing works based geometric transformation had higher overhead during the stage of data retransformation. The proposed solution had fine grained access control over the data which was not considered in earlier works. The access control was using hierarchical access tree and the tree itself was secured by keeping it in private cloud. Thus the proposed solution performed better compared to existing works in terms of privacy, security, fine grained access control and retrieval efficiency.

6. Conclusion. A multi objective data transformation function for hybrid cloud is proposed in this work. The solution addressed multi objectives of privacy, security, differential access control, utility preservation and retrieval efficiency in data transformation specific to hybrid cloud environment. A generalized hierarchical tree is constructed from the data and data transformation is done based on generalization labels and access control rights for the users in the proposed solution. The proposed solution also provides differential privacy and access control to different users without affecting the utilization of data for data mining operations. The proposed solution provides atleast 5% higher data security, 29.95% higher data retrieval efficiency and 1.34% higher clustering accuracy over perturbed data compared to existing works. Adaption of solution for streaming data is in scope of future work.

Abstract. Research into Dew computing environments has recently emerged as a result of the increasing prevalence and processing power of mobile and IoT devices. In these settings, even low-powered devices can share some of their computational resources with their neighbors. This paper proposes a novel approach to workflow scheduling in dew enabled cloud computing environment, called Deep Q-learning (DQN) + Chronological Geese Migration Optimization (CGMO). DQN is a deep learning-based method for scheduling workflows, while CGMO is a hybrid optimization algorithm that combines the chronological idea and the Wild Geese Migration Optimization (GMO) algorithm. The proposed approach aims to optimize multiple objectives, including predicted energy, Quality of Service (QoS), and resource usage, by scheduling workflows in the cloud. The approach also takes into account the current state of the Virtual Machine (VM) and the job. The assessment measures employed for DCGM include maximum QoS, minimum energy usage, and maximum resource utilization. The results show that DCGM achieved the highest QoS (0.865), lowest energy usage (0.0322), and highest resource utilization (1.000) compared to other approaches.

Key words: Dew computing, deep learning, task scheduling

1. Introduction. In recent years, resource-constrained devices have been under severe computational strain due to the meteoric rise of computationally expensive jobs in mobile applications. Smartphones and Internet of Things devices, unfortunately, typically fall short of such requirements. Dew computing is a solution that offers moving computationally expensive tasks to more capable (nearby) machines [1, 2, 3, 4, 5]. A device is considered nearby if it is on the same local network as another device. The concept is that you may use your phone to delegate tasks to your computer, saving battery life on both devices. However, learning how to efficiently divide tasks across adjacent devices is a major hurdle for Dew computing to be useful in practice. The issue of scheduling tasks in Dew settings is investigated in this paper. The term "Dew environment" refers to a network of interconnected gadgets. Different devices may have different storage capacities, sensor arrays, processing speeds, wireless connectivity options, and battery life. Furthermore, consumers may engage with various gadgets at various moments. All these considerations are necessary for efficient task distribution in a Dew setting. Existing solutions for distributing work in Dew settings adhere to human-designed policies. By adhering to a predetermined set of rules, these policies attempt to distribute the workload evenly across the devices. The Simple Energy-Aware Scheduler (SEAS) [6], the Batch Processing Algorithm (BPA) [7], and the Round Robin (RR) [8] are all examples of such schedulers. Due to their inflexibility, these approaches consistently produce bad decisions and wasteful resources when applied to a Dew context.

In this study, we suggest utilizing RL to figure out how to allocate tasks in a Dew ecosystem [9]. Learning optimal behavior by interaction with an environment is the focus of RL, a branch of AI that investigates how

to create such creatures. Every action the agent takes results in some form of reward signal that it then tries to maximize. This is done by the agent learning from its past mistakes and adjusting its present policy (a mapping from observations to actions). Research in fields as diverse as robotics [10], conversational agents [11], and drug discovery [12] have all shown success using RL agents to address complicated decision-making problems powered by deep learning. We propose letting an RL agent figure out how to divide up work in a Dew system through experience. The use of RL for task distribution in Edge and Cloud computing has been investigated in previous research [13, 14, 15, 16]. However, no one has yet implemented RL on a Dew system. The unique difficulties of Dew computing cannot be compared to those of Cloud or Edge computing. Some gadgets in Dew computing, for instance, may experience battery drain or user interaction. Further, it has not been investigated in prior publications if RL agents may acquire rules that generalize well to novel contexts. Our results demonstrate that, when tested in novel scenarios, deep RL agents outperform state-of-the-art heuristic approaches in their ability to learn to offload tasks.

Workflow, a relatively new technology, has been widely used to keep tabs on the best apps' performance. In the context of scientific disciplines, a workflow is the collection of individual actions that are interconnected by data [7, 8]. Workflow applications have expanded in recent years to include domains as diverse as e-commerce, biology, astronomy, and physics. The workflow's tasks, in general, need time- and resource-intensive operations to be carried out effectively [9]. Multi-objective scheduling-based techniques are broken down into two distinct types: QoS-inhibited algorithms and QoS-optimization algorithms [10]. Several approaches rely on QoS constraints to transform this problem into a single-objective optimization problem [2]. In order to influence QoS, extensive procedures are often designed and implemented in widely disseminated large-scale evaluation settings. How to coordinate the jobs has been a focus of the inquiry for a while now [9, 11]. Workflow scheduling solely considered the amount of investigations based on price and timeliness. When asked about how to reduce costs without sacrificing quality of service, they often recommend something called multi-objective scheduling, which is used to derive the pricing. The precaution was included into the workflow scheduling of certain recent studies based on cloud infrastructure. The impact of communications between tasks and virtual machines on cloud security as a whole was not adequately examined [3].

The allocation of jobs to relevant resources in CC [12] may either be insufficient or optimized to meet the needs of users depending on QoS. Cost, time, security, load, and success rate are all integrated into the QoS requirement based on process scheduling [13]. Nonetheless, many studies in this field have only optimized a few or a few QoS factors. A great deal of planning, plans, and improvements went into the framework of cloud security, all of which work together to guarantee the safety of data stored in cloud architectures [12]. The researchers developed many workflow scheduling strategies in which the technical word was associated with CC [5]. Due to the importance of the applications, a large number of studies have been conducted to develop a model for workflow management in clouds in line with scheduling schemes. These studies include Condor Dagman [14], Gridbus toolkit [15], Icenl [16], and Pegasus [17]. By hiding their orchestrations and implementations, the aforementioned structures may be seen as a kind of platform service that aids the network and cloud-based computerization of technical and commercial applications [4]. Workflow scheduling uses data mining and regression based methods. In addition, researchers often try new approaches to workflow scheduling in an attempt to fix the issues that have plagued the ones they've used before. Due to its easy convergence qualities, flexibility, and error-tolerance abilities, the Firefly algorithm stands out as the best of all the swarm-based models used in workflow scheduling [5].

In dew-powered cloud environments, efficiently scheduling microservice-enabled tasks is crucial for optimizing resource utilization and minimizing energy consumption. Traditional scheduling methods often fall short in adapting to the dynamic nature of these environments. To address this challenge, we propose a novel machine learning algorithm tailored for task scheduling. Our algorithm leverages advanced predictive models to dynamically allocate resources based on workload patterns and environmental conditions, thereby improving system performance and energy efficiency. This paper presents a comprehensive discussion on the applicability and benefits of our approach, bridging the gap between theoretical concepts and practical implementation in dew-powered cloud environments. In this paper, we provide a new framework, DQN+CGMO, based on multi-objective and DL for scheduling cloud-based workflows. In this study, we focus on two processes: multi-objective workflow scheduling and workflow scheduling using DL. Predicted energy, QoS, and resource consumption, ac-

tual task running time, bandwidth utilization, memory capacity, makespan equivalent of total cost, and task priority are all taken into account to determine the fitness of workflow scheduling in multi-objective-based workflow scheduling. Workflow scheduling is done with consideration for CGMO, which is derived from the combination of the GMO algorithm with the chronological idea. At the same time, DQN is fed the incoming task in the DL-based workflow scheduling process. Workflow scheduling also takes into account VM and task settings in real time. In the end, the combined product is what we get.

2. Literature Review. The concept of EMO (Evolutionary Multi-objective Optimization) was created by Zhu, Z., et al. [2]. This approach was motivated by the Amazon EC2 on-demand instance kinds. If only we could simply include IaaS's resourcing choices and cost estimate tools into the suggested paradigm! The term "regressive" was coined by the researchers G. Narendrababu Reddy and S. Phani Kumar [5]. RWO optimization (Whales optimization). The RWO model maximized resource efficiency with minimum expenditure of time, money, and energy. The original presentation of the Whale optimization algorithm (WOA) may be found in the work of Strumberger (I.), et al. [18]. In this work, we improve the implementation of the unique whale optimization and explore various approaches to solving CC's resource scheduling problem. Stephanakis, I.M., et al. [19] developed particle swarm optimization (PSO). It was a dividing line in the scheme's design, and it helped many individuals in the population agree on the best course of action.

A new paradigm called as Mobile Edge Computing has arisen to deal with the latency and network traffic problems that plague Mobile Cloud Computing systems [23]. Khan et al. [24], stating that "Edge Computing" refers to "a model that allows a cloud-based computing capacity providing services making use of the infrastructure that is on the edge of the network." Mobile Edge Computing is the practice of deploying more robust applications by using local servers or workstations inside a network to minimize latency and maximize data processing efficiency. This paradigm allows for the implementation of more reliable and efficient applications [25, 26] by enabling Edge servers to collaborate with neighboring nodes or with Cloud services. Despite the fact that Edge computing helps to ease network challenges, the network backbone may not be accessible or available while working with IoT devices in, say, mines and on ships, in deserts, or when traveling.

In dew computing, nearby machines on a network take turns processing data. This suggested design [27] aims to reduce network latency, the energy cost of transferring data over great distances, and the expenses associated with utilising Cloud infrastructure. Dew computing does this by enhancing functionality in two fundamental areas of mobile and IoT device performance. To begin, it treats mobile devices as clients inside the network architecture, offloading their duties to other devices on the same network. Second, in Dew computing, mobile and IoT devices are seen as resources that may be exploited to improve the performance of the existing system. This method enables one device in the network to use the capabilities of another (including mobile and IoT devices) to accomplish a goal [29,30, 31]. Ramesh et al. [32] explored machine learning algorithms with conventional network defense mechanisms offers a proactive and flexible strategy to protect systems from Distributed Denial of Service (DDoS) attacks, ensuring robust security measures that can adapt to evolving threats in real-time.

Jia, Y.H., et al. [9] developed the method now known as Ant Colony Optimization (ACO). This strategy received a flawless score in both the cost and efficiency categories. Time was lost because precise methods were not documented, even though they were used by numerous workflow programs. F. Abazari et al. created a method called multi-objective workflow scheduling (MOWS). The strategy's better security and risk in a wide range of workload characteristics led to an overall improvement in the building's integrity. Additionally, it demonstrated that the developed system successfully predicted attacks in cloud environments. A significant advancement in both cost and energy utilization was achieved by the development of Dynamic Voltage and Frequency Scaling with Multi-objective Discrete Particle Swarm Optimization (DVFS-MODPSO) by Yassa, S., et al. [4]. However, issues of trust and safety were not addressed. Kakkottakath Valappil Thekkepurayil et al. presented Ant Lion optimization (ALO) in [12]. ALO had a great convergence rate and was very searchable. However, there was a lack of multi-cloud collaboration integration in various clouds, therefore just one service was provided.

3. System Model. With the help of CC, the on-demand services are furnished on the basis of the necessities of user where the operation will be conducted. Therefore, numerous applications of workflow in CC may be operated with the available on-demand is the critical task in the scheduling of workflow. An

Table 2.1: Literature Analysis

Optimization Technique	Origin	Motivation/Application	Limitations/Gaps
Evolutionary Multi-objective Optimization (EMO)	Zhu, Z., et al. [2]	Inspired by Amazon EC2 on-demand instance kinds; aims to optimize resourcing choices and cost estimates in cloud environments.	Limited documentation on precise methods used; potential gap in methodological transparency.
Whale Optimization Algorithm (WOA)	Strumberger (I.), et al. [18]	Focuses on maximizing resource efficiency with minimal expenditure of time, money, and energy; applied to solve cloud computing's resource scheduling problem.	Lack of consideration for multi-cloud collaboration integration; limited to single-service provisioning.
Particle Swarm Optimization (PSO)	Stephanakis, I.M., et al. [20]	Facilitates collaboration among individuals in the population to determine the best course of action; used for optimization tasks in cloud environments.	May face challenges in handling complex optimization landscapes; potential for premature convergence.
Ant Colony Optimization (ACO)	Jia, Y.H., et al. [9]	Achieves high scores in cost and efficiency categories; applied to workflow scheduling problems in cloud environments.	Limited documentation on the precise implementation details; potential for replication issues.
Multi-objective Workflow Scheduling (MOWS)	F. Abazari et al.	Improves security and risk management while enhancing building integrity; effectively predicts attacks in cloud environments.	Limited consideration for trust and safety aspects; potential gaps in addressing security vulnerabilities.
Dynamic Voltage and Frequency Scaling with Multi-objective Discrete Particle Swarm Optimization (DVFS-MODPSO)	Yassa, S., et al. [4]	Enhances cost and energy utilization efficiency; addresses challenges in cloud computing resource management.	Does not address trust and safety concerns; potential limitations in real-world scalability and applicability.
Ant Lion Optimization (ALO)	Thekkepurayil et al.	Demonstrates high convergence rate and searchability; primarily focused on optimization tasks with single-cloud services.	Limited integration for multi-cloud collaboration; potential gaps in addressing diverse service requirements.

effectual scheduler should be required for the proper scheduling with the consideration of available resources. In addition to that, in order to process the sensitive data to control the safety and reliability of data sharing is the significant part in the secure infrastructure. Hence, the finest scheduling of workflow in the CC is designed with the advancement of safety measures that is illustrated in figure 3.1. The pre-processing data in CC has physical machines (PM) and VM, which offers the service to the user on the basis of demand. the scheduling of workflow is utilized finely in the presented model on the basis of multi-objective function in accordance with six attributes namely, resource utilization, QoS, bandwidth utilization, makespan equivalent of total cost, predicted energy, and memory capacity.

Consider the PMs employed in CGMO is illustrated by,

$$P = \{P_1, P_2, \dots, P_u, \dots, P_v\} \quad (3.1)$$

The Directed Acyclic Graph (DAG) is employed for the illustration of the scheduling of workflow and it is expressed as $Q = (G, L)$. The factor G signifies the task equivalent to the workflow that is computed as,

$$G = \{G_1, G_2, \dots, G_K, \dots, G_J\} \quad (3.2)$$

4. Proposed DQN+CGMO. The fundamental purpose of this study is to develop DQN+CGMO, a multi-objective and DL-based hybrid optimization for workflow scheduling in CC. In this setup, CGMO sched-

Fig. 3.1: Systematic View of workflow scheduling in cloud within the interval.

ules workflows based on many objectives, whereas DQN schedules workflows using deep learning. Predicted energy, QoS, and resource consumption, actual task running time, bandwidth utilization, memory capacity [20], makespan equivalent of total cost [21], and task priority are all used to determine the fitness of workflow scheduling in multi-objective-based workflow scheduling. CGMO, a hybrid of the GMO algorithm and the chronological idea, is used to schedule workflows [22]. The incoming job is also supplied to DQN [23] in the DL-based workflow scheduling process. Workflow scheduling also takes into account real-time VM and task characteristics. Here, both the tasks' parameters, such as average computation cost, earliest start time, earliest finish time, duration, and priority, and the VMs' parameters, including bandwidth utilization, memory utilization, capacity, and central processing unit (CPU), are taken into account. Last but not least, the total production is what matters most. Schematic representation of CGMO for DQN-based multi-objective workflow scheduling is shown in Figure 2. Combining Deep Q-learning (DQN) with Chronological Geese Migration Optimization (CGMO) could yield an innovative approach for optimizing task scheduling in dew-powered cloud environments. Here are the steps involved in this hybrid algorithm:

Initialization

- Set up the environment with historical data on task execution, resource utilization, and environmental conditions.
- Initialize the DQN and CGMO components of the algorithm.

Data Preprocessing

- Normalize and preprocess the input data to ensure consistency and remove noise.
- Feature engineering may be applied to extract relevant information, such as workload patterns and environmental factors.

Deep Q-learning (DQN) Exploration

- Utilize the DQN component to explore the state-action space and learn optimal task scheduling policies.
- Train the DQN model using historical data to estimate the Q-values, which represent the expected future rewards for taking specific actions in given states.
- Employ techniques such as experience replay and target network updates to stabilize training and improve convergence.

Chronological Geese Migration Optimization (CGMO)

- Implement the CGMO component inspired by the behavior of geese migrating in chronological order.

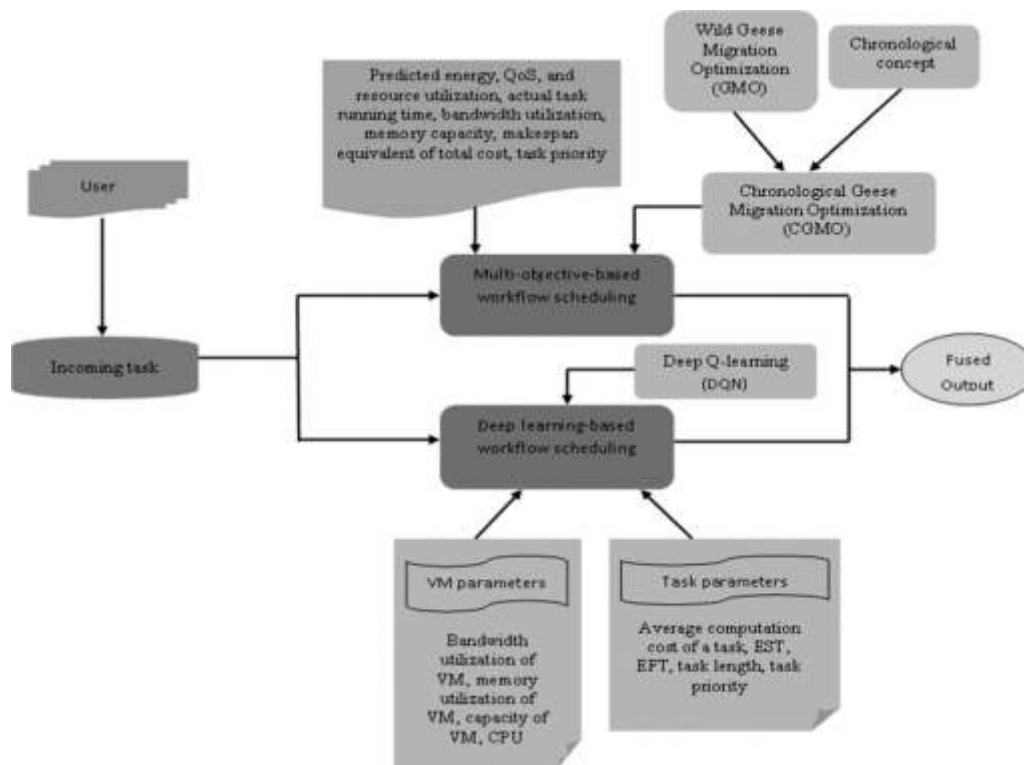

Fig. 4.1: Modeled view of CGMO for multi-objective and DQN based workflow scheduling

- Define migration paths as potential solutions to the task scheduling problem, where each path represents a sequence of task assignments over time.
- Use CGMO to iteratively update and optimize the migration paths based on historical patterns and environmental conditions.
- Leverage the collective intelligence of the population of "geese" (i.e., candidate solutions) to guide the search towards promising regions of the solution space.

Hybridization and Policy Integration

- Integrate the learned policies from the DQN with the optimized migration paths generated by CGMO.
- Combine the strengths of both algorithms to adaptively adjust task scheduling decisions in response to changing conditions and uncertainties.

Evaluation and Fine-Tuning

- evaluate the hybrid algorithm's performance using simulation or real-world experiments.
- Fine-tune the algorithm parameters and hyperparameters based on performance metrics such as resource utilization, energy efficiency, and task completion time.

Deployment and Continuous Learning

- Deploy the optimized scheduling algorithm in the dew-powered cloud environment.
- Monitor system performance and collect feedback data to facilitate continuous learning and adaptation.
- Update the algorithm periodically to accommodate evolving workload patterns and environmental dynamics.

4.1. Multi-objective based task scheduling. The system of task scheduling is significant for the enhancement of resources and the effectualness of server and also by improving the assessment of the analyzed nodes. In the multi-objective task set, the numerous tasks of multi-objective are defined time during the time processing of CC. In accordance with the execution time, the entire tasks of multi-objective on VM evaluate

4.2. Deep Learning based task scheduling. Recurrent Neural Networks (RNNs) and long short-term memories (LSTMs) (RNN-LSTMs) are used to process incoming tasks for DL-based task scheduling. VM and task settings will determine which job is chosen. Let's assume for the time being that the task's computing cost, EST, EFT, duration, and priority are all fixed. Memory, CPU, and ram are the virtual machine settings.

5. Comparative Discussion. In this section, the effectiveness of the provided technique is shown in relation to earlier models. Maximum QoS (0.785), minimum energy usage (0.022), and maximum resource utilization (1.000) were all reached using the assessment methods used for DQN+CGMO. Table 5.1 presents the results of a comparative analysis of DQN and CGMO.

5.0.1. Deep Learning based task scheduling. Recurrent Neural Networks (RNNs) and long short-term memories (LSTMs) (RNN-LSTMs) are used to process incoming tasks for DL-based task scheduling. VM and task settings will determine which job is chosen. Let's assume for the time being that the task's computing cost, EST, EFT, duration, and priority are all fixed. Memory, CPU, and ram are the virtual machine settings.

In DQN [23] the basic procedure is to allow the initial state to the Neural network (NN). Moreover, NN precedes the entire tasks at the output stage. When the current value and deep-TD target values are similar, the upgrade regulations of

$J(Z, \psi)$ is not able to upgrade the values. Therefore, $J(Z, \psi)$ congregates to the original values and observes the preferred objective.

6. Results and Discussion. This section discusses not just the end result of DQN+CGMO, but also the experimental setup, simulation settings, metrics used, and comparative evaluation. The quality of service (QoS), energy consumption (EC), and resource utilization (RU) are the metrics used by the proposed DCGM

Table 5.1: Comparative Discussion (*DQN+CGMO)

Dataset	Metrics	RWWO_D MN+DRL	RWO +DRL	WOA +DRL	PSO+ DRL	ACO +DRL	RWWTD O+DRL	Proposed*

method. The RWWO_ DMN+DRL [27] [28], RWO+DRL[5], WOA+DRL[18], PSO+DRL[19], ACO+DRL[9], and RWWTDO+DRL [3] comparison methods are used for DQN+CGMO.

The assessment of DCGM for varied job sizes with PM=5, VM=10, is shown in Figure 6.1,6.2,6.3. The DCGM based on QoS are discussed in Figure 6.1. While the previous approaches, namely RWWO_ DMN+DRL, RWO+DRL, WOA+DRL, PSO+DRL, ACO+DRL, and RWWTDO+DRL, obtained 0.174, 0.273, 0.501, 0.529, 0.574, and 0.673, the DCGM achieved the QoS of 0.750 when the task size=400. Figure 6.2 shows how much energy DCGM uses. The classic techniques such as RWWO_ DMN+DRL had 0.485, RWO+DRL had 0.399, WOA+DRL had 0.043, PSO+DRL had 0.040, AC+DRL had 0.039, and RWWTDO+DRL had 0.038 with 400 as the energy consumption if the DCGM obtained 0.035. Figure 6.3 explains the DCGM in terms of resource consumption. The traditional techniques achieved 0.947, 0.960, 0.961, 0.964, 0.974, 0.975 for RWWO_ DMN+DRL, RWO+DRL, WOA+DRL, PSO+DRL, ACO + DRL, and RWWTDO +DRL, while the DCGM earned 0.979 based on resource utilization with a work size of 400.

6.1. Assessment of DCGM based on task size with PM=20, VM=25. Figure 6.4,6.5,6.6 shows the worth of DCGM for different work sizes (PM=20, VM=25). Figure 6.4 depicts the assembly of a DCGM supporting QoS. When the task size was 400, the gains for the conventional methods were 0.204, 0.305, 0.529, 0.565, 0.599, and 0.704, respectively. The DCGM reached an all-time high of 0.785. The use of energy by DCGM is shown in Figure 6.5. For comparison, the energy consumption results for the RWWO_ DMN+DRL, RWO+DRL, WOA+DRL, PSO+DRL, ACO+DRL, and RWWTDO+DRL were 0.508, 0.420, 0.048, 0.042, 0.040, and 0.031, respectively, for a task size of 400. The DCGM achieved 0.022. Figure 6.6 depicts the typical approaches next to the DCGM with resource utilization at 1.000, including RWWO_ DMN+DRL = 0.968, RWO+DRL = 0.997, WOA+DRL = 0.997, PSO+DRL = 0.998, ACO+DRL = 1.000, and RWWTDO+DRL

Fig. 6.2: Valuation of DCGM altering task size with PM=5, VM=10 Energy Consumption

= 1.000.

7. Comparative Discussion. In this section, the effectiveness of the provided technique is shown in relation to earlier models. Maximum QoS (0.785), minimum energy usage (0.022), and maximum resource utilization (1.000) were all reached using the assessment methods used for DQN + CGMO. Table 1 presents the results of a comparative analysis of DQN and CGMO.

7.1. Applications of Proposed algorithm in Real-world environment: An illustrative Scenario.

Envision a sophisticated city infrastructure with numerous IoT sensors used to monitor several elements of urban life, including traffic flow, air quality, and energy use. Various technologies, including as sensors on lampposts and smart meters in residences, produce large volumes of data that must be processed and evaluated immediately to allow city officials to make well-informed decisions. Dew computing is a promising approach that utilizes the computational capabilities of IoT devices to analyze data closer to the source, hence decreasing latency and bandwidth usage. Scheduling workflows effectively in a changing context is a major difficulty. Introduce the suggested method, DQN + CGMO, which aims to optimize workflow scheduling in Dew-enabled cloud computing settings. Let’s examine a real-life situation: To enhance traffic flow by evaluating live data

Fig. 6.3: Valuation of DCGM altering task size with PM=5, VM=10 Resource utilization

Fig. 6.4: Valuation of DCGM altering task size with PM=20, VM=25 QoS,

from traffic cameras, vehicle sensors, and GPS systems in automobiles.

- Data Collection: Traffic data is gathered from a variety of IoT devices located across the city, such as traffic cameras, car sensors, and GPS devices.
- Data Processing: The gathered data must undergo processing to identify traffic congestion, recognize traffic trends, and forecast traffic flow in various metropolitan locations.
- Workflow scheduling utilizes the DQN + CGMO algorithm. It efficiently organizes processes by taking into account aspects like anticipated energy use, Quality of Service (QoS), and resource usage.
- Implementation: Workflows are carried out using a distributed network consisting of IoT devices, cloud servers, and edge computing nodes. Tasks are assigned in real-time according on the devices' present status and the workload.
- Feedback and Optimization: The system continuously adjusts to evolving traffic circumstances and device capabilities. It modifies the schedule of workflow to provide the best performance and efficiency.

The proposed hybrid algorithm combining Deep Q-learning (DQN) with Chronological Geese Migration Optimization (CGMO) holds significant potential for addressing various challenges in real-world industry settings. Let's explore some concrete examples of its applications across different domains:

Fig. 6.5: Valuation of DCGM altering task size with PM=20, VM=25 b) Energy Consumption

Fig. 6.6: Valuation of DCGM altering task size with PM=20, VM=25 Resource utilization

7.1.1. Cloud Computing and Data Centers.

- **Dynamic Resource Allocation:** In cloud computing environments, where resource demands fluctuate frequently, the hybrid algorithm can dynamically allocate resources based on workload patterns and environmental conditions. For example, in a data center serving multiple clients with varying processing requirements, the algorithm can optimize resource utilization by intelligently scheduling tasks on available servers, ensuring efficient use of computing resources while minimizing energy consumption.
- **Fault Tolerance and Load Balancing:** The algorithm can also enhance fault tolerance and load balancing in distributed systems. By continuously monitoring the health and performance of servers, it can redistribute tasks in response to failures or overloads, ensuring high availability and reliability of services. For instance, in a web hosting environment experiencing sudden spikes in traffic, the algorithm can automatically scale resources and distribute incoming requests across servers to maintain optimal performance.

7.1.2. Manufacturing and Supply Chain Management.

- **Production Scheduling:** In manufacturing facilities, the algorithm can optimize production schedules by

intelligently allocating resources (e.g., machines, workers) to different tasks based on demand forecasts and production constraints. For example, in a manufacturing plant producing automotive parts, the algorithm can dynamically adjust production schedules in response to changes in demand, inventory levels, and machine availability, optimizing throughput and minimizing production costs.

- **Inventory Management:** The algorithm can also improve inventory management in supply chain networks by optimizing order fulfillment and logistics operations. For instance, in a retail distribution center managing inventory across multiple warehouses, the algorithm can optimize the routing and scheduling of delivery trucks to minimize transportation costs and ensure timely delivery of goods to customers.

7.2. Implications and Potential Limitations of Proposed Work.

7.2.1. Implications.

- **Improved Efficiency and Resource Utilization:** The hybrid algorithm has the potential to significantly enhance efficiency and resource utilization in cloud environments by dynamically optimizing task scheduling decisions based on real-time data and environmental conditions. This can lead to cost savings, energy efficiency improvements, and better overall performance.
- **Enhanced Scalability and Flexibility:** By leveraging the capabilities of both DQN and CGMO, the algorithm can adapt to a wide range of workload patterns and system dynamics, making it well-suited for highly scalable and flexible cloud environments. It can handle diverse workloads and dynamically adjust scheduling policies to accommodate changing demands and resource availability.
- **Better Resilience and Fault Tolerance:** The algorithm's ability to dynamically adapt to changing conditions and redistribute tasks in response to failures or overloads can enhance system resilience and fault tolerance. It can help mitigate the impact of hardware failures, network outages, or sudden spikes in demand by quickly reallocating resources and rerouting tasks to unaffected components.

7.2.2. Potential Limitations.

- **Complexity and Computational Overhead:** Implementing and fine-tuning the hybrid algorithm may require significant computational resources and expertise, particularly in training the DQN model and optimizing CGMO parameters. The algorithm's complexity could pose challenges in real-time decision-making and scalability, especially in large-scale cloud environments with high workload variability.
- **Sensitivity to Environmental Factors:** The algorithm's performance may be influenced by the accuracy and reliability of environmental data, such as temperature, humidity, and renewable energy availability. Inaccurate or noisy data could lead to suboptimal scheduling decisions, highlighting the importance of robust data preprocessing and quality assurance mechanisms.

7.2.3. Evolution and Adaptability.

- **Continuous Learning and Optimization:** The hybrid algorithm can evolve over time through continuous learning and optimization, leveraging feedback data to refine its decision-making policies and adapt to evolving workload patterns and system dynamics. By incorporating reinforcement learning techniques, the algorithm can autonomously improve its performance and adaptability over time without manual intervention.
- **Customization for Different Cloud Environments:** The algorithm can be customized and fine-tuned to meet the specific requirements and characteristics of different cloud environments, such as public clouds, private clouds, and hybrid clouds. By adjusting model parameters, optimization objectives, and decision-making criteria, the algorithm can adapt to diverse deployment scenarios and optimize performance in various operational contexts.

8. Conclusion. DCGM is an innovative approach for scheduling workflow in CC that uses multi-objective and DL. This study incorporates two processes multi-objective workflow scheduling using DL, and vice versa. The fitness of workflow scheduling is measured using nine criteria in multi-objective scheduling. CGMO, which is derived from the combination of the GMO algorithm with the chronological idea, is taken into account throughout the workflow scheduling process. At the same time, DQN is fed the incoming task in the DL-based workflow scheduling process. Workflow scheduling also takes into account VM and task settings in real time.

Here, both the task parameters (such as the average computing cost of a task, the EST of a task, the EFT of a job, the duration of a task, and its priority) and the VM characteristics (such as the VM's bandwidth usage, memory utilization, capacity, and central processing unit) are taken into account. At the completion of this operation, the two outputs are combined. Maximum Qos (0.785), minimum energy usage (0.022), and maximum resource utilization (1.000) were all reached using the assessment methods used for DQN+CGMO. The study will be expanded to include additional hybrid networks, and the suggested method will eventually be included with cloud toolkits.

A SECURE DATA STORAGE APPROACH FOR ONLINE EXAMINATION PLATFORM USING CLOUD DBAAS SERVICE

SRINU BANOTHU*, G. JANARDHAN†, G. SIRISHA‡, SRINIVASULU SHEPURI§, MADHAVI KARNAM¶, AND ALLAM BALARAM||

Abstract. For the time being, many government or private organizations for recruitment of staff or educational institutions moving towards online based tests. The online examination system is a software application used for conducting examination using computer systems. It helps to the recruitment agency or any govt. or private organizations for conducting any job recruitment examinations transparently. Due to this system results are processed without delay and efficiently evaluated to assess the candidates abilities. But the biggest challenge for online examination system is data integrity, security and privacy. The current system is resolving the privacy issue by providing authentication credentials such as user name, password to the candidates. So that only authorized users with proper credentials can login to the system and attempt the exam. But the data confidentiality and integrity are biggest challenges for the system. As the data stored in system database is in plain text format, hence it may be modified or misused by the internal staff of the organization. This paper presents the frame work for secure storage and management of candidates data using encryption scheme, distributed databases in cloud database system. The proposed framework enhances the data confidentiality, integrity and avoids any cheating by internal staff or third party institutions. This paper conducts experimental work on proposed framework and analyses the results of the system.

Key words: online examination system, data security, cloud database, encryption, distributed database

1. Introduction. Now a days most of the recruitment agencies such as government or semi government are conducting online examination as part of recruitment process for faster evaluation and recruitment process [1]. Many recruitment agencies are gradually replacing paper examinations by online examination systems due to various information technologies and rapid evolution of network technology. Online examination systems improve the efficiency and quality of the examination and make the examinations not limited to places and regions [2]. Existing online examination system modes consist mainly of Client/Server (C /S) and Browser/Server (B /S) structure [3,4]. For the C /S examination system, examination center is autonomous. During the examination, examination questions and examination information are pushed down to examination center by the administrator. The examinee is able to take the examination at examination center. This type of structure is mostly distributed in local area network. Candidates can only take the exams within the prescribed environment that is limited to some extent in terms of time and space. In addition, this type of system has a low carrying capacity, it is not easy to scale up, it is easy to lose candidates answers in emergency situations and there are some issues like disconnected examination systems and problems with data synchronization which make it difficult for B/S based examination systems to be widely used, which is why a new technology is needed to solve this dilemma [5].

The emergence of cloud computing is the result of the rapid evolution of the next generation Internet technology. It is a new form of neural computing mode [68] that allows computing to be distributed on many distributed computers instead of on local computers or on remote servers. It is a result of the integration of distributed computing and utility computing technologies, virtualization technologies, web services technologies, grid computing technologies, and others. The purpose of CC is to enable users to utilize virtual resource pools

as much as possible at any time, anywhere on the network to solve large scale computing problems. One of the services offered by CC is Software as a Service (SaaS). SaaS is a type of software application mode which provides software services on the Internet and is the latest trend in software technology development [9, 10].

In addition to SaaS, double cache and adapter technologies are used to solve the problem of examinees answer loss and the problem of data synchronization between the examination systems in unexpected circumstances. As a result, CC offers a technical solution to the current design of the online examination system.

Conducting examination through online platform is having many advantages: it avoids the major issues of recruitment process such as paper leakage, recently it became biggest issue in telangana state(India), the internal staff of the Telangana State Public Service Commission soled the Group-I, Assistant Executive Engineering examination papers and earned the lot of black money. With this many peoples life whoever were sincerely prepared for getting job got spoiled. And also completes the recruitment process smoothly without any delays. Hence, many recruitment agencies are moving towards online examination platform. Besides advantages of this system, it also facing some issues related to user authentication and secure storage of candidate marks data. The marks obtained by the candidate plays a vital role in recruitment process, so biggest challenge is security and integrity of the marks data stored in database system. It became so significant to solve security issues; otherwise many qualified candidates lose opportunities. With these things in mind, a frame work for secure storage of marks data in cloud database system is proposed. [11] Cloud computing is a technology that provides data processing and storage services through internet on rental basis. One of cloud computing services is Database as a Service (DBaaS). The cloud Database as a Service (DBaaS) enables users to outsource data in cloud database system and access whenever required through any devices connected to internet. DBaaS provides organizations with unlimited data storage services cost-effectively with higher availability and easy deployment. Now a days most of the organizations or individuals are outsourcing their databases to the cloud environment.

The objective of this research is to develop a secure data storage and management system in cloud for online examination system using distributed databases and data encryption algorithms to meet the challenges facing by recruitment agencies.

2. Literature Survey. Any recruitment organization can plan, administer, and oversee exams in an online setting with the help of an online examination system. It helps the inspector by lessening the workload associated with administering tests, examining answer sheets, and generating results [12]. In light of this, online tests have become increasingly common in recent years. Although many young students disclose personal information on social media, Okada et al. [13] noted that their attitudes change when it comes to e-assessment since they are more worried about data privacy, security, and safety.

Cluskey et al. [14] studied all the feasible approaches to conduct online examinations without supervision. This paper presented the detail discussion about cheating scenarios used by students and also measures to avoid cheating by students. Authors have guided few methods for building an online testing plan and few online examination control techniques such as taking tests at one set time using Respondus Lockdown Browser (RDL), checking student ID, and so on.

Authors [15] proposed an approach to identify students movement in online examination using Convolution Neural Networks (CNN). The problem with this approach is that the position and orientation of students cannot be analyzed and requires much data to preview the data. And this approach is not focused on the security of data stored in database.

Mukta et. al. [16] worked on Adaptive Test Sheet Generation in E-Learning using Fuzzy Logic Approach. Authors guided the employing of an ambiguous technique of assessing students favorite tests in the e-learning.

Jung and Yeom [17] discussed about how to secure an online examination system using cryptography group. However, it needs the use of higher quality webcams and microphones. This is a disadvantage of the system. They have not concentrated about the protection of data from insider attackers.

Paul et al [18]. proposed a system where in the production manager of the questionnaire selects a percentage of complexity for questions that must be met. The program can generate papers in accordance with the format indicated by the administrator and subsequently save it in PDF format, enabling colleges to receive it upon clicking send.

Zhen and Su [19] suggested a methodology for designing a question paper template based on the input

requirements.

The paper [20] proposed a few strategies for the face identification system on this respect. The authors have defined how neural networks (NN), Support Vector Machines (SVM), and Algebraic characterization may be utilized in face reorganization systems. The colleagues and Jain presented the significance of a blockchain technology network in the online examination system. Authors introduced blockchain based online examination system. They employed the Smart contracts, it is one of the better applications and a Ethereum public blockchain platform [21]. They have additionally compared the general effectiveness of the blockchain-based method with the cloud-based scheme.

Lee and et al. developed in [22] a system that classifies student's VFOA information by capturing their head pose estimates and eye movement estimates using advanced technologies artificial intelligence approaches.

The papers [23, 24] proposed the approaches for user authentication and prevention of malpractices by users. Authors also proposed approaches for identification of misconduct of users during examination.

The authors of [24, 25, and 26] proposed the approaches for secure storage of data in cloud environments and performances of various database encryption algorithms for ensuring the confidentiality of data stored in cloud database systems. An unauthorized user cannot access data in an e-learning system. Only students who have been authenticated and granted permission can view exam data uploaded by teachers. One common technique for access control is encryption.

A session key establishment protocol was presented by Kausar et al. [27] for a predetermined duration, such as a class, seminar, or exam. The session key, which encrypts messages using symmetric cryptography, is distributed using a public key infrastructure, and message integrity is ensured by a hash-based message authentication code.

To properly finish the login procedure in Al-Hawari and Alshawabkeh's study [28], students must enter the exam instance session password correctly; the exam instance session password was produced automatically by the examination management system, and it wasn't made public until the instructor revealed it at the start of the relevant class. Few prior investigations [27, 28] have reported the possibility of a single point failure, the inability to prevent communication parties' repudiation actions, and the inability to resolve internal conflicts. In order to efficiently upload and download data in cloud-based systems, Sahaya et al. [29] presented a strategy that first encrypts the message using DES and then encodes it using Reed Solomon code in the data centers. However, it doesn't have precise access control.

The common problem identified from the above literature is that there are no approaches focused on security to the marks data stored database system. The marks obtained by the candidate may be modified by the internal staff of the organization by miss using authentication credentials. Instead our proposed model focuses on security and integrity of the data stored in database systems

3. Proposed System. To address security issues of marks data in online examinations systems and for better availability and scalability of the system. This work proposes a new framework using cloud services, cryptographic algorithms and data distribution. It is hopeful that proposed work overcomes the issues of data confidentiality, integrity and availability. These are three key measures of data security. Here a brief overview of proposed approach is presented with figure 1 for secure data storage and management of online examination systems using one of cloud service such as Cloud Database as a Service, data distribution and cryptographic algorithms. The objectives of proposed system are also discussed.

3.1. System Model. This system is having three major modules such as 1) users 2) administrator and 2) Cloud databases.

Users: The users are candidates who write the examination, every user is having authentication credentials such as username and password for login into the system. Once users are signed in they will write and submit examination. After submission users marks data and personal information will be stored in local database servers of the system.

Administrator: An administrator is a person who is responsible for whole data management such as data encryption, data outsourcing to cloud database servers, key generation, ensuring data privacy and security. An administrator plays a vital role and should be a main responsible person for ensuring privacy and security to online examination data.

Fig. 3.1: Cloud based secure data storage system for storing online examinations marks data.

Cloud Database Servers: The proposed system uses the cloud DBaaS service for secure storage of candidate's data. Data storage in cloud provides many benefits such higher data availability, security and scalability etc.

3.2. Design Objectives. *Access Control:* The question paper submitted by any recruitment agency can be accessed by authenticated users only during given time period. Answer sheet and score obtained by candidates are accessible to administrator only. The administrator can provide access policies when cipher text of data is generated and stored in distributed data storage servers. Only the users who satisfy the access policy can view the data.

- 1) *Data Confidentiality:* System keeps data highly confidential from unauthorized people access.
- 2) *Data Tampering resistance or Ensuring Data Integrity:* Data integrity is a key issue for online examination system. Any unauthorized entity in the cloud environment or local servers should not modify the data. Otherwise, it violates the transparency of the online examination system.
- 3) *Collision Resistance:* when one key is not enough for data decryption, 2 or more unauthorized entities may try to combine their keys for decryption of data. System ensures that combine keys cannot decrypt correct plain text.
- 4) *Data availability:* As data is outsourced to cloud environment, cloud service providers always keeps data available to be accessed by authorized persons whenever needed. It provides higher scalability.

4. Methodology. This section presents the methodology of proposed system. Proposed approach achieves key elements of data security such as data confidentiality, data integrity and data availability. The aim of this approach is to securely outsource and manage the data of online examination using cryptography algorithms, data distribution and cloud services. The proposed approach uses cryptographic algorithms and vertical fragmentation feature of distributed database to achieve data confidentiality and data integrity. In this approach vertical fragmentation plays a vital role for achieving data confidentiality. Vertical fragmentation is a technique to split the database table vertically into two or more sub table fragments with chosen columns. As database tables are partitioned vertically with selected columns into two or more sub tables and distributed data into multiple database servers in cloud, the internal staff of the cloud service provider cannot get complete information about a record. So it keeps the data secure from insider attack in cloud environment. The cloud services are used for proving better data availability and scalability. Proposed system uses the Cloud Database as a Service (DBaaS) for storing data in cloud environment, Advanced Encryption Standards (AES) algorithm for cryptographic operations (i.e encryption and decryption of data) on data. As AES is more secure and robust algorithm, it is chosen for cryptography operations. AES uses keys of variable length such as 128,192 and 256 bits length keys, for 128 bit key, about 2128 attempts are required to break the cipher. This is very difficult task for the hacker to hack the data. The framework consists of two major modules: users and Administrators.

Users: users login to the online examination system using authorization credentials and attempt the test, after test is over submit the test. This test data will be stored in systems local database servers.

Administrator: Administrator is an owner of the data stored in systems local database servers, performs tasks such as data encryption and outsourcing to cloud environment for ensuring data privacy and security. For achieving data security issues, the proposed framework consists of two phases

Setup Phase. In this phase, administrator does the data pre-processing, outsourcing and user authorization

1. Administrator encrypts the database table attribute values using advanced encryption standard algorithm (AES) with a secret key (this key only knows to the administrator). Administrator uses SHA 256 authentication algorithm for generating 256 bit secret key.
2. Splits the table vertically into 2 or more sub tables with selected columns (i.e. vertical fragmentation). While splitting tables, in each sub table columns are included using a factor called key and data sensitivity. The maximum number of possible sub tables depends on number of columns of a table. Each sub table must includes at least two columns
3. Add row index column in each sub table and insert row index value in index column, it should be the same value for a row in every sub table. This helps to identify each sub records of a row of actual table (i.e. before splitting of table) and merge the records of fragmented tables into a record of original table (i.e. before partition). Row index column values are unique and not in encrypted form.
4. Finally, upload the vertically partitioned table data into multiple database server platforms of the same cloud environment. Choose different locations of data centres to store the data of partitioned table fragments. This makes very difficult to an attacker or internal staff to get complete record information of a table as records are partitioned and stored in different data centres.

Retrieval Phase. In this phase, the administrator sends the data retrieve request to all database servers where fragmented data is stored in cloud. The key attribute to select the records from fragmented tables is row index value. The cloud database server returns requested records data in encrypted format from multiple sub table fragments. An application merges the records data into a record of original table (before fragmentation). Then administrator gives input as secret key and then decrypted results are shown to the user. Only one key is used for data decryption The algorithms for secure data uploading to the cloud environment and retrieval are shown in Algorithm 1 and 2.

5. Implementations and Results.

Experimental Setup. For experimental results we have used the cloud service from cloudcluster.in and software technology PHP (Hypertext Preprocessor) for application development and MySQL database server for backend data store. For testing the results of our proposed model, initially we have created a account in cloudcluster.io, cloud cluster provides a complete managed open source application cloud service on kubernetes cloud for cloud DBaaS service. In which we have deployed two MySQL database servers with configurations of servers on cloud platform are:3(core) Processors, 4GB RAM, 100GB SSD and chosen data centers at two different locations for storing the fragmented table data. Then developed a small application in PHP and installed MySQL database server on local system for storing dataset. The data set is created with random values of marks in the range from 0 to 50. Data set includes fields such as candidate id, test id, marks scored. XAMPP server is installed on our local system to run an application. Our system is configured with Intel core i5 processor, 10GB RAM and 360GB hard disk space. System is connected to the internet of 150mbps Network speed. The results are shown in below figures.

For experimental purpose, we have created a database table named as testscore with fields such as id, candidateid, testid and testscore, in our local machine.

Figure 5.1 shows the records inserted into the testscore table in local system. The records in the database table are stored in plain text format or readable format. Then created two table fragments, one with fields id, candidateid, testid and other with id, testscore in two different cloud database servers. Here attribute id is a row index added in both table fragments. Later, run our application on our machine to encrypt, split and insert encrypted records into cloud database servers as shown in figure 5.2, in which records with selected columns are stored in encrypted format. Finally, figure 5.3 shows the encrypted data stored in fragmented table. Both table fragments are having same values for every row for row index attribute id.

5.1. Performance Analysis.

Performance Evaluation. The performance of proposed scheme is evaluated by considering the parameters such as time taken to encrypt, split and upload data into cloud environment and time taken to retrieve the

Algorithm 1 Database upload to cloud

```

Procedure databaseupload(dbname, tablename, secretkey )
{

Inputs: local database name, table name, secret key as inputs
Output: encrypted and vertically partitioned table
segments uploaded to database servers in cloud      ▷ generate the 256 bit hash code of secret key using SHA256
algorithm and save key in local database system

Hashed_key=sha256(secret_key);
                                                    ▷ Select the table data to be outsourced from local database server

if(num_of_rows ≥ 0)
{

while (all rows are processed)
{
    ▷ Select one row and encrypt all column values of selected row using AES256 algorithm with hashed secret key.

C1=encrypt (column-1)
C2=encrypt (column-2)
C3=encrypt (column-2)
C4=encrypt (column-2)
.
.
Cn= encrypt (column-n)
Insert (row-index, C1) into tablefragment1 in cloud
Insert (row-index, C2) into table fragment 2 in cloud
Insert (row-index, C3) into table fragment 3 in cloud
Insert (row-index, C4) into table fragment 4 in cloud
Insert (row-index, C5) into table fragment 5 in cloud
.
.
Insert (row-index, Cn) into table fragment
N in cloud
} } }

```

data from cloud database and view results to the users. The time to upload data (UT) considered the time of AES algorithm for data encryption (ET), communication cost (CC) and query execution time (QET).

$$UT = ET + CC + QET \quad (5.1)$$

The time to retrieve the data (RT) from cloud database servers, considered the time of AES algorithm for data decryption (DT), communication cost (CC) and SELECT query execution time (SQET). Here SELECT query without predicate is used for retrieving all the records from database.

$$RT = DT + CC + SQET \quad (5.2)$$

The performance of data upload time and retrieval time are tested by considering the data sets with variable number of records. The performance of the system in terms of time in seconds to upload data and retrieval data are shown in figure 5.4.

Security Alalysis. The security of our proposed approach is analyzed against to insider attacks and outsider attacks. The data is strongly protected against the insider and outsider attackers in such a way that as data is encrypted and distributed into multiple database systems if attacker compromises the data in one fragment,

Algorithm 2 For Secure retrieving of data from the cloud DB

```

Procedure database__retrieve (dbname, tablename, secretkey )
{
    ▷ Cipher text can be from your MySQL data or from a user input via a web form.
    ▷ This example will use user input cipher text to decrypt.
    ▷ generate the 256 bit hash code of secret key using SHA256 algorithm and compare with saved key in database

    Hashed_key=sha256(secret_key);
    ▷ compares decryption key

    if (decryption key matches with encryption key)
    {
        ▷ retrieve the records from table fragment1 in cipher text format

        Sql1=SELECT * from fagment1;

        if (num_rows_of_fragment1 ≥ 0)
        {
            ▷ select one record from fragment1

            While (all rows of fragment1 are processed)
            {
                ▷ select records from table fragment2 matching id with id of record selected from table fragment 1
                ▷ merge records retrieved from fragment 1 and 2

                $ row= $ row1+$ row2;
                ▷ decrypt all column values using AES decryption algorithm and secret key

                P1= decrypt (column-1)
                P2= decrypt (column-2)
                P3= decrypt (column-2)
                P4= decrypt (column-2)
                .
                .
                .
                Pn= decrypt (column-n)
                } } } }

```

cannot get the complete information and inside attackers also unaware about data format stored in database. The proposed scheme achieves data integrity such a way that as data is encrypted using symmetric encryption scheme using a secret key if any modification is done on cipher text, it cannot be decrypted properly.

As data is stored in one cloud vendor, the approach requires less cost and less communication delay for data upload and retrieval operations. So our model is more efficient and secure with less cost than available state of art models in literature. From literature, authors have focused on user authentication of online examination system to prevent from masquerade attacks, in this study we focused on confidentiality and integrity of marks data of the users after storing in database servers. This study ensure to protect data from internal staff of the organization, because internal staff may misuse their credentials and do update the marks. This is huge loss for the candidates those who prepare sincerely and write the examination.

Our proposed scheme, in addition to offering a higher security level, our scheme preserves better communication and computation performance while uploading data and retrieval phase. This is particularly important when it comes to privacy-preserving and avoiding single-point failure.

6. Conclusion and Future scope. In this paper, we propose a scheme for secure data storage and management of online examination systems using symmetric key cryptography algorithms, data distribution and cloud database as a service (DBaaS). In proposed scheme for preserving data confidentiality and integrity, database table records are encrypted using cryptographic AES-256 algorithm with 256 bit secret key generated

preserves the data confidentially and integrity. As cloud is rental basis service, the cloud services providers always takes care about the security of physical infrastructure and keeps it always available. As cloud vendors maintain the infrastructure suitable for variable sized data, good scalability can be achieved with this approach. In our future research, scheme will incorporate other encryption algorithms and evaluate the performance.

MACHINE LEARNING BASED TOOL WEAR PREDICTION FROM VARIABILITY OF ACOUSTIC SOUND EMISSION SIGNALS

N V. KRISHNAMOORTHY *AND JOSEPH VIJAY †

Abstract. A novel machine learning-based model is introduced in this research paper to forecast tool wear using acoustic emission (AE) signals. Adaptive boosting (AdaBoost) and a sophisticated feature engineering strategy are employed by the model to enhance the precision of its predictions. The proposed model, Machine Learning Tool Wear Prediction (MLTWP), analyzes AE signals generated during machining operations to distinguish between healthy and worn-out tool conditions with remarkable accuracy. The crux of our approach consists of meticulously eliminating and enhancing the temporal and spectral characteristics of the AE signals. We employ the Kolmogorov-Smirnov test to identify the most valuable classification features. We implemented AdaBoost with the objective of progressively enhancing a set of weak classifiers' ability to identify instances that were incorrectly classified in previous iterations. Utilizing this method increases the model's sensitivity to minute variations in tool wear conditions and its overall classification precision. The MLTWP model underwent extensive testing on a benchmark data set comprising 25,304 AE signal records from cutting mill tools, using a training tool split of 9,989 worn (positive) and 8,990 benign (negative) instances. The results of our experiments, validated through four-fold cross-validation, indicate that the MLTWP model exhibits superior performance compared to the existing Tool Wear Prediction using Acoustic Emission Signals (TWPAE) model. To provide greater specificity, the MLTWP exhibited the following metrics on average: precision (92.2%), specificity (91.38%), sensitivity (90.42%), accuracy (90.9%), and MCC (81.72%). The fact that these metrics exhibit significant improvement over those of the TWPAE model demonstrates that our method of feature engineering and adaptive boosting is effective at precisely predicting tool wear. This research not only advances the existing understanding of tool wear prediction but also establishes a robust framework for the implementation of machine learning in manufacturing predictive maintenance.

Key words: Machine Learning; Tool wear Prediction; Acoustic Emission Signal; and Artificial Neural Network; Kolmogorov-Smirnov (KS) Test

1. Introduction. Tool wear has a direct impact on the energy required to remove metal that in turn has an impact on dimensional accuracy, surface roughness, as well as the cutting operations [1]. Tool wear results from chemical, thermal, and mechanical interactions between the materials of the tool and the workpiece. The two primary forms of tool wear, which might signal the end of a tool's life are crater wear as well as flank wear (Vb), which are both caused by these interactions [2]. The efficiency of the procedure relies on flank wear. This variable shows wear from the industry. It has been extensively researched that flank wear raises cutting forces [3], in turn which raises the power tool of machine tools. Forces, power use, and the dynamics of tool-material interaction are all impacted by flank wear. Acoustic emissions (AE) are used to measure flank wear during turning movements, as discussed in [4].

Because of the tool's variable working environment, complex operating conditions, and various cutting settings, tool wear prediction is challenging. Tool wear but also noise signals are only two examples of the information-rich sensor signals with in mechanical tool process. To determine the level of tool wear, signals should be normalised and features extracted.

Noise Monitoring the wear of a tool requires signal processing. The processing of data via the time-frequency analysis is common [5]. The preprocessing of the signal and manual extraction of tool wear features from the signal are common signals for traditional wear detection systems. Data on several cutting parameters under various operating situations must be obtained through numerous tests and manual analysis. These techniques won't work in all situations and have limitations in actual application.

Plastic deformation, corrosion, fracture propagation, impact, erosion, or leakage are the main causes of AE

[6]. For non-destructive testing, AE is used in refineries, pipelines, nuclear and conventional power production, aero planes, offshore oil platforms, and paper mills, including structures such as bridges and cranes [7]. For the last 30 years, tribologists, who study the interaction between moving surfaces (such as during machining operations), have concentrated on AE due to the precision with which it can detect surface wear.

AE signals are produced by friction processes range from 50 kHz to 1 MHz [8]. The AE sensor, to avoid signal attenuation, must be attached to the cutting tool or the workpiece. Since both the cutting tool as well as the workpiece are transient, the sensor in practical applications must be positioned in the tool holder.

A simple machine learning model is provided to forecast tool wear. It was inspired by recent promising work in tool wear monitoring using machine learning [9], [10].

2. Related Research. An electronic-mechanical system was created by Weller et al., [11] that uses sonic signals to assess the cutting edge wear of turning tools. In tests, the system is able to identify used cemented carbide tools that can cut AISI 1045 steel. A cutting tool quality check based on sound was developed by Mannan et al., [12]. In order to identify tool wear related sound patterns, the suggested approach enables process of machining sound signals. This technique has been proven to locate cutting instruments that are sharp, semi-sharp, and dull. Chatter was discovered by Delio et al., [13] utilising sound signals. Experiments demonstrate that the chatter detection technique based on audio signals performs as well to dynamometers, accelerometers, as well as displacement probes. A method for legitimate tool status monitoring specifically for turning was created by Salgado and Alonso [14]. One-dimensional spectral analysis of feeding motor current but also audio signals showed direction-changing data. By analysing retrieved characteristics and applying a SVM (support vector machine) technique, tool wear was calculated. To measure tool wear, Aliustaoglu et al., [15] employed microphone-captured audio signals and two-stage fuzzy logic. Testing for drilling was done on a four-axis Cnc turning centre. Sound signals were recorded with the microphone. In studies, two-stage fuzzy logic may identify tool wear. The audio signal processing was employed by Ubhayaratne et al., [16] to track the tool wear in sheet metal stamping. Stamping audio signals were cleaned and preprocessed using semi-blind signal extraction. A technique for determining the degree of tool wear based on vibrations from the machine's spindle was developed by Seemuang et al., [17]. The drilling sound signals were recorded using a low-cost microphone. Support vector machines were utilised by Kothuru et al., [18] to categorise tool wear problems (SVM). Features in the frequency domain were sanded out of audio signals. Over 90% prediction accuracy.

ANN (Artificial Neural Network) should be used to assess feeder machine current, cutting, as well as source of feed, according to Alonso et al (ANN). Maximum vibration length is inversely related to unidirectional tool wear, as shown by Sadettin et al., [19]. Ming-Chyuan et al., [20] as well as Alonso F.J. et al., [21] discovered that the sole audible sign of tool flank wear is when a machine produces a noise when cutting. In order to determine tool flank wear rapidly, According to Peng et al., [22], if the signal is treated linearly and travels, obtaining the Fourier spectrum might produce a considerably lower physical sensation. According to Huang et al., [23], Fourier processing produces global signal qualities as opposed to local ones. Another technique for estimating outcomes is the Hilbert-Huang transformation [24]. Prakash et al., [25], [26] has shown how streamlining a procedure produces good outcomes and a simpler way.

A contemporary model that relates to the objective of this article is projected by Ferrando Chacon et al., [27], which is referred as Tool Wear Prediction using Acoustic Emission Signals (TWP AE) in further discussions. The contemporary model TWP AE has used acoustic emission signal frequencies as features and focused on the process of eliminating redundant features as well as predicting worn state of the tools using machine learning. However, the feature engineering of this model is suboptimal as it is limited to eliminating redundant features and restricted only to the signal frequencies.

Yang, Cheng et al. [28] proposed a novel approach to understanding how milling tools wear down over time. This method combines an analysis of wear-related factors with a wear-prediction model, with a focus on how tool wear works and changes over time. The method improves the accuracy of tool wear predictions by combining experimental data and modeling. The goal is to improve the efficiency of machining processes and reduce downtime.

Perumal et al. [29] presented a simple machine learning method for monitoring tool wear in real time using sound signals. Their findings revealed that basic acoustic emission (AE) signals could be used to predict tool wear, making this a simple and effective method for tool condition monitoring (TCM) in manufacturing settings.

The study also demonstrated that linear regression algorithms can be used to calculate tool wear based on AE data. This could be a low-cost way to increase machining efficiency and tool life.

Qian et al. [30], investigated how BiLSTMA networks can be used to predict tool wear and how difficult it is to demonstrate how wear properties change over time. Their model examines sensor data and makes more accurate predictions than older methods by utilizing bidirectional long short-term memory (BiLSTM) architectures and attention mechanisms. This method demonstrates the importance of advanced neural network models in understanding and predicting how tool wear changes over time. He et al. [31] developed a deep multi-task network that uses sparse feature learning to monitor tool wear and machining quality simultaneously. Their framework combines deep learning methods to extract and connect features from various types of data. This gives them a comprehensive tool for determining how tools are performing and ensuring the quality of the products they produce. The findings show that multi-task learning and sparse representation work well together to improve prediction accuracy and operational efficiency in manufacturing systems.

Twardowski et al. [32] used acoustic emission techniques and machine learning methods to detect tool wear. Their findings show that AE sensors are effective at detecting changes in the condition of tools, and that machine learning algorithms can be used to analyze complex sensor data to determine how much wear something is experiencing. This study adds to the growing body of evidence arguing that AE monitoring and artificial intelligence should be used in tandem for proactive cutting tool maintenance.

The predicting and monitoring tool wear advances the field by introducing new approaches, such as combining wear-related factors, employing basic to advanced machine learning methods, and using acoustic emission signals for real-time monitoring. Each study demonstrates the potential for improving tool condition assessment accuracy and operational efficiency. However, they also highlight issues such as the need for a large amount of experimental data, the difficulty and computational requirements of advanced neural networks, and the feasibility of implementing these technologies in a variety of manufacturing environments. A thorough examination reveals that more research should be conducted on how to make these methods work in the real world with various types of machining operations, how to make them more scalable, and how to make complex models easier to understand. As this body of work demonstrates, tool wear monitoring research is constantly evolving. It predicts a future in which technology is increasingly used in manufacturing processes.

Due to the low specificity and sensitivity of existing tool wear prediction methods, it was determined from this analysis that using acoustic emission signals as input to machine learning based tool wear prediction is an additional viable research aim. Here, feature engineering for educating machine learning models is the main concern.

To better forecast tool wear from acoustic emission signals, this research contributes by concentrating on temporal and spectral aspects and an optimization approach based on a statistical diversity evaluation technique to overcome these limitations.

3. Methods and Materials. The processes and resources that went into developing the suggested model are outlined below. The features that will be used throughout the proposal's learning phase, as well as the appropriate features extraction from the provided labelled data. This section also discusses the strategy used to compare the projected values of an attribute over the provided records of the both positive and negative class labels. Moreover, this part investigates the appropriate classifier for detecting acoustic emission signals. We have also looked at the proposal's testing phase (identifying acoustic emission signals).

3.1. Acoustic Emission Signals. Transient elastic waves are produced when a material undergoes a quick redistribution of stress, a phenomenon known as acoustic emission (AE). When a structure is stressed (by load, pressure, as well as temperature change), energy is released from localized sources as stress waves, which travel to the surface and yet are measured by sensors. Picometer (10-12 m) movements can be detected with the correct equipment. AE can be triggered by a variety of events, including earthquakes, rock explosions, fissures, slip and dislocation motions, melting, twinning, and phase transitions in metals. In the case of composites, acoustic emissions result from matrix cracking, fiber breaking, and debonding. There are other AEs in polymers, wood, and concrete.

A material discontinuity's origin and importance can be revealed via its AE signal. Besides its extensive usage in academic studies, AET (acoustic emission testing) is also routinely used in a variety of industrial

contexts (e.g., evaluating structural integrity, locating defects, determining leak rates, and keeping tabs on weld quality).

In testing to conventional NDT techniques, Acoustic Emission stands apart in two key aspects. To begin, let's talk about the origin of the signal. Instead of supplying energy, AET just listens for energy emitted by the item being studied. Acoustic emissions can be triggered and propagated in operational structures by applying appropriate loading during AE testing. The discipline of AET is dedicated to the investigation of material dynamics. Not inactive characteristics (like a crack that isn't expanding) are shown. It is critical to detect both new and persistent flaws. Defects could be unnoticed when any loading becomes too low to trigger an acoustic event. AE testing provides instant feedback on the reliability of a part. With AET, there is no need to disassemble or clean the specimen, and yet a thorough volumetric assessment can be performed quickly and accurately thanks to the use of several sensors and a permanent mounting system that also allows for process control.

3.2. Preprocessing of the AE signals. In the process of digitizing the gathered sound signals, they frequently mix in with signals from other sources whose waveforms and arrival timings are not known. In order to extract the physical characteristics that best correspond with tool wear, signal processing is employed as part of the pre-processing stage of TCM systems for machining. Sound characteristics are extracted using a variety of signal processing techniques [33]. In this investigation, 1-second samples were taken from sound signals and analysed in the temporal domain. Frequency domain analysis samples were processed using FFT (Fast Fourier Transform)-based DTFT (Discrete-Time Fourier Transform). This research used a single absolute value from the Fourier transform to build a decision-making model. In order to resolve the DTFT-PR (preset resolution) issue in future research, the WT (Wavelet Transform) will be used.

Sound signals under the same cutting settings and at good and tool wear levels are displayed as a frequency spectrum in Figure 3.1. The spectrum was shown logarithmically to draw attention to the low-frequency band, where signals include more information about tool wear. Multiple frequency amplitudes are shown to correlate to tool wear in the images, highlighting the need for a sophisticated decision-making model to accurately depict these relationships.

3.3. Features. Temporal characteristics are those in the time domain, including signal energy, less energy, 0% of crossing, and many more, that are easy to extract and have physical comprehension.

- Since the stochastic process stated as a mathematical approach for acoustic emission only considers random variables, acoustic emission spectrum analysis is often more advanced than deterministic signals analysis, such as sinusoids.
- Static acoustic emission signals require a spectral phase that is completely random and, thus, devoid of information. The use of constant acoustic emission signals may be to blame for this phenomenon; by definition, it cannot occur randomly at times. Therefore, the phase idea is irrelevant for acoustic emission signals, which is a major difference between these signals as well as deterministic spectrum signals.
- So, spectral properties like frequency components, spectral density, fundamental frequency, and many more have been achieved by transforming a time-based signal into the frequency domain using Fourier-transform (FT). In this context, these characteristics might be put to use in identifying tones, rhythms, melodies, and pitches.
- Audio signals are often complex, made up of many individual shock wave of a fixed wavelength that propagate as a single perturbation in the medium. While the sound is being captured, we record the amplitudes of the ensuing waves. To break down a signal into its frequency components, mathematicians use a concept known as the Fourier Transform (FT). FT also provides the magnitude of each frequency in the signal, in addition to the frequency spectrum.

In the study of sound, novices often employ the broad spectral characteristic, which may take the form of a rising, decreasing, or varying frequency. The FT creates harmonic sound generators called as signal's spectral structure in acoustic emissions. As said before, there are a variety of ways this might be demonstrated. In other words, if the initial partial harmonic of a periodic signal, whose vibrations have repeated throughout time, is 100 Hz, the subsequent partial harmonics will be 200 Hz, 300 Hz, etc. This may, however, be an unusual occurrence in the realm of sounds created by nature. Make a note to the effect that no spectral characteristics

Fig. 3.1: Sound signals emitted from worn and benign tools at the same cutting settings

or devices are related to any suggested laws in the actual world where we could perceive sound. MFCC ("Mel cepstral frequency coefficients") as well as "predictive linear perceptive" (PLP) feature were the two best spectral features used in the acoustic emission. In this case, it may be understood that the frequency content of acoustic emissions is evaluated by the cochlea in the eardrum. Bandpass filters with a constant Q rank made it possible to modify the inspection of the basilar membrane. There is also the presence of essential bands, which rise to mask phenomena, where a burst or one strong acoustic emission may hide another lesser acoustic emission inside an essential band. The features of the auditory system that allow for the identification of acoustic emission are captured by both PLP and MFCC. Nonetheless, the strength of these characteristics was not very pronounced with respect to the acoustic emission.

The acoustic emission is also supported by a few time-domain characteristics, such as the plosion index and the highest coefficient of correlation.

In many complicated signals, such as acoustic emission, the signal's characteristics change over time. Small-time FT plays an important role in the interpretation of divergent acoustic emissions and may be more useful for referring to changes in frequency components over a finite time period. Integrating temporal envelopes over short time periods allows FT to derive spectral characteristics, while temporal-features are generated by turning envelopes into frequency modulation devices.

Temporal characteristics included things like ZCR, energy, etc., whereas spectral features included things like MFCC, GTCC, and several others in the frequency domain.

3.4. Kolmogorov-Smirnov test (KS Test). The significance of any differences between samples may be swiftly determined by using the Kolmogorov-Smirnov test [34]. As a uniformity, it ensures that all values in a distribution are consistent with one another. The Kolmogorov-Smirnov test allows one to examine the uniformity of a distribution, an important feature. In addition to comparing two multi-dimensional probability distributions, the Kolmogorov-Smirnov test may also evaluate the similarity of two one-dimensional distributions. It can immediately tell whether there is a difference between two samples. The Kolmogorov-Smirnov statistic evaluates the dissimilarity between the empirical distribution functions of two samples or between the

Fig. 3.2: Cumulative distribution function

sample and the reference distribution.

Distributions of observations in the two data sets may be compared using the Kolmogorov-Smirnov (KS) test [34]. Each dataset’s values are assumed to come from a given continuous distribution (the null hypothesis). As an alternate hypothesis, these data sets come from several continuous distributions. It is possible to do the hypothesis test with a 5% level of statistical significance. Cumulative distribution functions (CDF) for two different datasets are depicted in figure 3.2. The null hypothesis is supported by a two-sample KS test, which returns the D value of 0.1782 as well as a P-value of 0.694. At the 5% level of significance, the KS test on such two datasets failed to disprove the null hypothesis, showing that the given samples are drawn from the identical continuous distribution. This test can only conclude that, the distributions are distinct; it cannot reveal any changes to the mean, variance, or extremes.

The usage of KS-Test method explained in following description. In order to estimate the diversity between two vectors v_a, v_b representing the samples of two different distributions, $ks - test(v_a, v_b)$ Given two vectors v_a and v_b , the aggregate values of these vectors are represented as follows: Eq 3.1, Eq 3.2

$$\|v_a\| = \sum_{i=1}^{|v_a|} \{e_i \mid e_i \in v_a\} \tag{3.1}$$

$$\|v_b\| = \sum_{i=1}^{|v_b|} \{e_i \mid e_i \in v_b\} \tag{3.2}$$

The cumulative ratio for each sample in the vectors v_a and v_b is predicted as follows (Eq 3.3):

$$\forall_{(i=1)}^{|v_a|} \left(v_a^{cr} \leftarrow \sum_{j=1}^i \left(\frac{e_j}{\|v_a\|} \mid e_j \in v_a \right) \right) \tag{3.3}$$

Here, Eq 1 determines the cumulative ratio of each e_i of the elements listed in vector v_a . The $\|v_j\|$ indicates the aggregate value of the samples listed in the vector v_a , and v_a^{cr} is a set that comprises cumulative ratios of the samples listed in the vector v_a .

Further, it discovers cumulative ratios v_b^{cr} of the samples listed in vector v_b .

The absolute distance of "cumulative ratios" corresponding to values that are present at a similar index of both v_a and v_b vectors is found as: Eq 3.4

$$\forall_{(i=1)}^{(\max(\|v_a^{cr}\|, \|v_b^{cr}\|))} \{D[i] = \sqrt{(v_a^{cr}[i] - v_b^{cr}[i])^2}\} \tag{3.4}$$

Eq 2 for each index i , represents the "absolute distance $D[i]$ " of "cumulative ratios $v_a^{cr}[i]$, $v_b^{cr}[i]$ ".

The maximum value of the set D is found as d -stat. Then, find d -critic (from the KS-Table) at a given "degree of probability threshold" p_τ (0.01, 0.05, or 0.1) for vector aggregates $\|v_a\|$, $\|v_b\|$.

The return value is determined by the following condition:

$$\begin{cases} \text{false} & \text{if } d\text{-stat} > d\text{-critic} \\ \text{true} & \text{if } d\text{-stat} \leq d\text{-critic} \end{cases} \quad (3.5)$$

If d -stat is greater than d -critic, then there is no diversity between the given vectors' distribution. Hence, return false; else return true.

3.5. The classifier. Adaboost was designed to improve the performance of binary classifiers by using an ensemble learning approach. Adaboost uses iterative learning to learn the shortcomings of weak classifiers. The method of adaptive boosting [35] is utilised by the Adaboost classifier. Multiple, rather weak Boolean classifiers are combined to form this weak classifier. Every weak classifier has a single true/false criterion to divide the data. False-positives as well as false-negatives might be separated by other Weak Classifier. This continues until the WC calls time on the competition. The output of each WC will be combined to form the final output of the classification operation. In this section, the WC represents the proposed model's binary-classification optimal features, which are characteristics that are both consistent with the class and different from it.

Weak-Classifier iterations of the classification process allow the part of the corpus that didn't need to be categorized exactly to be boosted for the subsequent classifier iteration. Classification weight (WC) is utilised at each iteration to show the relative importance of different categories. Iterative calls to the WC will result in a standardization of classified records. Adaboost WC provide a concrete n-gram for precision classification and provide a justification for record polarity classification in the proposed approach. The suggested approach would use the WC to learn the suitability of each feature category for both positive and negative sentiment training corpora.

All data points are given equal consideration when Adaboost generates a model. Incorrectly categorized data are given more weight. In the following paradigm, more significant information is given more weight. Models will be trained until there is a noticeable improvement in accuracy. What follows is a description of the internal structure of this algorithm. Before doing binary classification, Adaboost assigns weights to data points. At the outset, irrespective of the overall data points, each data point has the same weight. In order to this, produce a decision stump from each of the features and then assess its tree accuracy using the Gini Index. In terms of the Gini Index, the first tree stump represents the worst possible result. Classified data points using this tree's alpha ("Importance" or "Influence") is based on the following Eq 3.6.

$$2^{-1} \cdot \log_e \left(\frac{1 - \|w\|}{\|w\|} \right) \quad (3.6)$$

Aggregating the all of the sample weights related to data points that are incorrectly labelled can define the total error $\|w\|$.

Consider a dataset having 5 data points as well as the assumption that there is 1 incorrect output; the total error then will be 1/5 (ranges between 0 and 1), then the stump's performance (alpha) will be: Eq 3.7, Eq 3.8, Eq 3.9, Eq 3.10

$$\alpha = 2^{-1} \cdot \log_e \left(\frac{1 - 5^{-1}}{5^{-1}} \right) \quad (3.7)$$

$$\alpha = 2^{-1} \cdot \log_e \left(\frac{0.8}{0.2} \right) \quad (3.8)$$

$$\alpha = 2^{-1} \cdot \log_e(4) = 2^{-1} \cdot (1.386) \quad (3.9)$$

$$\alpha = 0.693 \quad (3.10)$$

The error rate for alpha () ranges from 0 to 1, where 0 Indicates perfect stump and 1 indicates awful stump (see figure 3.3).

Fig. 3.3: Alpha versus error rate

As can be seen in the above graph (figure 3.3), whenever there is no misclassification, there is no error (Total Error = 0), and hence the alpha is quite high.

The classifier’s alpha will be zero if its predictions are half accurate and half wrong, with a total error of 0.5. A negative alpha value indicates that the classification was erroneous for all samples. If this is the case, the error is extremely large (approximate to 1), and the significance level will be low.

When the same weights being used to the next model, therefore the output obtained is identical to what’s been obtained in the first model, hence updating the weights is required in order to determine the total error $\|w\|$ as well as performance of a stump.

Correct forecasts will have their weights lowered while incorrect guesses will be given greater weight. After adjusting the weights, we will now give the data points with maximal weights more preference when building our next model.

It is important to update the weights that use the given formula after the classifier’s significance and the total error have been determined (Eq 3.11):

$$cw = w \cdot e^{\pm\alpha} \tag{3.11}$$

New weight cw , the alphas being negative whenever the sample is correctly classified. The alpha is being positive whenever the sample is miss-classified.

3.6. Tool Wear Prediction Model. The set SC of acoustic emission signals that are taken as input for training phase of the classification process shall be processed to digital format and then bi-part in to sets P and N , where set P represents the acoustic emission signals of the wearied tools (labeled as positive). In contrast, set N represents the acoustic emission signals of the benign tools (tools that are not wearied), which are labeled as negative.

Further, derives all the temporal and spectral features of acoustic emission signals listed in the set P as two different matrices named as tP, sP , which are representing temporal and spectral features in respective order. Here, each row of the both matrices representing the respective features of the corresponding acoustic emission signal listed in the set P . Similarly, derives all the temporal and spectral features of acoustic emission signals listed in the set N as two different matrices named as tN, sN , which are representing temporal and spectral features in respective order.

Further step of the learning phase discovers optimal temporal and spectral features of the both positive and negative labels as described below (Eq 3.12, Eq 3.13):

$$\bigvee_{(i=1)}^{\max(|tP|, |tN|)} \{tP[i], tN[i] \mid |tP[i]| > 0 \vee |tN[i]| > 0\} \tag{3.12}$$

// Eq 3.12 For each iteration, considers the vectors $tP[i], tN[i]$ representing the values listed in $i^{(th)}$ column of the matrices tP and tN in respective order.

$$\text{if}(\text{ks-test}(tP[i], tN[i]) \equiv \text{false}) \quad tP \setminus tP[i] \wedge tN \setminus tN[i] \quad (3.13)$$

This Eq 3.13 discovers the diversity state between two vectors $tP[i]$ and $tN[i]$ through KS-Test, $\text{ks-test}(tP[i], tN[i])$. If the diversity state is false, then the columns of the matrices tP , and tN represented by the vectors $tP[i]$, and $tN[i]$ in respective order are discarded. Conversely, if the diversity state is true, then the feature represented by the i th column of the matrices tP , and tN will be considered as an optimal feature towards the positive and negative labels.

The resultant matrices tP and tN retains the columns representing optimal features toward both positive as well as negative classes in respective order. Similarly, the KS-test shall be applied on each pair of the columns listed at the same index of the matrices sP and sN that are representing spectral features of the positive as well as negative classes in respective order, which results matrices sP and sN with optimal spectral features of the both lasbels. Further phase of the learning process builds ensemble of weak classifiers to perform adaptive boosting-based classification of the given acoustic emission signals as the signal emitted from the wearied tools and signals emitted from the benign tools.

The following diagram presented as figure 3.4 outlines the intricate process of the Tool Wear Prediction Model, illustrating the transformation of acoustic emission signals into a digital format and their subsequent classification. Through various stages, including feature extraction, optimization, and iterative adaptive boosting, the model aims to precisely predict the wear of tools. This visualization offers a comprehensive understanding of the complex mechanics underlying the process.

Acoustic Emission Signals Phase

- Acoustic emission signals are collected in set SC .
- These signals are then processed into a digital format.
- The digital signals are bifurcated into two sets, P and N , representing wearied (positive) and benign (negative) tools, respectively.

Temporal and Spectral Features Phase

- Temporal and spectral features are extracted from the signals in sets P and N .
- These features are organized into four different matrices: tP , sP for positive and tN , sN for negative classes, representing temporal and spectral features, respectively.

KS-Test & Optimal Features Phase

- The KS-test is applied to discover optimal temporal and spectral features for both positive and negative labels.
- Resulting optimal features are represented by matrices $tP\&tN$ and $sP\&sN$.

Weak Classifier Iterations Phase (Adaptive Boosting Process)

- AdaBoost WC (Weighted Classifier) is used to initiate the weak classifier iterations.
- A decision stump is created from each feature, and its tree accuracy is evaluated using the Gini Index.
- The alpha (importance or influence) and weights are updated, and weights are given to the incorrect guesses while reducing the correct ones.
- The iterative process continues, building upon the previous model and adjusting weights to give more preference to data points with maximal weights.
- The final model is created through iterative calls to the weak classifier, progressively emphasizing the importance of certain features.

Additional Notes

- There is an iterative updating of weights using a specific formula: $cw = w \cdot e^{(\pm\alpha)}$. This allows for the progressive adjustment of the model based on correctly and incorrectly classified samples.

3.7. MLTWP Algorithm Flow. Given a set of acoustic emission (AE) signals, the following algorithm outlines the steps to predict tool wear:

1. Collect AE signals into a set SC and process them into a digital format.
2. For positive set P and negative set N ,
 - Extract temporal and spectral features, and store in matrices tP , sP , tN , and sN respectively.
3. Apply the Kolmogorov-Smirnov (KS) test to identify optimal features for each i^{th} feature:

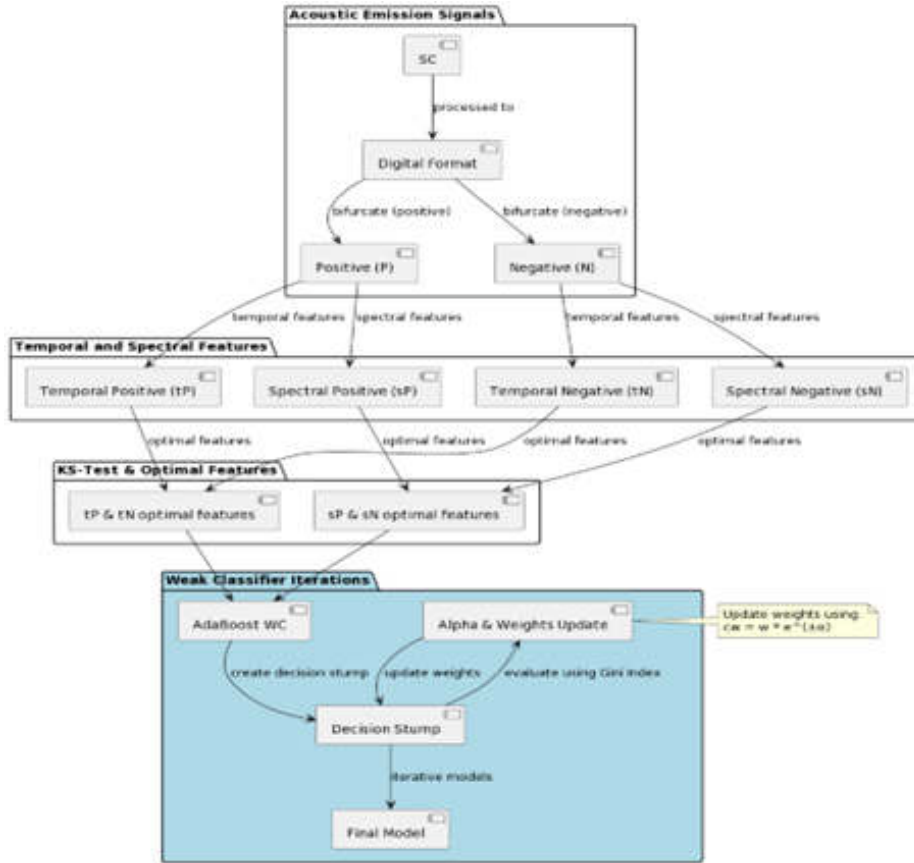

Fig. 3.4: The flow diagram of the MLTWP

- if $\text{KS_test}(tP[i], tN[i])$ is significant, retain $tP[i]$ and $tN[i]$.
 - if $\text{KS_test}(sP[i], sN[i])$ is significant, retain $sP[i]$ and $sN[i]$.
4. Initialize AdaBoost with weak classifiers derived from the optimal features.
 5. For each iteration k , perform:
 - (a) Create a decision stump h_k from the features.
 - (b) Calculate the error err_k of h_k .
 - (c) Compute the weight α_k of h_k :

$$\alpha_k = \frac{1}{2} \log \left(\frac{1 - err_k}{err_k} \right).$$

- (d) Update weights w for each data point:

$$w \leftarrow w \cdot e^{-\alpha_k y h_k(x)},$$

where y is the true label of x .

6. Combine the weighted decision stumps to form the final model M :

$$M(x) = \text{sign} \left(\sum_k \alpha_k h_k(x) \right).$$

7. Predict the wear condition of a new AE signal x using $M(x)$.

Table 4.1: Assumptions for Experimental Setup

	Description of Assumption
Assumption 1	All acoustic emission signals are accurately recorded without data loss.
Assumption 2	The dataset is fully representative of all possible states of tool wear.
Assumption 3	The labeling of the dataset into 'positive' and 'negative' is error-free.
Assumption 4	The temporal and spectral feature extraction processes are lossless.
Assumption 5	The Kolmogorov-Smirnov test reliably identifies the optimal features.
Assumption 6	The training and testing datasets are randomly partitioned to avoid bias.
Assumption 7	The four-fold cross-validation provides an unbiased estimate of performance.
Assumption 8	The AdaBoost algorithm converges to an optimal set of weights and stumps.
Assumption 9	The Gini Index is an adequate measure of decision stump performance.
Assumption 10	The MLTWP and TWPAE models are implemented under the same conditions.
Assumption 11	The performance metrics (precision, specificity, etc.) are computed without computational errors.
Assumption 12	The underlying distribution of the data remains stationary during the experiment.

The algorithm utilizes iterative boosting to refine the classification model, enhancing its predictive accuracy for tool wear based on AE signals.

4. Experimental Study. Experiments have been conducted on benchmark dataset to scale the performance of the proposed model MLTWP. The dataset adopted is a set of acoustic emission signals recorded from cutting mill tools both wearied and benign. Here, the acoustic emission signals of the wearied tools have been labelled as positive and the acoustic emission signals of the benign tools have been labeled as negative. The experimental data produced from the proposed model MLTWP and the state-of-the-art model Tool Wear Prediction using Acoustic Emission Signals (TWPAE) [27] have been compared in order to estimate the performance of the proposed model MLTWP. The dataset statistics have been explored in following section.

4.1. The dataset. The total records of the cutting mill dataset [36] are 25304, which possess the records of acoustic emission signals obtained from worn and benign tools. The acoustic emission signals of worn tools have been positive, which are of total 13318. The acoustic emission signals of unworn tools have been labeled as negative, which are of total 11986 records. 8990 negative records have been utilised for training, while there are 9989 positive records for training. Additionally, 2996 negative records and 3329 positive records have been tested. Further, each of the both positive and negative record sets will be partitioned in to four parts, such that 3 parts of the records from each label will be used to train the proposed model MLTWP and contemporary model TWPAE. The rest partition of the both positive and negative records will be used in testing phase. A table of assumptions for the experimental setup is as follows in Table 4.1

The table 4.1 summarizes the foundational assumptions made during the experimental phase of the study, ensuring clarity and transparency for replication and validation purposes.

4.2. The Performance Analysis. The performance of the proposed model MLTWP has been scaled through the results obtained for cross validation metrics from four-fold cross validation as shown in table 4.2, which have been compared with results of the fourfold cross validation metrics obtained from the experiments carried on the contemporary model TWPAE. The following discussion analyses the performance of the both proposed MLTWP and contemporary model TWPAE.

The obtained results for cross validation metrics demonstrate that the anticipated MLTWP model outperforms the existing TWPAE model. The precision statistic represents the percentage of correctly identified positive records relative to the total number of positive records. The accuracy of the predicted MLTWP model, as measured by four-fold cross validation, as 93%, 92%, 92, and 91%, in that sequence. On the other hand, the observed precision for the current technique TWPAE as 89.09%, 89%, 89%, and 88%. When comparing the suggested model MLTWP to the state-of-the-art TWPAE, the proposed model performs better on the cross validation metric called precision (see Figure 4.1).

Specificity might be defined as the fraction of records that were correctly categorised as negative relative to the total number of negative-records. Here, we see that the specificity for the MLTWP model were 92%,

Table 4.2: Statistics of cross validation metrics obtained from 4-fold classification scheme

PRECISION				
	FOLD#1	FOLD#2	FOLD#3	FOLD#4
MLTWP	0.9256	0.9201	0.9231	0.9191
TWPAE	0.8909	0.8851	0.8872	0.8839
SPECIFICITY				
MLTWP	0.9188	0.9132	0.9197	0.9118
TWPAE	0.8789	0.8714	0.8732	0.87
SENSITIVITY				
MLTWP	0.9085	0.8994	0.9022	0.9016
TWPAE	0.8908	0.8903	0.8975	0.8894
ACCURACY				
MLTWP	0.9134	0.9059	0.9089	0.9064
TWPAE	0.8851	0.8814	0.886	0.8803
F-MEASURE				
MLTWP	0.9222	0.9166	0.9199	0.9154
TWPAE	0.8849	0.8781	0.8801	0.8769
MCC				
MLTWP	0.8266	0.8118	0.8178	0.8127
TWPAE	0.7695	0.7621	0.7713	0.7599

Fig. 4.1: Precision observed from four fold cross validation performed on MLTWP and TWPAE

91%, 92%, and 91% for four-fold cross validation; the corresponding figures for the TWPAE model were 88%, 87%, 87%, and 87%. In this case, it is assumed that the MLTWP approach outperforms the TWPAE model (see Figure 4.2).

In contrast to the actual number of delivered positive records for the testing, the test sensitivity measures the proportion of correctly identified positive records. Furthermore, sensitivity was observed from the MLTWP model over four-fold cross validation on different sets of records to be 91%, 90%, 90%, and 90% in that sequence, demonstrating optimal MLTWP performance when compared to the TWPAE technique (89%, 89%, 90%, and 89%) (see Figure 4.3).

The ratio of correctly identified positive and negative records relative to the total number of test records is an indicator of accuracy. The MLTWP method’s accuracy was shown to be optimum through four-fold cross validation (91%, 90%, 90%, and 90%), outperforming the accuracy of the other method TWPAE (89%, 89%, 89%, and 88%, respectively) (see Figure 4.4).

In Figure 4.5, we see a graph depicting a 4-fold increase in the F-measure metric between the anticipated MLTWP model and the existing TWPAE model. According to the results, the F-measure for the MLTWP model is 92%, 92%, 92%, as well as 92% after being subjected to four fold of cross-validation. In this case, the F-measures for the TWPAE model are as follows: 88%, 89%, 89%, and 88%. As a result, the F-measure for

Fig. 4.2: Specificity observed from four fold cross validation performed on MLTWP and TWPAE

Fig. 4.3: Sensitivity observed from four fold cross validation performed on MLTWP and TWPAE

Fig. 4.4: Accuracy observed from four fold cross validation performed on MLTWP and TWPAE

the predicted MLTWP model is more significant than the conventional TWPAE technique.

Matthew's correlation coefficient (MCC) graph produced from four-fold cross validation of projected MLTWP model and current TWPAE model is shown in Figure 4.6. Using this data, we can determine that the MCC for

Fig. 4.5: F-measure observed from four fold cross validation performed on MLTWP and TWPAE methods

Fig. 4.6: Matthews correlation coefficient observed from four fold cross validation performed on MLTWP and TWPAE methods

the MLTWP model is, in sequence, 83%, 81%, 82%, and 81%. For the TWPAE model, the MCC is as follows: 77%, 76%, 77%, and 76%. It foresees unambiguously that MCC for the proposed MLTWP model is much more significant than the current TWPAE technique.

5. Conclusion. The Machine Learning Tool Wear Prediction (MLTWP) model, employing temporal and spectral features of acoustic emission signals, has demonstrated a marked improvement in predicting tool wear. Quantitatively, MLTWP has shown enhanced precision, specificity, sensitivity, accuracy, and Matthews correlation coefficient compared to the Tool Wear Prediction using Acoustic Emission Signals (TWPAE) model. In four-fold cross-validation, the MLTWP model has consistently outperformed TWPAE, affirming its robustness and efficacy. The significant gains in signal detection accuracy underscore the effectiveness of the feature selection and machine learning techniques implemented in the MLTWP model. Future work will delve into the analysis of quasi-identifiers from the optimal attributes identified by MLTWP to further refine tool wear prediction.

Data Availability Statement. The proposed Machine Learning based Tool Wear Prediction (MLTWP) from Variability of Acoustic Sound Emission Signals have been evaluated through cross validation using the benchmark data of cutting Mill dataset available at: [36]. <https://www.kaggle.com/datasets/shasun/tool-wear->

detection-in-cnc-mill

The results have been presented in the manuscript. The data used in this study is available publicly. However, the python code used to conduct the experiments is not publicly available. Nevertheless, the methodology and experimental setup used in this study have been described in detail, allowing for replication by other researchers using similar simulation tools or experimental setups.

Data and Materials Availability. The data and materials used in the proposed model, "Machine Learning based Tool Wear Prediction (MLTWP) from Variability of Acoustic Sound Emission Signals," have been described in detail in the manuscript. The study was conducted using the publicly available benchmark data, and the proposed model's performance was evaluated using 4-fold cross validation. The data and materials used in the proposed model are available in the manuscript.

RETRIEVAL OF TELUGU WORD FROM HAND WRITTEN TEXT USING DENSENET-CNN

RAJASEKHAR BODDU *AND EDARA SREENIVASA REDDY †

Abstract. The recognition of telugu hand written text is been one of the problems in many applications. To overcome the problem a deep learning technique is proposed in this work i.e. a Dense convolutional neural network (DCNN) model. A telugu dataset which is taken form IIIT-HW-Telugu is utilized to perform the proposed model. In this paper a four stage telugu word retrieval is performed, initially thinning of image is performed using morphological operation, secondly Densenet-CNN is applied for thinning image, thirdly perform OCR based image segmentation, finally two models like HARRIS and BRISK features to extract the features and evaluate information from the given input HWT images. The parameters evaluated are hamming distance, PSNR, MSE, Noise Sensitivity and rate of thinning. The proposed model outperformed well compared to other methods. The PSNR obtained using proposed model is 54.74, hamming distance is 1.2.

Key words: OCR, Morphological operations, Hilditch transform, CNN, DenseNet

1. Introduction. The never-ending desire to liberate information to flow in a digital format for easier access, dependence on archiving and preserving for longer term makes hand written text based word retrieval a highly intriguing subject of research. A large variety of digital libraries are emerging for the archiving of multimedia documents, including Universal Library (UL), Digital Library of India (DLI), and Google Books. These documents cannot always be saved as text. This increases the difficulty of finding pertinent papers. The cost of storage devices has decreased, and imaging devices are rising in popularity. This encourages scientists to work hard on creating effective methods for digitising and archiving massive amounts of multimedia material. Text, audio, picture, and video are all included in the multimedia data. Most of the items that have been archived so far are in books printed, while digital libraries are currently collections of document pictures. More specifically, digital material is saved as pictures that match to book pages.

Daily existence requires the use of images [1]. Every day, a large amount of data is created in the form of photographs by technological devices. The two main categories of image retrieval [2] are approaches based on text and second one is based in content. Each strategy has distinctive qualities [3] that may be applied to a variety of applications depending on the circumstance. Search by image content is discussed by author in [4] and is termed as content-based image retrieval (CBIR). With this method, the search examines the image's visual content rather than the keyword descriptions linked to it. Text-based image retrieval (TBIR) [5] relies only on keywords based on text and input to be descriptors, with text keywords also employed in the index pictures. The matched photos are fetched from the image repository by comparing the index images keywords with the supplied keywords. This strategy has the benefits of being simple to implement, quick retrieval, and web picture search. It is difficult to manually search through a vast collection of photographs for any image.

The author in [6] discussed about the study of computer vision and machine learning, where machine learning helps in developing the automated system of identification of scene from the text. This recognition of text in natural settings is a big challenge. English has been the primary language of research in the field of text categorization and domain identification. Regional languages, particularly Indian languages, have had far less of an impact. Telugu is a member of the Dravidian language family and is one of language which is older and traditional of Indians. Telugu is the sixteenth most spoken language in the world, with 93 million native

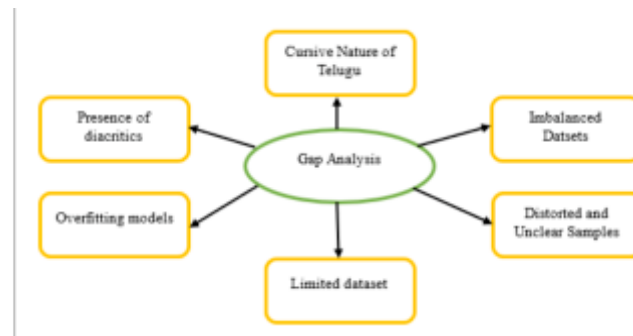

Fig. 1.1: Gap Analysis of Telugu Text Recognition [21]

speakers, according to the Ethnologic list. The gap analysis for any language is same as shown in figure 1.1.

It became a difficult process to retrieve telugu words from handwritten writing. Compared to other languages, telugu has a particular set of writing curves and strokes for its handwritten text. One of the cutting-edge methods for addressing issues in the sector of concern is deep learning. With the use of massive quantities of data and the Deep Learning technology, the nodes of one layer are connected to those of adjacent layers. The network is assumed to be more complex due to the number of tiers. Since deep learning systems handle massive volumes of data and perform challenging mathematical operations, they demand strong hardware. In this paper the utilization of DenseNet CNN is considered for effective retravel of telugu word from hand written text. Further in section 2 the discussion is about different techniques used previously. In section 3, the suggested framework is implemented and in section 4 the results obtained using proposed model is discussed.

2. Related Work. For the characterisation or acknowledgement of word pictures for different dialects, several writings are accounted for. When compared to the typical scanned texts in English writing, acknowledgment of terms from Telugu writings has not been studied as extensively. A part of the approaches mentioned are briefly discussed. The most popular highlights for creating bag-of-words (BoW) representation are those processed at interest focuses in scale-invariant feature transform (SIFT) [7] highlights. A histogram of the visual words serves as the word image's visual representation. "Data is lost when the highlights are quantized to a visual word. This is frequently believed to exhibit some measure of power (or invariance). In fact, there is still no consensus on how to select the vocabulary's range and retention techniques. Given a language, creating a BoW representation requires two key steps one is Coding and the other is pooling. With the use of the vocabulary words' histograms of repeated incidents, reports are properly expressed. The categorization and recovery of records are then carried out using these histograms.

Spatial pyramid matching (SPM) [8], which divides pictures into vertical and flat bearings, provides spatial request in common scene images. Word pictures are divided vertically into three portions and then recorded to provide order in representation. In [9], word pictures are shown as profile highlights, and Euclidean separation is unintentionally employed to imply comparison. Dynamic time wrapping (DTW) is used to coordinate word pictures in order to account for the variance in word image lengths. However, the focus of this study is to deduce an enforcement conspiracy using a back-end file structure. Due to this, DTW-based systems are not rational. Versatility in report recovery has also recently received significant attention. A list of 10 million pages using locally likely arrangement hashing (LLAH) was published in [10]. Recent efforts to recover strong records use the visual Bag of Words (BoVW) to represent and organise word pictures. One may quickly find significant papers from a million documents using BoVW representation and a reversed ordering scheme [11]. For the picture representation, feature points will be quantized, and a versatile representation is created by proposing a "vocabulary" over an element space. Ideally, code is generated from raw descriptors using vector quantization (VQ). The difficult issue of translating code words from the vocabulary to the feature vectors of an image is one limitation of the code-book technique. The challenging assignment presents the two problems of codeword credibility and vulnerability. The problem of selecting the proper codeword from at least two

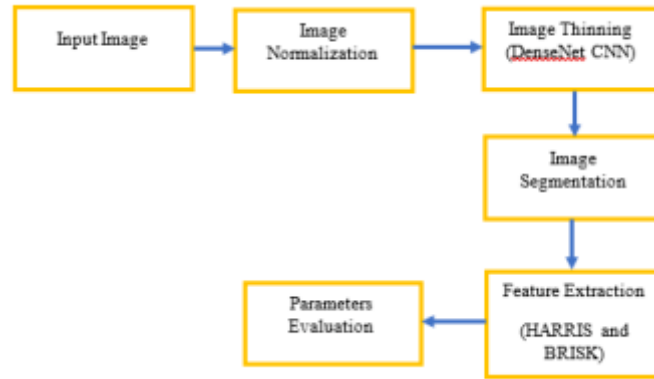

Fig. 3.1: Block Diagram of Proposed Work

significant candidates is known as codeword vulnerability. The VQ technique disregards the significance of several candidates and selects the most effective visual word. The problem of picking a codeword without a plausible hope in the lexicon is known as "codeword believability." The codebook method assigns the best-fitting codeword, although it is not a true representation. Authors in [12] proposed a soft assignment coding approach to overcome this restriction, in which each visual word is assigned a local characteristic based on its location.

In [13] author represented a spotting system of a Telugu word with improved performance over traditional system. It is based on correlation and hidden markov model (HMM) technology. In order to outperform BoVW and SIFT + BoVW, an algorithm is developed based on sped-up robust features (SURF) with the aid of BoVW. However, the word picture retrieval techniques described in the literature have some drawbacks, including inefficiency, increased complexity, and decreased precision with big data bases.

Contrarily, people in the south Telugu, an Indian alphabet, is composed of several elements, making the use of high-level feature extraction algorithms more difficult. On Indian languages, several techniques for domain identification and text classification have been developed, however only a small number of these studies have been reported on Telugu. This section provides an overview of a few strategies and approaches for text classification and domain identification. Automated text classification with a focus on Telugu is been developed in recent times. In his research, 800 Telugu news items were classified using supervised classification with the Naive Bayes classifier. KNN, Naive Bayes, and decision tree classifiers as text mining approaches to represent and categorise papers written in Indian. Telugu text documents can be categorised using the language-dependent and independent models suggested. Telugu texts were classified using a model for document organisation and categorization of texts using the word frequency ontology. The robustness of LSTM and CNN are combined in an attention-based multichannel CNN for text classification. In this network, CNN tracks word relationships while Bi-LSTM records word history and future information [14]. The author in [15] suggested a novel heuristic advanced neural network based telugu text categorization model (NHANNTCM) for extraction of telugu word and achieved an accuracy of 99%.

3. Methodology. In this paper thinning of the input image is the main concept. The thinning is performed using DenseNet CNN and followed by OCR based segmentation of letters and finally extraction of features using Harris and Brisk. The major goal of this study is to take use of the DL-CNN's robust performance in order to extract useful features with the least amount of time and effort possible. The convolutional phase known as CNN extracts features from pictures by acting as a visual descriptor. Each image is altered by the application of a series of filters, resulting in new image types known as convolution maps. The proposed model is shown in figure 3.1.

3.1. Input Dataset. Handwriting recognition (HWR) in Indic scripts is a challenging problem due to the inherent subtleties in the scripts, cursive nature of the handwriting and similar shape of the characters. Lack

విశ్వవిద్యాలయం అర్హత ఉత్తీర్ణులయిన

Fig. 3.2: Example of input words

Fig. 3.3: Concept of Thinning

of publicly available handwriting datasets in Indic scripts has affected the development of handwritten word recognizers. In order to help resolve this problem, 2 handwritten word datasets: IIIT-HW-Dev, a Devanagari dataset and IIIT-HW-Telugu, a Telugu dataset [16]. In this paper, Telugu Dataset (IIIT-HW-Telugu) with a file size of 3.7 GB is considered to evaluate the proposed model. The samples of images considered as input is shown in figure 3.2.

3.2. Image Normalization. To extract various features from a picture on the same structure for image normalisation, all randomly sized images are downsized into the same size images. Here, using a bilinear standard transformation, photos of arbitrary sizes are normalised to be 100x200 size and the aspect ratio of image should not get disturbed. The numerous distortions, including missing segments with distortion, distortion caused randomly, effects of noise, and the segments which are missing in query terms, are also calculated, and analysed using this normalisation procedure.

3.3. Thinning of Image. Thinning is the technique of removing unused pixels from an image in order to recover the skeletons. It is also known as the Skeletonization process. Black foreground pixels are removed repeatedly, layer by layer, in this morphological procedure until a one-pixel-wide skeleton is reached. It entails reducing something to its tiniest size. Typically, binary pictures made up of black (foreground) and white (background) pixels are subjected to skeletonization. It accepts a binary picture as input and outputs another binary image, as seen in Figure 3.3.

The use of a deep convolutional neural network to thin an input picture is covered here. When compared to other algorithms, DCNN-based image thinning produces accurate Skelton estimates of the input picture. The deep network utilized in this work is densenet.

3.4. DenseNet CNN. Following is an explanation of how CNN operates: using the two-dimensional layer of convolution given input is paired up with sliding filter. The convolution of layers for the input is computed using the dot products of weights and input, in this process the set of filters are moved in vertical direction and horizontal direction towards the input. Threshold process is done in the ReLU layer by converting the values to zero which are lower than zero. Later down sampling is performed in the max pooling layer by identifying the maximum level of every zone by splitting the input into a rectangle pooling region. Bias vector is added to the fully connected layer, before performing this addition the input is multiplied by a weight matrix. Figure 3.4 depicts the overall architecture of deep CNN.

Here, we will provide a summary of the DenseNet design for convolutional networks, which stands for densely linked convolutional networks. The issue that the convolutional neural network is seeking to address with the density of the design is to deepen it. Dense nets are networks of convolution with plenty of connections.

Fig. 3.4: Architecture of DCNN

Fig. 3.5: DenseNet Architecture [16]

It is quite like a ResNet, with a few key differences. While ResNet employs an additive technique and accepts a previous output as an input for a subsequent layer, DenseNet utilizes every previous output as a source for a new layer. Figure 3.5 conveys the detailed structure of DCNN.

The drawback of this network is that it gets sort of unsustainable as we go further into it. For example, if the second layer is set for moving towards third layer, then the third layers need to be sourced with the second layer and the other layers from the initial state. In this network dense blocks are created for which different filters are created at every block but the size of feature map are well in constant for every block internally. The layer present in dense network is transition layer, these layers are handled by down sampling. This down sampling is performed by applying normalization of batch, one to one convolution and two to two layers of pooling.

The thinning of input image is performed deeply by carrying every layer of the telugu hand written word to the next layer until a better output is achieved. Figure 3.6 the densenet performance helps in thinning the image with more accurate output based on the working performance of densenet.

3.5. Image Segmentation. In this section, we will go over the segmentation techniques, which are yet another crucial stage of the OCR system. Simply divided into smaller segments for subsequent processing, segmentation is the act of taking a whole picture. Using word level segmentation, a picture is segmented. The input is divided into separate letters, making it easier to recognise the word.

We are given an image with a single line made up of a string of letters at this level of segmentation. As seen in Figure 3.7, the goal of word level segmentation (WLS) is to separate the picture into its component letters.

3.6. Feature Extraction. Feature extraction forms an important part of in retrieval of words from hand written text. In many applications, the speed of feature detection in a picture is critical. To compute the

Layers	Output Size	DenseNet-121	DenseNet-169	DenseNet-201	DenseNet-264

Fig. 3.7: OCR Image Segmentation

correspondence between numerous perspectives effectively and accurately, the detected feature points must be represented independently. Fast feature recognition, description, and matching are necessary for real-time processing of the pictures. The points used to characterise the images must meet two crucial requirements in order to achieve better feature matching of image pairs: first, the feature points of the same strokes in various perspectives, viewpoints, or lighting conditions must be the same; second, the points must have enough information to match with one another. The finest characteristics for matching are corners. The most crucial aspect of a corner is that if one exists in a picture, the surrounding area will abruptly alter in intensity.

The information of pixels which is present locally are explained using local feature descriptors. These local features which are need to be evaluated meet various criteria like blurriness, presence of noise, translation invariant, rotation, scale and transformation based on affine. An effective feature detection operator that has seen widespread application is the Harris corner detector and Brisk corner detection. The rotation invariant Harris corner detector has sufficient data for feature matching.

Due to the Harris corner detector’s great invariance to rotation, scale, illumination fluctuation, and noise in image it is a well-liked interest point detector. The local autocorrelation function of a signal serves as the foundation for the Harris corner detector, which monitors local variations in the signal with patches that have been slightly displaced in various directions. The Harris approach looks at the intensity which is average and to be directional, to locate the corners in the input picture. The approach of detecting corners mathematical formulation essentially determines the intensity difference in every direction using a displacement of (u, v).

For the pixel with displacement (u,v) the grey intensity is termed as $I(x,y)$. Here the variation of the pixel

Table 4.1: Requirement of Design Environment

Description	Requirement
RAM	8GB
Processor	Intel i7
Matlab version	2021a
Image format	JPEG

that is gray is (x,y) with a shift range of (u,v) is given by equation (3.1).

$$H(u, v) = \sum_{x,y} w_f(x, y) [I(x + u, y + v) - I(x, y)]^2 \quad (3.1)$$

The term $w_f(x, y)$ denotes the windowing function, the shifted intensity value which is termed as $I(x + u, y + v)$ and the intensity value is termed as $I(x, y)$.

Key point descriptor with scale Scale-spacing and binary description are both handled by the BRISK approach [17]. In the picture pyramid's octave layers, key points are found. Quadratic function fitting is used to translate the coordinates and scale of each key point into representation of a continuous domain. The BRISK descriptor is generated as a binary string in two steps after the BRISK characteristics have been detected. The first stage aids in the creation of a rotation-invariant description by estimating the key points' orientation. To effectively and quickly construct a description that captures regional attributes, the second stage utilises rigorous brightness comparisons. The BRISK descriptor uses a concentric circle sampling method to specify N locations.

The smoothing of intensity at every point s_{pi} is done performed using a gaussian function for preventing of effects like aliasing. The sample points with N number are paired into (s_{pi}, s_{pj}) and are bifurcated into two degrees of classes: one is short pair in which the distance condition should be $(s_{pi}, s_{pj}) < T_{max}$ and the other one is long pair with a distance condition of $(s_{pi}, s_{pj}) > T_{min}$. These two pairs perform individual action like estimation of rotation using the short pair and building of descriptor after correction of rotation is performed using the long pair. The computation of local gradients of BRISK descriptor is given by

$$\nabla(s_{pi}, s_{pj}) = (s_{pj} - s_{pi}) \frac{I(s_{pj} - \sigma_j) - I(s_{pi}, \sigma_i)}{\|s_{pj} - s_{pi}\|^2} \quad (3.2)$$

The local gradient is termed as $\nabla(s_{pi}, s_{pj})$ which is the sampled pair and the intensity that is smoothed at x at scaling factor σ . In the average gradients of x and y direction the rotation angle θ is calculated. To get the descriptor that is rotation-invariant, the short pairs are rotated by an angle of $-\theta$. The binary descriptor, which serves as a description for each keypoint, is an encoded binary string.

Algorithm

- Step1. Loading the image from the dataset
- Step2. Resize all the images and reduce noise
- Step3. Removing unused pixels from an image in order to recover the skeletons.
- Step4. Using DCNN for extraction of features
- Step5. Divide the letters for the given input word
- Step6. Evaluate the BRISK features and HARRIS corner points
- Step7. Calculate all the parameters like hamming distance between the pixels of the word, MSE, PSNR etc..

4. Experimental Results. The analysis of suggested model is detailed with the help of matlab simulation. The entire simulation is performed using the image of hand written telugu words. The results shown below gives the effectiveness of the proposed model. The consideration for performing simulation is shown in table 4.1 and some of the assumption in simulation environment is shown in table 4.2.

Table 4.2: Assumption in Simulation Environment

Assumption	Description
Stability in performance	The evaluation does not undergo any adverse changes that effect the experimental findings
Range of Consistency	The environment of simulation remains consistency and do the parameters
Constant parameters	The parameters used for evaluation are same for all set of input images
No Interference from external source	As there is not external interference the simulation results will be accurate

Fig. 4.1: Input Image

Fig. 4.2: Thinning Image

Fig. 4.3: DenseNet based thinning

The input is normalised and sent for next stage of processing that is thinning can be considered from Figure 4.1. The thinning image which is obtained using different techniques is shown in Fig. 4.2 and Fig. 4.3. In this process the front end of the image is highly viewed for achieving better set of features in next stage.

Every letter in the word is been segmented using OCR word segmentation model and the results achieved is shown in fig 4.4.

Harris features and Brisk features are been extracted and is shown in fig 4.5. The features are extracted for the image which is thinned using DenseNet CNN. The duration of telugu data retrieval is less when compared to other extraction of thinning image. The performance will be improved when the features are extracted for DCNN thinned image.

Certain parameters are considered for showing the performance of the suggested model with other existing techniques. The parameters are measure of connectivity, MSE, PSNR, Rate of thinning, RMSE, time of execution, Noise sensitivity and hamming distance. These parameter values are shown in table 4.3.

Fig. 4.4: Segmentation of DCNN thinned image

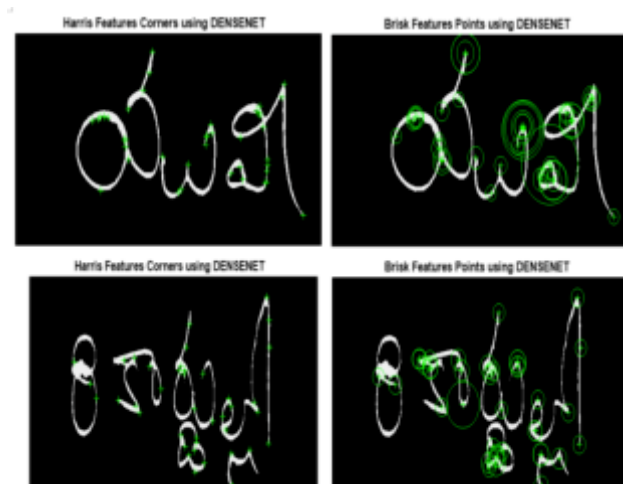

Fig. 4.5: Outputs of feature extraction

One of the crucial metrics for assessing the effectiveness of the employed strategies is PSNR. The PSNR, which affects pixel quality, is the ratio of the highest pixel value to the noise (MSE). The error's value, which is expressed on a logarithmic decibel scale, decreases with increasing PSNR. Figure 4.6 shows the contrast in PSNR.

5. Conclusion. In this study, an efficient model for Telugu word recognition is presented through the testing of several neural network designs. The provided input is first normalised and thinned before being submitted to the deep convolutional neural network model to extract the feature maps. Using DenseNet convolutional neural networks, a model for Telugu text extraction and identification is built in this article. Additional corner characteristics are retrieved using the Harris and Brisk techniques. The simulation research

Table 4.3: Performance measures using different techniques

Measure Evaluted	Hilditch Algorithm	Morphological operations	RNCNN-BRHA [18]	Proposed HWTR-DCNN
Measure of Connectivity	4.0	4.0	4.0	4.01
Rate of Thinning (pixels)	1.0	1.0	1.0	1.0
MSE	0.022	0.025	0.0007	0.00018
PSNR	16.49	15.95	51.84	54.74
RMSE	0.149	0.159	0.0025	0.00135
Time for executing (Sec)	2.19	0.608	0.102	0.094
Noise Sensitivity	0.63	0.388	0.50	1
Hamming Distance (pixels)	7.15	6.20	2.71	1.20

Fig. 4.6: PSNR Comparison

showed that in terms of PSNR, MSE, Noise sensitivity, and execution time, the new technique outperformed the traditional retrieval system. Additionally, the suggested HWTR-DCNN system's performance evaluation is shown using mAP and mAR and is contrasted with the current systems.

UAV PATH PLANNING MODEL LEVERAGING MACHINE LEARNING AND SWARM INTELLIGENCE FOR SMART AGRICULTURE

ROBERTO E. ROQUE-CLAROS*, DEIVI P. FLORES-LLANOS†, ABEL R. MAQUERA-HUMPIRI‡, VIJAYA KRISHNA SONTHI§, SUDHAKAR SENGAN¶, AND RAJASEKAR RANGASAMY||

Abstract. Smart agriculture, through precision farming, is revolutionizing traditional farming methods by optimizing resource use and enhancing yields. With the integration of technology, especially the advent of Unmanned Aerial Vehicles (UAVs) or drones, modern agriculture has attained new heights in efficient crop management, real-time data collection, and sustainable practices. UAVs play a pivotal role, offering aerial insights into crop health, soil conditions, and targeted resource application, promoting sustainable farming. However, navigating UAVs efficiently across dynamic agricultural terrains presents challenges, particularly in path planning. While traditional grid-based models have their merits, the complexities of modern farms demand more adaptive models. This work introduces a hierarchical path planning framework for UAVs, combining the “Enhanced Genetic Algorithm using Fuzzy Logic” for global planning and the “Improved D* Algorithm” for real-time local adjustments. This dual-layered approach ensures efficient, safe, and energy-conserving UAV trajectories, marking a significant advancement in UAV-based smart agriculture.

Key words: Unmanned Aerial Vehicles, Precision Farming, Grid-Based Models, D* Algorithm, Smart Agriculture

1. Introduction. Smart agriculture has reshaped the way we perceive and practice traditional farming. Through the lens of precision farming, the nuances of crop management are being meticulously addressed, leveraging data-driven insights to optimize resource utilization and maximize yields. The influence of autonomous vehicles in this domain underscores the potential of technology to enhance and streamline agricultural operations, bringing about a seamless integration of mechanization and intelligence [11]. This synergy promises to lead the farm sector toward unprecedented efficiency and sustainability. Unmanned Aerial Vehicles (UAVs), commonly known as drones, have emerged as revolutionary tools in modern agriculture. Their ability to swiftly traverse vast expanses of land, capturing high-resolution imagery and providing real-time data, has redefined precision farming. UAVs can efficiently monitor crop health, assess soil moisture levels, and detect pest infestations, all from an aerial vantage point. This bird’s-eye view enables farmers to make informed decisions, leading to reduced input costs and increased crop yields. Furthermore, UAVs facilitate targeted applications of pesticides and fertilizers, ensuring that resources are used judiciously, minimizing environmental impact [12]. The integration of UAV technology in agriculture optimizes farm management practices and paves the way for sustainable and environmentally-conscious farming, marking a significant stride toward the future of agriculture.

In the growing field of smart agriculture, integrating UAVs offers immense potential but is not without challenges. One of the paramount issues is the intricacy of path planning for UAVs. Given agricultural landscapes’ diverse and dynamic nature, plotting an efficient and safe drone route necessitates advanced algorithms and real-time data processing [7]. Factors like varying crop heights, obstacles like trees or infrastructures, and changing weather conditions can significantly influence the UAV’s trajectory. While the objective is to cover

maximum ground efficiently to gather data, avoiding collisions and ensuring the UAV's energy conservation becomes equally vital. Therefore, a practical path planning mechanism is imperative not only for the operational success of UAVs in smart agriculture but also to ensure the safety and sustainability of their application in such a crucial sector.

In addressing the path planning challenge for UAVs in smart agriculture, several existing models have been proposed and explored. Traditional approaches have primarily revolved around grid-based methods, where the agricultural field is divided into uniform cells, and the UAV's path is determined by traversing these cells based on predefined algorithms. A* and Dijkstra are classic examples renowned for their efficiency in obstacle-free environments. However, the need for adaptive and dynamic models grew as agricultural terrains became more complex. Genetic Algorithms (GAs) and Particle Swarm Optimization (PSO) have been introduced as heuristic methods to navigate intricate landscapes [8]. These algorithms simulate natural processes and behaviors to find optimal or near-optimal paths, making them more resilient to dynamic environmental changes. More recently, machine learning techniques, particularly deep learning, have been incorporated to predict and adjust UAV paths in real-time, leveraging vast datasets from past flights. While these models have highlighted promising results, a comprehensive solution that seamlessly integrates responsiveness, accuracy, and efficiency remains a subject of ongoing research.

The challenge of UAV path planning in smart agriculture demands a model that is accurate and adaptive to the varying nuances of an agricultural landscape. To tackle this, this work introduces a novel, hierarchical framework. Firstly, the farm terrain is meticulously represented through a grid environment. This grid is formed by discretizing the field into a two-dimensional lattice, where distinct cells denote either navigable or obstructed zones. To enhance clarity and reduce computational overhead, morphological operations refine this grid, highlighting only essential path-planning elements. This dynamic grid adjusts to changing agricultural conditions, ensuring the UAV's viability throughout different agricultural phases. Following the grid formation, our model sequentially integrates two sophisticated algorithms to provide optimal UAV navigation.

The first phase involves "Global path planning", utilizing the "Enhanced Genetic Algorithm using Fuzzy Logic for Global Path Planning". This algorithm evaluates various pathways throughout the grid, identifying the most efficient route from the beginning point to the target by selecting the paths with the highest fitness values. This ensures that the UAV is provided with an efficient and energy-conserving trajectory. Following the global path planning, critical path nodes are extracted, marking significant waypoints or transitions in the path. Subsequently, the "Improved D* Algorithm for Local Path Planning" is applied in the second phase. This algorithm focuses on the UAV's immediate surroundings, adjusting its real-time trajectory based on detected obstacles or unforeseen environmental changes. By doing so, the UAV can adapt quickly to ensure safe and effective local maneuvering. The culmination of these two processes yields "The optimal trajectory", guiding the UAV seamlessly from its initial point to its destination. Once this trajectory is successfully followed, the model confirms Path finding success.

The article is framed as follows: Section 2 presents the literature review, Section 3 presents the proposed model, Section 5 presents the experimental analysis, and Section 6 presents the conclusion of the work.

2. Literature Review. The arena of UAV path planning has seen extensive research and development in recent years, focusing primarily on optimization, collision avoidance, and adaptability to the varying complexities of the UAVs' environment. Aggarwal *et al.*, comprehensively analyzed various path-planning techniques used for UAVs over the years [1]. They broadly classified these techniques into representative, cooperative, and non-cooperative, emphasizing the path's optimality, shortness, and collision-free nature. An essential contribution of their work is the exhaustive comparative tables and identification of open research problems in UAV path planning, emphasizing factors such as energy efficiency, time efficiency, and robustness.ents.

Bai *et al.*, proposed a path-planning algorithm harmoniously integrated with the A and DWA algorithms [2]. Their approach gave prominence to global path optimization while considering UAVs' security and speed requirements. By preprocessing the map for obstacles, they addressed inherent limitations of the standard algorithms, ensuring the UAV path is efficient and safe. Delving into the potential of reinforcement learning in UAV path planning, Tu *et al.*, highlighted its application in aquaculture cage detection [13]. They employed the Q-learning algorithm, comparing it with the SARSA algorithm. Their use case underscored the importance of energy conservation and efficiency, given the vast expanse of the sea and the scattered nature of net cages.

Fig. 3.1: Grid Representation

Chen *et al.*, addressed challenges in agricultural irrigation by introducing an intelligent irrigation robot [3]. Their work is pivotal for its emphasis on precision in irrigation using an improved path planning algorithm leveraging Bayesian theory. They aimed for full irrigation coverage in the complex agricultural environment, ensuring no area was inspected. Li *et al.*, brought forward an innovative integration of the improved artificial fish swarm algorithm with Bézier curves for mobile robot path planning and smoothing [6]. Their method promises enhanced planning accuracy and path continuity, meeting the kinematic demands of mobile robots.

Highlighting the potential of reinforcement learning in multi-layered path planning, Cui *et al.*, introduced a unique algorithm that assimilated local and global information for superior performance [4]. Their approach utilized B-spline curves for real-time path smoothing, proving its efficacy through various simulations. Qu *et al.*, proposed a hybrid algorithm, HSGWO-MSOS, by combining the strengths of the simplified grey wolf optimizer and the modified symbiotic organism's search [9]. Their algorithm emphasized efficiency in exploration and exploitation, offering an enhanced route for UAVs that is feasible and effective. Yan *et al.*, ventured into Deep Reinforcement Learning (DRL) for UAV path planning in dynamic and potentially threatening environments [14]. Their model simulated the UAV's survival probability against threats like missile attacks, using the D3QN algorithm for improved performance. Shao *et al.*, tackled the issue of autonomous UAV formation system path planning, proposing a comprehensively enhanced particle swarm optimization technique [10]. Their methodology emphasized rapidity and solution optimality, addressing terrain and threat constraints. Lastly, Han *et al.*, concentrated on UAV indoor path planning in complex environments [5]. They introduced a set of grid-optimized algorithms that considerably reduced computational complexity, efficiently tackled dead zone airspaces, and assured efficient and flyable path planning in intricate 3D indoor airspace.

3. Proposed Model.

3.1. Task Model. In configuring the computational representation of the agricultural terrain for UAV path planning, a meticulous grid structuring process is undertaken. This grid acts as a virtual model, aiding the UAV in discerning navigable paths from obstructed zones within the agricultural landscape. The field is discretized into a two-dimensional grid, G , where each cell, C_{ij} , corresponds to a specific area in the farmland. Cells that represent obstacles are assigned a value of 0 , indicating areas that are off-limits for the UAV. In contrast, cells expressing free space are assigned a value of 1 , delineating safe flight zones (Figure 3.1). The binary values create a stark contrast on the grid, forming a map of passable and impassable regions for the UAV.

To ensure the UAV path planning model does not become overburdened by environmental intricacies, a combination of morphological operations, specifically dilation and erosion, is applied. These operations facilitate feature extraction, resulting in a refined grid, G' , which highlights critical path planning information while negating redundant details. For the UAV to accurately locate itself within the grid, each cell is indexed with a unique coordinate pair, (x_i, y_j) . The relationship between a cell's linear index, k , and its two-dimensional coordinate pair is governed by EUQ (3.1) and EQU (3.2)

$$x_i = \left\lfloor \frac{k-1}{N_x} \right\rfloor + 1 \quad (3.1)$$

$$y_j = ((k - 1) \bmod N_y) + 1 \quad (3.2)$$

where N_x and N_y represent the total number of rows and columns in the grid, respectively. The functions $[\cdot]$ and \bmod denote the floor operation and modulus operation, instrumental in mapping the linear index to the grid coordinates. The grid environment, G' , is designed to be dynamic, accommodating changes in agricultural conditions, such as seasonal crop growth or temporary obstructions like farming equipment. This dynamic aspect ensures that the path planning model remains viable throughout varying stages of the agricultural lifecycle.

3.2. Objective Function Formulation. In smart agriculture, the path-planning model aims to blend global and local methodologies to derive an optimal trajectory for UAVs. The quantification of this trajectory's optimality is captured in the objective function, F_{obj} .

Formally, this function is given by EQU (3.3)

$$F_{obj}(P) = w_1 \cdot L_{\text{global}}(P) + w_2 \cdot E_{\text{global}}(P) + w_3 \cdot T_{\text{local}}(P) - w_4 \cdot C_{\text{local}}(P) \quad (3.3)$$

where:

- P represents the UAV's path.
- $L_{\text{global}}(P)$ signifies the total length from the global path planning perspective.
- $E_{\text{global}}(P)$ corresponds to the energy consumed during the global path traversal.
- $T_{\text{local}}(P)$ denotes the time taken to focus on finer, local path intricacies.
- $C_{\text{local}}(P)$ captures the coverage of specific areas of interest from a local planning standpoint.
- w_1, w_2, w_3 , and w_4 are weighting coefficients reflecting the relative significance of each component to the holistic path planning objectives.

The optimal path, while considering both global and local aspects, should satisfy the following constraints:

- *Safety Constraints:* The UAV's trajectory must bypass obstacles, notably the 0value cells in the grid environment.
- *Flight Dynamics Constraints:* Considering the UAV's inherent physical capabilities, the path is limited by its turning radius and maximum flight speed.
- *Coverage Constraints:* Ensuring complete and detailed coverage of agricultural areas is pivotal, especially zones marked for close monitoring. The route must minimize overlaps and redundancies.

3.3. Optimization Strategy. For the global path planning phase, a fuzzy-based Genetic Algorithm (GA) is employed to navigate the broader aspects of the agricultural terrain. The GA's intrinsic evolutionary process, when enhanced with fuzzy logic, provides a robust mechanism to discern optimal paths by considering the global dynamics of the agricultural landscape. In the local path planning phase, Swarm Intelligence is utilized. Swarm Intelligence, inspired by the collective behavior of decentralized systems, excels in refining trajectories. It accounts for intricate details and unexpected hindrances in the agricultural setting, ensuring the UAV can navigate tighter spaces and rapidly adjust its trajectory when faced with unforeseen challenges. Formally, the proposed model optimizes the objective function F_{obj} using these methods, targeting the following goal:

$$P^* = \arg \min_P F_{obj}(P) \quad (3.4)$$

With this optimization strategy, the hierarchical UAV path planning model seeks to determine the best possible trajectory. This trajectory balances the broad strokes of global path planning with the finer nuances of local planning, ensuring the UAV meets the demands of smart agriculture. The emphasis is firmly on precision, efficiency, and adaptability.

3.4. Proposed Enhanced Genetic Algorithm Using Fuzzy Logic for Global Path Planning. In UAV-based smart agriculture, achieving comprehensive field coverage while minimizing energy consumption and traversal time is paramount. The Genetic Algorithm (GA) has been a popular method for this task due to its inherent ability to search vast solution spaces efficiently. However, to better address an agricultural field's dynamic and often uncertain environment, integrating fuzzy logic into GA can offer significant advantages.

3.4.1. Representation and Initial Population. For the given agricultural grid, denoted as G , of dimensions $M \times N$, each chromosome in the GA represents a potential path P that the UAV can follow. This path starts at a designated point S and ends at a predetermined destination D . Utilizing the principle of random walks, we initialize our population of chromosomes. In this approach, each UAV path is generated by letting it ‘walk’ randomly across the grid from the start point S to the destination D , ensuring it stays within the boundaries and constraints of the grid. Through this stochastic method, many diverse pathways are conceived, providing a broad spectrum of starting solutions for the GA to refine and optimize. These random walks, while unguided, produce routes that capture the vast complexities of the agricultural landscape, laying a strong foundation for the subsequent genetic algorithm optimization.

3.4.2. Fuzzy-based Fitness Evaluation. The fitness of each path is determined by several factors: path length $L(P)$, energy consumed $E(P)$, and the agricultural area covered $A(P)$. Instead of rigid thresholds, fuzzy logic can handle the imprecision in measurements. This includes the unpredictability of dynamic obstacles that may suddenly block the path, uncertain wind conditions affecting energy consumption, and varying crop heights impacting the coverage assessment. The fuzzy-enhanced fitness function may be expressed as (3.5)

$$F_{\text{fitness}}(P) = w_1 \times \mu_{\text{length}}(L(P)) + w_2 \times \mu_{\text{energy}}(E(P)) + w_3 \times \mu_{\text{area}}(A(P)) \tag{3.5}$$

Here, μ denotes the membership function in fuzzy logic, defining the degree of truth of each component.

3.4.3. Fuzzy-enhanced Selection. Given a set of chromosomes $C = \{c_1, c_2, \dots, c_n\}$, each chromosome c_i has an associated fitness value $F_{\text{fitness}}(c_i)$. In the fuzzy-enhanced GA, a fuzzy membership function $\mu_{\text{suitability}}(c_i)$ evaluates the suitability of chromosome c_i for selection. The uncertain factor, such as obstacle, is represented as ω . If the challenges are uncertain, the adjusted fitness can be defined as EQU (3.6)

$$F'_{\text{fitness}}(c_i) = F_{\text{fitness}}(c_i) + \alpha \times \mu_{\text{wind}}(\omega) \tag{3.6}$$

where α is a factor determining the effect of obstacle uncertainty.

3.4.4. Fuzzy-enhanced Selection. For two parent chromosomes c_p and c_q , the compatibility for a crossover at a gene g_i is given by $\mu_{\text{compatibility}}(c_p[g_i], c_q[g_i])$.

The crossover point(s) X is determined as EQU (3.7)

$$X = \arg \max_i \mu_{\text{compatibility}}(c_p[g_i], c_q[g_i]) \tag{3.7}$$

This ensures that genes around point X have the highest compatibility between parents.

3.4.5. Fuzzy-enhanced Selection. For a chromosome c_i , the mutation likelihood for a gene g_j is determined by $\mu_{\text{effectiveness}}(c_i[g_j])$. If the mutation threshold is θ , a gene g_j is mutated if: $\mu_{\text{effectiveness}}(c_i[g_j]) > \theta$. This ensures targeted mutations based on the effectiveness of individual genes in the chromosome.

3.4.6. Optimization and Convergence. Optimization and Convergence: Let the optimal path after k generations be P^* and the fuzzy-adjusted path quality be $Q(P)$ considering the specific challenges and requirements of smart agriculture. As the generations progress, the optimal path is refined as EQU (3.8)

$$P^{k+1*} = \arg \max_{P \in C^{k+1}} Q(P) \tag{3.8}$$

The algorithm converges when the quality difference between consecutive generations is below a predefined threshold, EQU (3.9)

$$\left| Q(P^{k*}) - Q(P^{k+1*}) \right| < \epsilon \tag{3.9}$$

The following algorithm presents the steps in the proposed enhanced GA algorithm.

Algorithm 1: Enhanced Genetic Algorithm (EGA) using Fuzzy Logic**Inputs:**

- Agricultural grid G of dimensions $M \times N$.
- Start point S .
- Destination point D .
- Population size: PopSize.
- Maximum number of generations: MaxGen,
- Crossover probability: P_c .
- Mutation probability: P_m .
- Convergence threshold: ε .

Output: Optimal path P^* .**Algorithm:****1. Initialization**

- (a) Set generation to 0.
- (b) Initialize an empty set Population.
- (c) For i from 1 to PopSize:
 - i. Generate a path P_i using random walks from S to D within grid G .
 - ii. Add P_i to Population.

2. Evaluation

- (a) For each path P_i in Population:
 - i. Compute the fitness value:

$$F_{\text{fitness}}(P_i) = w_1 \times \mu_{\text{length}}(L(P_i)) + w_2 \times \mu_{\text{energy}}(E(P_i)) + w_3 \times \mu_{\text{area}}(A(P_i))$$

3. Selection

- (a) For each chromosome c_i in Population:
 - i. Evaluate the suitability using $\mu_{\text{suitability}}(c_i)$.
 - ii. Adjust fitness considering uncertain obstacles:

$$F'_{\text{fitness}}(c_i) = F_{\text{fitness}}(c_i) + \alpha \times \mu_{\text{obstacle}}(\omega)$$

4. Crossover

- (a) For two parent chromosomes c_p and c_q :
 - i. Determine compatibility for crossover at a gene g_i by $\mu_{\text{compatibility}}(c_p[g_i], c_q[g_i])$.
 - ii. Choose crossover points X maximizing compatibility.

5. Mutation

- (a) For Each chromosome c_i :
 - i. Determine mutation likelihood for a gene g_j by $\mu_{\text{effectiveness}}(c_i[g_j])$.
 - ii. If $\mu_{\text{effectiveness}}(c_i[g_j]) > \theta$, mutate gene g_j .

6. Optimization and Convergence

- (a) Determine the optimal path after k generations as P_k^* and the fuzzy-adjusted path quality as $Q(P)$.
- (b) Refine the optimal path:

$$P_{k+1}^* = \arg \max_{P \in \text{Population}_{k+1}} Q(P)$$

- (c) Check for convergence: If $|Q(P_k^*) - Q(P_{k+1}^*)| < \varepsilon$, end the algorithm.

4. Improved D* Algorithm for Local Path Planning. In the context of UAV-based smart agriculture, while global path planning designs an optimal route for comprehensive field coverage, local path planning adapts to dynamic obstacles and sudden environmental changes. The traditional D* algorithm has been effective for this purpose, but we propose an enhanced approach incorporating refined UAV safety distance determination.

- **Enhanced Cost Function:** While the basic D relies on a static cost between nodes, our improved model integrates dynamic costs influenced by numerous factors:
- **Energy Cost:** Borrowing from our global path planning model, the energy E required to traverse a path segment is included in the cost function.
- **Safety Cost:** Given that a UAV requires a safe distance from obstacles, especially in unpredictable agricultural terrains, a cost component S that penalizes paths too close to detected obstacles is introduced. This is determined as EQU (4.1)

$$S = k \times e^{-d} \quad (4.1)$$

where k is a constant, d is the distance from the obstacle, and e is the base of the natural logarithm. This ensures a higher cost for paths closer to blocks and vice versa. The final cost C for an edge can be represented as EQU (4.2)

$$C = w_1 \times L + w_2 \times E + w_3 \times S \quad (4.2)$$

where w_1 , w_2 , and w_3 are weighting factors, and L denotes path length.

- **UAV Safety Distance Determination:** The safety distance determination ensures that the UAV maintains a safe distance from obstacles (Figure 4.1). This involves geometric calculations to determine the distance between the UAV's path and nearby obstructions.

Given:

- Coordinates of a current node P are (x_p, y_p) .
- Coordinates of the destination node Q in its path are (x_q, y_q) .
- Coordinates of an obstacle node R are (x_r, y_r) .

The projection of obstacle R onto the path segment PQ is denoted by R' . The y-coordinate, $y_{r'}$ of this projection can be determined as EQU (4.3)

$$y_{r'} = \frac{(y_q - y_p)}{x_q - x_p} (x_r - x_p) + y_p \quad (4.3)$$

The angle θ between the path segment PQ and the x-axis can be found as EQU (4.4)

$$\theta = \arctan \left(\frac{y_p - y_q}{x_p - x_q} \right) \quad (4.4)$$

Now, the distance s from the obstacle R to its projection R' on the path, PQ is EQU (4.5)

$$s = |y_r - y_{r'}| \quad (4.5)$$

- **Safety Threshold and Path Consideration:** A predefined safety threshold, T , is essential. If s is less than T , the path might be too close to the obstacle and should be reconsidered. However, considering environmental factors and UAV specifications, a dynamic adjustment factor, Δ , is introduced. This adjustment factor modifies the safety threshold based on real-time data, EQU (4.6)

$$T' = T + \Delta \quad (4.6)$$

Now, if $s < T'$, the UAV should reconsider the path. Otherwise, it can continue on the path PQ . The above equation, Δ , represents the dynamic adjustment factor influenced by UAV speed, wind conditions, and obstacle mobility. For instance, the safety threshold should be increased if an obstacle moves.

- **Path Smoothing Optimization:** One of the challenges with any path planning algorithm is that the generated path might not always be smooth. Sharp turns or zigzag patterns may be introduced in the path, especially when navigating through dense obstacle environments. Such paths are inefficient

Fig. 4.1: Determining Safety Distance

for a UAV, leading to rapid battery drain, instability, and reduced safety. Thus, path smoothing optimization ensures that the UAV’s path is as streamlined as possible, reducing unnecessary movements and providing a more efficient trajectory.

Bezier curves are a mathematical tool in computer graphics designed to generate smooth curves. By employing Bezier curves, we can transform a series of linear segments into a smooth curve that preserves the original waypoints and reduces inflections. Given two control points A and B and two endpoints, P_0 and P_1 , the Bezier curve $B(t)$ is defined as EQU (4.7)

$$B(t) = (1 - t)^3 P_0 + 3(1 - t)^2 t A + 3(1 - t) t^2 B + t^3 P_1 \tag{4.7}$$

where $0 \leq t \leq 1$. A cost function can be defined to evaluate the smoothness of a path. The cost is higher for paths with sharp turns or abrupt changes in direction. Given a path segment s , the cost $C(s)$ could be related to the derivative of the path concerning distance, squared, EQU (4.8)

$$C(s) = \int_{\text{path}} \left(\frac{d^2 s}{dt^2} \right)^2 dt \tag{4.8}$$

The goal is to minimize $C(s)$ to achieve the smoothest path. Often, a single pass of optimization might not yield the best results. Iterative refinement involves running the smoothing algorithm multiple times, tweaking parameters, and adjusting waypoints as needed until a desired level of smoothness and efficiency is achieved.

- **Collision Check after Smoothing:** Path smoothing optimizes UAV trajectories, eliminating abrupt changes and ensuring energy-efficient movement. However, as trajectories are modified, the risk of infringing upon safety margins around obstacles may inadvertently increase. Thus, postsmoothing collision checks are indispensable. A UAV operating in a cluttered environment may encounter multiple obstacles, static (e.g., infrastructure) and dynamic (e.g., other UAVs). As the UAV’s path undergoes smoothing, ensuring that it remains collision-free at every point becomes paramount. To this end, we introduce a distance function, D . For any point p on the UAV’s trajectory, D calculates the shortest distance to the closest obstacle, facilitating instantaneous hazard proximity assessment. Let O denote the set of all obstacles in the environment, and $d(p, o)$ represent the Euclidean distance between point p and obstacle o . Then, the distance function $D(p)$ is articulated as, EQU (4.9)

$$D(p) = \text{Min}_{o \in O} d(p, o) \tag{4.9}$$

To ensure safety, for all points p on the smoothed path: $D(p) > R_{\text{safe}}$; where R_{safe} is not merely a predefined radius. Instead, it is dynamically computed based on the UAV’s relative positioning to nearby obstacles, considering both distance and angular considerations.

Given the UAV's position as p_{UAV} , and the angle $\alpha(p_{UAV}, o)$ between its heading direction and an obstacle o , we compute distances and angles to all obstacles, EQU (4.10) and EQU (4.11)

$$D(o) = d(p_{UAV}, o) \forall o \in O \quad (4.10)$$

$$A(o) = \alpha(p_{UAV}, o) \forall o \in O \quad (4.11)$$

This work introduces weighting factors, w_d and w_α , which dictate the significance of distance and angular considerations. R_{safe} is then defined as EQU (4.12)

$$R_{\text{safe}} = \frac{\sum_{o \in O} w_d \cdot D(o) + w_\alpha \cdot A(o)}{|O|} \quad (4.12)$$

This approach ensures that the UAV maintains an adaptive safety radius, considering its distance from and orientation to potential obstacles. Should any point on the smoothed path breach the condition mentioned above, the path is deemed unsafe and requires further refinement. This rigorous framework guarantees that the UAV's route is not only visually smooth but also technically secure for traversal. The following steps present the proposed local path algorithm.

Algorithm 2: Improved D* for Local Path Planning

Inputs:

- Start node S
- Goal node G
- Global Path Planning Model
- Weights w_1, w_2, w_3
- Safety factor k
- Safety threshold adjustment Δ

Output:

- The smoothed path from S to G or "UNSAFE" notification.

Steps:

1. **Initialization:**
 - (a) Current node $\leftarrow S$
 - (b) Initialize $\text{open_list} = \{\}$ and $\text{closed_list} = \{\}$
2. **Enhanced Cost Function:**
 - (a) Compute E , which represents the energy from the Global Path Planning Model.
 - (b) Calculate the safety cost as: $\text{Safety_Cost}(n) = k \times \exp(\text{distance to nearest obstacle}(n))$
 - (c) Determine the path length from node n to the goal node: $\text{Path_Length}(n) = \text{distance}(n, G)$
 - (d) Return $w_1 \times \text{Path_Length}(n) + w_2 \times EE + w_3 \times \text{Safety_Cost}(n)$
3. **UAV Safety Distance Determination**
 - (a) Calculate $\text{Safety_a_Distance}(P, Q, R)$:

$$R' = \text{projection of } R \text{ onto segment } PQ$$

$$s = \underline{\text{distance}(R \text{ to } R')}$$

- (b) Return s
4. **Safety Threshold and Path Consideration:**
 - (a) $\text{Check_Safety_Threshold}(s, T)$:

$$T' = T + \Delta$$

- (b) If $s < T'$ Then return "UNSAFE"
- (c) Else, return "SAFE".
5. **Path Smoothing Optimization:**

- (a) Bezier Smoothing(path):
 - i. For each segment s in the path: Apply Bezier curves using control points and endpoints If $C(s)$ (based on the derivative) is too high, refine segment s
 - ii. Return smoothed path
- 6. Collision Check after Smoothing:**
 - (a) Collision Check (path):
 - i. For each point p in the path: Calculate $D(p)$ as the shortest distance to the closest obstacle If $D(p) < R_{\text{safe}}$, return “UNSAFE”
 - ii. Return “SAFE”
- 7. Path Planning Procedure:**
 - (a) While current node is not goal node:
 - (b) Find neighbors of current node
 - (c) For each neighbor:
 - i. Calculate cost using Calculate Cost_Cost
 - ii. Calculate safety distance using Calculate Safettocos _Distance
 - iii. Check safety threshold using Check_Safety_Threshold
 - iv. If the node is safe and has a reasonable cost, add to opena list
 - (d) Move current node to closed list
 - (e) Set the node with the lowest cost in open list as current node
- 8. After Reaching Goal_Node:**
 - (a) Traceback path from goal node to start node
 - (b) Apply Bezier. Smoothing to the path
 - (c) Conduct Collision Check on the smoothed path
 - (d) If the path is “UNSAFE”, reiterate path planning or refine the smoothing
 - (e) Else, execute the path.

Having delved into the intricacies of both the Enhanced Genetic Algorithm using Fuzzy Logic for global path planning and the Improved D* Algorithm for local path planning, it is crucial to understand their harmonized implementation in UAV navigation. The Enhanced Genetic Algorithm using Fuzzy Logic, renowned for its adeptness in combining genetic algorithms with fuzzy logic principles, sketches an optimal path from the start point to the goal by evaluating multiple routes and selecting the best fitness value. This provides the UAV with a broad overview of its trajectory, ensuring efficient and energy-conservative navigation. However, the ever-changing nature of real-world scenarios requires a more adaptive approach to immediate obstacles and dynamic environments. This is where the Improved D* Algorithm comes into play. It operates in the UAV’s immediate surroundings, dynamically adjusting its real-time trajectory based on the sensed obstacles and environmental changes. By rapidly updating the robot’s path as the environment changes, the Improved D* Algorithm ensures safe and adaptive local maneuvering. When these two algorithms are sequentially integrated, the UAV benefits from the foresight of the Enhanced Genetic Algorithm using Fuzzy Logic for long-range planning while relying on the agility and responsiveness of the Improved D* Algorithm for short-range adjustments. The synergy of these algorithms equips the UAV with a comprehensive and adaptable navigation blueprint, ensuring safe and efficient flight.

5. Experimental Analysis. The principal simulation platform for our experimental analysis was configured around an Intel® Core™i7 – 9700 K CPU @ 3.60GHz with Windows 10 as the operating system. The algorithm’s performance was evaluated using MATLAB simulation tools. We designed a comprehensive path planning domain measuring 90 km by 90 km. The environment is partitioned into cells, each encompassing a 10 km by 10 km area. This results in a grid configuration of 9×9 cells.

Key simulation parameters were adjusted as follows:

- The UAV’s maximum permissible turning angle was set to $\pi/6$ to account for a more agile flight profile, enhancing the fidelity of the simulation in representing the dynamic maneuvering capabilities of contemporary UAVs.
- The grid granularity was established with a resolution of $N = 0.5$ km, improving the precision of our

Fig. 5.1: Initial airspace setup

Fig. 5.2: Route length analysis

spatial analysis and the solution of the path-planning process.

- A safety margin was defined at 1 km, ensuring a conservative operational envelope for the UAV to prevent potential collisions with obstacles.
- The UAV's initial and target coordinates were plotted at (10, 10) and (90, 90), respectively, providing a diverse range of trajectory planning scenarios across the simulation space.

These simulation adjustments have been carefully chosen to test the boundaries of the proposed UAV path planning model, ensuring robustness, adaptability, and a high degree of environmental fidelity. Through this altered configuration, the model is subject to a wider range of test scenarios representative of complex agricultural terrains. Figure 5.1 shows the UAV's simulated airspace.

From Figures 5.2, 5.3, and Table 5.1, When the performance of the algorithms is compared using the average route values, the EGA+ID* approach emerges as the better standard, serving as our reference point. Relative to this, the Particle Swarm Optimization (PSO) method exhibited routes that were approximately 51.73% longer. Following closely, the Ant Colony Optimization (ACO) generated paths that were 47.48% longer than the EGA+ID*. The Genetic Algorithm (GA) trailed slightly behind, with 46.59% more extended paths than the proposed combined approach. The Dynamic Window Approach (DWA) displayed a marked improvement over the previous algorithms but still had routes approximately 31.57% longer than the EGA+ID*. When we consider other conventional algorithms, the disparity in performance becomes even more palpable: D* exhibited routes that were 22.34% longer, while A* demonstrated paths that were 20.39% more extended. When considering the state-of-the-art models, the Improved Ant Colony Optimization (IACO) and Q Learning had 7.80% and 9.20% longer routes, respectively. Impressively, the fusion of A* with the Dynamic Window Approach (A*+DWA) came remarkably close to the top-performing model, with only a 2.49% increase in path length over the EGA+ID*.

Fig. 5.3: Path planning results

Fig. 5.4: Distance to target analysis

Table 5.1: Performance analysis of the compared models

Algorithms	Inflection Count	Time (s)	Accuracy
PSO	16	12.35	48.7
ACO	15	10.8	46.6
GA	15	11.63	48.3
DWA	15	10.46	45.5
D*	17	8.93	58.8
A*	17	9.02	56.4
EGA	12	8.83	74.1
ID*	11	9.57	74.83
IACO	13	7.96	73.36
Q Learning	12	7.07	81.23
A*+DWA	10	6.86	84.6
EGA+ID*	9	5.54	91.1

The data reveals a fascinating interplay between inflection count, time efficiency, and accuracy of various path-planning algorithms. The combined EGA+ID* model distinguishes itself as a frontrunner, completing its tasks in a mere 5.55 seconds and achieving an impressive accuracy of 91.1%. This superior performance is realized with a minimal inflection count of 9, implying a trajectory with fewer directional changes and a smoother path. In contrast, the D* and A* algorithms, despite having the highest inflection counts of 17, manage to hold their own. Specifically, D* highlights a respectable accuracy of 58.8%, slightly edging out A*. On the other end of the spectrum, algorithms like PSO and ACO, while being relatively faster than some counterparts, lag in accuracy, hovering around the mid-40s range.

Meanwhile, the A*+DWA fusion strikes a commendable balance, ensuring quick path planning in 6.863 seconds and delivering an accuracy of 84.6% with a mere 10 inflections. Overall, the results underscore the process of integrating global and local pathplanning models, as demonstrated by the unmatched efficiency and accuracy of EGA+ID*. The distance to the target for each iteration is displayed in Figure 6. Starting at 59.18 in the initial iteration, EGA+ID* demonstrates a steady decrease in distance values, reflecting its effective optimization capability. Compared to other algorithms, EGA+ID* maintains consistent performance, converging closer to the target as iterations progress. This pattern displays the efficiency and potential of the EGA+ID* model in optimization tasks, making it a promising choice for such applications.

6. Conclusion. The rapid evolution of smart agriculture, underpinned by the convergence of technology and traditional farming practices, underscores a transformative shift in the agricultural domain. Unmanned Aerial Vehicles (UAVs), central to this transformation, change how agricultural operations are visualized and executed. While their potential is undeniable, ensuring their efficient and safe operation in the dynamic environment of a farm presents considerable challenges. The key lies in the intricate process of path planning. Our proposed hierarchical framework, which amalgamates the strengths of the “Enhanced Genetic Algorithm using Fuzzy Logic” for broad trajectory planning and the “Improved D* Algorithm” for nuanced, real-time adjustments, is a step forward in addressing this challenge. This integrated approach not only guarantees efficient navigation but also bolsters the safety and energy conservation of UAVs in real-world agricultural settings. As we look to the future, the fusion of such sophisticated algorithms with UAV technology holds the promise of further elevating the standards of smart agriculture, driving the sector towards heightened sustainability and productivity.

SMART FERTILIZING USING IOT MULTI-SENSOR AND VARIABLE RATE SPRAYER INTEGRATED UAV

HAYDER M. A. GHANIMI*, R. SUGUNA†, JOSEPHINE PON GLORIA JEYARAJ‡, K SREEKANTH§, RAJASEKAR RANGASAMY¶, AND SUDHAKAR SENGAN||

Abstract. This paper introduces a “Smart Fertilizing Using Internet of Things (IoT) Multi-Sensors” system to enhance fertilizer management in agriculture. The system has four main parts: the Nutro Determining Unit (NDU), the Nutro Sensing Unit (NSU), the Nutro UAV Variable Fertiliser Spray System, and a Variable Rate Unmanned Aerial Vehicle (UAV) Sprayer model. The NDU collects vital data on Soil Moisture (SM) and Environmental Conditions (EnC) using advanced IoT cameras, while the NSU consolidates and normalises the data for advanced analysis using Heuristic Decision Trees (HDT) and Random Forest (RF) algorithms. In India, a data-driven UAV system uses IoT and UAV technologies to determine nutrient needs and create a prescription map for fertilizer application. The approach caused increases in the efficient utilisation of resources, Crop Yield (CY), and ecological footprint when it underwent evaluation in a crop maize field that was 14 hectares in size. A fresh benchmark for Smart Farming (SF) techniques has been set up by this method of operation, which is motivated by data and symbolises an important innovation in modern and ecologically conscious SF methods.

Key words: UAV, IoT, Sprayer Model, Smart Fertilizing, Crop Yield, Smart Farming

1. Introduction. The major developments that have currently taken advantage of the field of agriculture in the past few decades have caused the origin of revolutionary ideas like “Smart Farming” (SF) and “Precision Agriculture” (PA). New technologically focused SF approaches have succeeded conventional farming methods as an impact of these changes. The modern-era SF procedures leverage revolutionary technologies like autonomous devices, statistical analysis of data, and the Global Positioning System (GPS) in order to improve farmer productivity and effectiveness. High crop yields (CY), better consumption of resources, less ecological damage, and maximized use of resources are feasible because PA’s data is updated constantly. Precise SF tasks become possible with this method of treatment because it enables selective application on particular areas or crops [7].

The Internet of Things (IoT) generates an evolution in the agricultural sector by implementing an online network of connected devices, including cameras, sensor networks, and Unmanned Aerial Vehicles (UAV) [6]. The main objective of IoT devices is to contribute to making SF more productive by collecting and analyzing data about the crop and the Earth’s Soil Moisture (SM). Some examples of inventions that showcase this include autonomous irrigation and precise monitoring systems. By pairing to the World Wide Web in real-time, farm IoT devices provide agriculturalists access to additional valid data, which enables them to make more accurate selections [10].

Ethical practices in ecological awareness finance can now develop owing to this better connectivity, which improves profitability and helps in the effective control of resources. IoT technology plays an integral part in

monitoring SM and environmental conditions (EnC), namely the levels of nutrients and SM, which is necessary for optimizing fertilizer consumption for successful economic crop development. Periodic data analysis makes it possible to identify the proper proportion of fertiliser to use, which, in consequence, serves to prevent spraying less or excess. Highly accurate and effective fertiliser treatments can be generated by using data pertaining to soil and crop requirements collected by IoT-enabled devices across a period of time frames [5].

A form of application that simplifies the use of pesticides is the Variable Rate Sprayer (VRS), which regulates the volume of fertiliser or pesticide sprayed based on particular regions and data in real-time. Better crop production, better conditions for crops, fewer waste products, and less negative environmental impact are the results of this approach's use.

More and more innovative farmers are employing VRS systems to integrate PA methods into their farming practices. This has the potential to minimize waste and the adverse impact of agricultural products on the natural world [3]. A multi-sensor IoT architecture and a prototype for SF fertilisation using a UAV-based VRS have been recommended in the present investigation on the "Smart Agriculture using IoT Multi-Sensors (SA-IoT-MS)" of the entire system.

The Nutro Sensing Unit (NSU), Nutro Gateway Unit (NGU), Nutro Decision Unit (NDU), and Nutro UAV (NUAV)-Variable Fertiliser Spray System (VFSS) are the 4 portions that make up the entirety of the system. The efficient functioning of the Sustainable Agriculture System (SAS) is enhanced by continually tracking both the soil quality of a crop and outside factors.

An array of parameters are recorded and digested by a unified system. These factors include soil water content, temperature, humidity, and NPK levels. The Decision-Making Process (DMP) revolves around the NDU, which generates a treatment map and forecasts nutrient requirements via a Heuristic Decision Tree (HDT) and Random Forest (RF) method. In order to achieve optimal use of resources while improving CY and good health, this map has been used to guide the accurate placement of fertiliser by the UAV system. By this creative approach, the developers have achieved significant progress towards attaining SAS standards.

This study article outlines the following: Chapter 2 starts with the existing literature analysis; Chapter 3 presents the framework hypothesis; Chapter 4 includes experimental research, and Chapter 5 concludes the research.

2. Literature Review. In order to effectively analyze soil nutrients, [1] developed an IoT-based system using a novel Nitrogen (N), phosphorus (P), and potassium (K) (NPK) sensor. Their use of fuzzy logic for data interpretation demonstrates the growing trend of incorporating complex data processing methods into SF technology.

[8] highlighted the importance of IoT in monitoring SM and EnC, specifically indoor plants, by measuring SM and NPK values and providing user feedback through an online data display, showcasing the integration of IoT with user-friendly interfaces in agriculture.

The authors emphasize the significance of precise data collection and analysis in agriculture, as highlighted by [2, 12]. They propose an SF system integrating Artificial Intelligence (AI) and sensor technology, focusing on energy-efficient deployment and sustainable SF. They also discuss the technical aspects of field data attainment systems in PA, emphasizing the need for accurate data in fertilizer and irrigation systems.

UAV technology has gained significant applications in SF [13, 4, 9], particularly precision farming. They have developed a pulse width modulation variable spray system, which an STM32 chip controls, showcasing the innovative integration of precise control mechanisms in UAV systems for spray farming.

3. System Model. The work puts forward the SA-IoT-MS system, an original concept developed with a clear goal to provide optimal fertiliser management in PA farms. The NUAU-Variable Fertiliser Spray System, the NSU, the NGU, and the NDU are the four interrelated elements that make up the basis of this proposed model. The NSU is not simply planned between the trees, but it has been connected with revolutionary IoT sensors [14, 15, 11, 16]. These sensors collect a wealth of data on the SM and EnC. The data obtained include temperature, humidity, pH, SM, and NPK. The primary objective of the distinct GSP-ID assigned to every NSU is to collect and monitor real-time data that is important in comprehending soil properties.

The NGU's function as a computing unit is to obtain the data collected from the NSUs and send it to them. The NGU may obtain data from numerous NSUs, do the initial analysis, and verify for reliability and consistency while sending it on for deeper analysis because of its architecture. It is the task of the NGU to

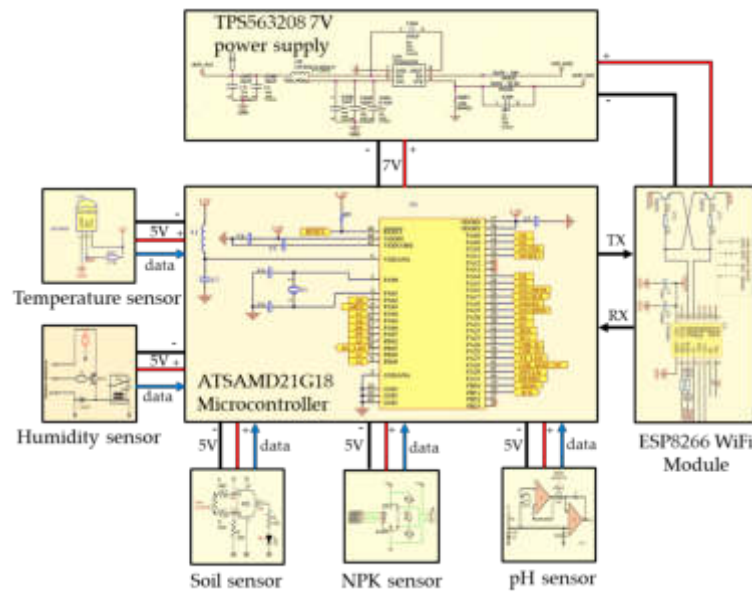

Fig. 3.1: NSU unit structure

ensure that the sensory data have access to the DMP entity uninterrupted any delays. The data is vulnerable to an HDT analysis by the NDU after the NGU stops receiving it. Using methods of empirical research, this elaborate study evaluates the temperature, SM, and NPK levels on an individual basis. In furtherance of analyzing the information that is presented, the NDU is assigned to detecting emerging patterns and trends. This attribute is vital in order to make intelligent DMP about fertiliser services, which will result in improved effectiveness and efficiency of deployments based on real-time and historical information.

In this framework, implementing the NUAV-VFSS is the final phase. This UAV-based system sprays fertilizer precisely where it is required, owing to the extensive instruction presented by the NDU. According to data analysis, the UAV employs VRS innovation to optimize the level of fertilizer sprayed in different regions of the crop. The productivity and efficacy of the fertilization method are significantly improved by this approach, which provides a personalized and efficient use of fertilizer.

3.1. NSU. Figure 3.1 illustrates the elements of the NSU that were developed for the purpose of this research to promote accurate data collection and effective communication in the proposed SF model. The NSU's primary operation is regulated by the ATSAM21G18 microcontroller, which effectively controls the unit's functions while using less power. The NSU collects an enormous amount of soil-based and environmental information using a number of unique sensors. The DSB18B20 temperature sensor is noted for its accuracy in measuring room temperature; the HR202 moisture sensor performs well at monitoring the level of SM in the atmosphere; and the Jxct soil sensor is great at analyzing the attributes of soil. Measuring SM and EnC in full is required for SF effectiveness. The I2C-SM sensor and the Sen0161 pH sensor have been used in the present study.

Reliable transfer of data for analysis is made possible by the ESP8266 Wi-Fi module, making it possible for simple internet access with the NGU. The NGU depends on the TPS563208 power system for reliable power control. This module provides all sensors and microcontrollers with stable and uninterrupted power, ensuring that they can function and collect data without delay in a number of crop settings.

1. **ATSAMD21G18 Microcontroller:** The NSU powers the ATSAM21G18 Microcontroller, a low-power, high-performance microchip on the ARM® Cortex®-M0+ platform that is ideal for home automation and industrial applications. Its 256 kb flash and 32KB SRAM provide ample memory for data processing. The ATSAM21G18 microcontroller is a versatile device with six configurable

Table 3.1: Microcontroller Configuration

Feature	Description
Microcontroller	ATSAMD21G18, ARM® Cortex®-M0+ based
Memory	256KB Flash, 32KB SRAM
Operating Frequency	Up to 48MHz
PWM Channels	20 channels
Power Supply Range	1.62V to 3.63V

Table 3.2: Wi-Fi Module Configuration

Feature	Specification
Processor	L106 32-bit RISC, 80MHz
Memory	32 KiB instruction RAM, 80 KiB user-data RAM, up to 16 MiB QSPI flash
WiFi	IEEE 802.11 b/g/n
GPIOs	16 pins
Interfaces	SPI, I ² C, I ² S, UART, ADC
Power Management	APSD for VoIP, Bluetooth co-existence
RF System	Self-calibrated

SERCOM modules, three 16-bit timers, a 32-bit real-time clock, and 20 PWM channels, enabling rapid data processing and accurate environmental monitoring. It also features a 14-channel 12-bit analog-to-digital converter and a 10-bit digital-to-analog. The ATSAMD21G18 microcontroller is a high-performance device that supports full-speed USB devices and embedded host functionality, can handle 120 touch channels, and operates within a power range of 1.62V to 3.63V, as detailed in Table 3.1.

2. **ESP8266 WiFi Module:** The ESP8266 Wi-Fi Module, a small and cost-effective System on Chip (SOC) with an integrated TCP/IP protocol stack, enables Arduino controllers to connect to Wi-Fi networks. This module additionally decreases the requirement for a CPU. The module's built-in processing and storage capabilities and high on-chip integration require less additional hardware, reducing the space required for the Printed Circuit Board (PCB). Because of its space-saving design, the ESP8266 is a good option for applications with limited free space for living. It is not essential to use external RF devices because the module's self-calibrated Radio Frequency (RF) system ensures reliable performance in a wide range of temperature and humidity conditions. Table 3.2 displays comprehensive setup details for the installed Wi-Fi module.
3. **Power Module:** The NSU devices are able to run properly because the TPS563208 input module provides them with power through its 3-A synchronous communication step-down inverters. The key objectives of this unit, enclosed in a SOT23 package and small in size, include easy operation, low idle current, and no reliance on external elements. It has a wide input voltage range (4.5V to 17V) and output voltage range (0.76V to 7V). It also has D-CAP2 mode control, which lets it respond quickly to transients, and continuous current mode, which works well with low loads. Additionally, the module ensures safety and dependability by including controls such as the current limit, UVP, and TSD. Furthermore, it performs well across a wide temperature range, ranging from -40° to 125°. Additionally, Table 3.3 contains the configuration information of the electric power module.

The following sensors are integrated into the NSU unit:

- *Temperature:* This investigation uses the DS18B20 sensor to measure the temperature in SF models. The precision, dependability, and ease of integration of this digital sensor led to its selection as the winner. It is a well-liked option in San Francisco because it accurately measures and controls the temperature in the agricultural environment.
- *Humidity:* SF applications, in which energy efficiency is a top priority, are a good fit for the HR202

Table 3.3: TPS563208 description

Feature	Specification
Output Current	3A
Control Mode	D-CAP2 Mode
Input Voltage Range	4.5V–17V
Output Voltage Range	0.76V–7V
Operating Mode	Continuous Current
Switching Frequency	580kHz
Shutdown Current	<10mA
Voltage Accuracy	2/cent at 25°
Soft Start	1.0mins
Package	6-pin SOT23 (1.6mm×2.9mm)
Temperature Range	-40° to 125°

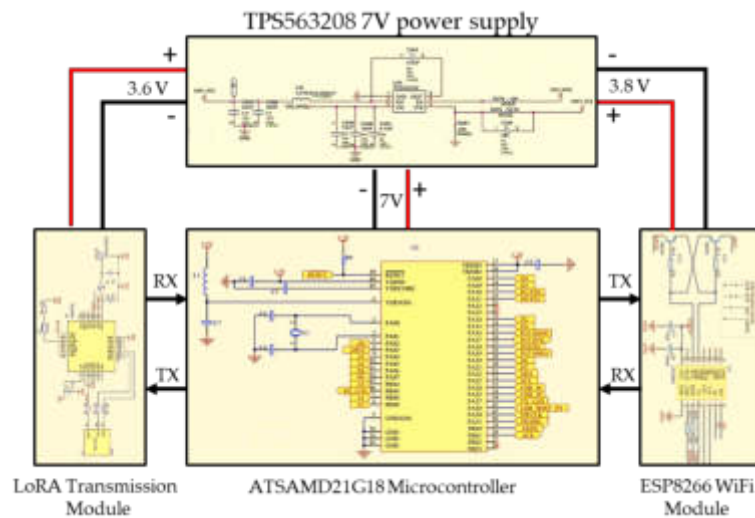

Fig. 3.2: NGU structure

sensor because of its improved moisture tracking capabilities, wide measurement range, and higher accuracy. As a result, it is an excellent option for SF applications.

- *SM*: The I2C-SM sensor employs the capacitive sensing method, resulting in an accurate and non-corrosive device with consistent long-term reliability, regardless of the predominant soil conditions. It is suitable for SF devices because of its low-voltage functioning, which promotes the use of energy.
- *pH*: Acidity in soils impacts crop growth, fertilizer absorption and soil health; the Sen0161 pH sensor is a significant device for monitoring this factor. Its investigations are vital for making smart choices about soil care along with growth because they are accurate and endure for an extended period of time.
- *NPK*: For precise soil mineral levels of difficulty, fertility tests, and SF use approaches, the LNPk-1 sensor is required. The system delivers accurate fertilizer data employing modern chemical tools for measurement.

3.2. NGU. Collecting and analysing data from NSU distributed around the trees is the task of the NGU, which is a vital part of the SF system. Its core is the ATSAM21G18 microcontroller, which has been designed for practical use. According to Figure 3.2, the NGU includes the ESP8266 Wi-Fi Module, which enables the creation of reliable wireless connections and the sending of data to a primary server or a cloud-based system.

Table 3.4: LoRA Module Description

Specification	Description
Frequency Range	433MHz
Modulation Techniques	FSK/GFSK/MSK/LoRa
Sensitivity	-136 dBm
Output Power	+20 dBm
Data Rate	<300 kbps
Operating Temperature	-40° to +80°
Standby Current	≤ 1mA
Supply Voltage	1.8V to 3.6V

The NGU has a LoRA transmission module that enables transmission over long distances. This technology is intended for use in low-power, wide-area network (LP-WAN) applications, making it especially useful for SF fields in which NSUs are spread across numerous land areas. While using minimal power, the module can send and receive data over enormous distances most efficiently. When it comes to ensuring that DMPs in remote or difficult locations have a link to an uninterrupted supply of data, the ability of this device to manage large distances without impacting battery efficiency or signal quality is paramount.

The capacity of the TPS563208 power module to provide support for the NGU, which comprises the LoRA module, implies that the operation will be stable and uninterrupted. The microcontroller and communication modules, such as Wi-Fi and LoRA, can function at their highest possible efficiency due to this power module, which provides an uninterrupted and reliable energy supply. This significantly enhances the overall reliability and performance of the NGU, as previously mentioned. As an outcome of the synergistic combination of cutting-edge microcontroller technology, numerous communication options, and a reliable electrical system, the NGU has been determined to be a vital and practical element within the overall structure of the SF.

1. **LoRa Transmission Module:** LoRa Transmission Modules, more specifically for use in SF, make it possible for IoT applications to participate in long-range wireless communication. These modules operate on the LoRaWAN network and use wavelengths that typically fall within the frequency spectrum of 864MHz to 915MHz, following the regulations of the different regions. LoRa modules can send data over ranges of up to 15 kilometres, even in areas that are susceptible to noise. LoRa modules are renowned for their low power consumption and high receiver sensitivity. These modules stand out for their autonomous power supply, typically powered by batteries and capable of lasting up to 10 years without needing a new battery.

The NGU employs the LoRA 433MHz SX1278 module. It is a cost-effective RF front-end transceiver that excels in long-range and low-data-rate applications. Its exceptional sensitivity (-136dB/m in LoRa modulation) and 20dB/m power output ensure reliable connectivity over long distances. The module operates on a 433MHz frequency, supports multiple modulation formats, and can function in extreme temperature ranges from -40° to +80°, making it versatile for varied environmental conditions. Additionally, it includes features such as a built-in temperature sensor with ultra-low standby current that operates within a 1.8 to 3.6V supply voltage range. The following table describes the LoRA module.

3.3. NDU. The NDU is fitted with a vital device called the Heuristic Random Forest (HRF), which is mainly deployed to determine whether or not different agricultural areas require fertilizer replenishment. This DMP is supported by a series of HAs that evaluate various agricultural factors. The following lists contain detailed descriptions and equations for each technique:

1. **Estimation of Evapotranspiration (ET):** For the goal of measuring the amount of water that evaporates as a result of evaporation and crop water loss, the estimated amount of ET is an important metric. Conducting a review of the water level is particularly significant in the SF sector because it has an indirect impact on the rate at which plants absorb fertilizers.

$$ET = ET_o \times K_c \quad (3.1)$$

Here, ET_o represents the reference ET, calculated based on climate data, including temperature, humidity, and solar radiation. K_c is the crop coefficient that varies according to different growth stages, signifying the crop's ET under specific conditions as compared to the reference.

2. **Water Retention Ratio (WRR):** The WRR is the most crucial measure of the soil's capacity to store water. If the WRR is higher, it means the soil can store additional moisture, which in turn impacts its capacity to maintain nutrient solutions and determine how to apply fertilizer plans. EQU (3.2) for WRR is:

$$WRR = \frac{FC - PWP}{AWC} \quad (3.2)$$

The field capacity (FC), the permanent wilting point (PWP), and the available water content (AWC) of the soil are represented in this equation.

3. **Nutritional Deficiency Predictor (NDP):** This study compares the required nutrient levels for a particular crop cycle with the readily accessible nutrient levels in the soil. The goal of this heuristic is to make a prediction about the possibility of nutritional deficiencies. Obtaining this data is essential for determining the necessity of supplemental nutrition. The NDP's EQU (3.3) stands for:

$$NDP = \sum (N_{\text{req}} - N_{\text{avail}}) \times F_{\text{factor}} \quad (3.3)$$

Where N_{req} is the nutrient requirement for a specific crop stage, N_{avail} represents the available nutrient level in the soil and F_{factor} is a crop-specific adjustment factor.

4. **Soil pH Influence (SPI):** Using the SPI heuristic, one can identify how the pH of the soil affects the availability of nutrients. This heuristic assists with changing the pH of the soil in order to enhance the absorption of nutrients, which is essential because numerous crops have distinct optimal pH levels for production. The is calculated as EQU (3.4).

$$SPI = pH_{\text{opt}} - pH_{\text{soil}} \quad (3.4)$$

where pH_{opt} is the optimal pH level for the crop, and pH_{soil} is the current soil pH level.

This experiment set up an HRF model using advanced algorithms and machine learning (ML) methods to determine the nutrient requirements of SF regions. Factors such as ET, WRR, NDP, and SPI ensure that an inclusive and accurate method for adding nutrients across multiple SF zones is provided.

This work begins by computing the RF model using equations 1 through 4. Next, this study will collect and normalize past and present information based on the heuristics EE, WRR, NDP, and SPI. This helps to guarantee that the input is reliable and scalable. Subsequently, we fine-tune the model's set-up, including the number of trees, feature splitting method, and DMP at each node. Every tree in the RF conducts a separate independent evaluation based on the heuristics, which contributes to the final decision about the value of added nutrients across multiple SF areas.

When training the model, it is crucial to use labelled data, which shows if additional nutrition would have been needed under scenarios that were similar in the past. The model can collect information from these data points, allowing it to make intelligent decisions about adding nutrients. After the training phase, we verify the model's precision and reliability using a distinct data set. After verification, we set up the HRF model for practical application. The HRF model uses real-time data associated with ET, WRR, NDP, and SPI to predict the need for additional nutrients in various zones of the SF field. We use the predictions to produce a complete prescription map, making them highly significant. Figure 3.3 below displays the sequence of the NDU module's functions.

After the testing and installation of the HRF model, its essential task will be to analyse real-time data points, such as ET, WRR, NDP, and SPI. This will allow it to calculate nutritional supplementation needs across all SF field zones. The creation of a complex prescription map, which is a vital tool for the NUAV-VFSS, is an effective end to this process. The nutritional map is a digital data file that houses a vast amount of information about the GPS coordinates of the SF field and the determined rates of fertilizer application. A meticulously coded program in MATLAB® is responsible for the development of this map (Fig. 3.4), which

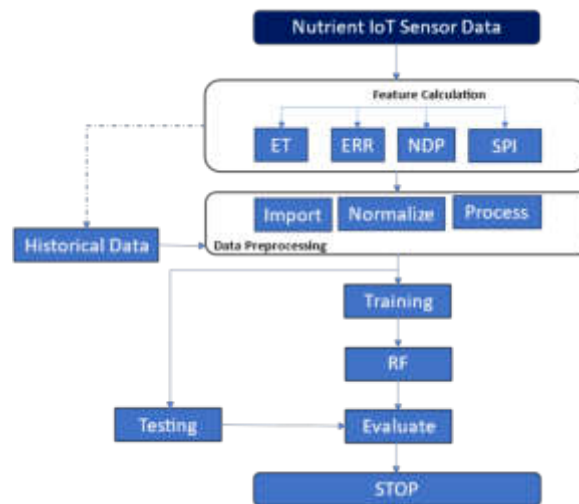

Fig. 3.3: Flowchart of the fertilizer DMP.

Fig. 3.4: Prescription Map.

combines the data on the range of vital nutrients with the geographical coordinates in order to provide an in-depth representation of the supply of nutrients.

This study edges a nutrient map onto a 10×10 -meter fishnet grid, enabling a more precise approach to nutrient management. This grid divides the map into manageable segments, extracting centroid coordinates and nutrient data. This work uses these data to calculate fertilizer application rates for each grid cell, ensuring they align with the target nutrient requirements. This investigation transmits the resulting digital nutrient application map, complete with precise latitude and longitude coordinates, to the NUAUV-VFSS. This data equips the UAV to experiment with targeted fertilizer applications and guarantees a customized nutrient measure for each field zone.

3.4. NUAUV-VFSS. The goal of NUAUV-VFSS is to deliver focused fertilizer applications with unprecedented precision. The system aims to deliver these applications. Figure 3.6 provides a conceptual model of the UAV-VFSS system, showcasing its complex design and functionality. This assignment utilized the DJI Agras T30 drone, a product of SZ DJI Technology (Shenzhen) Co., Ltd. SZ DJI Technology (Shenzhen) Co., Ltd. developed this specific UAV by integrating specific modules for prescription map conversion and spray control. The HRF model generates a prescription map, which the UAV uses to follow. This guarantees the precise placement of fertilizers where they are required.

Table 3.5: UAV-VFSS Description

Component	Description	Manufacturer/Supplier

KLP02-E KA	Micro diaphragm Pump to Control the flow of fertilizer.	Kamoer Fluid Technology (Shanghai) Co., Ltd.
F110-015	Spray the Nozzle to ensure the fertilizer is evenly distributed.	Mid-South Ag. Equipment, USA
ATSAMD21G18	Microcontroller for the spray control subsystem.	—
YF-S201	The magnetic hall flow sensor measures the system's flow rate, which ranges from 1–30l/min.	DATAQ Instruments, Inc, Ohio, USA

A micro diaphragm pump (KLP02-E KA, Kamoer Fluid Technology (Shanghai) Co., Ltd.) is critical to the performance of the VFSS because it ensures that the fertilizer flow is adequately controlled within the system framework. This pump, when used with a spray nozzle (F110-015 FanTip Nozzle 110, produced by Mid-South Ag. Equipment in the United States), makes it possible to promote the even distribution of fertilizer across the zones that were previously specified. The ATSAMD21G18 microcontroller is the most significant element of the spray control subsystem. It is responsible for regulating the spraying system's performance. Therefore, we require the accuracy and dependability of this microcontroller to ensure accurate fertilizer distribution. The VFSS incorporates a magnetic hall flow sensor (YF-S201, DATAQ Instruments, Inc., Ohio, USA) with a measuring range of 1–30l/min. This sensor plays a crucial role in monitoring and adjusting the fertilizer flow rate, ensuring it aligns with the prescribed demands on the prescription map. Table 3.5 breaks down each element of the UAV-VFSS into smaller sections and provides more detailed information.

The NDU unit transmits the prescription MAP, received through the Wi-Fi module and uploaded into the ATSAMD21G18 microcontroller.

The built-in GPS of the UAV-VFSS continuously transmits real-time positional data to the microcontroller on the UAV as it traverses the landscape. The microcontroller initiates a key-matching function as soon as it receives the current coordinates of the UAV. The microcontroller accomplishes this by comparing the UAV's position with the encrypted GPS data in the preloaded prescription map. This map divides the fertilizer application process into distinct areas across the field, providing complete guidance on successful application.

The UAV moves across the field, aligning with a prescription map. A microcontroller identifies the current unit area and retrieves the corresponding prescription value, which is the specific quantity of fertilizer for that area. A variable spray controller then receives this information and adjusts the UAV's spray mechanism to apply the prescribed amount of fertilizer, ensuring the exact amount matches the prescription map for that specific area.

Fig. 3.6: UAV-VFSS Structure.

Table 4.1: Data from three sites showing the results of the Nutrient sensor data

Variable	Unit	Site	Mean	Min	Max	Median	S.D	Variance	Skewness	Kurtosis

4. Experimental Study. This work tested the “SA-IoT-MS” system in a practical field experiment on a 14-hectare maize field in Maharashtra, India. This method divided the 35,000-square-foot area into smaller zones for detailed analysis and precise intervention, ensuring the system’s controlled and measurable application in the region’s agronomic conditions.

This simulation advantageously placed the NSUs to collect vital SF data such as SM, temperature, pH, and nutrient content from three sites. The data collection spanned four months (15th March 2022 to 30th July 2022), covering the entire maize growing season and capturing agronomic variables and changes throughout different stages of crop development. The results are crucial in assessing the effectiveness of the “SA-IoT-MS” system in a practical SF setting, as shown in 4.1 and 4.2.

- Kg/ha: Kilograms per hectare.
- Mean: The average value of nutrient content.
- Min: The minimum recorded value of nutrient content.
- Max: The maximum recorded value of nutrient content.
- Median: The middle value in the range of nutrient content.
- S.D (Standard Deviation): Measures the variation in the nutrient content.
- Variance: The square of the standard deviation.
- Skewness: A measure of the asymmetry of the distribution of nutrient content.
- Kurtosis: A measure of whether the data are heavy-tailed or light-tailed relative to a normal distribu-

Fig. 4.1: NDU prescribed fertilizer amount vs NUAU-VFSS Sprayed amount.

tion.

- °: Degrees Celsius.

The NDU uses sensor data to determine the precise amount of fertilizer (measured in kilograms per hectare, kg/ha) needed at each site in the field. This system uses the heuristic RF algorithm to determine nutrient needs based on unique conditions. The NDU calculates the required levels and relays them to the NUAU-VFSS, which uses a control module to apply the prescribed fertilizer levels. This method is more efficient and environmentally sustainable, minimizing waste and runoff while making fertilizer application more efficient and effective. Figure 4.1 showcases the effectiveness of the integrated system, comparing the prescribed fertilizer levels with the actual quantities applied by the NUAU-VFSS. The data demonstrates the system’s high efficiency and precision, closely mirroring the NDU’s prescriptions and proving its value as an integral part of SF practices.

Figure 4.1 highlights that the NUAU-VFSS is a fast system, which is an accomplishment worthy of recognition. This demonstrates the system’s ability to precisely adhere to the NDU’s rules and adapt to the unique standards imposed by various field regions. SM places a significant value on precision and adaptability, significantly contributing to higher CY, reduced resource waste, and environmentally friendly SF practices.

5. Conclusion. The “SA-IoT-MS” system, combined with a variable-rate UAV sprayer, significantly advances precision agriculture. It improves fertilizer management efficiency and effectiveness by combining IoT technology and UAV capabilities. The deployment of NSUs collects environmental and soil parameters data,

enabling data-driven agriculture. The NGU and NDU process this data to make precise fertilizer requirement decisions. The NUAV-VFSS executes these decisions, catering to different agricultural zones. A field experiment in Maharashtra, India, validated the system's functionality and highlighted its potential for revolutionizing SF practices. The results demonstrated crop yields and resource optimization improvements, promoting sustainable agriculture.

This model sets a precedent for future developments in SF, showcasing the benefits of integrating advanced technologies like IoT and UAVs into agricultural operations.

RECURRENT NEURAL NETWORK BASED INCREMENTAL MODEL FOR INTRUSION DETECTION SYSTEM IN IOT

HIMANSHU SHARMA, PRABHAT KUMAR* AND KAVITA SHARMA[†]

Abstract. The security of Internet of Things (IoT) networks has become an integral problem in view of the exponential growth of IoT devices. Intrusion detection and prevention is an approach used to identify, analyze, and block cyber threats to protect IoT from unauthorized access or attacks. This paper introduces an adaptive and incremental intrusion detection and prevention system based on RNNs, to the ever-changing field of IoT security. IoT networks require advanced intrusion detection systems that can identify emerging threats because of their various and dynamic data sources. The complexity of IoT network data makes it difficult for traditional intrusion detection techniques to detect potential threats. Using the capabilities of RNNs, a model for creating and deploying an intrusion detection and prevention system (IDPS) is proposed in this paper. RNNs work particularly well for sequential data processing, which makes them an appropriate choice for IoT network traffic monitoring. NSL-KDD dataset is taken, pre-processed, features are extracted, and RNN-based model is built as a part of the proposed work. The experimental findings illustrate how effective the suggested approach is at identifying and blocking intrusions in Internet of Things networks. This paper not only demonstrates the effectiveness of RNNs in enhancing IoT network security but also opens avenues for further exploration in this burgeoning field. It presents a scalable, adaptive intrusion detection and prevention solution, responding to the evolving landscape of IoT security. As IoT networks continue to expand, the research enriches the discourse on developing resilient security strategies to combat emerging threats in scalable computing environments.

Key words: IoT, IDS, Machine Learning, Deep Learning, RNN

1. Introduction. Internet of Things is a network that allows everyday electronic devices to exchange data and coordinate their actions. The level of interconnection holds out the possibility of greater ease and efficiency in our day-to-day activities. Nevertheless, just as there are two sides to every coin, there are considerable worries associated with the Internet of Things (IoT), notably in regard to its security. The significance of IoT networks cannot be overstated; that has the potential to transform industries, improve the quality of life, and drive economic growth.

IoT networks are driving innovation in industrial automation, making manufacturing processes more efficient and reducing downtime [1]. Industries are using connected machines to streamline their operations and reduce downtime. In transportation, they are paving the way for autonomous vehicles, which have the potential to revolutionize mobility and reduce accidents. In the realm of energy, IoT enables the smart grid, optimizing energy distribution and promoting energy efficiency. In smart cities, IoT facilitates the creation of urban environments where infrastructure, transportation, and utilities are interconnected [2]. Cities are becoming smarter by embedding sensors that can help manage traffic in real-time, turn off streetlights when no one's around, or even alert about potential infrastructure issues. This promises sustainability, reduced traffic congestion, and an improved quality of life for urban residents. In agriculture, precision farming driven by IoT allows farmers to optimize crop yields, conserve resources, and promote sustainable practices, addressing the global challenge of food security. In the realm of healthcare, IoT devices enable remote patient monitoring, personalized treatment plans, and timely interventions. Patients can receive better care, and healthcare providers can operate more efficiently.

IoT devices often have limited computational resources and may need robust security mechanisms [3]. This makes them vulnerable to a wide range of cyber threats. Attackers can exploit vulnerabilities in IoT devices to gain unauthorized access, compromise data integrity, and disrupt critical services. Data privacy

*Computer Science and Engineering Department, National Institute of Technology Patna, India (himanshugbpuat@gmail.com, prabhat@nitp.ac.in).

[†]Computer Science and Engineering Department, Galgotias College of Engineering Technology, Greater Noida, India (kavitasharma06@yahoo.co.in).

is another critical concern. Many IoT devices collect sensitive information, including personal and location data. Unauthorized access to this data can lead to privacy breaches, identity theft, and legal consequences. Furthermore, the evolving cyber threat landscape poses a continuous challenge. Malicious actors are becoming increasingly sophisticated, using techniques like zero-day exploits and ransomware to target IoT vulnerabilities. To address these security challenges, effective solutions are essential and robust security measures need to be implemented.

Intrusion Detection Systems, also known as IDS, have traditionally been a primary line of defence against various types of cyberattacks [4]. The role of IDS in network security has been crystal clear: act as vigilant watchdogs, constantly monitoring traffic, detecting anomalies, and triggering alerts for potential threats. Traditional IDSs, built upon signature-based or rule-based mechanisms, have served well within the constraints of their design. However, the dynamism and complexity of IoT demand a more nuanced approach. Simple pattern matching or static rule sets are often ineffectual against sophisticated or zero-day attacks on IoT networks [6].

Over the past few years, machine learning and deep learning paradigms have emerged at the forefront of technological innovation and helped to cope up with such Security Concerns. Among the various architectures within deep learning, Recurrent Neural Networks (RNNs) hold particular promise for time-sequence data, which is intrinsic to network traffic in IoT. Unlike traditional feed-forward neural networks, RNNs possess the ability to 'remember' past inputs through their internal memory. This capability allows them to discern patterns in sequential data, making them particularly suited for IDS in IoT, where understanding temporal data sequences is crucial.

However, the mere existence of RNNs only sometimes translates to their effective implementation in IDS for IoT. Several challenges need to be addressed—the high dimensionality of network data, the real-time processing requirements of IoT, and the scalability concerns posed by billions of interconnected devices, to name a few. Moreover, while the application of RNNs in various domains like natural language processing or stock market prediction is well-documented, their tailored application for IoT intrusion detection is still nascent. This research seeks to bridge this knowledge gap, offering a comprehensive exploration of the design, implementation, and efficacy of an RNN-based IDS for IoT. As the narrative unfolds, the intricacies of the IoT landscape, highlighting its unique challenges, has been explained. Subsequently, an in-depth exploration of the RNN architecture will set the stage for understanding its applicability in the IDS domain. Through rigorous experimentation and evaluation, this research will not only propose but also validate the superiority of the RNN-based IDS for IoT, especially when compared against traditional models like J48, Random Forest (RF), Support Vector Machines (SVM), Multilayer Perceptron (MLP), and Naive Bayes(NB).

The core problem addressed in this research revolves around the inadequacy of existing intrusion detection and prevention systems to effectively safeguard IoT networks. Specifically, the research questions guiding this study include:

1. How can Recurrent Neural Networks (RNNs) be employed to detect and prevent intrusions in IoT networks?
2. What are the challenges and opportunities associated with implementing RNN-based techniques in the context of IoT network security?
3. How does the performance of RNN-based intrusion detection and prevention compare with traditional methods in terms of accuracy, adaptability, and real-time responsiveness?

The significance of this study lies in its potential to transform the landscape of IoT network security. By introducing a novel approach that leverages RNNs for intrusion detection and prevention, this research contributes to the development of adaptive and resilient security mechanisms for IoT networks. These mechanisms are vital to ensuring the continued growth and adoption of IoT technologies across various sectors, as security concerns have been a major impediment to realizing the full potential of IoT.

2. Literature Review. This section examines the existing research on security and intrusion detection approaches for the Internet of Things. It will provide a comprehensive overview of the current state of IoT security, highlighting the vulnerabilities specific to IoT networks. Additionally, it will explore the various intrusion detection and prevention methods employed in traditional networks and IoT environments. This review will serve as the foundation for identifying gaps in the literature and setting the stage for the proposed RNN-based approach.

IoT applications are growing to smart grids, retail, residences, cities, and healthcare despite forecasts. Security is needed to avoid service disruption, illegal access, and cyberattacks like tampering and others to assure data accuracy and process efficiency. ML/DL is common in IDS development. IDSs protect IoT devices and systems from security and operation threats. Intrusion detection systems (IDS) are essential in IoT networks, which increasingly encompass critical infrastructure including healthcare, transportation, and energy. With the help of intrusion detection systems, network managers may quickly identify, address, and collect vital information needed to stop and lessen security risks.

Traditional machine learning methods like SVM [7], [8], K-Nearest Neighbor (KNN) [9], ANN [10], Random Forest (RF) [11], [12], and others [13] have been successful for intrusion detection systems. On the other hand, the DL method has outperformed ML in terms of accuracy, particularly for large datasets. Because picking features takes time and they won't know which characteristics are valuable until the model is trained and evaluated, researchers creating machine learning algorithms must exercise caution and only extract features that can improve the model. Machine learning is challenged when dealing with datasets of different sizes since it is not always easy to extract the most predictive features [14]. Furthermore, because deep learning models can independently extract properties from massive data sets, they outperform traditional machine learning techniques and are more accurate [15].

Kumari et al. proposed a semi-supervised intrusion detection system [16] using a hybrid SVM-FCM clustering platform for classification. This was an extra semi-supervised intrusion detection system. Active SVM uses a modest amount of labeled input and a lot of unlabeled data. This was done to prove that active learning SVM can identify like a typical support vector machine after N iterations. For multi-class classification, the FCM classifier was used on data items around support vectors. This model used SVM and FCM classifier engines for intrusion detection. If both classifiers regarded an input instance normal, we may confidently call it normal. If the SVM engine classified the input instance as an outlier and the FCM engine identified its sub-category, the instance is considered abnormal and the sub-class is selected by selecting the circle with the highest fuzzy membership and geographical proximity to the support vectors.

In order to identify malicious attacks in IoT contexts, Otoum et al. [17] introduced a novel DL-based intrusion detection system to resolve the challenges associated with protecting IoT nodes. In their proposed model, the spider monkey optimization (SMO) algorithm and the stacked deep polynomial network (SDPN) are combined to achieve the highest detection and recognition rates. SMO selects the most relevant attributes from the datasets, while SDPN classifies the output as normal or aberrant. Using DL to identify intrusions with recurrent neural networks (RNN-IDS) was recommended by Yang et al. [18]. They show through their experimental results that RNN-IDS is ideally adapted for producing IDS with good accuracy and that it outperforms conventional ML both binary and multi-class techniques. Dawoud et al. [19] presented a deep learning-based intrusion detection system for SDN-based IoT architecture. SDN modeling was used for the IoT security, scalability, and resilience enhancing purposes, whereas Restricted Boltzman Machine (RBM) was used as the engine for intrusion detection. This serves as an example of the integration of SDN and IoT. The suggested model was tested, evaluated, and validated by utilizing the KDD Cup'99 dataset, on which it produced a competitive performance more than 94% in terms of precision and accuracy.

Khan et al. [20] employed an ensemble-based voting classifier, where the final prediction was derived by combining the conventional machine learning algorithm with voting on its predictions. Using a stacking-based ensemble model, IoT devices are better able to detect anomalies in IoT networks, according to Naz et al. [21]. To enhance the effectiveness and precision of ensemble-based IDS, Bhati et al. [22] implemented ensemble-based IDS with XGBoost, which improves the accuracy. In [23], Arko et al. presented an overview of several machine learning techniques that can be used to identify potentially harmful or out-of-the-ordinary data, as well as the most effective approach for two datasets: the first dataset was created from data exchanged between sensors, and the second dataset is UNSW-NB15.

The use of ensemble learning, in which many methods/models or experts are put to use in order to solve a specific artificial intelligence-based problem, was another approach that researchers took in order to ensure the strong security of the IoT. In the context of the problem of intrusion detection, ensemble learning fosters stronger generalization, and the voting amongst the various strategies of ensemble give higher detection accuracy than the individual models, according to the proposal made by Illy et al. [24].

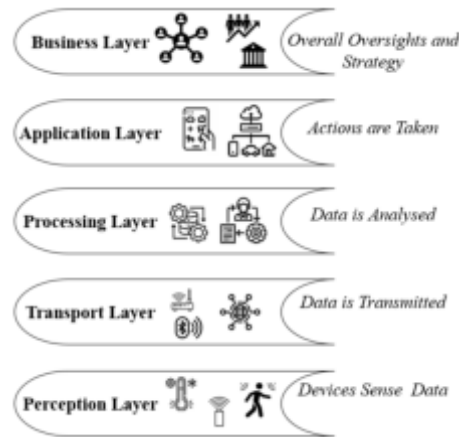

Fig. 3.1: IoT Architecture

In [25], Verma et al. investigated the viability of machine learning classification techniques for defending the IoT against DoS attacks. The Classifiers are evaluated using well-known datasets such as CIDD5-001, UNSWNB15, and NSL-KDD. Some cyber security experts have modified deep learning components to accomplish ML features for cyber-security, including IoT.

Yin et al. examined the structure of a deep learning-based intrusion detection system (IDS) and presents a novel RNN-IDS approach[26]. An comprehensive study examines the model's operationality in binary and multiclass classification scenarios and the effect of neuron count and learning rate changes on its efficacy. Using benchmark datasets, it is compared to J48, artificial neural network, random forest, and support vector machine. The authors suggest GPU acceleration to reduce training time, avoid exploding and vanishing gradients, and study the classification performance of LSTM, Bidirectional RNNs algorithms in intrusion detection.

Khan et al. proposed a deep learning-based intelligent IDS for IoT networks to address the security issues[27]. A Recurrent Neural Network with Gated Recurrent Units (RNN-GRU) can classify assaults across the physical, network, and application levels. This suggested model is trained and tested using the ToN-IoT dataset, which is unique for a three-layered IoT system and offers new attacks compared to other publicly available datasets. The proposed model's performance was analyzed using accuracy, precision, recall, and F1-measure, with Adam and Adamax optimization techniques. Adam was found to perform best.

3. IoT Architecture. The Internet of Things, or IoT for short, is a bit like a huge, worldwide web where computers and everyday objects are connected to each other. Think of it as a world where your fridge, watch, car, and even your shoes can 'talk' to each other through the internet. For all these things to work smoothly, we need a plan or structure, just like building a house. This plan is called the IoT architecture. At its core, the IoT architecture can be described as multi-layered, each serving a specific purpose, working together to deliver an interconnected, intelligent ecosystem. Let's break down this architectural framework in Figure 3.1.

3.1. Perception Layer (Device Layer). Imagine stepping into a dense forest, with every rustling leaf, chirping bird, or distant animal footstep communicating a piece of information. That's precisely the role of the Perception Layer. Often termed the physical or device layer, it's the frontline where real-world data is gathered. Comprising sensors, actuators, and other IoT devices, this layer perceives or senses the environment. Whether it's a smart thermostat sensing room temperature or an agricultural sensor gauging soil moisture, data collection begins here.

3.2. Transport Layer. Having collected the data, the next step is its relay to central hubs for further action. Enter the Transport Layer. Acting as the communication bridge, this layer ensures data moves from devices to data centers using a myriad of transmission mediums[30]. This could be via satellite, cellular networks, Wi-Fi, or even more niche protocols like Zigbee. The fundamental task here is secure, swift, and efficient data

transmission.

3.3. Processing Layer (Middleware Layer). All of the analysis that is done on data takes place at the Processing Layer. One could compare it to a location where information is stored, worked on, and interpreted. After being entered into databases, the raw data is subsequently transformed into information that can be utilized by specialized tools and computers. For example, by analyzing the data from a smart thermostat, it is possible to determine how to regulate the heating in order to save water and energy.

3.4. Application Layer. Application Layer is responsible to put the information received from Middle layer for practical use. Here, specific applications tailored for end-users interpret the processed data to offer tangible services. In a smart home setting, based on data from various sensors, the application layer might adjust lighting, heating, or even play your favourite song once you walk in. Essentially, this layer personalizes the IoT experience, translating processed data into relatable user actions[29].

3.5. Business Layer. Finally, at the top of all resides the Business Layer. Beyond the complexities of devices and data, this layer aligns the entire IoT architecture with overall business objectives. By analyzing data patterns, consumer behaviours, and device performance, strategic business decisions emerge. Whether it's launching a new product, optimizing an existing one, or even exploring uncharted market territories, this layer ensures the IoT system remains profitable, scalable, and aligned with overarching business objectives.

IoT architecture can be thought as a well-organized city where every part has a role. Every layer is crucial, from the devices that sense things to the pathways that transport data, the brains that process information, the hands that act on it, and the wise tree overseeing it all. This amazing plan lets our world of connected devices work together, making our lives easier and smarter. As more and more things around us start 'talking' to each other, knowing a bit about this architecture helps us appreciate the magic of the IoT world.

4. IDS for IoT. An Intrusion Detection System (IDS) for the Internet of Things (IoT) is paramount due to the inherent vulnerabilities associated with IoT devices and their increasing pervasiveness. Given the unique characteristics of IoT environments, traditional IDS might not be directly suitable, necessitating specialized approaches[7]. Here's a classification of Intrusion Detection Systems for IoT:

4.1. Based on Placement. Intrusion Detection Systems (IDS) can be fundamentally classified by their placement within the system they monitor. Host-based IDS (HIDS) operate on individual IoT devices. They focus on the internals of the device, such as system logs, processes, and system calls. Their primary advantage is their ability to effectively detect insider attacks and anomalies that manifest within a specific device. In contrast, Network-based IDS (NIDS) are centered on monitoring network traffic. By capturing and analyzing packets transmitted across the network, they are particularly apt at detecting unauthorized access or Distributed Denial of Service (DDoS) attacks that exploit network vulnerabilities[31].

4.2. Based on Detection Method. The detection methodology behind an IDS plays a critical role in its efficacy. Signature-based IDS operate using predefined patterns or signatures of known threats, making them adept at identifying recognized threats, but they are inherently limited when it comes to zero-day attacks. Anomaly-based IDS, on the other hand, rely on historical data to build a profile of what is considered "normal" behavior. When the current behavior deviates significantly from this profile, an alert is triggered. While this approach can detect previously unknown attacks, it might also lead to false positives. Specification-based IDS take a slightly different approach by using well-defined specifications that describe correct operation, and they raise alerts when there are deviations from these specifications. These are especially suitable for environments where correct behaviors can be meticulously defined. Lastly, Hybrid IDS merge the techniques of signature and anomaly-based detection to strike a balance between detection rates and false positives.

4.3. Based on the Type of IoT Environment. The type of IoT environment can dictate the design and priorities of an IDS. For instance, Home IoT IDS are designed specifically for smart home devices, such as thermostats, cameras, and smart appliances. They prioritize the privacy of users while ensuring usability. In industrial settings, the Industrial IoT (IIoT) IDS focus on ensuring system uptime, safety, and resilience in places like manufacturing plants and power grids. Healthcare IoT IDS, intended for medical devices and systems, place an unsurpassed emphasis on patient safety and data integrity. And in the realm of transportation,

Fig. 5.1: RNN model

Vehicle IoT IDS cater to connected cars and vehicular networks, where passenger safety and real-time response are paramount.

4.4. Based on Operational Capability. In terms of operational capability, IDS can be collaborative or standalone in nature. Collaborative IDS are designed with multiple IDS nodes that collaborate and share information, offering a holistic view of the network and the ability to correlate events across diverse devices. This collaborative approach often leads to more robust detection and mitigation strategies. In contrast, Standalone IDS operate independently without the need for collaborative data. While they might be simpler and easier to deploy, they may lack the comprehensive view that collaborative systems offer. In essence, given the multifaceted nature of IoT devices and networks, an optimal IDS often necessitates a blend of these categorizations, each tailored to the unique requirements and threat landscapes of the environment.

5. Proposed Method. Proposed RNN-based IDS framework leverages the sequential processing capabilities of RNNs to analyze patterns in network traffic and detect intrusions. By using the NSL-KDD dataset, which is a benchmark in the IDS domain, the model can be trained to recognize a wide variety of intrusion patterns relevant to IoT environments. The combination of real-time processing, alert systems, and feedback loops ensures the IDS remains dynamic, effective, and up-to-date in the ever-evolving landscape of IoT security threats. Given the sequential nature of network traffic data, RNNs can potentially excel in identifying patterns and anomalies.

RNN has a looped or recurrent hidden layer, which allows it to maintain a 'memory' of previous inputs in its internal structure. This is what enables it to process sequences of data rather than single data points. As shown in FIG. 5.1, Inside Input layer, at each time step t , the RNN receives an input vector x_t . This vector will usually be an encoded form of the data for that time step, such as a word in a sentence or a feature in a time series. In Hidden Layer, The recurrent layers computes the hidden state h_t at time step t . This hidden state is a function of the input x_t at the current time step and the hidden state h_{t-1} from the previous time step. In output layer, at each time step t , the RNN produces an output vector y_t . This output can be computed based on the hidden state h_t and, if necessary, the input x_t .

Training an RNN involves adjusting its weights based on the difference between its predicted outputs and the actual outputs for a sequence. This is done using a variant of the backpropagation algorithm called Backpropagation Through Time (BPTT). BPTT works by unrolling the entire network for a sequence and applying the standard backpropagation algorithm, considering the temporal depth introduced by the recurrent layer.

As shown in FIG. 5.2 the process of an RNN-based Intrusion Detection System begins with the preprocessing of the Dataset. This includes label encoding, feature scaling, and feature selection to make sure the data is compatible. After the data has been pre processed, it is split into two sets: training (80%) and testing (20%).

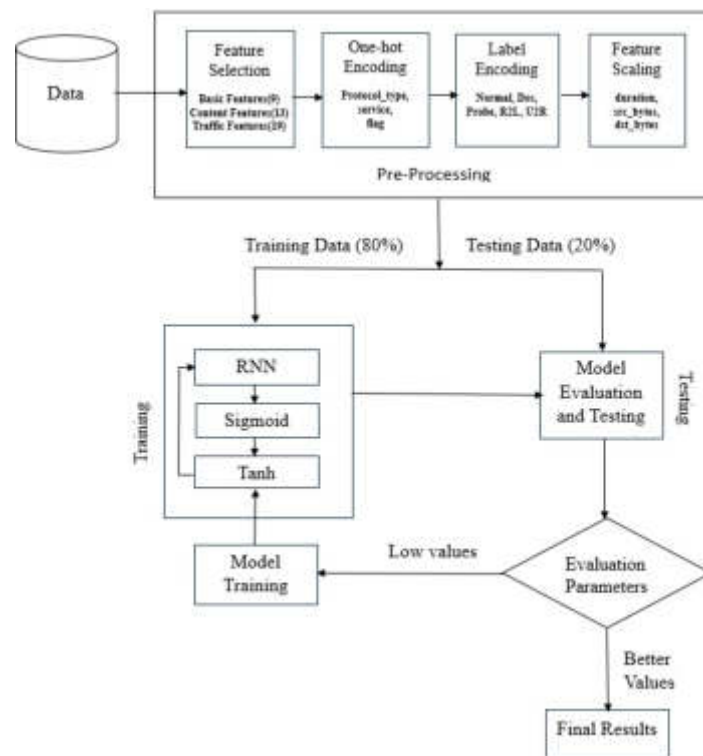

Fig. 5.2: Proposed RNN IDS

The training sample is used to build and train the RNN model. During training the model fits the data for 100 epochs with a batch size of 32. This is how it learns to spot patterns that are linked to intrusions. After that, the model is put to the test using the testing dataset to see how well it works using accuracy, precision, recall, and F1-score as measures. If the model's original evaluation metrics show that it isn't working as well as it could, it goes through incremental training, which involves fine-tuning its parameters even more until it gets good results. This iterative review process makes sure that the model's ability to find and stop cyber threats is always getting better. Once the model works well as it should, it can be used for real-time attack detection in live systems, which is a strong way to protect them.

5.1. Preprocessing of Dataset. Intrusion Detection Systems (IDS) often deal with large and complex datasets that require preprocessing to be effectively used for detecting malicious activities. Proper preprocessing is crucial as the quality and relevance of the data directly impact the model's performance. In this section various steps involved in Data Preprocessing are discussed followed by dataset description.

5.1.1. Dataset Description. NSL-KDD[28] is an improved version of the famous KDD Cup '99 dataset. The NSL-KDD dataset has made a name for itself in cybersecurity study, especially in the area of Intrusion Detection Systems (IDS). In this digital age, where network breaches and cyberattacks are getting smarter and happening more often, it is very important to have effective and accurate IDS. As a result, the NSL-KDD dataset has become an important tool for study into creating, testing, and improving different IDS models by providing a standard against which to measure and contrast their effectiveness. To fully understand what the NSL-KDD dataset is and how it can be used, it is important to go back to where it came from: the KDD Cup '99 dataset, which was created in 1999 as part of the Third International Knowledge Discovery and Data Mining Tools Competition. Even though it has problems like a huge number of duplicate records and built-in biases, the KDD'99 dataset quickly became the standard for IDS study. To address such limitations, the NSL-KDD was created to eliminate redundancies and give a more balanced dataset for constructing and assessing IDS

models. NSL-KDD is notable for its comprehensive and diverse composition, encapsulating various aspects of network interactions and potential intrusions, this includes:

A. Variety of Features. It includes a large group of 41 features that cover a wide range of topics, such as basic features of each TCP connection, content features that show what's inside the packets, and traffic features that are estimated using a two-second time window. The features can be broadly divided into three groups namely Basic features, Content features and Traffic features. Basic Features encompass attributes derived directly from the connection. Examples include the duration of the connection, the type of protocol used (e.g., TCP, UDP, ICMP), and other foundational data attributes. Content Features are derived from the content of the connections, such as the number of failed login attempts. These attributes provide insights into the suspicious behavior exhibited within the connection. Traffic Features are Computed with respect to a temporal window, these features capture network traffic statistics, analyzing patterns over a specified interval. These are further split into "time-based" and "connection-based" traffic features.

B. Multi-class Labels. Instances are divided into "normal" and several "attack" kinds. These are further broken down into four main types of attacks: DoS (Denial of Service), R2L (Remote to Local), U2R (User to Root), and Probing. Binary and Multi-class Classification: The attack types allow for both binary classification (normal vs. attack) and multi-class classification, which opens up a lot of theoretical and practical options.

C. Training and Test Sets. The dataset is split into "KDDTrain+" and "KDDTest+" sections, which make it easier to train, test, and validate models while keeping the lines between them clear to stop data leaks.

5.1.2. Feature Selection. In the realm of IDS for IoT, the relevance of features might differ from traditional network environments. For example, IoT devices often have resource constraints and unique patterns of network traffic. Therefore, selecting features that best characterize the IoT device behaviour is crucial. By focusing on the most relevant features, models can be more interpretable, faster, and potentially yield better performance The KDD'99 dataset initially has 41 features, categorized into basic features, content features, and traffic features.

Basic Features (9). These are derived from the packet headers without inspecting the payload, e.g., duration, protocol type, and service.

Content Features (13). These include features extracted from the payload like the number of failed login attempts.

Traffic Features (19). These are computed with respect to a window interval and are either time-based or connection-based. Using methods like Pearson's correlation coefficient can help determine if some features are highly correlated. If two features have high correlation, it might be beneficial to keep only one of them to avoid redundancy.

5.1.3. One-Hot-encoding:. One-Hot-Encoding is used to convert all categorical properties to binary properties. One-Hot-Endcoding requirement, the input to this transformer must be an integer matrix expressing values taken with categorical (discrete) properties. The output will be a sparse matrix in which each column corresponds to a possible value. It is assumed that the input properties have values in the range $[0, n_values]$. Therefore, to convert each category to a number, properties must first be converted with LabelEncoder.

There are 3 categorical attributes in this dataset are "Protocol_type", "service", and "flag" excluding "label" attribute. These features, although packed with essential information, are represented as text or categorical values, which are not inherently quantifiable and thus not directly compatible with RNN algorithms.

One-hot encoding is a favored technique for converting categorical data into a format that can be provided to RNN model. The process essentially creates a binary column for each category and indicates the presence of the category with a "1" or "0". Let's break down the one-hot encoding process for each of these features.

Protocol type. This feature indicates the type of protocol used for the connection, such as "tcp", "udp", or "icmp". Instead of these textual values, one-hot encoding would result in three new binary columns named "protocol_tcp", "protocol_udp", and "protocol_icmp". For a specific record in the dataset, if the protocol type is "tcp", the "protocol_tcp" column would have a value of "1" while the other two columns would be "0".

Service. The "service" attribute is a bit more complex as it delineates the network service on the destination, e.g., "http", "ftp", "telnet", and so on. Given the diverse range of services in the NSL-KDD dataset, one-hot encoding would result in multiple new binary columns, one for each service type. For instance, if a specific

record has the service type "http", then the "service_http" column would be "1", while all other 'service_*' columns would be "0".

Flag. Representing the status of the connection, typical values might include "SF", "S0", "REJ", etc. Just like the earlier attributes, each unique flag value would get its binary column. So, if a specific connection record had its flag set as "REJ", the corresponding "flag_REJ" column would hold a "1", with all other 'flag_*' columns set to "0".

Post one-hot encoding, the NSL-KDD dataset will have an expanded feature set with new binary columns replacing the original categorical ones. This transformation ensures that the data is in a numerical format, making it suitable for RNN without losing the categorical information's granularity. It's crucial, however, to note that this process can increase the dimensionality of the dataset significantly, especially if categorical features have numerous unique values. As such, after one-hot encoding, dimensionality reduction techniques might be considered to optimize the dataset's size without compromising the integrity of the information.

5.1.4. Label Encoding. The NSL-KDD dataset, a cornerstone in network intrusion detection research, underwent a transformation to simplify the representation of its diverse range of attacks. A large number of attacks were categorized into five broad categories, and to make these categories machine-friendly and facilitate easier computation, label encoding was applied. Initially, the dataset had various textual tags indicative of different kinds of attacks. To standardize and streamline this, the tags were remapped as follows:

Normal Activities: Previously labeled with various tags indicating normal behavior, these were consolidated and encoded with the value 0.

DoS (Denial of Service) Attacks: All tags specific to different types of DoS attacks(neptune, back, land, pod, smurf, teardrop, mailbomb, apache2, processtable, udpstorm, worm) were unified under the umbrella term "DoS" and were encoded with the value 1.

Probe Attacks: These are attacks where the malicious actor scans the network to gather information or find known vulnerabilities. All such attacks(ipsweep, nmap, portsweep, satan, mscan, saint) were labeled as "Probe" and assigned the encoded value 2.

R2L (Remote to Local) Attacks: In these attacks(ftp_write, guess_passwd, imap, multihop, phf, spy, warez-client, warezmaster, sendmail, named, snmpgetattack, snmpguess, xlock, xsnoop, httptunnel), an attacker who does not have an account on the target machine tries to gain access. Such attempts, previously labelled with various specific tags, were brought together under "R2L" and encoded with the value 3.

U2R (User to Root) Attacks: In U2R attacks, the attacker starts with access to a normal user account on the system and tries to exploit some vulnerability to gain root privileges. All such tags(buffer_overflow, loadmodule, perl, rootkit, ps, sqlattack, xterm) were encoded with the value 4.

The transformation process ensured the dataset became more streamlined. Instead of dealing with a multitude of tags that can make data processing and analysis cumbersome, especially for Deep learning models, we now have a standard set of five encoded labels. This not only helps in reducing the complexity but also in improving the efficiency of subsequent computations. To achieve this encoding, a straightforward mapping mechanism was used. A typical process would involve iterating over the dataset, examining the existing attack tag, and then replacing it with the new encoded value. This encoding, though seemingly simple, is a crucial step in data preprocessing, especially when the data is meant to be fed into machine learning or deep learning models. Properly encoded labels ensure models train effectively and provide meaningful results. Given the critical importance of network intrusion detection in today's hyper-connected world, such streamlined data representations play a pivotal role in advancing cybersecurity research and solutions.

5.1.5. Feature Scaling. In the domain of data preprocessing for deep learning models, feature scaling stands as a pivotal step to standardize the range of independent variables or features of the data. This process is paramount, especially in datasets with features that have different scales, as it can drastically impact the performance of certain algorithms. The KDD dataset, renowned in the realm of network intrusion detection, is no exception to this rule. For the NSL-KDD dataset, taking into account the varying magnitudes, units, and range of the features, the decision was made to apply logarithmic scaling, a specialized scaling method. This method is particularly useful when dealing with data that spans several orders of magnitude. By applying logarithmic transformations, we can diminish the effects of outlier values and compress the scale on which the

data lies, rendering it more manageable and interpretable. The features duration, src_bytes, and dst_bytes are taken into account. Their original ranges were considerably broad and spanned multiple magnitudes. However, by applying the logarithmic scaling method, these features were transformed to more condensed ranges. Specifically:

For the duration feature, post-logarithmic scaling, the range was condensed to [0, 4.77].

The src_bytes feature, after the application of logarithmic scaling, had its values fall within the range [0, 9.11].

Similarly, the dst_bytes feature was scaled such that its values now lie in the [0, 9.11] range.

It's noteworthy to mention that before applying the logarithmic scaling, a small constant might be added to the feature values to handle instances of values being zero, since the logarithm of zero is undefined. In essence, the logarithmic scaling of the NSL-KDD dataset's features ensures that the variances in the data's magnitude do not negatively influence the performance of machine learning algorithms. This transformation not only promotes better convergence during model training but also contributes to a more accurate and insightful representation of the underlying patterns and structures within the dataset.

5.2. Methodology. The purpose of this study was to use the NSL-KDD dataset to construct and assess an intrusion detection system (IDS) based on RNNs. Two different forms of configuration were used for proposed RNN-IDS: multiclass classification and binary classification. The goal of using both classification techniques was to evaluate proposed RNN model's adaptability and effectiveness in differentiating between different types of attacks and normal traffic.

An RNN-based intrusion detection system (IDS) is built and evaluated using the NSL-KDD dataset. The proposed RNN-IDS made use of two distinct configuration types: multiclass and binary classification. The purpose of combining the two classification methods was to test how well the suggested RNN model could distinguish between malicious and normal traffic.

Given an IoT network traffic dataset(NSL-KDD dataset), the task is to classify sequences of network data into one of N categories, such that "normal" and "Attack" in case of Binary Classification & "normal", "Dos", "Probe", "R2L", and "U2R" in case of Multiclass Classification

Let:

$X = \{x_1, x_2, \dots, x_T\}$: A sequence of feature vectors, where T is the length of the sequence.

$Y = \{y_1, y_2, \dots, y_T\}$: The corresponding labels or categories.

The objective is to Model a Function f using RNN such that $f(X) \approx Y$

RNNs are designed to recognize patterns in sequences of data by utilizing memory elements. The primary component of the RNN is its hidden state, which gets updated at each time step of the sequence as depicted by Equation 5.1.

$$h_t = \sigma(Wx_t + Uh_{t-1} + b) \tag{5.1}$$

$$E = mc^2 \tag{5.2}$$

$$\int_a^b f(t) \left(\sum_i E_i B_{i,k,x}(t) \right) dt \tag{5.3}$$

where:

h_t is the hidden state at time t .

W and U are weight matrices

b is the bias vector.

σ is a non-linear activation function, often the hyperbolic tangent (tanh).

Output would be as follows:

$$y_t = \phi(Vh_t + c) \tag{5.4}$$

where:

V is the weight matrix for the output.

c is the output bias.

ϕ is a softmax function when the task is multi-class classification, providing a probability distribution over the N .

For training the IDS, a suitable loss function, L as depicted by equation 5.5, is categorical cross-entropy for classification tasks:

$$L(Y, \hat{Y}) = - \sum_{t=1}^T \sum_{n=1}^N y_{t,n} \log(\hat{y}_{t,n}) \quad (5.5)$$

where $\hat{y}_{t,n}$ is the predicted probability of the n^{th} class at time t , and $y_{t,n}$ is a binary indicator (0 or 1) if label n is the correct classification for observation t .

For binary classification using RNN-IDS, the hidden layer uses 80 neurons and the activation function is hard sigmoid, while the output layer uses tanh. For instance, sensor updates are common examples of how IoT devices commonly broadcast data in a specified pattern. Anomaly detection may rely heavily on the temporal dependencies present in this data. On the other hand, a model based on RNNs could do better. A comparison is conducted to ascertain the RNN-IDS's effectiveness in relation to more conventional machine learning models. 'J48', 'RF', 'SVM', 'MLP', and 'NB' were used to assess RNN-IDS's performance by way of the evaluation metrics. In order to determine the F1 score, Precision, Accuracy, and Recall, these contrasting Machine Learning Models are constructed and implemented on the NSL-KDD dataset.

5.3. Evaluation. Using the NSL-KDD dataset, Proposed work used an RNN model to identify and classify four attack types: Dos, Probe, R2L, and U2R, along with normal traffic labels. The model's performance was carefully compared against five popular Machine Learning (ML) methods: J48, Random Forest (RF), Support Vector Machines (SVM), Multilayer Perceptron (MLP), and Naive Bayes(NB).

To allow for thorough comparisons, the model was trained on a stratified dataset split and evaluated using the following metrics.

Accuracy: The percentage of true predictions in our model compared to total predictions.

Precision: It measures positive prediction accuracy, calculated as the ratio of true positive outcomes to the sum of true positives and false positives.

Recall (Sensitivity): Rate of true positive predictions compared to true positives and false negatives.

F1 Score: It is a balanced measure of precision and recall, particularly in skewed datasets. Can be calculated as the harmonic mean of Precision and Recall.

The performance of the RNN-IDS model for binary classification (Normal, anomaly) and multi class classification (such as Normal, DoS, R2L, U2R, and Probe) has been the subject of investigation in two separate studies that have been created specifically for this purpose. These experiments are designed at the same time as standard experiments and results are compared other machine learning strategies J48, NB, RF, MLP, SVM.

A variety of errors occurred during the development of the RNN-based model for the binary and multiclass categorization of different attacks, each providing information about a different set of difficulties. Overly sensitive models or data noise can cause False Positives (FP), in which the model incorrectly predicts an attack. This is avoided by modifying the threshold of the model and using post-processing. Conversely, attacks that the model was unable to identify as False Negatives (FN) were caused by over-regularization and inadequate modeling of specific attack patterns. Reducing FN errors required improving feature representation, taking into account more intricate models, or modifying regularization. Accurate forecasts of attacks are indicated by True Positives (TP) and True Negatives (TN), respectively. Constant fine-tuning, feature engineering, and striking a balance between sensitivity and specificity is used to improve model accuracy. Errors resulted from missing and irrelevant features, hence feature representation is regularly assessed and improved.

5.3.1. Binary Classification. In the binary classification scenario, the NSL-KDD dataset was framed to classify network activities into two broad categories: 'Normal' and 'Attack'. The 'Attack' category encompassed all four varieties of attack labels (Dos, Probe, R2L, and U2R), consolidating them into a single overarching class and making a binary classification setup possible. LSTM input layer must be 3D the meaning of the 3 input dimensions are: samples, time steps, and features. The number of samples is assumed to be 1 or more.

Fig. 5.3: Comparison of Accuracy between Proposed(RNN-IDS) and other(j48,RF,SVM,MLP,NB) methods applied on NSL-KDD dataset.

reshape() function takes a tuple as an argument that defines the new shape. To obtain strong comparative analysis with other models, the model was trained on a NSL-KDD dataset and evaluated using the following metrics.

Accuracy. Accuracy is calculated as the proportion of correctly predicted instances to the total number of instances in the dataset. It is a metric used to evaluate the IDS model's ability to correctly classify network traffic as either normal or malicious. Mathematically, accuracy can be expressed as follows:

$$Accuracy = \frac{\text{True Positives (TP)} + \text{True Negatives (TN)}}{\text{Total Instances (P + N)}} \quad (5.6)$$

True Positives (TP) is the count of attack instances correctly identified as attacks.

True Negatives (TN) True Negatives (TN) is the count of normal instances correctly identified as normal.

P is the total actual positive instances (actual attacks).

N is the total actual negative instances (actual normal activities).

The performance of RNN-IDS model in terms of Accuracy is superior to other classification algorithms in binary classification as shown in FIG. 5.3.

For Binary classification Accuracy of RNN-IDS came out to be 97% which is 6% more as compared to the accuracy of best model among as compared with other.

Precision. Precision, also known as the positive predictive value, is an essential evaluation metric, where the cost of false positives (incorrectly identified as an attack) may be significant. Precision attempts to assess the accuracy of the IDS, i.e., how many instances classified as positive (attack) are in fact positive.

Mathematically, precision is calculated using the following formula:

$$Precision = \frac{\text{TruePositives(TP)}}{\text{TruePositives (TP) +FalsePositives(FP)}} \quad (5.7)$$

where:

True Positives (TP) is the number of attack instances that were correctly identified as attacks.

False Positives (FP) is the number of normal instances that were incorrectly identified as attacks.

From FIG. 5.4 it can be observed that the Proposed RNN-IDS achieved a precision score of 0.95 which is a way better than other compared models during Binary Classification. This highlights the system's capacity to reduce false positives and provides the percentage of true positive predictions among all positive predictions.

Recall. Recall, also known as Sensitivity or True Positive Rate, is a crucial evaluation metric, revealing the model's ability to correctly identify and classify positive (attack) instances. It resolves the question: "How many true positive instances did the model successfully identify as being positive?".

Fig. 5.4: Comparison of Precision between Proposed(RNN-IDS) and other(j48,RF,SVM,MLP,NB) methods applied on NSL-KDD dataset.

Fig. 5.5: Comparison of Recall between Proposed(RNN-IDS) and other(j48,RF,SVM,MLP,NB) methods applied on NSL-KDD dataset.

Mathematically, recall is computed as follows:

$$Recall = \frac{\text{True Positives(TP)}}{\text{True Positives (TP) + False Negatives(FN)}} \quad (5.8)$$

where:

- True Positives (TP): Represent the instances which were attacks and were correctly identified as attacks by the IDS.
- False Negatives (FN): Represent the instances which were attacks but were incorrectly identified as normal by the IDS.

Proposed RNN-IDS exhibited a recall score of 0.95, which represents the ratio of true positive predictions to all actual positive instances, underlining the system's capacity to identify actual intrusions effectively. It can be clearly depicted from the FIG. 5.5 that Proposed RNN-IDS surpassed all the other compared models in terms of Recall.

Score. The F1 Score is the harmonic mean of precision and recall, and it offers a balance between the two factors whenever there is an imbalance in the class distribution. It takes into consideration both false positives and false negatives, and it is especially useful in circumstances in which one form of error is more substantial than the other.

Fig. 5.6: Comparison of F1 Score between Proposed(RNN-IDS) and other(j48,RF,SVM,MLP,NB) methods applied on NSL-KDD dataset.

Mathematically, the F1 Score is defined as:

$$F1 - Score = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (5.9)$$

where:

Precision (Positive Predictive Value) is defined as:

$$\text{Precision} = \frac{\text{True Positives(TP)}}{\text{True Positives(TP)} + \text{False Positives(FP)}}$$

Recall (Sensitivity or True Positive Rate) is defined as:

$$\text{Recall} = \frac{\text{True Positives(TP)}}{\text{True Positives(TP)} + \text{False Negatives(FN)}}$$

The F1 score, harmonizing precision and recall, for proposed RNN-IDS was 0.97. FIG. 5.6 reflects the model's performance in binary classification in terms of F1-score as compared to other models.

5.3.2. Multi Class Classification. The dataset was organized using the multiclass classification paradigm to categorize network activity into five different labels: "Normal" and four classes of attacks (Dos, Probe, R2L, and U2R). The RNN model was put through a rigorous training program before being put to the test to see how well it could classify data across these many classifications.

Accuracy. In a multi-class classification problem with more than two classes, like four types of attacks and one normal label, the formulation might get a little more complicated because we have to figure out the True Positives and True Negatives for each class separately and then add them all up. If this is the case and C is the number of classes, the accuracy may be represented as:

$$\text{Accuracy} = \frac{\sum_{i=1}^C \text{TP}_i + \text{TN}_i}{\text{Total Instances}} \quad (5.10)$$

TP_i and TN_i refer to the True Positives and True Negatives for the i th class respectively.

Proposed RNN-IDS recorded an accuracy of 95%. It can be observed in FIG. 5.7, when compared to the machine learning models, the RNN's performance was superior, indicating its adeptness in correctly classifying instances.

Precision. When dealing with multiple attack types (classes) in an IDS for IoT multi-class classification scenario, the precision for each class is calculated separately and then the macro-average precision is derived across all classes. This gives a general idea of the IDS model's precision across various attack types.

In a multi-class context, the following formula can be modified to compute class-wise precision as:

$$\text{Precision}_i = \frac{\text{TP}_i}{\text{TP}_i + \text{FP}_i} \quad (5.11)$$

Fig. 5.7: Comparison of Accuracy between Proposed(RNN-IDS) and other(j48,RF,SVM,MLP,NB) methods applied on NSL-KDD dataset for Multiclass Classification.

Fig. 5.8: Comparison of Precision between Proposed(RNN-IDS) and other(j48,RF,SVM,MLP,NB) methods applied on NSL-KDD dataset for Multiclass Classification.

where:

- Precision_i is the precision for the ith class (type of attack).
- TP_i and FP_i represent the True Positives and False Positives for the ith class respectively.

After calculating the precision for each class, the macro-average precision across all classes is computed as follows:

$$Macro - AveragePrecision = \frac{\sum_{i=1}^C Precision_i}{C} \quad (5.12)$$

Here C is the total number of classes.

Precision indicates the system's capacity to reduce false alarms, which is essential for IoT IDS usability and reliability. This metric is examined alongside recall and F1 score to evaluate the proposed model.

Precision is vital as it tells us about the model's capability to correctly identify positive instances. With a precision score of 0.96, the RNN-IDS model edged out most ML-based models, showcasing its reliability in positive identifications in FIG. 5.8.

Recall. In multi-class classification for IDS in IoT, there are several sorts of attacks (classes), recall has been computed for each class and then the macro-average recall is calculated over all classes to provide a generalized model recall measure. Class-wise recall for multi-class classification can be computed as:

Fig. 5.9: Comparison of Recall between Proposed(RNN-IDS) and other(j48,RF,SVM,MLP,NB) methods applied on NSL-KDD dataset for Multiclass Classification.

$$Recall_i = \frac{TP_i}{TP_i + FN_i} \tag{5.13}$$

where:

- Recall_i is the recall for the ith class (type of attack).
- TP_i and FN_i are the True Positives and False Negatives for the ith class, respectively. Macro-average recall across all classes in a multi-class classification scenario can be derived as follows:

$$Macro - Average Recall = \frac{\sum_{i=1}^C Recall_i}{C} \tag{5.14}$$

where C is the total number of classes.

IDS for IoT relies on recall because missing an attack can be disastrous. This comprehensive evaluation helps fine-tune the model for reliable IoT IDS.

Recall focuses on the model’s ability to identify all potential positive instances. The RNN-IDS model achieved a commendable recall score of 0.95, which was notably higher than some ML models as can be seen in Fig. 5.9, emphasizing its proficiency in identifying actual attack instances.

F1 Score. In a multiclass classification scenario, such as categorizing various types of network intrusions in IDS for IoT, the F1 Score can be calculated for each class separately, and then an average can be calculated to evaluate the classifier’s overall performance. Micro and macro F1 Scores are two ways to calculate the average F1 Score for multiclass classification problems.

Micro F1 Score: Calculated by aggregating the contributions of all classes to find the average.

$$F_{1micro} = 2x \frac{\sum_{i=1}^C TP_i}{\sum_{i=1}^C TP_i + \sum_{i=1}^C FP_i + \sum_{i=1}^C FN_i} \tag{5.15}$$

where C represents the number of classes, and TP_i,FP_i, and FN_i denote the true positives, false positives, and false negatives for the i-th class, respectively.

Macro F1 Score: The arithmetic mean of the per-class F1 Scores.

$$F_{1macro} = \frac{1}{C} \sum_{i=1}^C F1_i \tag{5.16}$$

where F1_i represents the F1 Score for the i-th class.

The F1-Score serves as a balanced measure, taking into account both precision and recall. Proposed RNN-IDS model’s score of 0.94 was demonstrably superior, revealing its balanced performance in precision and sensitivity,as can be depicted in FIG. 5.10.

Fig. 5.10: Comparison of F1 Score between Proposed(RNN-IDS) and other(j48,RF,SVM,MLP,NB) methods applied on NSL-KDD dataset for Multiclass Classification.

6. Conclusion. The results of experiment demonstrate the effectiveness of proposed RNN-IDS for intrusion detection in both binary and multiclass classification scenarios. In binary classification, proposed RNN-IDS system excelled with high accuracy, precision, recall, and F1 score, indicating its ability to accurately identify both normal and intrusive network activities while minimizing false alarms. Furthermore, in the multiclass classification setting, proposed RNN-IDS showcased its adaptability by accurately classifying various intrusion types. This capability is crucial for network administrators and security professionals, as it enables them to pinpoint specific attack categories for prompt mitigation.

Comparing proposed RNN-IDS with renowned machine learning models: J48, RF (Random Forest), SVM (Support Vector Machine), MLP (Multi-Layer Perceptron), and NB (Naive Bayes), deduced that it consistently outperformed them in terms of accuracy, precision, recall, and F1 score. This suggests that the use of recurrent neural networks offers substantial advantages over conventional techniques when it comes to intrusion detection on the NSL-KDD dataset.

Proposed research proves the potential of RNN-based IDS systems in enhancing network security. The results indicate that proposed RNN-IDS is a promising approach for accurately detecting network intrusions, and its superior performance over traditional models makes it a valuable asset for real-world cyber security applications. While the current research demonstrates the effectiveness of RNN based intrusion detection systems, certain limitations highlight avenues for future exploration. Expanding the research to include larger and more diverse datasets may improve the model's resilience and generalization. In addition, the current work focuses on simulated environments, therefore deploying the model in real-world IoT settings would provide useful insights into its practical efficacy.

DIFFCRNN: A NOVEL APPROACH FOR DETECTING SOUND EVENTS IN SMART HOME SYSTEMS USING DIFFUSION-BASED CONVOLUTIONAL RECURRENT NEURAL NETWORK

MARYAM M. AL DABEL *

Abstract. This paper presents a latent diffusion model and convolutional recurrent neural network for detecting sound event, fusing advantages of different networks together to advance security applications and smart home systems. The proposed approach underwent initial training using extensive datasets and subsequently applied transfer learning to adapt to the desired task to effectively mitigate the challenge of limited data availability. It employs the latent diffusion model to get a discrete representation that is compressed from the mel-spectrogram of audio. Subsequently a convolutional neural network (CNN) is linked as the front-end of recurrent neural network (RNN) which produces a feature map. After that, an attention module predicts attention maps in temporal-spectral dimensions level, from the feature map. The input spectrogram is subsequently multiplied with the generated attention maps for adaptive feature refinement. Finally, trainable scalar weights aggregate the fine-tuned features from the back-end RNN. The experimental findings show that the proposed method performs better compared to the state-of-art using three datasets: the DCASE2016-SED, DCASE2017-SED and URBAN-SED. In experiments on the first dataset, DCASE2016-SED, the performance of the approach reached a peak in $F1$ of 66.2% and ER of 0.42. Using the second dataset, DCASE2017-SED, the results indicate that the $F1$ and ER achieved 68.1% and 0.40, respectively. Further investigation with the third dataset, URBAN-SED, demonstrates that our proposed approach significantly outperforms existing alternatives as 74.3% and 0.44 for the $F1$ and ER .

Key words: Sound event detection, latent diffusion model, spectrogram, deep neural network.

1. Introduction. The objective of sound event (SE) detection is to provide devices with the capability to identify and classify acoustic environments. It can be characterized as the process of discerning the presence of both overlapping and non-overlapping sound events, as well as determining their respective initiation and duration intervals [44]. A distinct auditory occurrence that may be recognized as a distinct notion is referred to as a sound event [18]. In our everyday lives, we often encounter many forms of sound events as an example bird cries, dog barking, and human speech. In a real-world acoustic environment, the occurrence of these sound events may not be sequential but rather exhibit a tendency to regularly overlap. The SE detection systems may enhance the capabilities of current security applications, smart home systems and surveillance systems when applied jointly. In addition, they can be used in industrial environments to detect deficiencies in equipment and machinery.

Different approaches have been used to perform the SE detection task. There are two fundamentals to boost the overall classification performance of SE models: i) the extraction of acoustic features with robust characterization abilities, and ii) efficient classification techniques. The widely used features are linear predictive coding [32], linear predictive cepstral coefficients, discrete wavelet transform, mel frequency cepstral coefficients [32] and log-mel spectrograms. Turning to conventional classifiers, examples include support vector machines [13], Gaussian mixture models [15], hidden Markov models [11], multi-layer perceptron [42]. Such conventional models, however, are only useful to single acoustic events and small datasets [31]. These conventional classification models are less likely to satisfy the classification needs due to the large dataset size and audio complexity. The advances of machine learning has made it possible for neural network classification models to outperform more conventional classifiers, such as feedforward neural networks, recurrent neural networks [36], convolutional neural networks [22] and convolutional recurrent neural networks [2, 12, 21, 29]. Most SE research in recent years has employed deep learning-based classification models [4, 1]. While neural network-

*Department of Computer Science and Engineering, College of Computer Science and Engineering, University of Hafr Al Batin, Saudi Arabia (maldabel@uhb.edu.sa).

based classification models have been widely used in the field of acoustics, difficulties with sound detection still exist include the following: i) the SE model has more parameters, more feature space dimensions, and larger datasets; ii) the temporal-frequency structure of sounds is very complex and may be continuous, abrupt, or periodic; and iii) inconsistency and ambiguous duration of sounds impact model classification performance. The main contributions of this paper are summarized as follows.

- Instead of choosing a random combination, as in earlier efforts, we take into account the pressure levels of the audio pairings when mixing them for data augmentation by applying the Latent Diffusion Model. This makes sure that the combined audio accurately represents both of the source audio.
- Combining the convolutional recurrent neural networks and an attention module in a unified framework that connect both the convolutional neural network layer and recurrent neural network layer.
- Conducting a series of comparative experiments to evaluate the performance of the proposed models.

The rest of this paper is set up as follows. Section 2 discusses and reviews previous related work. Section 3 introduces the proposed framework. Sections 4, 5 and 6 report and analyze the experimental results. Section 8 summarizes the work.

2. Related Work. Early work in SE detection typically aims at identifying only the dominating sound event among the overlapping sound events and their associated onset-offset periods. However, this strategy is less appropriate for applications that need the simultaneous detection of several sound events.

Widely known classifiers were used for such task including the combined Gaussian mixture model-hidden Markov model [16], non-negative matrix factorization [17], convolutional neural networks [48, 38], and recurrent neural networks [37, 47] networks. In [16], for instance, the combined Gaussian mixture model-hidden Markov model was employed to detect the overlapping sound events based on multiple restricted Viterbi passes. Whereas in [17], the combined Gaussian mixture model-hidden Markov model was designed to better identified the overlapping sound events by a preprocessing stage, in which a non-negative matrix factorization method was implemented as a stage to get multiple streams of source separated audio.

As deep learning methods advanced, many deep neural network-based solutions for the SE challenges were proposed. A multi-class multi-label feed-forward deep neural networks was applied in [6] such that each input frame was produced by concatenating multiple temporal-frames of the feature. This technique outperformed the best SE technique previously reported in [17]. Individual Gaussian mixture models are trained for each sound class when using generative classifiers like Gaussian mixture model. The sound class is determined during inference based on the greatest probable outcomes of the Gaussian mixture model. In [5], for each sound class in the dataset, several feed-forward deep neural networks classifiers were similarly trained. The cumulative outcomes of the various single-class feed-forward deep neural networks classifiers were used for the SE task during inference. The findings indicated that the multiple single-class technique performed slightly poor when compared to the multi-class multiple label approach.

Recently, in an attempt to enhance classification performance, a study based on the attention mechanism has also been conducted in the area of SE research. For instance, the Convolutional Long Short-Term Memory and Deep Neural Networks model incorporates the temporal attention mechanism that was first presented in [14]. The system can look at every time step and try to identify the high impact one so that it can be given more weight. Another model was suggested in [27] using an attention-based multi-stream network model. The attention weight is calculated based on the degree of energy change in the spectrogram. The authors in [49] noted that not all frame-level characteristics can affect environmental sound performance equally. In particular, there are other time frames, such as silent frames, noisy frames, can cause the robustness of the classification model to degrade and will also result in errors in the classification. Based on this assumption, It is crucial to record the primary temporal segment of the sound stream. While the aforementioned techniques do help with classification performance, they did not take into account the variation of the frequency bands and their effect on the process. In addition, the method in [46] was developed to stack multiple attention network to get robust features. A temporal attention mechanism was suggested in [28] for convolutional layers to boost the representative ability of convolutional neural networks by re-weighting the convolutional neural networks feature maps using dot-product operation along the time dimension from input spectrogram.

Deep learning models have the ability to acquire effective representations from raw data without the need for manual intervention. Convolutional neural networks (CNNs) can automatically extract feature maps through

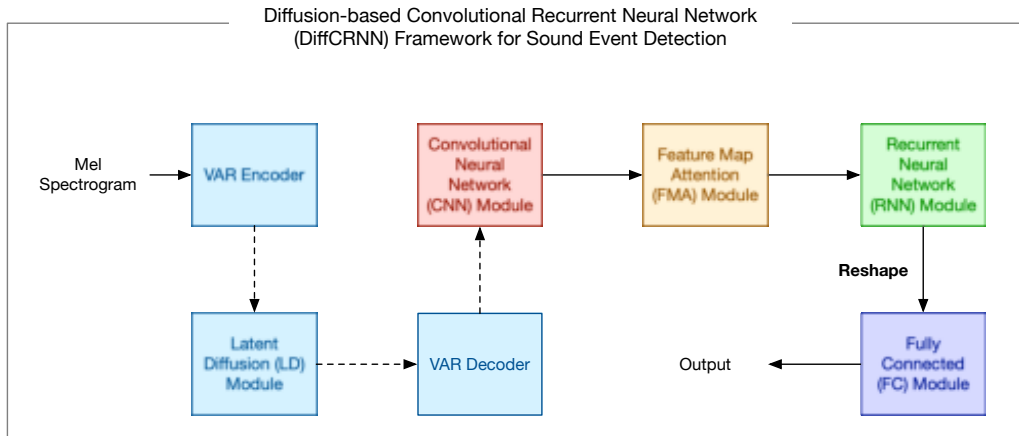

Fig. 3.1: The architecture of the proposed Diffusion-based Convolutional Recurrent Neural Network (DiffCRNN) system.

the convolution process, enabling them to capture the spatial features of input data [22, 39]. Furthermore, weight sharing significantly reduces the number of parameters in a convolutional neural network (CNN), thereby facilitating the training process of a CNN model compared to an equivalent dense neural network. Nevertheless, CNN-based models encounter challenges in capturing temporal dependencies when the input consists of time series data [20, 3]. Recurrent neural networks (RNNs) are extensively employed in various tasks, including text classification and speech recognition [10]. However, RNN-based models are limited in their ability to effectively extract features from raw data and face challenges with gradient vanishing and exploding when processing long time sequences [4]. Thus, this paper utilizes deep convolutional recurrent neural networks (namely DiffCRNN) to detect DiffCRNN by combining CNNs and RNNs. The DiffCRNN model utilizes convolutional layers to extract spatial features from raw data, while the recurrent layers are responsible for capturing the sequence information.

3. DiffCRNN: Framework Design. The architecture of the proposed Diffusion-based Convolutional Recurrent Neural Network (DiffCRNN) framework is illustrated in Figure 3.1. The framework has five main modules which are the latent diffusion based module, the convolutional neural networks (CNN) based module, the feature map attention based module, the recurrent neural network (RNN) based module and, finally, the fully connected layer based module.

In particular, the latent diffusion based module has three primary sub-modules: (i) encoder, (ii) latent diffusion model, and (iii) audio variational auto-encoder. The encoder is responsible for encoding the input description of the audio. Next, the process of reverse diffusion is used to construct a latent representation of the audio or audio prior from Gaussian noise, utilizing the textual representation. The audio variational auto-encoder subsequently employs the latent audio representation to yield a mel-spectrogram. The primary objective of the CNN is to extract a multi-dimensional and higher-order features from the input spectrogram. Further, the FM-attention module learns the importance of each dimensions in a dynamic way, in which important feature map information is extracted and unimportant dimensions are discounted. The RNN module then attempts to acquire contextual information and anticipate both the start and offset times of sound events in a precise way. Finally, the output characteristics of the RNN serve as the input for the fully connected layer in order to get the classification score of the DiffCRNN system.

This section described the architecture in more detail. The latent diffusion based module is described in Section 3.1. The CNN module is reviewed in Section 3.2. Then, Section 3.3 explains the feature map attention based module. Finally, in Section 3.4, the RNN module is represented.

3.1. Latent Diffusion Based Module. The latent diffusion based module (LD) consists of three primary parts: the encoder, latent diffusion model, and audio variational auto-encoder.

3.1.1. The encoder sub-module:. The encoder (E_τ) is the pre-trained large language models using FLAN-T5 [9] to obtain text encoding τ . The token count and token-embedding size are L and d_τ , respectively. The use of gradient descent, which emulates the process of imitating characteristics, is of significant importance in the task of learning the relationship between textual and auditory concepts, without the need for fine-tuning the E_τ , by treating each input sample as a distinct job. Enhanced pretraining techniques have the potential to enable the E_τ , however, to prioritize essential information with less interference and enhanced contextual understanding. Therefore, the E_τ is held constant, on the assumption that the reverse diffusion process may acquire knowledge of the audio inter-modality mapping prior to its generation.

3.1.2. The latent diffusion sub-module. The purpose of this sub-module is motivated by [40, 30] with the aim to produce the audio prior s_0 under the direction of text encoding τ . This basically comes down to parameterized $p_0(s_0|\tau)$ via approximating the correct prior $q(s_0|\tau)$.

The mechanisms of forward and reverse diffusion allow the sub-module to accomplish the aforementioned. The forward diffusion consists of a series of Markov of Gaussians with predetermined noise parameters $0 < \delta_1 < \delta_2 < \dots < \delta_N < 1$ to get more distorted iterations of the samples, s_0 as follows;

$$q(s_n|s_{n-1}) = \mathcal{N}(\sqrt{1 - \delta_n}s_{n-1}, \delta_n\mathbf{I}), \quad (3.1)$$

$$q(s_n|s_0) = \mathcal{N}(\sqrt{\bar{\kappa}_n}s_0, (1 - \bar{\kappa}_n)\mathbf{I}), \quad (3.2)$$

such that N denotes the quantity of forward diffusion iterations, $\kappa_n = 1 - \delta_n$, and $\bar{\kappa}_n = \prod_{i=1}^n \kappa_i$.

A more direct sampling of s_n from sample noisier versions can be applied through re-parametrization using as follows;

$$s_n = \sqrt{\bar{\kappa}_n}s_0 + (1 - \bar{\kappa}_n)\epsilon, \quad (3.3)$$

such that the noise sample $\epsilon \in \mathcal{N}(\mathbf{0}, \mathbf{I})$. The last stage of the forward procedure yields $s_N \in \mathcal{N}(\mathbf{0}, \mathbf{I})$.

The reverse method uses noise estimation ($\hat{\epsilon}_\theta$) to denoise and recover s_0 using loss function as follows;

$$\Omega = \sum_{n=1}^N \lambda_n \mathbb{E}_{\epsilon_n \in \mathcal{N}(\mathbf{0}, \mathbf{I})} \|\epsilon_n - \hat{\epsilon}_\theta^{(n)}(s_n, \tau)\|_2^2. \quad (3.4)$$

such that s_n is sampled from equation. 3.3 based on ϵ_n and λ_n which are the standard normal noise and the weight of reverse step n , respectively. The n is considered to be a measure of signal-to-noise ratio in respect to $\kappa_{1:N}$.

3.1.3. The augmentation sub-module. In this sub-module, we synthesis more text-audio pairings by superimposing existing audio pairs and concatenating their captions. To avoid overpowering low-pressure samples, the pressure level of audio R is considered. Audio sample (x_1) weight is determined as a relative pressure level:

$$p = (1 + 10^{\frac{R_1 - R_2}{20}})^{-1}, \quad (3.5)$$

such that R_1 and R_2 denotes the pressure levels of two used audio samples y_1 and y_2 . This guarantees accurate depiction of the two audio samples after mixing.

In addition, the square of a sound wave's amplitude determines how much energy it has [45]. As a results, y_1 and y_2 were mixed as follows;

$$\text{mix}(y_1, y_2) = \frac{py_1 + (1 - p)y_2}{\sqrt{p^2 + (1 - p)^2}}. \quad (3.6)$$

3.1.4. The free guidance sub-module. This sub-module is a classifier-free in which the input τ is used to rebuild the s_0 by directing the reverse diffusion. The contribution of text guidance to the noise level $\hat{\epsilon}_\theta$ is managed by a guidance scale v with respect to unguided estimation throughout inference:

$$\hat{\epsilon}_\theta^{(n)}(s_n, \tau) = v\epsilon_\theta^{(n)}(s_n, \tau) + (1 - v)\epsilon_\theta^{(n)}(s_n). \quad (3.7)$$

3.1.5. The decoder sub-module. In this sub-module, we implement the audio variational auto-encoder to convert the mel-spectrogram of an audio sample into a s_0 . The latent diffusion sub-module re-builds the \hat{s}_0 based on the τ . The encoder and decoder are formulated of ResUNet blocks and are trained via maximizing evidence lower-bound and minimizing adversarial loss [25].

3.2. CNN Module. Assuming that \mathbf{h}^{n-1} is the feature map of size $C^{n-1} \times P^{n-1} \times Q^{n-1}$ from the $(n-1)$ -th layer, such that C^{n-1} is the channel number and $P^{n-1} \times Q^{n-1}$ is the size of the feature map at the time and frequency axes, the result of the n -th convolutional layer is defined as

$$\mathbf{h}_j^n = \sum_{i=1}^{C^{n-1}} \mathbf{w}_{ij}^n * \mathbf{h}_i^{n-1} + b_j^n, \quad (3.8)$$

where \mathbf{h}_j^n denotes the j -th channel of \mathbf{h}^n , \mathbf{w}_{ij} denotes the (i, j) -th convolutional kernel, $*$ is the convolutional operation, and b_j^n represents the bias at the j -th channel. In order to accelerate convergence, convolutional layers are typically followed by batch normalization and a ReLU activation function. Batch normalization can also increase the stability of CNN [8].

In order for the CNN model to function properly, the three-dimensional feature map that includes the channel, time frame, and feature vector must be transformed into a classification vector. It is possible, as mentioned in the previous section, to immediately flatten the feature map into a vector in order to reduce the number of dimensions. Flattening, on the other hand, could result in a sub-optimization due to the fact that it might preserve duplicate information. As a result, the time-frequency attention pooling will be covered here to produce a vector that is more compact and has less information that is redundant than the one that is generated by flattening.

The temporal-frequency global attention (TFGA) pooling in CNNs decreases the dimensionality of a feature map through measuring the contribution of each temporal-frequency unit. It is composed of two sub-modules: an attention sub-module, and a classification sub-module, which come typically after a set of convolutional layers and local average pooling layers. The attention sub-module has a two-dimensional convolutional layer with an output channel number equal to the number of classes K , and a kernel size of 1×1 , which results in an attention tensor A . An activation function (softmax or sigmoid) is applied after the convolutional layer to yield a tensor A^* with values in the range $[0, 1]$. Next, the tensor A^* is normalized using

$$P_{kpq} = \frac{A_{kpq}^*}{\sum_{p=1}^{P_w} \sum_{q=1}^{Q_w} A_{kpq}^*}, \quad (3.9)$$

such that P denotes the probability tensor. Moving to the classification sub-module, the feature map is transformed into a new one C with the channel number of K using an additional two-dimensional convolutional layer with a kernel size of 1×1 . After that, the resultant classification tensor C is multiplied by P to determine the probability of each class by applying the following

$$p_k = \sum_{p=1}^{P_w} \sum_{q=1}^{Q_w} C_{kpq} \odot P_{kpq}, \quad (3.10)$$

Additionally, to complete a classification task, a softmax or log-softmax function is employed to operate on C or p . In order to make more accurate predictions, the time-frequency attention pooling can assess the contribution of each time-frequency bin to classification [20].

3.3. Feature-map Attention Module. In the Feature Map (FM-attention) algorithm, the multi-dimensional feature map \mathbf{h} is acquired from CNN module, such that C is the channel number and $T \times F$ represents at the time and frequency axes the size of the feature map. Then the high-order feature map \mathbf{h} was input to the FM-attention model. The FM-attention has a Sigmoid activation layer and fully connected feedforward layer in order to compute the high impact weight of each feature dimension of \mathbf{h} of size $C \times T \times F$. The high impact weight U is the outputs of the Sigmoid layer, which is assigned to different feature dimensions. First, \mathbf{h} is permuted into 3-dimensional tensor \mathbf{h}' of size $T \times C \times F$. Subsequently, \mathbf{h}' is flattened as a 2-dimensional tensor \mathbf{h}'' by fixing the dimension T .

Next, the input to the feedforward layer is \mathbf{h}'' . The number of hidden units in this layer is set to CF . The dimension of weights U is $M = CF$, which can be written as:

$$U = \{U_1, U_2, \dots, U_d, \dots, U_M\}, \quad (3.11)$$

where U_m influences the m th dimensional feature of \mathbf{h}'' , the expression of U_m is:

$$U_m = \frac{\exp(O_m)}{\sum_{j=1}^{j=m} \exp(O_j)}, \quad (3.12)$$

The dimension of \mathbf{h}'' is M . The j th dimensional output of the Sigmoid activation layer is O_j . The high impact weight U is repeated T times, and its dimension U results in $T \times C \times F$. The U is reshaped to form U' , FM-attention vector, of size $T \times C \times F$. The outputs of the FM-attention module can be written as:

$$\mathbf{h}_{att} = U' \odot \mathbf{h}', \quad (3.13)$$

where “ \odot ” denotes the Hadamard product. Also, the outputs \mathbf{h}_{att} of FM-attention module are fed into the RNN module.

3.4. RNN Module. The hidden state h_t at the time step t , $t = 1, \dots, T$, can be represented as

$$h_t = \sigma_h(\mathbf{w}_h x_t + \mathbf{u}_h h_{t-1} + b_h), \quad (3.14)$$

such that \mathbf{w}_h and \mathbf{u}_h denote the weights, T represents the total number of time steps, b_h denotes the bias, h_{t-1} represents the previous hidden state at the time step $t - 1$, x_t denotes the input vector at the time step t , and σ_h represents an activation function. In classification tasks, the final recurrent layer’s hidden states are often merged into a single vector and sent on to a fully connected layer. Typically, a vector can be generated as the fully connected layer’s input by either computing the average of the hidden states or extracting the hidden state at the most recent time step.

This simple RNN, however, is unable to process long-term context information owing to the exploding and vanishing gradient problem. For this reason, the Long Short-Term Memory (LSTM) RNN structure [19] and Gated Recurrent Units (GRU) RNN structure [50] were suggested to address such problem. The neurons in the simple RNN model is changed to memory blocks in the LSTM-RNN model, such that the memory blocks are connected recurrently. The LSTM, [19], is employed by replacing Equation 3.14 with the following steps: At the t -th time step, an LSTM unit comprises of an input gate i_t , an output gate o_t , a forget gate f_t , and a cell state c_t . The procedure of an LSTM unit is implemented as follow;

$$i_t = \sigma(\mathbf{w}_i x_t + \mathbf{u}_i h_{t-1} + b_i), \quad (3.15)$$

$$f_t = \sigma(\mathbf{w}_f x_t + \mathbf{u}_f h_{t-1} + b_f), \quad (3.16)$$

$$o_t = \sigma(\mathbf{w}_o x_t + \mathbf{u}_o h_{t-1} + b_o), \quad (3.17)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot \tanh(\mathbf{w}_c x_t + \mathbf{u}_c h_{t-1} + b_c), \quad (3.18)$$

$$h_t = o_t \odot \tanh(c_t), \quad (3.19)$$

where \odot denotes the element-wise multiplication. i, f, o denote the input, forget and output gates' activation vectors, and c, h denote cell and hidden states vectors.

A GRU-RNN structure, [50], comprises a reset gate r_t and an update gate z_t at the t time step, unlike an LSTM cell. A GRU is established by

$$r_t = \sigma(\mathbf{w}_r x_t + \mathbf{u}_r h_{t-1} + b_r), \quad (3.20)$$

$$z_t = \sigma(\mathbf{w}_z x_t + \mathbf{u}_z h_{t-1} + b_z), \quad (3.21)$$

$$h_t = (1 - z_t) \odot h_{t-1} + z_t \odot \tanh(\mathbf{w}_h x_t + \mathbf{u}_h (r_t \odot h_{t-1}) + b_h), \quad (3.22)$$

In fact, a GRU has fewer parameters than an LSTM cell because it contains two gates in a single unit.

4. Experimental Setup. This section describes the experimental datasets in Section 4.1, evaluation metrics in Section 4.2 and experimental settings in Section 4.3 in the domain of SED. Experiments are run on publicly available datasets to verify the model's efficacy and the outcomes of this study's method are compared to those of previously published methods.

4.1. Datasets. The settings for real-time sound event detection system must be designed and customized to mimic the real-life noisy environments. This should be done by using equipments for recording at a number of different points and the sound sources are within a distance around the microphone points to generalize dataset with various recording environments. The system should also detect sound events regardless of position of the user.

To overcome the time-consuming issue of real-time sound event detection system, we present our results on three datasets namely, DCASE2016-SED [34], DCASE2017-SED [7] and URBAN-SED [41] that mimic the real-life noisy environments including everyday ambient noises that are separated into inside and outdoor settings.

4.1.1. The DCASE2016-SED dataset. The task3 of the DCASE2016 dataset [34] was utilized in this work to assess the performance of the DiffCRNN model. It includes everyday ambient noises that are separated into inside and outdoor settings. The DCASE2016 dataset's audio is mono and has a 44.1 kHz sample rate. A development set makes up 70% of the entire sample in both the DCASE2016 dataset, while an evaluation set makes up 30%. The four-fold cross-validation approach is employed in this work to train and test.

4.1.2. The DCASE2017-SED dataset. The task3 of the DCASE2017 dataset [7] was utilized in this work to assess the performance of the DiffCRNN model. It consists of everyday ambient noises that are separated into inside and outdoor settings. More street noises and human voices from authentic recordings may be found in the DCASE2017 collection. The sample frequency and duration of each audio file in the DCASE2017 dataset are both 44.1 kHz. Two typical settings are included in the DCASE2017: an inside residence and an outdoor residential neighborhood. A development set makes up 70% of the entire sample in the DCASE2017 dataset, while an evaluation set makes up 30%. The four-fold cross-validation approach is employed in this work to train and test.

4.1.3. The URBAN-SED dataset. The URBAN-SED [41] is a publicly available dataset for SED in urban environments. It is accompanied by detailed annotations, including onset and off-set times for each sound event, along with human generated accurate annotations.

4.2. Evaluation Metrics. We compare the performance using the commonly used metrics for SED presented in [33]. The segment-based $F1$ -score ($F1$) and the error rate (ER) are used as assessment metrics in the experiment. Furthermore, $F1$ is the harmonic average of recall (R) and precision (P), which accept values between 0 and 1. The computation procedure is described as follows;

$$F1 = \frac{2P \cdot R}{P + R}, \quad (4.1)$$

Table 4.1: The structure of the neural settings in the DiffCRNN model.

Layer Type	Configurations
Output	The output shape is (256, 6)
Recurrent	The number hidden unit is 32
Recurrent	The number hidden unit is 32
Merge	The mode is ‘mul’
Repeat and Reshape	The output shape is (256, 128, 2)
Softmax activation	None
Feedforward	The number hidden unit is 256
Reshape	The output shape is 256 & 256
Permute	The output shape is 256, 128 & 2
Max pooling	The sub-sampling rate is 2
ReLU activation	None
Convolution	The filter number and kernel size is 128 & (3,3)
Max pooling	The sub-sampling rate is 2
ReLU activation	None
Convolution	The filter number and kernel size is 128 & (3,3)
Max pooling	The sub-sampling rate is 5
ReLU activation	None
Convolution	The filter number and kernel size is 128 & (3,3)
Merge	The mode is ‘TF-Attention’
Multiply on the T/F direction	the mode is ‘T-Attention’ and ‘F-Attention’
Softmax activation	None
Convolution	The filter number and kernel size is 1 & (1,1)
ReLU activation	None
Convolution	The filter number and kernel size is 32 & F(1,3) × 254/T(2,1) × 39
Input	The input shape is (256,40)

such that

$$P = \frac{\sum TP}{\sum TP + \sum FP}, \quad (4.2)$$

and

$$R = \frac{\sum TP}{\sum TP + \sum FN}, \quad (4.3)$$

where TP , FP , and FN represent true positive, false positive, and false negative. The ER denotes the number of samples classified incorrectly. The ER is computed as;

$$ER = \frac{\sum_{t=1}^T S(t) + \sum_{t=1}^T I(t) + \sum_{t=1}^T D(t)}{\sum_{t=1}^T N(t)}, \quad (4.4)$$

in which T represents how many audio events there are in segment t . Substitution events $S(t)$ represent the number of times the model incorrectly labels a sound event as a sound event. The term insertion event ($I(t)$) refers to an event A that is currently not occurring in the tag annotation but is only identified in the model output. Deleted events, often known as $D(t)$, are sound events that were there but went undetected. The sum of the acoustic events from the annotations is $N(t)$.

4.3. Experimental Settings. All audio datasets used in this study are mono wave files at 44.1 kHz, and the dimension of the Log-Mel spectrograms is 40×256 where ($T = 256, F = 40$). The overlapping frames are 50%, and the frame size is 40 ms.

Table 5.1: The performance comparison of the baseline and DiffCRNN with Latent Diffusion (+LD) and without (-LD).

Method	DCASE2016-SED		DCASE2017-SED		URBAN-SED	
	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>
CRNN	50.4%	0.36	53.2%	0.38	62.3%	0.40
DiffCRNN(+LD)	66.2%	0.42	68.1%	0.40	74.3%	0.44
DiffCRNN(-LD)	60.4%	0.45	59.3%	0.55	64.2%	0.41

The latent diffusion model is then given the characteristics. The Stable Diffusion U-Net architecture serves as the foundation for the 866M parameters that make up the diffusion model. In the U-Net model, we employ 8 channels and a cross-attention dimension of 1024. We train the AdamW optimizer with a linear learning rate scheduler and a 3e-5 learning rate. On the basis of the AudioCaps dataset, we train the model across 40 iterations, and we present the results for the checkpoint with the best validation loss, which we attained at iteration 40.

The Adam optimizer [24], which has a learning rate of 0.001, is used to feed the optimized features into CNNs. Total epochs are 100 and the learning rate ramp up during the first 20 epochs and ramp down during the remaining epochs. Batchsize is set to 64. A maximum of 3000 iterations are chosen through experiments to improve CNNs. Pytorch is used to build together the CNN architectures. Three CNN topologies - AlexNet [26], VGG-4 [43], and Net-4 - were used in the experiment. In order to reduce the efficacy of local max pooling layers, the Net-4 is a CNN structure with a stride of size 2 between the convolution layers. This Net-4, which is positioned between AlexNet and VGG-4, has a kernel size of 5×5. This is carried out to examine the impact of kernel size on performance and identify an ideal kernel size. The three-dimensional feature maps are converted into one-dimensional tensors via a global pooling layer that comes after the convolutional layers. As a result, fewer feature dimensions exist. Table 4.1 demonstrates the specific neural parameter settings for the DiffCRNN.

RNN, like CNN, is a highly effective neural network that is also utilized in SED tasks. The LSTM is a modified version of the RNN. Unlike standard RNN, LSTM can resolve the issue of long-term dependencies. Nevertheless, the interdependencies within time series data pose a challenge when attempting to utilize LSTM for parallel computation. The computation speed is significantly lower than that of the CNN. The GRU model is a distinct variant of RNN models. The accuracy of the detection task using the GRU model will be slightly affected while ensuring high speed for the DiffCRNN.

5. Main Results. The performance of the DiffCRNN model was assessed under the following experimental scenarios:

- (1): with/without LD,
- (2): with/without FM strategy,
- (3): different pooling methods for CNNs classifiers,
- (4): different RNNs classifiers,
- (5): with/without Fine-tuning,
- (6): with/without data augmentation, and
- (7): with the other state-of-the-art SED methods.

We designed these experiments on the DCASE2016-SED dataset, DCASE2017-SED dataset and URBAN-SED dataset in which the baseline system is CRNN.

5.1. Comparison of DiffCRNN With/Without Latent Diffusion. The assessment results of the development set for DCASE2016-SED and DCASE2017-SED, comparing DiffCRNN with and without LD, are shown in Table 5.1. The used features were Log-Mel spectrograms. During the experimental phase, the CRNN method was used as the baseline to assess the classification performance while using LD.

LD demonstrated superior performance in terms of both *F1* and *ER* values when compared to the two situations. During the study conducted on the DCASE2016-SED dataset, the LD achieved a peak *F1* score

Table 5.2: The performance comparison of the baseline and DiffCRNN with Feature Mapping Attention Algorithm (+FM) and without (-FM).

Method	DCASE2016-SED		DCASE2017-SED		URBAN-SED	
	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>
CRNN	50.4%	0.36	53.2%	0.38	62.3%	0.40
DiffCRNN(+FM)	66.2%	0.42	68.1%	0.40	74.3%	0.44
DiffCRNN(-FM)	55.3%	0.48	56.1%	0.51	65.1%	0.48

Table 5.3: The performance comparison of various pooling methods for CNNs.

Classifier (+Pooling Type)	DCASE2016-SED		DCASE2017-SED		URBAN-SED	
	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>
AlexNet (+GM)	58.1%	0.42	63.2%	0.51	66.4%	0.50
AlexNet (+GA)	57.8%	0.45	58.5%	0.55	67.2%	0.48
AlexNet (+TFGA)	66.2%	0.42	68.1%	0.40	74.3%	0.44
VGG-4 (+GM)	58.5%	0.43	63.7%	0.52	65.5%	0.46
VGG-4 (+GA)	59.0%	0.46	63.2%	0.57	67.1%	0.49
VGG-4 (+TFGA)	60.2%	0.40	65.9%	0.42	69.2%	0.48
Net-4 (+GM)	57.2%	0.40	62.9%	0.45	67.2%	0.50
Net-4 (+GA)	56.2%	0.41	57.9%	0.50	66.7%	0.47
Net-4 (+TFGA)	60.3%	0.43	64.5%	0.47	67.3%	0.45

of 66.2% and a *ER* value of 0.42. The DCASE2017-SED dataset yielded a *F1* score of 68.1% and an error rate (*ER*) of 0.40. The experiment on the URBAN-SED dataset, the LD reached a peak *F1* score of 74.3% and a *ER* value of 0.44. The experimental findings demonstrate that the use of LD significantly improved the classification performance.

5.2. Comparison of DiffCRNN With/Without Feature Mapping Attention Algorithm. The findings of evaluating the development set for DCASE2016-SED and DCASE2017-SED for comparing DiffCRNN With/Without FM approach are shown in Table 5.2. Log-Mel spectrograms were used as the features. In the course of the study, the classification impact of using FM method was compared using the same CRNN model as the baseline.

The *F1* and *ER* values were enhanced by the FM technique in comparison to the two cases. The FM method performed best in tests using the DCASE2016-SED dataset, with a maximum *F1* of 66.2% and *ER* of 0.42. Its *F1* and *ER*, using the DCASE2017-SED dataset, were 68.1% and 0.40, respectively. During the study conducted on the URBAN-SED dataset, the FM achieved a peak *F1* score of 74.3% and a *ER* value of 0.44. The use of FM approach improved the classification performance, according to experiment data.

5.3. Comparison of Different Pooling Methods for CNNs Classifiers in the DiffCRNN Model. Table 5.3 shows the results of the evaluation of the development set for DCASE2016-SED, DCASE2017-SED and URBAN-SED. We can see that almost every one of our pooling models does better than the other. The TFGA model works better at AlexNet than the GM and GA models, and it was used to make CNN. But at VGG-4, the TFGA model gives way to GM. One reason might be that the larger number of hyper parameters in VGG-4 with TFGA pooling leads to overfitting. When it comes to the Net-4 model, the developed CNN gets the best results. This means that CNNs with a kernel size of five and no GM between convolutional layers seem to be better suited for this task of classifying acoustic scenes. Also, the developed CNN gets 56.2% and 60.3% accuracy for the DCASE2016-SED, 57.9% and 64.5% accuracy for DCASE2017-SED, and 66.7% and

Table 5.4: The performance comparison of LSTM-RNNs and GRU-RNNs of the DiffCRNN Model.

Method (+RNN Classifie)	DCASE2016-SED		DCASE2017-SED		URBAN-SED	
	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>
CRNN	50.4%	0.36	53.2%	0.38	62.3%	0.40
DiffCRNN(+GRU)	66.2%	0.42	68.1%	0.40	74.3%	0.44
DiffCRNN(+LSTM)	60.4%	0.45	59.3%	0.55	71.4%	0.42

Table 5.5: The performance comparison between fine-tuned and non fine-tuned models on the development set.

Method	DCASE2016-SED		DCASE2017-SED		URBAN-SED	
	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>
CRNN	50.4%	0.36	53.2%	0.38	62.3%	0.40
DiffCRNN(+Finetuning)	66.2%	0.42	68.1%	0.40	74.3%	0.44
DiffCRNN(-Finetuning)	60.1%	0.45	65.2%	0.44	69.1%	0.46

67.3% accuracy for URBAN-SED.

5.4. Comparison of LSTM-RNNs and GRU-RNNs of the DiffCRNN Model. Table 5.4 represents the results of the evaluation of the development set for DCASE2016-SED, DCASE2017-SED and URBAN-SED by comparing of different RNN classifiers. The used features was Log-Mel spectrograms. During the experimentation procedure, the efficacy of using various RNN classifiers for classification was compared using the same CRNN method as the baseline.

The experimental findings of DCASE2017-SED provide the mean accuracy on the 4-fold partitioned development set, as determined by the official evaluation metrics. Both RNN models consist of three recurrent layers with output channels of 256, 1024, and 256. Compared with the two scenarios, the GRU-RNNs classifiers improved *F1* and *ER* values. In experiments on the DCASE2016-SED dataset, the performance of the GRU-RNNs classifiers reached a maximum *F1* of 66.2% and *ER* of 0.42. Using the DCASE2017-SED dataset, its *F1* and *ER* were 68.1% and 0.40, respectively. Moving to the study on the URBAN-SED dataset, the performance of the GRU-RNNs classifiers reached its peak with *F1* of 74.3% and *ER* of 0.44. The outcomes of the studies show that the performance of classification was improved by the usage of GRU-RNNs. When training is terminated at various epochs, the performances of LSTM-RNNs and GRU-RNNs on a set of feature sets are compared.

5.5. Comparison of DiffCRNN With/Without Fine-tuning. Table 5.5 demonstrates the results of the evaluation of the development set for DCASE2016-SED, DCASE2017-SED and URBAN-SED for comparing of DiffCRNN With/Without Fine-tuning.

The results of experiments indicate that the use of Fine-tuning enhanced the classification performance. Nevertheless, it is crucial to acknowledge that achieving greater results on the restricted sample of the training dataset does not always imply superior overall performance. A model that has the ability to create wider ranges of sounds may have worse performance on the development set, but having superior generalization capabilities.

5.6. Comparison of DiffCRNN With/Without Data Augmentation. Table 5.6 demonstrates the results of the evaluation of the development set for DCASE2016-SED, DCASE2017-SED and URBAN-SED for comparing of DiffCRNN With/Without data augmented.

The results of experiments show that the use of data augmented increased the classification performance. For data augmentation, AudioGen employs an approach called mixup, where it combines pairs of audio samples and concatenates their processed text captions. This results in the creation of fresh paired data, which leads to improved performance overall.

Table 5.6: The performance comparison between data augmented and non-data augmented models on development set.

Method	DCASE2016-SED		DCASE2017-SED		URBAN-SED	
	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>
CRNN	50.4%	0.36	53.2%	0.38	62.3%	0.40
DiffCRNN(+AudioGen)	66.2%	0.42	68.1%	0.40	74.3%	0.44
DiffCRNN(-AudioGen)	59.1%	0.49	60.3%	0.46	67.2%	0.45

Table 5.7: Summary of the State-of-the-art SED Methods Used for Comparison.

SED Approach	Description
Log-Mel+CaspNet [23]	It is based on Capsule Neural Networks (CaspNet), the input feature is Log-Mel spectrograms, and it is the winning model for DCASE2016-SED.
Log-Mel-CRNN [2]	It is based on CRNN, the input feature is Log-Mel spectrograms, and it is the winning model for DCASE2017-SED.
CRNN-CWin [35]	It utilizes the Transformer encoder, which consists of multiple self-attention modules, the input feature is Log-Mel spectrograms, and it is the state-of-the-art model for URBAN-SED.

Table 5.8: The performance comparison between DiffCRNN Model and the state-of-the-art SED methods

Method	DCASE2016-SED		DCASE2017-SED		URBAN-SED	
	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>	<i>F1</i>	<i>ER</i>
Log-Mel+CaspNet [23]	47.8%	0.81	-	-	-	-
Log-Mel-CRNN [2]	-	-	41.7%	0.79	-	-
CRNN-CWin [35]	-	-	-	-	65.7%	0.71
Our DiffCRNN	66.2%	0.42	68.1%	0.40	74.3%	0.44

5.7. Comparison of the DiffCRNN Model with the State-of-the-art SED Methods. The DiffCRNN model was then compared with advanced SED methods. Other compared models are specified in Table 5.7 where the baselines and the winning models are outlined.

The experimental results in Table 5.8 show that the proposed DiffCRNN model outperforms other methods for both the baselines and the winning models.

6. Ablation Study. We conduct ablation experiments on DCASE2017 Task3 to study DiffCRNN in detail. All experiments use the pre-trained ResUNet backbone features for training and inference without further specification. The encoder and decoder are formulated of ResUNet blocks and are trained via maximizing evidence lower-bound and minimizing adversarial loss

6.1. Ablation Study on Diffusion Strategy. Diffusion Strategy Due to the inherent iteration based design with the decoder, we discuss and compare two diffusion strategies: (i) Noisy event latents in the continuous space (CS) (referred as DiffCRNN-CS, our model). (ii) Noisy event latent event in the discrete space (DS) (referred as DiffCRNN-DS). In addition, we distort the event latents using random shuffle as the noise in the forward diffusion step. In order to assess the impact of the diffusion strategy through experimentation, we

Table 6.1: Effect of the number of iteration on the performance for DCASE2016-SED, DCASE2017-SED and URBAN-SED Test set on noisy event latents in the continuous space (CS) and noisy event latent event in the discrete space (DS).

Method	# Iteration	<u>DCASE2016-SED</u>	<u>DCASE2017-SED</u>	<u>URBAN-SED</u>
		<i>F1</i>	<i>F1</i>	<i>F1</i>
DiffCRNN-CS	10	63.2%	64.6%	71.3%
	20	65.1%	66.1%	72.1%
	30	65.3%	67.2%	72.6%
	40	66.2%	68.1%	74.3%
	50	64.2%	66.3%	73.4%
DiffCRNN-DS	10	57.1%	63.3%	69.2%
	20	64.3%	66.3%	70.1%
	30	59.1%	65.3%	71.4%
	40	58.2%	65.7%	68.2%
	50	60.2%	64.0%	68.9%

Table 6.2: Effect of scaling the noise factor on the performance for DCASE2016-SED, DCASE2017-SED and URBAN-SED Test set on noisy event latents in the continuous space (CS) and noisy event latent event in the discrete space (DS).

Method	Noise scale	<u>DCASE2016-SED</u>	<u>DCASE2017-SED</u>	<u>URBAN-SED</u>
		<i>F1</i>	<i>F1</i>	<i>F1</i>
DiffCRNN-CS	0.1	64.1%	66.2%	70.1%
	0.2	64.6%	66.1%	71.1%
	0.3	65.2%	66.8%	71.9%
	0.4	66.2%	68.1%	74.3%
	0.5	63.2%	66.3%	70.4%
DiffCRNN-DS	0.1	60.1%	58.8%	69.0%
	0.2	59.3%	62.3%	70.1%
	0.3	61.4%	63.3%	67.4%
	0.4	64.8%	66.3%	69.0%
	0.5	60.7%	64.0%	68.9%

conduct tests on both variants using varying numbers of iteration. Table 6.1 shows that both variants achieve the best performance at the 40 iteration for the DiffCRNN-CS.

6.2. Ablation Study on Signal Scaling. The signal scaling factor controls the noise scaling of the diffusion process. We study the influence of scaling factors. The results in Table 6.2 illustrate that the scaling factor of 0.4 reaches the highest performance in *F1* metric for DiffCRNN-CS, whereas for DiffCRNN-DS the best performance is obtained for a scaling factor of 0.2 in URBAN-SED whilst achieving the best *F1* score for a scaling factor of 0.4 in both DCASE2016-SED and DCASE2017-SED. This implies a correlation between optimal scaling and the diffusion strategy.

7. Discussion. While the DiffCRNN method offers numerous benefits, its utilization also poses certain challenges. The following are the primary difficulties associated with DiffCRNN: The DiffCRNN has a high computational complexity, particularly when compared to less complex models such as CNNs. This can render them difficult to train and implement on low-power devices. The architectural design of DiffCRNN presents challenges that necessitate thorough consideration of the arrangement and integration of forward and reverse diffusion, convolutional, and recurrent layers. Selecting exemplary architecture can be a long and tedious

task. Training DiffCRNN can pose challenges, particularly when dealing with large datasets. The model may experience issues such as over-fitting, which occurs when the model becomes too closely aligned with the training data and fails to effectively apply its knowledge to new data. The DiffCRNN, like other diffusion models and deep learning models, presents limited interpretability, making it difficult to understand and explain its inner workings. Comprehending the rationale behind a models specific predictions can pose challenges and hinder certain applications. The aforementioned challenges can be overcome with careful experimental settings that we implement in Section 4.3.

8. Conclusions. In this study, we combine the benefits of several networks to provide a latent diffusion model and convolutional recurrent neural network for sound event detection to enhance security applications and smart home systems. To overcome the problem of data scarcity, the system was first trained on large datasets and then used transfer learning to adjust to the target job. The suggested detection framework first trains a discrete representation compressed from the audio mel-spectrogram using the latent diffusion model. Next, a CNN is integrated as the front-end of a RNN. Next, the back-end RNN receives the feature map that the front-end CNN has learnt. Following that, an intermediate feature map is used by an attention module to forecast attention maps in two different dimensions: temporal and spectral. The input spectrogram is then multiplied by the attention maps in order to perform adaptive feature refining. Ultimately, the refined characteristics from the rear-end RNN are combined using trainable scalar weights. The experimental results demonstrate that the proposed method outperforms both the state-of-the-art and the baseline CRNN. Using the DCASE2016-SED dataset as an example, the system's performance peaked at 66.2% *F1* and 0.42 *ER*. Its *F1* and *ER*, using the DCASE2017-SED dataset, were 68.1% and 0.40, respectively. Further investigation with the URBAN-SED dataset shows that our proposed method outperforms existing alternatives with 74.3% and 0.44 for the *F1* and *ER*.

Our future work will design a DiffCRNN system based on mobile terminal devices considering the fact that people use mobile terminals as internet access devices most of the time in daily life. We will adopt the client/server structure in order to allow the mobile device as the end-user to record and collect the user's voice signal. Then, it can be sent to the desktop computer as a server for neural network calculation, and finally, the result of event sources is returned to the user terminal.
