ENHANCING LEARNING ABILITIES IN STUDENTS USING A COGNITIVE NEUROSCIENCE MODEL BASED ON BRAIN-COMPUTER INTERFACE SIGNAL ANALYSIS

REBAKAH GEDDAM*AND PIMAL KHANPARA†

Abstract. Computational intelligence is used to create artificially intelligent systems with the ability to learn, adapt, and solve problems. Learners' computational abilities can be improved with the help of Cognitive Neuroscience techniques. Computational intelligence refers to the ability of a learner based on the complex operations of the brain in the four relevant dimensions: Visual (V), Aural (A), Kinematic (K), and Reading/Writing (R/W). Our proposed framework consists of electroencephalogram (EEG) data acquisition, signal extraction, and EEG signal categorization to assess students' cognitive learning abilities. Our proposed approach uses an EEG device equipped with a microprocessor, a Think Gear (TGAM) EEG sensor, and a PCB of 16 dry electrodes. The EEG device and the remote processing device are connected by Bluetooth. The EEG signal provides the students with neurofeedback on their cognitive learning capability. The feedback obtained through the learning process will be endowing to improvise computational intelligence. The statistical derivative, Pearson Co-efficient, is used to find the correlation among the derived attributes. The attributes considered are the learner's gender, stream, age, and geographical region. The results obtained highlight that gender, stream, and age have no correlation with the detectable learning index, and the most accurate learners are kinesthetic ones. Bi-modal learners, who can maintain focus while reading and using their kinematic abilities, had the second-highest learning capacity.

Key words: Neurofeedback, Brain-Computer Interface, Cognitive Ability, Learning Index, Cognitive Neuroscience

1. Introduction.

The ability of the human brain to grasp information, process it at a level of comprehension, and recollect it proficiently is what defines memory. Human cognition encompasses the psychological processes and procedures used in the collecting, organizing, retrieving, and utilization of information. Perception, attention, memory, language, reasoning, figuring out solutions, and making choices are just a few of the many mental activities that make up cognition [25]. The aptitude to retort to the problem solution is based on the knowledge consequent. The cognitive ability of learners can be enhanced by identifying their brain capacities' strengths and improving their retention process. To continuously acquire learning skills, the cognitive process needs to be developed. Human cognition is the capacity to transform short-term memory into a knowledge base. The concepts that map the brain-computer interface to human cognition are explained in detail in the following sections.

1.1. Human Cognition.

The evolution of human cognition has been an interesting subject of research for decades. Humans are the only intelligent species that focus on thoughtfulness and extracting reasoning from the information acquired. The extraordinary cognitive abilities have evolved into a knowledge base in every aspect of our lives [42]. Millions of neurons exist in the brain, which excite and transmit information, particularly in the cognition phase.

In the teaching-learning environment, it is important to study the changes in cognitive ability while a learner is trying to attain some information and process it into knowledge. This research can be used to identify the cognitive developmental milestones that students reach at different cognitive stages as well as the factors that affect individual differences in cognitive development [31]. When intellectual abilities emerge in the brain, it is crucial to comprehend human cognition within a BCI (Brain Computer Interface) framework. The capacity from the neuron and the sympathetic function in relation to the cognitive abilities are passed down to current complex human abilities. These abilities include comprehending, remembering, evaluating, and understanding.

1.2. Cognitive Skills. Cognitive science is the way to apprehend the working functions and behavioral aspects of human brains. To understand how the brain makes decisions to complete a task, cognitive science requires knowledge of a variety of fields, such as Computational Intelligence (CI), Neurofeedback (NF), and Artificial Intelligence (AI) [7]. Cognitive science pursues comprehending brainpower and conducting experiments to develop learning ability. During the learning phase, learners face difficulties that divert their focus from attaining knowledge [10]. Neurofeedback plays a vital role in reinforcing the ability of the learners to excerpt information.

Based on prior experience, the knowledge obtained will be adapted into a beneficial context. The process of collecting and deciphering sensory data from the environment is known as perception [12]. The ability to concentrate on a particular stimulus or activity while ignoring irrelevant information is referred to as attention. Capturing, preserving, and extracting information through time periods is the process of remembering. Making decisions and forming judgments based on memory is the process of reasoning. Cognitive abilities are the basic capacities of the human brain required for thinking, reading, learning, remembering, reasoning, and paying attention. Combined, they absorb data and contribute it to the body of knowledge people need for their daily lives, careers, and educational pursuits. Cognitive skills have a major role in how the brain interprets new information. This implies that if any of these abilities are compromised, the person's capacity to comprehend, retain, or apply the information will be impacted regardless of the type of material given to them. Most learning challenges are caused by one or more deficiencies in cognitive ability. By developing cognitive skills, students can use their brains to complete tasks, process information efficiently, and comprehend it. Intensifying cognitive skills can help learners perform better in almost every aspect of academics.

1.3. Bloom's Taxonomy for enhancing Cognitive skills. A system for classifying and organizing various levels of cognitive learning is called Bloom's Taxonomy [6]. Six degrees of cognitive learning that extend from lower-order to higher-order thinking abilities are included in the taxonomy:

- *Remembering:* At this stage, facts and definitions need to be remembered from memory.
- *Understanding:* This stage entails understanding the information's meaning, which could involve interpreting or summarising it.
- *Applying:* This phase involves applying the information to a new situation, such as using a concept to address a novel problem.
- *Analyzing:* This phase comprises breaking down the data into its individual elements and examining their relationships.
- *Assessing:* At this stage, decisions are made regarding the information, including its relevance and credibility.
- *Creating:* At this stage, data is utilized to generate a new idea, such as a product or a design that solves an issue.

These are six key cognitive-process classes, from the simplest to the most composite. When learners master evaluating, assessing, and creative skills, their cognitive abilities improve significantly. Bloom's taxonomy helps students pinpoint their areas for improvement, become more knowledgeable and proficient, and advance to a higher level of comprehension of the academic material [6]. When trained, the brain improves effectiveness and productivity by transferring information to knowledge [1]. Bloom's Taxonomy can be used to assess cognitive skills, which can also predict learning outcomes and academic achievement from acquiring strong skills [36]. Facilitators may utilize the taxonomy to create learning objectives, gauge student comprehension, and create tests and activities that foster higher-order thinking abilities.

1.4. Computational Cognitive Neurofeedback. Cognitive Neurofeedback draws renewed awareness as a process to self-regulate individual brain activity, which directly amends the core neural process of cognition. Neurofeedback is a type of biofeedback that helps people control their brain activities by monitoring brain waves and sending a feedback signal to the subject [5]. The audio and/or video feedback is typically provided using neurofeedback. Positive or negative feedback is generated for favorable or undesired brain actions. The learners can utilize this technique as a method for cognitive enhancement [29] [27]. In this paper, we have presented a neurofeedback framework conversing significant features applicable to the collection of electroencephalography (EEG) signals. The elements pertinent to a practical comprehension of neurofeedback for identifying learning styles are considered for designing this framework. All the practical concerns regarding evaluating learning styles

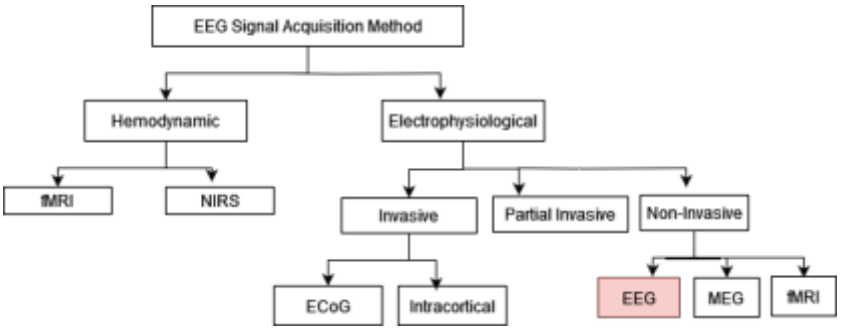

Fig. 1.1: BCI Signal Acquisition Methods

are demonstrated for improved learning skills using neurofeedback. The results also show improved academic skills through frontal beta waves. Neurofeedback supports volitional regulator brain activity using non-invasive recordings. The learning ability gets reinforced subconsciously by changing the brain wave excitation. By generating electrical movement over a procedure of extent and strengthening, the brain absorbs to administer and achieve higher concentration levels. Cognitive neuroscience enables learners to comprehend how their brains function for decision-making, awareness, thought processes, and behavior.

1.5. Brain-Computer Interface. A direct communication channel between the brain and a computer or other external devices is made possible via Brain-computer Interfaces (BCI) [12]. They have potential uses in various domains, including rehabilitation, affective computing, robotics, gaming, and neuroscience, and they provide a greater degree of flexibility by enhancing or replacing human peripheral functioning capability. A brain-computer interface (BCI) is a computer system that gathers, analyzes, and translates brain signals into commands that are transmitted to an output device to carry out a desired action. Therefore, BCIs do not use the brain's usual output channels, which are peripheral nerves and muscles. The term "BCI" describes equipment that uses and monitors signals produced by the Central Nervous System (CNS). EEG equipment can be used to provide an interface between a computer and the human brain. An EEG machine captures brain waves without generating an output that modifies the user's surroundings. The signal is acquired by placing sensors (electrodes) that read the amplified electric charge [40]. The brain neurons excite, producing a small amount of electric current that is amplified and collected through the electrodes using a noninvasive method as described in Fig.1.1. This work projects the use of the invasive method under electrophysiological activity. Spontaneous signals are gathered through BCI to study EEG patterns connected with the cognitive features of brain mapping [37]. For BCI applications, signals can be acquired using a variety of techniques, such as:

- *EEG:* EEG is the most popular technique for gathering signals for BCI applications. EEG electrodes are applied to the scalp to assess the brain's electrical impulses. Signal processing and relevant characteristics are extracted and used to operate the computer or other external devices.
- *fMRI:* Functional Magnetic Resonance Imaging (fMRI) analyses changes in brain blood flow using radio waves and a magnetic field. These modifications are used to infer brain activity and for BCI applications.
- *Electrocorticography (ECoG):* Electrodes are positioned on the outermost layer of the brain to record electrical activity. Compared to EEG, this method offers a higher spatial resolution when used in research and therapeutic contexts.
- *Magnetoencephalography (MEG):* MEG is the process for determining the magnetic fields generated by brain electrical activity. This technique is applied in research settings and offers excellent temporal and geographical resolution.
- *Near-Infrared Spectroscopy (NIRS):* NIRS analyzes variations in the brain's blood's oxygen and carbon dioxide levels. The approach can be applied in real-life situations and is non-invasive.

Fig.1.1 depicts different methods used to acquire the brain signals.

1.6. Research Contributions. To improve adaptivity in e-learning systems, this study explores the potential of NeuroSky's Mindset headset as a non-invasive technique for monitoring attention and meditation levels. Incorporating Brain-Computing Interface (BCI) assessments into an e-learning environment allows tracking variations in learners' preferred perceptual learning modalities, which are classified according to the VARK model (Visual, Auditory, Read/Write, and Kinesthetic). The following comprise the research contributions of this paper:

- A pioneering cognitive neuroscience model that leverages BCI signal analysis to enhance learning abilities in students. This model offers a novel pathway toward optimizing educational outcomes by integrating neuroscience principles with technology.
- With the awareness of each student's distinct brain patterns, teachers can facilitate their lesson plans and content delivery techniques to optimize learning outcomes and foster a more productive and diverse learning environment.
- Clustering algorithms are deployed to identify similar trends and preferences among students by organizing them into discrete clusters based on comparable learning characteristics.

2. Related Work. Cognitive ability, which includes functions like attention, memory, and reasoning ability, refers to the capacity of the human brain to process, store, and retrieve information. It is currently one of the most researched and stable determinants of academic performance. This section discusses the evolution of the application of brain signals to identify individuals' learning styles.

Acquisition of brain signals solves the challenge of perceiving what actually exists in the brain. The acquisition of the signals, interpretation, and analysis of the signals affect the derivation of the learning ability of the user [34]. Signal acquisition prompts complex processes in some of the brain areas. An indigenous current is engendered when neurons are elicited. The potential difference is amplified and collected as EEG waves. These signals are produced during the synaptic movement of the dendrites in the brain's cerebral cortex, as suggested in [2]. The membrane potential directed in the direction and inflated through channels entails mostly sodium, potassium, calcium, and chlorine ions [37]. According to the authors of [39], a BCI machine that performs pattern recognition and signal processing can infer signal activity from the brain. As per the work proposed in [30], BCI can be seen as a communication scheme expediting individuals to connect with their environments during the segment where the operation of peripheral nerves and muscles does not transpire.

Researchers in [41] proved that BCI constructs a different strategy of connecting an individual's brain signals to peripheral devices such as computers, synthesizers, and assertive appliances by accessing the sensory-motor nerves channel for relaying the brain signals. As discussed in [28], cognitive neuroscience improves academic performance by predicting the impact on learning styles. A range of neuropsychological tests and training are used to assess cognitive function in patients with brain injuries while they are receiving treatment. However, considering the typical problems that patients have, problems with ecological validity arise. As per the research presented in [14], a spatial memory task may be incorporated into any virtual environment and has good ecological validity. For the purpose of performing trials to uncover cognitive impairments by personalizing surroundings and target objects for each user, both healthy individuals and those with brain injuries were taken into consideration.

In [38], a game-based approach is suggested to assess and improve cognitive abilities. The characters in the game use varying positions to evaluate the players' attentiveness. If the learner's attention is diverted, the game exits, making the player pay full attention. A significant improvement was observed in learning abilities through such cognitive games. The work in [46] delves into nine well-known effects, three from each of the areas of perception/action, memory, and language — and discovers that they are quite dependable. They can be replicated not only in online settings but also with non-native participants without the effect size being diminished. This work concluded that some cognitive tasks are sufficiently constrained to capture behavior from outside influences, such as the testing environment and recent prior experience with the experiment, to produce extremely robust effects.

The learning style is a conventional communication style that monitors and articulates the information and builds behavioral patterns. The lead to determining the learning styles in a classroom setting can predict the available data into meaningful information for customization of learning. When a facilitator is teaching, accessing learning styles is challenging and competitive. Learning styles reflect how learners accept and choose

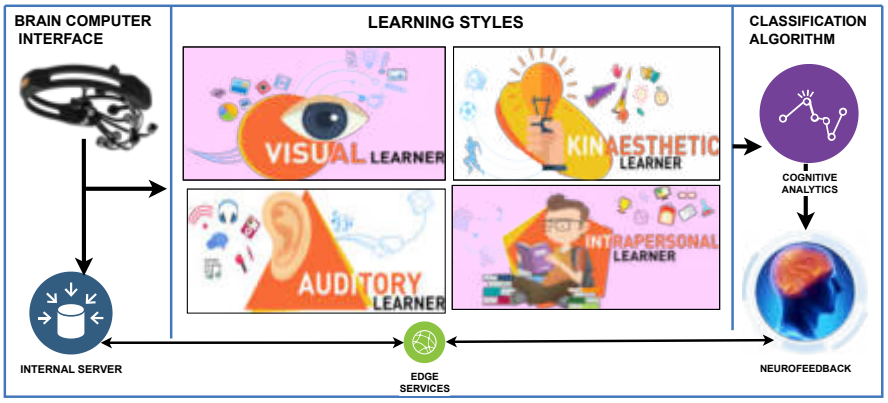

Fig. 3.1: Proposed Framework for Human Cognition Assessment through BCI

to comprehend, establish, and replicate the content. Cognitive psychology outlines learners' variances in the attainment of knowledge and their impression of the content and retrieval of information. Ultimate wisdom for beginners contrasts understanding, viewpoint, and alertness in the present scenario and is described in the association of intellectual senses. The detectable learning index is the pattern the learner inhibits while acquiring content. The learning index demonstrates the ideal way for beginners to obtain proper knowledge. Technically, an individual's learning style is a distinct way through which the learners understand the attention techniques and embrace the content. It is essential to find digital markers for the attention span of the learners to understand their learning behavior.

Table 2.1 provides the summary of the existing work in the domain of identification of people's learning styles using BCI. This summary highlights the input and statistical methods utilized by various studies, the Machine Learning (ML) or Deep Learning (DL) models employed, evaluation metrics, and the learning styles considered for the study. This table also compares our proposed approach with the existing ones and shows how it differs regarding the parameters mentioned above.

3. Proposed Framework. Our proposed framework consists of a model to identify a learner's learning style by acquiring EEG signals from the brain. As shown in Fig.3.1, the framework is implemented in two phases. The first phase involves the acquisition of brain signals, followed by a phase that determines the user's learning ability. The outcome generated by the first phase is provided as input to the subsequent phase.

The activities associated with both phases of our proposed framework are as follows:

- **Phase 1:** This phase is responsible for collecting the brain signals to evaluate the learners' cognitive abilities.
- **Phase 2:** Based on the acquired brain signals in the first phase, this phase attempts to decipher the learning abilities by computing the DLI (Detectable Learning Index). This index is essential to determine the attention span of learners as well as to obtain Neurofeedback from them. Learning styles are identified for each subject based on the processing involved in this phase.

The application scenario in our framework is a complete method for obtaining and analyzing electroencephalography (EEG) signals straight from the brain to determine each learner's distinct learning style. Enhancing student performance and cognitive development can be achieved by fostering more effective and engaged educational experiences through an understanding of and accommodation for varied learning styles.

3.1. Learning Styles. As per the VARK model of learning, different learning styles for learners are depicted in Fig.3.2. Most subjects follow any one or more of the following learning styles: Visual (V), Aural or Auditory (A), Reading/Writing (R/W), and Kinesthetic (K). The fundamental characteristics of learners having different learning styles are discussed below:

- *Visual (V):* As their name implies, visual learners retain information better when they see it. They like information to be presented in an eye-catching way. This type of learning usually involves paying great

attention to details and nonverbal cues, as well as mentally imagining scenarios to help with knowledge processing.

- *Aural (A):* Information is frequently retained more easily by auditory (or aural) learners when it is heard. Rather than actively engaging in class or taking notes, they usually find it easier to listen to others explain the information and can usually regurgitate it back to them.
- *Reading/Writing (R/W):* When new knowledge is delivered in the form of words and text, those who favor reading and/or writing as their preferred learning styles usually retain it the best. They like

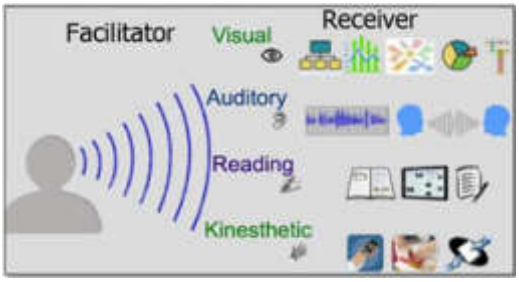

Fig. 3.2: Learning Style Classification (VARK)

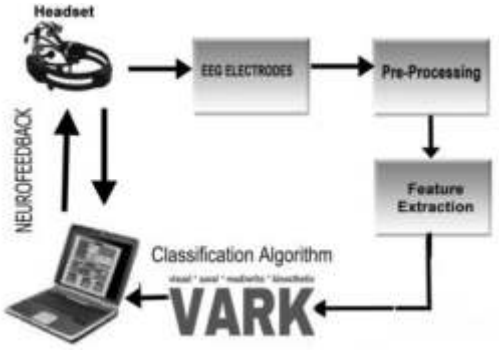

Fig. 3.3: Workflow of the Proposed Framework

reading definitions, compiling information into lists, and synthesizing it in ways that make the most sense to them.

- *Kinesthetic (K):* Kinesthetic learners acquire knowledge through "trial and error" methods. Therefore, for them, practical experience is essential. To better understand how things work, they like to work out physically and handle things directly.
- *Multimodal (M):* Some learners don't have any strong preferences when it comes to learning styles. They adjust to the requested or in-use style as they learn. Typically, multimodal preferences are VARK combinations. Using more than one of the above-mentioned learning styles is necessary. Any two learning styles, for instance, Visual and Kinesthetic (VK), can be combined to create a bimodal VARK style. Any three learning styles can be combined to create a trimodal VARK style. For example, consider a trimodal combination of Kinesthetic, Read/Write, and Aural (ARK). Some individuals with multimodal learning styles find that learning and communicating need the use of multiple styles. Using just one learning style makes them feel insecure.

3.2. Identification of Learning Styles. To identify a person's learning style, our proposed framework implements four major processes that are mapped with the two phases, as discussed previously. The list of these processes is as follows:

1. Extracting cognitive signals through EEG
2. Pre-processing EEG signals
3. Feature Extraction from pre-processed signals
4. Categorization of signals using Clustering

These processes are depicted in Fig.3.3 and described in the following subsections.

3.2.1. Extracting Cognitive Signals through EEG. Dynamic activity in the brain involves neural arrangement processing and circulation of neural activity. The chemical changes in the brain's grey matter

indicate cognition, which occurs during the excitation of neurons [18]. The potential of neuroscience is to find the relation between the external activity taking place and the effect of the same on the neuron information. The information is processed in the brain trails while executing cognitive tasks such as understanding, interpreting, and analyzing.

The cognitive data can be collected using different methodologies like placing dry electrodes or wet electrodes on the scalp [3] [17] [9]. Such non-invasive methods are usually used for academic tracking purposes. Depending on the chemical and electrical changes occurring in the brain, cognition processes like perception, memorization, understanding, developing insights, and reasoning are evaluated. Learner attention is often stimulated by playing cognitive games that require full attention while using BCI devices.

In the proposed framework, EEG signals are acquired from the headset that has three dry electrodes. These electrodes are positioned on the forehead of the subject and used to send or collect the amplifying signals. In this case, these electrodes serve as a touching base point for the reference electrode placed at the ear lobe. A microcontroller connected with these electrodes via Bluetooth acquires and interprets the signals.

The EEG equipment is connected to a computer via Think Gear software. The appropriate functions corresponding to the supplement of the instinctive mind are distinguished by a headset complemented by the NeuroSky Think Gear sensor. It spurts as a backdrop procedure progressively charging a wide computer system outlet through granting requests from the other domain to join. The solicitations accumulate instructions from the associated Think Gear.

3.2.2. Pre-processing of EEG Signals. In order to collect and process brain signals, modern BCI technology makes use of wireless headphones as well as portable interfaces and processing equipment. The degree to which subjects are able to comprehend the material is determined by their spatial memory recall dimension. BCI technology, which uses hardware and software-based communication systems to enable humans to interact with their surroundings without using peripheral nerves or muscle inputs by using control signals produced from EEG activity, is widely used to measure spatial memory. It is based on the calibration of electrical signals that reflect and measure different types of brain activity.

When a brain is actively engaged or paying attention, it emits a signal that is known as an ”attention signature.” In the learning environment, a facilitator/teacher needs to understand students' learning styles that are directly proportional to their attention signatures.

The headset continuously analyses the data, producing alpha, beta, and other waveforms that are output to the EEG power spectrum. In addition to the eye blink, values for attention and meditation are recorded. The artifacts are removed, and the concentration focus is interpreted in the sale of 1-100. The acquired values are split into three thresholds; the range 0–20 is classified as being below the attention span threshold. The range of improvement in achieving focus is defined as being between 20 and 40. Range values of 40–60 are regarded as unbiased. High attention value values are defined as those with a measurement above 60.

3.2.3. Feature Extraction. The input data acquires features of the frequency domain, such as head movement, eye blinking, and alpha, beta, gamma, and theta waves. Beta waves are the EEG signals associated with cognition. To distinguish between the normal and abnormal waves in EEG signals, feature extraction is applied using Principal Component Analysis (PCA) and Blind Source Separations (BSS) [16] [22]. Since beta waves indicate a learner's attention and focus, acquired signals must be categorized into distinct thresholds according to the standard frequency to determine cognitive development [23].

The feature vector has been trimmed to reduce the complexity of the feature extraction process without sacrificing any pertinent information. Therefore, optimal discrimination features are essential for deciphering the learner's learning style pattern and practically recognizing various patterns.

3.2.4. Categorization of Signals through Clustering. This stage aims to identify the subject's learning style by classifying their brain signals into different categories based on the pre-determined range of frequencies. Table 3.1 shows the brain signals with their frequency ranges. This table and Fig.3.4 depict that each frequency range corresponds to a specific category of brain waves and particular types of activities. Based on this frequency range specification, the acquired EEG signals are categorized as Delta, Alpha, Gamma, Beta, and Theta.

Every brain signal has a state of mind linked with it, and there are two categories for every frequency, such

Table 3.1: Frequency Range of Brain Signals

Brain Signal Category	**Frequency Range**
Alpha	8 - 13 Hz
Beta	14 - 30 Hz
Delta	$<$ 3.5 Hz
Gamma	30 - 100 Hz
Theta	4 - 7 Hz

Table 3.2: States of Mind associated with different types of Brain Signals

State of Mind	**Brain Signal Category**
Relaxation (Meditating/Daydreaming/Mental Readiness)	Alpha
Alert (Engaged in learning/problem-solving/mentally challenging tasks)	Beta
Sleep (Dreaming/Deep Sleep)	Delta
Anxiety (Depression, Stress)	Gamma
Deep Relaxation (light sleep/drifting off to sleep)	Theta

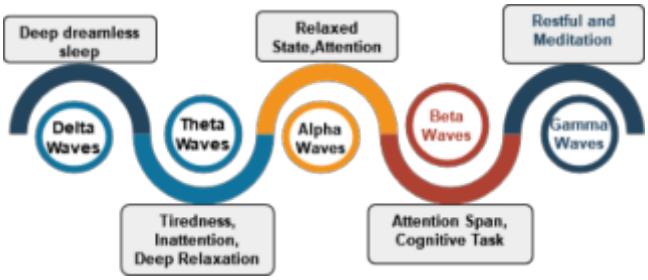

Fig. 3.4: Classification of Brain Signals

as spikes and field potential [25]. Based on this, the brain distinguishes between various forms of learning styles. From Table 3.2, it is evident that learning and maintaining high concentration cause beta waves to be produced. Here, we use the Detectable Learning Index (LI) to determine the learning style based on the frequencies of beta waves. In our experimental setup, the participants were given different types of activities that generated beta waves. Different clustering methods were then used to identify individuals' learning style preferences.

3.3. Proposed Algorithm. The algorithm followed by our proposed framework consists of a total of 7 steps. The exact sequence of these steps is explained below and depicted in Fig.3.5:

Step 1: The BCI data signals are collected through wearable headsets.

Step 2: The signals are converted into the CSV format by excluding artifacts like eye-blink and head movement through signal pre-processing techniques.

Step 3: X is the variable to check whether the headset's connection is established; the value of X is assigned as 1 if the connection is established.

Step 4: The signals are further classified as "Beta waves," signifying attention span and cognitive ability.

Step 5: The signals are recorded with a notation of a special number delegated to the learner to avoid demographic details.

Step 6: The signals are collected at a span of 1 second, the recorded signals are obtained for the planned time, and the software will store the signals in CSV format.

Step 7: Check the value of X. If X is 1, repeat the entire process. End the data collection process if X

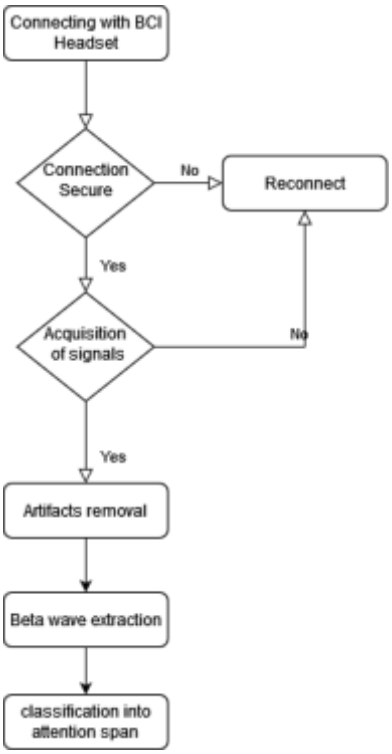

Fig. 3.5: Proposed Algorithm

changes or the connection is lost.

4. Results and Discussions. After the EEG signals are categorized, an analysis is conducted to see how Bloom's taxonomy and Kolb's [19] observable learning styles relate to one another. It is widely recognized that Kolb's learning style model can help improve performance, particularly in higher education. Kolb proposed the idea that individuals have varying preferences regarding learning methods. The choice of learning style is determined by combining two distinct learning styles. This section discusses the experimentation-related details and results obtained. Performance analysis is also presented in this section.

4.1. Experimental Setup. The main objective of our work is to determine how students' academic performance improves when they can reason, apply, and create in the higher order of Bloom's taxonomy when they are aware of their capacity for learning. The statistics clearly state that learners mostly furnish their learning styles in the prime years of education. Modifications of teaching strategies that involve both intellectual and practical learning should be considered to meet the needs of students.

Our experiment involved 280 healthy students from an educational institute in Gujarat, India. These undergraduate students were enrolled in a technical course in the domain of computer engineering and participated voluntarily in this study. The participants were aged 18 to 25. Out of 280 students, 168 were male, and 112 were female. The Gujarat region was divided into three subregions: North Gujarat, South Gujarat, and Middle Gujarat. Regional data was collected to check if it impacted the participants' attention levels or learning styles.

The Neorosky EEG sensor was placed at the forehead of the participants. The experiment was conducted in a quiet setting without any noise. Before being permitted to record their brain EEG signals, participants were instructed to take deep breaths and calm themselves down. Then, the participants were provided with different kinds of content, including visual images or pictorial data, aural or audio recordings, a manuscript for reading, and puzzles to solve. While going through the provided visual, aural, reading/writing, or kinematic

Table 4.1: Clustering Methods

Clustering Method	Number of Clusters	Learning Style
DBSCAN	3	V, A, K
Simple K-Means	4	V, A, K, M
Hierarchical	4	V, A, K, M

content, participants continually produce Beta waves at one-second intervals for two minutes.

Using the NeuroSky EEG headset, the brain waves were recorded for a total of 122 seconds. Here, the first and last seconds were used to begin and end the recording of EEG signals. The collected signals database comprised 34160 entries, 280 rows representing the participants, and 122 columns representing seconds.

During the experimentation, it was found that every participant generated a unique EEG brain wave. The EEG brain waves collected through EEG sensors varied largely. Hence, the normalization of EEG brain signals was performed prior to their classification. The amplitude of Beta waves was higher in response to the provided visual, aural, reading/writing, or kinematic learning material based on the preferred learning style of the participant. Based on such patterns, our proposed framework categorized learners as visual (V), aural (A), strong readers (R), kinematic (K), or multimodal (M). During our testing period, visual learners produced a higher range of Beta waves when they were presented with pictorial data or visual images. Auditory learners responded with high Beta waves when they listened to audio recordings. Strong readers produced high amplitude for Beta waves when they were given a manuscript to read. The frequency of Beta waves was higher when kinematic learners attempted to solve the given puzzles. A few learners showed high Beta waves for more than one type of content; hence, they were identified as multimodal learners. Some visualizations of brain signals generated from the NeuroSky EEG headset are presented in Fig.4.1 for different categories of learning styles.

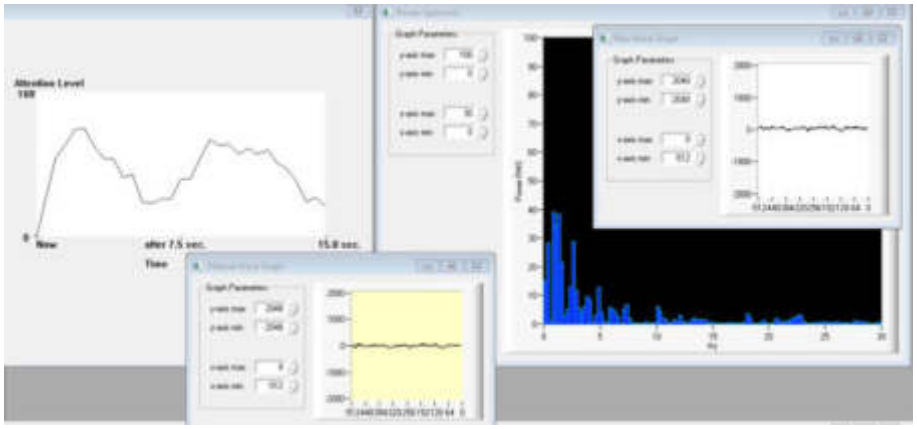
4.2. Clustering for Classification. Clustering is an essential tool for classification problems because it enables preprocessing and feature engineering. We applied three popular clustering algorithms to group participants into clusters based on their respective learning styles: K-means Clustering, DBSCAN Clustering, and Hierarchical Clustering. Participants were divided into four clusters: Cluster 1 for visual learners, Cluster 2 for auditory learners, Cluster 3 for kinesthetic learners, and Cluster 4 for multimodal learners. Table 4.1 represents the clustering methods employed, the number of clusters generated, and the corresponding learning style for the three clustering algorithms.

4.2.1. K-means Clustering. K-means clustering [13] is one of the most commonly employed unsupervised machine learning algorithms for grouping data points into clusters or groups according to similarity. For clustering learners based on their preferred style of learning, the following steps were used to perform K-means clustering:

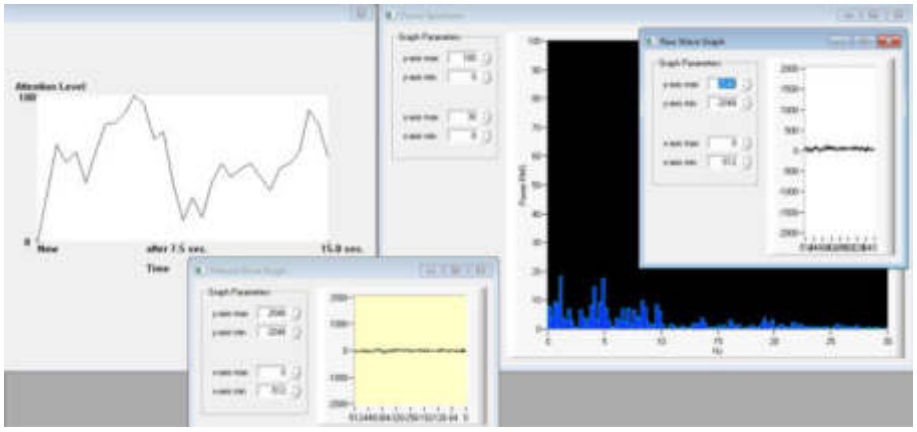
- Choose K data points at random as the initial cluster centroids from the dataset.
- Using Euclidean distance, assign each data point to the cluster whose centroid is closest to it.
- Recalculate the cluster centroids using the average of the data points allocated to each cluster.
- Repeat the assignment and centroid update processes until convergence (when the centroids no longer vary appreciably or a predetermined number of iterations is reached).

Fig.4.2 presents the visualization of the clustering performed by the K-means clustering algorithm. The centroids, represented by points in red at coordinates (centroids[:, 0], centroids[:, 1]), are overlaid on the plot. The data points (X[:, 0], X[:, 1]) are colored according to their respective clusters, with each cluster corresponding to one of the following learning style preferences: Visual, Audio, Kinesthetic, and Multimodal. Table 4.2 shows the confusion matrix for the K-means clustering. There are four clusters considered here. Learning Styles included in this algorithm are four, namely auditory (A), kinesthetic (K), visual (V), and multimodal (M). Participants exhibiting a specific learning style are assigned to the corresponding clusters.

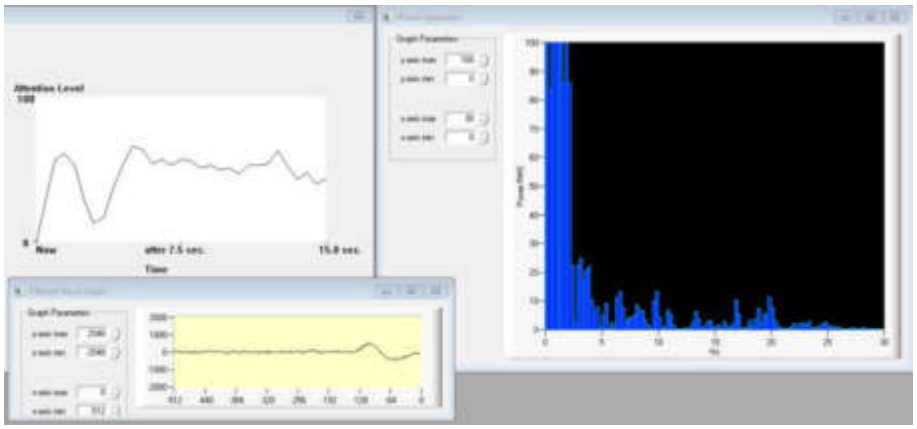
4.2.2. DBSCAN Clustering. The widely-used clustering technique DBSCAN (Density-Based Spatial Clustering of Applications with Noise) [11] is used in machine learning to find clusters in a dataset that vary



(a) Aural



(b) Visual



(c) Multimodal

Fig. 4.1: Visualization of Brain Waves for Visual, Aural, and Multimodal Learning Styles

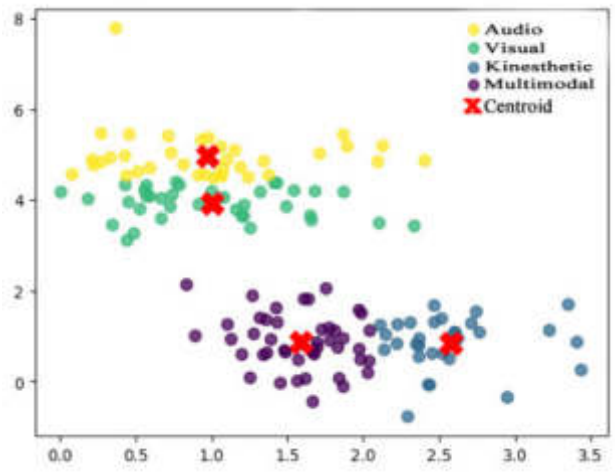


Fig. 4.2: Visual Representation of K-means Clustering

Table 4.2: Confusion Matrix for K-means Clustering

	Cluster Number				
Learning Style	0	1	2	3	**Total**
K	41	15	0	28	84
A	0	36	0	35	71
V	34	0	27	22	83
M	14	11	0	15	40
Total	89	62	27	100	

in size and shape. This clustering algorithm can detect clusters of arbitrary shape or size without having prior knowledge of the number of clusters. In our experiment, the following steps were followed to apply DBSCAN clustering:

- Choose a data point at random.
- Recursively build a cluster by adding all reachable core points to it for each core point or boundary point that hasn't been allocated to a cluster yet.
- A cluster comprises all the points that can be accessed from a central location. Noise is defined as any unassigned points that remain.

Fig.4.3 illustrates the result of DBSCAN clustering algorithm. The confusion matrix for the DBSCAN clustering is shown in Table 4.3. Each item in the matrix denotes the number of instances the algorithm assigned to a specific cluster. The numbers 0, 1, and 2 designate the clusters. The table's rows correspond to the four learning styles — auditory (A), kinesthetic (K), visual (V), and multimodal (M). The columns of the table correspond to the various clusters. There are 70 instances when the DBSCAN approach has resulted in an inaccurate clustering. In Cluster 0, there are 37 outlier data; in Cluster 1, there are 2 outlier data; and in Cluster 2, there are 24 outlier data.

4.2.3. Hierarchical Clustering. Another popular clustering technique for hierarchically grouping related data points is hierarchical clustering [21]. The steps that were used to implement the hierarchical clustering algorithm for our experimentation are listed below:

- Assign every data point a cluster of its own. Every data point is first regarded as a singleton cluster.
- Determine the distance or similarity between every two clusters.
- Using the selected distance or similarity measure, identify the two nearest clusters.

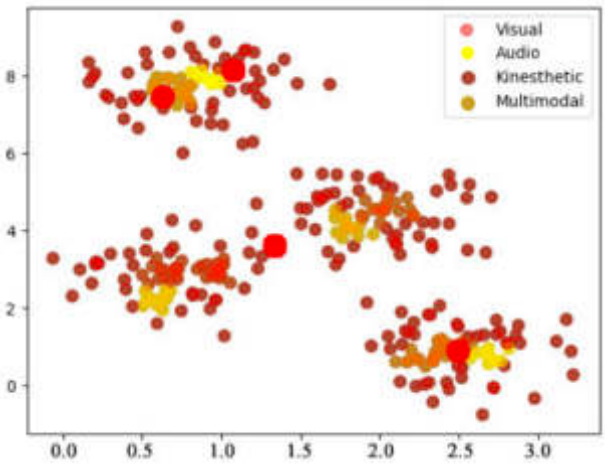

Fig. 4.3: Visual Representation of DBSCAN Clustering

Table 4.3: Confusion Matrix for DBSCAN Clustering

	Cluster Number			
Learning Style	0	1	2	**Total**
K	44	0	18	62
A	0	0	29	29
V	27	30	0	57
M	14	5	6	25
Total	85	35	47	

Table 4.4: Confusion Matrix for Hierarchical Clustering

	Cluster Number				
Learning Style	0	1	2	3	**Total**
K	26	0	0	36	62
A	0	29	0	0	29
V	8	0	49	0	57
M	11	12	0	0	23
Total	45	41	49	36	

- Determine the new cluster's distances and similarities to every other cluster again.
- Until there is just one cluster left, or until there are four clusters total, keep merging the nearest clusters and updating the distance matrix.

The number of clusters for this algorithm is four. These clusters are labeled as clusters 0, 1, 2, and 3. Four learning styles are considered here. Auditory (A), kinesthetic (K), visual (V), and multimodal (M) are learning styles for which the clusters are formed. The performance of the Hierarchical clustering is found to be almost similar to the performance of the DBSCAN algorithm. The visual representation of the hierarchical clustering is depicted in Fig.4.4. Table 4.4 represents the confusion matrix for the hierarchical clustering.

4.2.4. Performance Evaluation. By comparing an object's similarity to its own cluster to that of other clusters, a silhouette score is a technique for evaluating the quality of clusters created by a particular algorithm [4]. Every data point is given a silhouette coefficient, with values ranging from -1 to 1. An object is well-matched

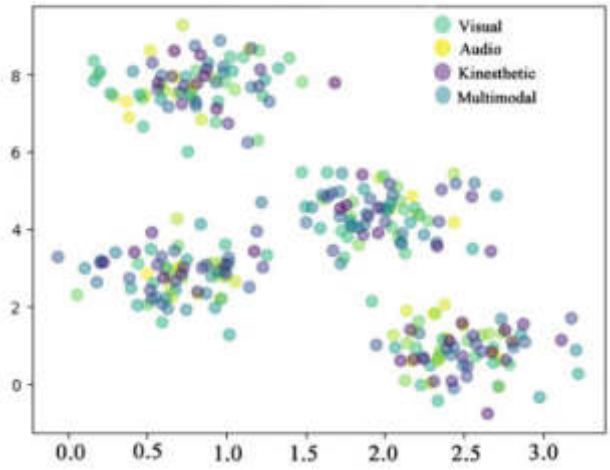

Fig. 4.4: Visual Representation of Hierarchical Clustering

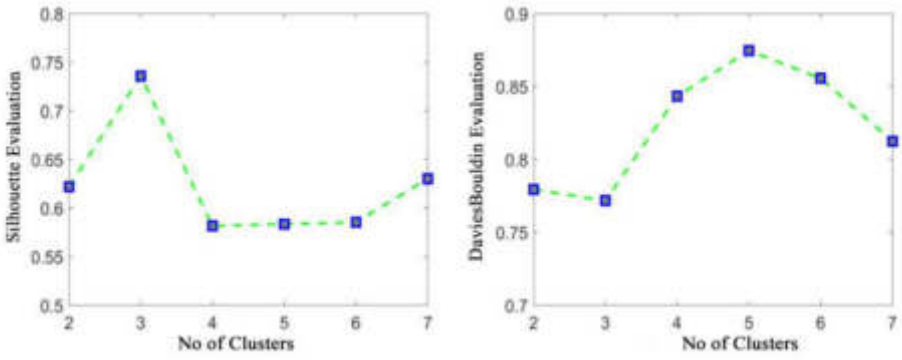

Fig. 4.5: Comparision of Silhouette Score and Davis-Bouldin Index

to its own cluster if its silhouette coefficient is high and poorly matched to neighboring clusters if it is low.

Another matrix for evaluating cluster quality is the Davis-Bouldin index [4]. It serves as a criterion for selecting and validating clusters. The average distance between each cluster point and its centroid is determined for each cluster using the Davis-Bouldin index. Additionally, it calculates how similar each pair of clusters' centroids are to one another. The ratio of within-cluster dispersion to between-cluster similarities is averaged to get the index.

Both these metrics are essential for assessing and improving clustering results, providing the opportunity to decide which clustering algorithms are most appropriate and effective for the given scenario. The outcome of both these metrics are shown in Fig.4.5. Better clustering quality is indicated by lower values for the Davis-Bouldin index, whereas higher values indicate poor clustering quality. Values approaching +1 for the silhouette score imply better clustering, whereas values closer to -1 indicate potential issues with clustering. Fig.4.5 shows that the DBSCAN clustering method outperforms the other two clustering methods.

4.3. Detectable Learning Index (DLI). When beta wave generation is higher for a given amount of time, learners are practically adapted to raise their degree of concentration. Our study highlights that technical undergraduate students will become more proficient learners if they can identify their learning preferences. During our experiment, the outcomes obtained regarding the participants' learning styles are shown in Table

Table 4.5: VARK Cognition Values of Participants

Sr. No.	V	A	RW	K	Max	Min	DLI	P	Va
1	78.59	52.67	70.48	64	78.59	52.67	Video	Video	T
2	61.64	57.73	58.46	58.78	61.64	57.73	Video	Video	T
3	63.91	44.36	68.57	66.18	68.57	44.36	RW	RW	T

7	67.58	78.21	58.68	52.78	78.21	52.78	Aural	Aural	T
8	33.42	74.83	70.6	58.25	74.83	33.42	Aural	Kine	F
9	33.26	74.83	58.68	52.78	74.83	33.26	RW	RW	T
10	43.43	45.32	31.15	40.7	45.32	31.15	Aural	Kine	F

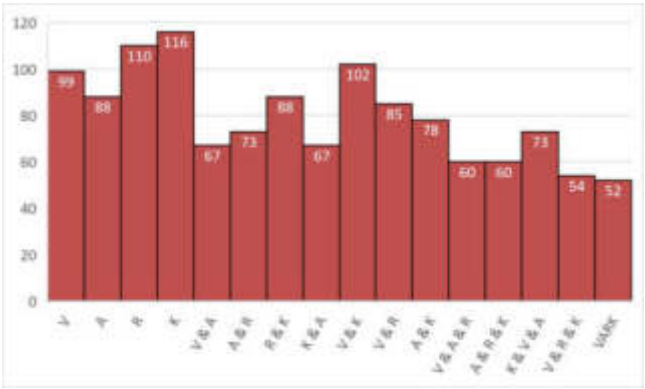

Fig. 4.6: Detectable Learning Index (DLI) for Four Sessions

4.5 for 10 students. Each row represents the values obtained for a particular participant.

For 10 participants, Table 4.5 includes columns for cognition values for V, A, R/W, and K learning styles, Maximum (Max) and Minimum (Min) of the cognition values, the DLI (Detectable Learning Index), actual learning preference of the participant (P) and the result of the validation (Va). The eSense algorithm of NeuroSky was used to obtain the cognition values for V, A, R/W, and K learning styles. The level of mental "focus" or "attention" is indicated by this algorithm. It represents a range of cognitive operations in the form of values. These values range from 0-100 and are sampled at the rate of 1 Hz for 2 minutes. When participants concentrate on the given content, their attention level rises; when they become distracted, it falls. The average of the attention level values are presented in Table 4.5 when the participants were given different types of learning materials.

The DLI represents the learning style computed by our proposed framework. For a total of 280 participants (N=280), four learning styles, Visual (V), Auditory (A), Reader/Writer (R/W), and Kinesthetic (K) are considered for generating the DLI. As discussed in the previous section, different clustering methods were used to identify the learning style, and based on this, the DLI was obtained. To validate the obtained DLI values, the actual learning styles of the participants were used as they provided them. The DLI values were compared with the actual learning styles of the participating students. If these two matched, the result of the validation, as depicted in the last column of Table 4.5, Va (Validation), was marked T (True), otherwise F (False).

In our experimental setup, the sample size N is 280, for which the statistical analysis has described a confidence level of (95%) with a margin of error of (5%). Out of 280 participants, 180 students (64.19%) were validated through a single learning modal, and 243 students accommodated the multi-modal learning style, resulting in 87% of students. The statistics show that of the learners with a single preferred skill (n=187,

Table 4.6: Detectable Learning Index (DLI)

Single Modal 64.19%	**Bi-modal 46%**	**Tri-modal 30.9%**	**Multi-modal 24.8%**
V-67%	VA-34%	VAK-3.8%	VARK-24.8%
A-45%	AR-32%	KVA-50.6%	
R-66%	VR-54%	ARK-28.3%	
K-77%	AK-52%	VRK-24.45%	
	VK-56	VAR-28.3%	
	RK-60%		

Table 4.7: Pearson Correlation Analysis

Parameter	**Pearson Correlation Co-efficient**	**Mean**	**Standard Deviation**
Gender	0.01	0.70	0.46
Stream	0.0123	0.02	0.27
Region	0.014	1.47	0.63
Age	0.065	19.21	1.09

67%) were engrossed in visual style, 126 learners (45%) had high Beta wave spikes while listening to the given content. 183 out of 280 learners (65.24%) have shown a high focus level while reading and writing to a given program, 193 learners, constituting 69.24% out of the complete sample size, have shown a high concentration level while subjected to debugging a program as presented in Table 4.6. This table shows the percentage of participants identified with specific learning styles based on their DLI that can be categorized as single-modal (a single learning style), bi-modal (a combination of any two learning styles), tri-modal (a combination of any three learning styles), and multi-modal (a combination of more than three learning styles).

4.4. Correlation between Learning Style and Demographic Parameters. In our study, the students who volunteered were 18 to 25 years old. The total count of participants was 280, out of which 168 students were male and 112 were female. We selected participants from the three regions of the Gujarat state: North Gujarat, South Gujarat, and Middle Gujarat. To assess whether any correlation exists between students' learning styles and parameters like Gender, Age, and Region, we applied a popular correlation method, Pearson Correlation [24]. The mean, standard deviation (SD), and Pearson Correlation Coefficient values computed for these parameters for all 280 participants are shown in Table 4.7.

The degree of the linear relationship between the two variables was determined by the Pearson correlation. It ranges from -1 to 1, where a value of -1 indicates a total negative linear correlation, a value of 0 indicates no correlation and a value of +1 indicates a total positive correlation. The Pearson correlation coefficient determines the degree of the linear relationship between two variables. A two-tailed test determines if a sample is more or less than a range of values by using a critical area with two sides of a distribution. The Sig(2-tailed) p-value was used to determine if the correlation was significant. Table 4.7 depicts the correlation obtained between different parameters associated with the learners.

As indicated in Table 4.8, the Pearson Correlation coefficient was computed to determine the independence of age with respect to the attention level. The results of the two-tailed test showed a value of -0.149, which is significantly lower than 0.5 and indicates no association between age and the observed attention levels for Beta waves and the learning styles. If each learner is given a unique learning environment, they all possess the same capacity for learning.

Table 4.8: Correlation between Student Age and Learning Style

		Age	**Learning Style**
Age	*Pearson Correlation*	1	-0.149**
	Sig. (2-tailed)		0.013
	N	280	280
Learning Style	*Pearson Correlation*	-0.149**	1
	Sig. (2-tailed)	0.013	
	N	280	280

4.5. Discussions. Our work indicates that undergraduates studying computer learning are simply accustomed to diving right into the practicals before fully grasping the concepts. Thus, the four learning styles — V, A, R, and K — are considered in this work. To prepare the teaching material or course content based on students' preferred learning styles, the following recommendations can be useful:

- V - Visual capability of the learners to understand through pictures, charts, differences in images, movies, figures and codes, and flowcharts.
- A - Aural/Auditory capability to understand from Audio clips, Podcasts, Group Study, and Audio Books.
- R/W - Reading/Writing capability of learners to comprehend manuscripts, programs, algorithms, textual descriptions, subject reference books, etc.
- K - Kinesthetic learners have the ability to solve problems through coding, debugging, and practical implementation. Such techniques should combine visual and/or auditory learning styles to emphasize multi-sensor learning.

5. Limitations and Future Scope. The proposed framework has a few limitations. The sample size of 280 learners may not be adequate to forecast the overall learning style of all the students enrolled in a particular course. Future research may include more learners to assign to the appropriate learning styles. Furthermore, the impact of various parameters associated with learners, such as prior domain knowledge, students' social and economic status, and other distinctive features, should be considered for improved accuracy. Additionally, in this work, the learning styles are derived only from EEG signals. Integrating additional learning assessment characteristics, such as body language, sign language, and facial expressions, can enhance the effectiveness of the teaching-learning process in real-world educational setups. Also, longitudinal data can provide insights into the sustainability and persistence of the observed enhancements in student learning.

6. Conclusions. This paper investigates the relationships between students' brain waves and their respective learning styles. Our proposed framework categorizes students based on their VARK learning styles. The participants are given different types of learning material for two minutes to understand their inclination towards specific learning modes and styles. Participants' beta brain waves are captured while they go through the visual, auditory, reading/writing, or kinesthetic content, and a database for the same is generated every second. Machine learning clustering algorithms such as K-means, DBSCAN, and Hierarchical are used to validate this dataset. This proposed approach proves to be a significant addition to the conventional teaching-learning paradigm for improved level of learning. Our research also established that various parameters associated with students, such as age, gender, region, etc., do not significantly correlate with their learning style preferences.

Due to the dissimilarities of the learner's understanding approach in the technical domain, it is recommended that the design of the course content, study material, and teaching methodologies be in a direction that befits the requirements of learners. Academic productivity will increase as a result, and the course outcomes will get better. Furthermore, considering that the practical training is hands-on, it is suggested that the related activities be included in the course curriculum. The study finds that if a learner's preferred learning style is determined, it will help them absorb information and turn it into knowledge. The student will be able to concentrate as the knowledge is added, and the activity will start to seem like fun rather than a tedious chore. The neurofeedback will train the mind to become more perceptive and capable of handling expected and

unexpected malfunctions.

Learners can increase their efficiency by developing their natural cognitive ability. If the detectable learning styles follow instructional references with interactive problem-solving techniques, animations for kinematic learners, a graphical representation for visual learners, distinct color coding for reading/writing learners, and a storytelling approach for aural learners, an urge to learn can be enhanced. Machine Learning (ML) algorithms can be used to implement the analysis regarding the future scope of the study.

Data Availability Statement. The data supporting this study's findings are available on request from the corresponding author. The data are not publicly available due to information that could compromise the privacy of research participants.

IN THE EDUCATIONAL NEXUS: UNDERSTANDING THE SEQUENTIAL INFLUENCE OF BIG FIVE PERSONALITY TRAITS, MAJOR IDENTITY, AND SELF-ESTEEM ON ACADEMIC OUTCOMES THROUGH CLUSTERING ALGORITHMS

REBAKAH GEDDAM*, PIMAL KHANPARA†, HIMANSHU GHIRIA‡, AND TVISHA PATEL§

Abstract. This study investigates the relationship between the Big Five personality traits, major identity, self-esteem, and academic outcomes in education. It uses clustering techniques to examine the impact of these factors on students' academic performance. The research reveals unique patterns when considering personality traits, major identity formation, and self-esteem. The findings highlight the importance of considering these factors when understanding academic attainment trajectories. The study uses popular clustering methods like K-means, DBSCAN, and Hierarchical clustering to reveal latent clusters and provide unique profiles with different combinations of major identity orientations, personality traits, and self-esteem levels. The performance of clustering algorithms is also evaluated using standard assessment metrics. The findings offer insights into the sequential influence of these factors on academic outcomes, guiding the design of student-centric learning materials and providing a framework for promoting successful academic results through an all-encompassing strategy for student development.

Key words: Big Five personality traits, K-means Clustering, DBSCAN Clustering. Hierarchical Clustering, Academic Performance.

1. Introduction. Personality psychology is a discipline dedicated to examining human personality and individual variations. Emotional, behavioral, and cognitive patterns that are persistent, distinct, and consistent are characteristics that define an individual's attitude [11] [5]. These features not only help us understand human behavior in everyday situations better, but they also help us categorize others who have similar tendencies [22] [4].

Comprehending the complex dynamics of individual differences has become essential to optimizing learning outcomes in education [39]. The realization that learners possess a variety of cognitive and behavioral inclinations has sparked a paradigm shift towards personalized learning strategies, whereas traditional pedagogical approaches have concentrated on standardized methodologies. The comprehensive framework of the Big Five personality traits [27], a psychological foundation famous for clarifying the complex facets of human nature, is essential to enhancing students' learning abilities [36].

Academic achievement correlates with mental health and influences how a student's role changes when they move from student life to a professional career. According to the research [27], students who performed poorly academically also worried about not doing well on examinations and not graduating, which led to increased stress, worry, and sleeplessness and had a long-term effect on their mental health [24]. On the other hand, pupils who excelled in school made a smoother transition from school to the workforce, giving them an advantage in the job market [41].

The framework for categorizing and understanding human personality is the Five-Factor Model (FFM), commonly known as the Big Five personality traits [33]. These traits are broad aspects of personality that cover a variety of particular attributes and actions. The following five factors are:

1. *Openness to Experience (O):* This characteristic demonstrates a person's creativity, curiosity, and openness to new experiences. Individuals with low openness tend to be more conventional, pragmatic, and averse to change, whereas individuals with high openness tend to be creative, daring, and curious [13].

‡Department of Computer Science and Engineering, Institute of Technology, Nirma University, Ahmedabad, India
§Department of Computer Science and Engineering, Institute of Technology, Nirma University, Ahmedabad, India

2. *Conscientiousness (C):* Conscientiousness is a person's level of responsibility, organization, self-control, and goal-directed behavior. While those with low conscientiousness may be more impulsive, disorganized, and irresponsible, those with high conscientiousness are typically organized, dependable, goal-oriented, and conscientious [10].
3. *Extraversion (E):* Extraversion measures how gregarious, confident, gregarious, and extroverted a person is in social situations. Generally speaking, extraverted individuals are gregarious, energetic, and enjoy forming social bonds. They also seek out stimuli in their environment. Conversely, introverts are more quiet, contemplative, and reserved; they enjoy smaller social events or solo pursuits [12].
4. *Agreeableness (A):* Agreeableness is the level of warmth, empathy, cooperation, and care a person displays for others. Individuals with high agreeableness tend to be cooperative, kind, and trustworthy. They also value harmony and preserving healthy relationships. On the other hand, those with low agreeableness levels could interact with others in a more resentful, doubtful, and competitive manner [28].
5. *Neuroticism (N):* Anxiety, sadness, rage, and susceptibility to stress are unpleasant emotions associated with neuroticism (also known as emotional stability). People who score low on neuroticism are typically emotionally stable, calm, composed, and even-tempered. In contrast, those who score high on neuroticism are more likely to experience anxiety, mood swings, and emotional instability [30].

1.1. Importance of Big Five Personality Traits in the Education Domain. It is impractical to undervalue the significance of the Big Five personality trait analysis in education because it is an effective tool for comprehending and improving the learning process [7] [16]. An assessment of these traits is essential in an educational setting for the following principal reasons:

- *Personalized Learning:*
  The Big Five personality trait analysis's capacity to identify and consider learners' unique differences is one of its most important achievements. Educators can better meet their students' requirements, preferences, and strengths by customizing assignments, learning environments, and teaching methods based on their understanding of each student's unique personality profile [19].
- *Academic Performance Prediction:*
  Studies have repeatedly demonstrated links between specific personality qualities and successful academic performance. For instance, conscientiousness is frequently linked to improved study habits and grades, while being open to new experiences may indicate the capacity for innovative problem-solving. By exploring these correlations, instructors can predict which students might need extra help or extracurricular activities [29].
- *Increasing Student Engagement:*
  Students' approaches to assignments, interactions with classmates, and involvement in course assignments are all influenced by their personality traits [32]. Teachers aware of these variations can design course contents that enhance students' motivations, interests, and learning preferences, boosting involvement and engagement levels in the classroom [38].
- *Enhancing Social Dynamics:*
  The Big Five personality traits significantly shape interpersonal communications and social interactions in educational environments [3]. With this information, educators may build harmonious peer relationships, settle disputes, and establish an inclusive learning environment that values diversity in opinion and expression.
- *Career Path and Personal Development:*
  Knowing one's personality qualities can help one make important decisions about job inclinations, vocational interests, and personal growth paths. This goes beyond simply succeeding academically [6]. Teachers can assist students in choosing their future paths and utilizing their special skills and talents by incorporating personality tests into career counseling and assistance programmes.
- *Promoting Mental Health and Well-Being:*
  Certain personality qualities, like neuroticism, may make a person more vulnerable to mental health issues like stress and anxiety [8]. Teachers aware of these elements can put them into practice by encouraging students to exercise self-care, supporting their emotional resilience, and giving them access

to the right tools and services [25].

In a nutshell, analyzing the Big Five personality traits provides a comprehensive framework for comprehending the complex relationships among individual deviations, educational outcomes, and learning processes. Educators can use this information to design more effective, individualized, and inclusive learning environments that enable students to succeed academically, socially, and personally.

1.2. Research Contributions. The following are the major contributions of this article:

- The Big Five personality traits and their effects on academic success are explored, along with the introduction of personality psychology in the context of educational achievement.
- Comprehensive review and analysis of existing research in personality psychology and academic achievement is presented.
- A comprehensive framework outlining the sequential influence of Big Five personality traits, major identity, and self-esteem on academic outcomes is proposed.
- Popular clustering techniques (K-means, DBSCAN, Hierarchical clustering) are utilized to uncover complex relationships among personality traits, major identity, and self-esteem.
- Based on the obtained results, distinct personality profiles among student participants are identified and characterized.
- Discussion of existing challenges, suggested personalized educational approaches, and future research directions are presented.

1.3. Taxonomy of the Paper. The rest of the paper is organized as follows. Section 2 delves into prior research on analyzing personality traits and discussing the key contributions of the existing solutions. Section 3 outlines the objectives of the proposed model, experimental setup, data acquisition process, data cleaning and preprocessing, and key features of our proposed framework to analyze the relations among Big Five personality traits, major identity, and self-esteem for the participating students through statistical analysis. Different Clustering algorithms and their implementations are discussed in Section 3.5. The results are analyzed to derive the linkages between the education outcome and other psychological factors in section 3.6. This section also evaluates the performance of different clustering outcomes using standard metrics. Finally, Section 4 concludes the study by explaining the effect of analyzing student personality attributes on academic achievements.

2. Related Works. Incorporating machine learning (ML) approaches into educational research has established novel pathways for comprehending the complex connections between individual differences and educational achievements. This section summarizes the latest developments in machine learning algorithms' application to analyze the Big Five personality traits in educational settings. A thorough overview of state-of-the-art techniques and their impact on educational practices and policies is presented by investigating major studies, methodologies, findings, and implications.

To predict students' academic achievement, the authors of [35] created a prediction model that combines demographic and personality traits. Partial least squares and mathematical modeling of structural equations were used to collect and analyze data from 305 students studying at Al-Zintan University in Libya. Research presented in [17] analyzing the Big Five personality traits of 1735 female and 565 male teacher candidates found that teacher candidates are more extraverted than non-teaching counterparts, highlighting the importance of considering personality group differences in teacher recruitment and training.

The work in [18] used the Big Five Factor model and temporal difference learning analytics to investigate how personality variables affected learning. At the same time, students with high neuroticism had mood swings, and those with higher conscientiousness, openness to experience, and emotional stability performed better. Academic improvement Success requires both conscientiousness and extraversion. Based on the OCEAN big five personality theories, the work in [37] examined how well machine learning algorithms such as SVM, Random Forest, and Neural Network classified students' personalities. With an accuracy of 76%, the Neural Network approach was the most accurate, followed by Random Forest and SVM, with an accuracy of 56% and 40%, respectively. This work aimed to determine if machine learning algorithms may use personality traits to predict students' academic success.

The work in [40] describes a decision tree, gradient boosting decision tree (GBDT), and cat boost approach for personality trait analysis. The Big Five attributes offer dimensional criteria for characterizing people's

behaviors and traits through a statistical and semantic combination. The technique uses preprocessed data trained to predict personality types through heatmaps and broken lines analysis. Because personality types are predictable when employing conventional algorithms, the results demonstrate the viability of this approach in psychometric analysis. Another work presented in [21] explores the connection between academic procrastination and personality qualities in young adults. Using a correlational research methodology, it measures procrastination tendencies and the Big Five qualities. The results may inform the creation of individualized programs to help young people attain better academic results and time management skills. Educational institutions, counselors, and lawmakers may find this information helpful in developing interventions that will lessen procrastination.

Age, gender, ethnicity, the Big Five personality traits, and children's self-efficacy were all linked to academic cheating behaviors that authors examined in [42]. According to the findings, boys cheated more than girls, and youngsters cheated less as they grew older. However, no significant correlation was found between cheating and either of the Big Five personality traits or self-efficacy. The results indicate that academic cheating is a problem that emerges in early to middle childhood and that personal traits must develop further before they have strong correlations. [1] examined personality traits' impact on biology students' academic performance in Makurdi, Nigeria. The study involved 384 students and found no significant difference in personality traits based on gender or offered biology. This suggests that gender does not influence personality traits and academic performance. The study recommends improving biology performance and providing male and female students equal opportunities.

The study of the four-dimensional Dark Tetrad personality model in Arab society and its connection to cyber-fraudulent trolling were investigated in [2]. 1093 fourth-year university students majoring in science and literature were involved. The model mediated the relationship between traits of the personality and cyber-fraudulent trolling, and the results indicated a stable model with correlational relationships between the model and the Big Six personality factors. The correlation between gender, academic specialization, and cyber-fraudulent trolling scores was insignificant. This study, [34], investigated the connection between math students' attitudes and teachers' personalities. Teachers in a public school were found to have high levels of conscientiousness, openness, and agreeableness based on data obtained from 118 students. Students expressed poor self-efficacy, moderate curiosity, anxiety, self-concept, and high levels of extrinsic motivation in mathematics. The study's findings, which indicated the significance of instructors in fostering positive surroundings and positive personalities to support learning, showed a somewhat favorable link between teachers' personalities and students' attitudes. Table 2.1 summarizes the input methods, machine learning or deep learning techniques utilized, performance metrics, and personality traits (O = Openness to Experience, C = Conscientiousness, E = Extraversion, A = Agreeableness, N = Neuroticism) for the existing state-of-the-art solutions using the Big Five personality traits in the academics.

An increasing quantity of research in the academic world supports the conclusion that personality traits significantly impact students' academic success. How these traits have an effect is twofold: first, the new human capital theory suggests that certain personality traits boost academic achievement; second, matching personality traits to specific majors creates psychological and motivational incentives. Through their self-efficacy, personality traits within these two pathways impact students' final academic achievements, though the precise nature of this relationship is still unclear. Moreover, there is a major difficulty in the complex matching model between personality traits and professional traits. Consequently, our research avoids the difficulties of matching personality traits with majors by focusing on a specific set of professional students. The emphasis is rather on examining how a student's personality traits affect their core identity in a certain professional context. Adding a new, factual foundation to this research domain is the aim of investigating the dual mediating chain impact between major identity and self-efficacy.

3. Materials and Methods. The main objective of our proposed framework is to analyze the impact of Big Five personality traits (openness, conscientiousness, extraversion, agreeableness, and neuroticism) among undergraduate college students, especially on their learning outcomes. We used various clustering techniques to identify the personality attributes of the participating students. This section describes the experimental setup, data collection, and preprocessing steps, highlighting our proposed framework to meet the objectives.

Table 2.1: Analysis of the Existing Approaches using Big Five Personality Traits for Education Domain

Paper	**Input Method**	**Statistical Method**	**ML/DL Model**	**Performance Metrics**	**Personalities**
[35]	Survey questionnaire with Likert scale	Partial Least Squares (PLS), Structural Equation Modeling (SEM)	-	Accuracy, Efficiency of Model Performance	O, C, E, A, N
[17]	Computer-assisted telephone interviews	MANOVA, Confidence Intervals	-	Internal Consistency, Retest Reliability	O, C, E, A, N
[18]	Questionnaire, Aptitude Tests	Structural Equation Modeling (SEM), Descriptive and Analytical Approach	Random Forest, J48, Naive Bayes	Personality traits correlation, prediction accuracy	O, C, E, A, N
[37]	50-item Likert Scale	Descriptive Statistics, Machine Learning Algorithms	Support Vector Machine (SVM), Random Forest (RF), Neural Network (NN)	Accuracy (76%, 56%, 40%)	O, C, E, A, N
[40]	Pre-processing, Data Conversion, Data Cleansing	Analysis in brokenlines and Heatmap	Decision Trees, GBDT, Cat Boost	Predictive accuracy: Decision Trees - 0.52, GBDT - 0.68, Cat Boost - 0.78	O, C, E, A, N
[21]	Big Five Inventory-10 (BFI-10), General Procrastination Scale	Pearson Correlation Coefficients, T-tests	-	-	O, C, E, A, N
[42]	Zoom Recruitment	Correlation Analysis, T-tests	-	-	O, C, E, A, N, Self-efficacy
[1]	Five-Factor Inventory Questionnaire (FFIQ), Biology Performance Test (BPT)	Mean, Standard Deviation, ANOVA, T-tests	-	-	O, C, E, A, N
[2]	Dark Tetrad four-dimensional personality scale, Cyber Fraudulent Trolling scale, Big Six personality factors scale	Correlational Analysis, Mediation Analysis	Linear Regression, Mediation Analysis	Correlation Coefficients, Mediation Effects	O, C, E, A, N
[34]	Questionnaires from 118 randomly selected Students	Correlation Analysis	-	Correlation Coefficient	O, C, E, A, N

3.1. Experimental Setup. During the data collection process, 1016 undergraduate students from an engineering college in Gujarat volunteered to participate. These students were between 18 and 24 years old. Of the 1016 participants, 642 were male, and 374 were female. All participants were from the same technical background and thus had the same fundamental knowledge of that technical domain.

The participants were given a standardized questionnaire based on the Big Five Inventory (BFI) and similar

Table 3.1: Questionnaire Used in the Proposed Framework

	Extraversion	**Neuroticism**	**Agreeableness**	**Conscientiousness**	**Openness to Experience**
Q1	I am a party animal.	I don't often feel down.	I make fun of people.	I focus on the details.	I have really good ideas.
Q2	I'm not a big talker.	I get upset easily.	I have no interest in the troubles of other people.	I refuse to do my work.	I have a lot on my mind.
Q3	Being among people makes me feel at ease.	I'm easily stressed out.	I don't really care about other people.	I finish chores immediately.	My imagination is not very strong.
Q4	Being the center of attention doesn't bother me.	My emotional swings are frequent.	I am sensitive to the feelings of others.	I adhere to a schedule.	I take some time to think things through.
Q5	I strike up discussions.	I quickly get annoyed.	My care for other people is little.	I'm prepared at all times.	I have trouble grasping abstract concepts.
Q6	At gatherings, I converse with a wide range of people.	A lot of things bother me.	I understand the emotions of others.	I work meticulously.	Abstract Ideas don't appeal to me.
Q7	I prefer to remain unnoticed.	I get depressed often.	People stimulate my curiosity.	I screw up a lot of stuff.	My vocabulary is extensive.
Q8	I don't have much to say.	I get mood swings a lot.	My heart is gentle.	I enjoy discipline and organization.	My understanding of things is swift.
Q9	I keep quiet around new people.	Most of the time, I am relaxed.	I make people comfortable.	I leave my stuff around.	I make use of tricky words.
Q10	I prefer not to be the center of attention.	I'm easily agitated.	I make time for other people.	I'm terrible at putting things back in their place	My imagination is powerful.

scales. The questionnaire consisted of 50 questions/statements in total. There were 10 questions/statements for each personality trait from the Big Five model. Each Big Five personality trait is evaluated using a sequence of statements or questions in the questionnaire. Participants were required to respond to each statement or question using a Likert scale (Strongly Disagree, Disagree, Neutral, Agree, Strongly Agree). Participants were made aware of the purpose of the study and the fact that their answers would be recorded before the exam started. They were asked to affirm their consent after finishing the test.

The questionnaires were circulated via email or other digital channels, accompanied by a clear explanation outlining the survey's purpose and significance. Upon receiving student responses, the data was stored on our computer for thorough analysis. Furthermore, to ensure accessibility and future reference, the results were also stored in the cloud. This dataset now serves as the fundamental repository for training and testing the machine learning model, promising valuable insights into the determinants of undergraduate academic performance. The questions included in the questionnaire are shown in Table 3.1.

3.2. Data Preprocessing. The steps involved in preparing data from a microscopic perspective for statistical analysis are explained in this subsection. The feature selection reasoning is described in detail, focusing on the standards for limiting the selection to particular columns. We investigate the conversion of categorical values into numerical representations and discuss how this could affect reliable clustering analyses. The crucial significance that data preparation plays in maintaining the integrity of subsequent analyses is highlighted in this section. The procedure includes converting and modifying unprocessed data to guarantee its quality, relevance, and compatibility for further investigation.

Fig. 3.1: Proposed Model Architecture

After the file has been downloaded from the cloud server, the data is scrutinized to ensure it is in an easily processed format. This procedure involves removing redundant or irrelevant columns and unwanted columns. The data is also cleaned up to remove outliers, inconsistent data, and missing values. The category responses are converted into numerical form so clustering algorithms can utilize them. The data is normalized as needed to guarantee that each feature has the same scale.

We finally divide the columns based on a question list to categorize the data according to particular questions or themes. After grouping and categorizing the questions, the extraversion attribute was assigned to questions 1 through 10 in our form. Likewise, questions 11–20 assess neuroticism, 21–30 assess agreeableness, 31–40 assess conscientiousness, and 41–50 assess openness. We remove any missing values from the data collection to ensure the data is accurate and complete.

3.3. Proposed Framework. This section examines the complex relationships between critical psychological factors and how they affect academic performance. We analyze the association between personality traits and academic performance based on the Big Five personality traits model: neuroticism, agreeableness, extraversion, and conscientiousness. We integrate major identity and self-esteem into the paradigm to fully comprehend their mediating roles. We aim to identify unique patterns and groupings in the data using advanced clustering techniques. We offer insights into how combinations of personality traits, major identity, and self-esteem influence different academic outcomes. Our framework aims to provide detailed insights into the complex connection between psychological traits and academic success in the educational setting.

Based on the synthesis of prior research, it has been observed that conscientiousness, as one of the Big Five personality traits, often exhibits a positive direct impact on students' academic performance. Additionally, it can indirectly enhance academic performance by fostering improved self-esteem. Other dimensions of personality traits may have different effects depending on certain contextual elements like circumstances, cultural variations, and professional backgrounds. Major identity, on the other hand, tends to contribute to elevated self-esteem and positively affects academic achievement. The mechanism through which personality traits affect major identity is unclear. Still, there is a potential to measure the alignment between personality attributes and majors for students in the given academic disciplines within particular environments.

Building upon these insights, as shown in our proposed architecture in Fig.3.1, aims to examine the effects of personality attributes on major identity, academic self-esteem, and academic performance. Moreover, the combined impact of both factors' chain mediating effects will be analyzed to observe the possible implications of assessing how personality traits influence academic success.

Here, the direct impact of personality attributes on academic performance is denoted by D_{pa}; the independent mediating effects of major identity and self-esteem are denoted by I_i and I_e, respectively; the joint chain mediating effect of major identity and self-esteem is denoted by I_{ie}; and the total impact of personality attributes on academic performance is denoted by T_{pa}. The coefficient vector of attributes associated with a

Table 3.2: Statistical Significance of Samples Aggregated based on Personality Traits

Personality Traits	Mean	Median	Standard Deviation
Extraversion	32.30556	32	3.111979
Neurotic	29.27778	30	4.865474
Agreeable	33.97434	34	4.637148
Conscientious	31.91667	31.5	3.555397
Openness	31.15278	30	3.928739

personality type is represented as β. x_i represents the vector of independent variables related to an individual i.

$$D_{pa} = F(\beta_{pa}, x_i) \tag{3.1}$$

$$I_i = F(\beta_{pi} \cdot \beta_{ia}, x_i) \tag{3.2}$$

$$I_e = F(\beta_{pe} \cdot \beta_{ea}, x_i) \tag{3.3}$$

$$I_{ie} = F(\beta_{pi} \cdot \beta_{ie} \cdot \beta_{ea}, x_i) \tag{3.4}$$

$$T_{pa} = D_{pa} + I_i + I_e + I_{ie} \tag{3.5}$$

3.4. Statistical Analysis. To find the relationship between the variables in our proposed assessment approach, we first constructed a structural equation model for each of the following: academic performance, self-esteem, major identities, and the Big Five personality traits. These effect estimation results are then used to compute the chain mediation effects produced by both variables and the mediation effects of the significant identity and self-esteem factors. Initially, there were a total of 50,800 samples in the dataset. After removing 49 inadequate samples and 67 outliers, 50,684 observations remained. A more thorough analysis of the psychometric characteristics of the Big 5 Personality traits might be conducted using these data. The statistics of the aggregated personality traits are shown in Table 3.2.

3.5. Clustering Techniques. Using various clustering techniques, grouping students according to their academic achievement indicators and personality trait profiles is essential. Clustering allows for examining students' academic performance metrics and personality traits, gaining valuable insights that can be used to improve academic advising, prevent dropouts, personalize curriculum, support research and policy development, and allocate resources optimally in educational settings [9]. Our proposed framework implements popular clustering techniques such as K-means, DBSCAN, and Hierarchical clustering.

3.5.1. K-means Clustering. K-means clustering is a useful tool in student support systems and educational research when it comes to investigating the Big Five personality traits for academic achievement [23]. With this approach, different student profiles or clusters were found according to their academic performance and personality characteristics. The dataset was divided into five clusters, each representing a grouping of students with related attributes. This enables educators to better understand the relationship between academic success and personality traits. Students were placed into groups using K-means clustering based on shared personality qualities, including neuroticism, agreeableness, extraversion, conscientiousness, and openness, as well as the academic achievement indicators accompanying them. This segmentation made academic advice, early intervention, dropout prevention, and curriculum modification possible, making targeted support techniques and personalized interventions possible. However, while using this approach to analyze the Big Five personality traits for academic achievement, it's important to consider the constraints of K-means clustering, such as sensitivity to initial centroid location and the requirement to provide the number of clusters beforehand.

Table 3.3: Statistical Parameters of Student Cluster groups

	Cluster 1		Cluster 2		Cluster 3		Cluster 4		Cluster 5	
	Mean	SD	Mean	SD	Mean	SD	Mean	SD	Mean	SD
Extraversion	32.2142857	2.85803557	32.2068966	3.17728262	33.3571429	2.91809975	30.7692308	2.45431633	31.6722312	2.7965321
Neurotic	23.7857143	4.42684298	31.2068966	3.7174269	31.4285714	4.38690072	27.9230769	0.5756396	27.5423365	3.1973822
Agreeable	34.7857143	3.50873545	33.8965517	2.15510345	34.8571429	4.06829453	30.3846154	2.40315375	30.9427364	2.8753924
Conscientious	29.7857143	3.36321639	31.1724138	2.90147365	34.7857143	3.42633856	32.6153846	3.1265233	31.2788427	3.1635921
Openness	30.92857	3.514547	29.89655	2.368541	35	3.70328	28.61538	2.338259	29.7146581	2.697812
N = 50684	9859		13896		11291		8846		6792	
Percentage	19.45		27.42		22.28		17.45		13.4	

3.5.2. DBSCAN Clustering. An effective method for comprehending the complex relationships between students' personalities and their academic success is to apply DBSCAN (Density-Based Spatial Clustering of Applications with Noise) clustering to the analysis of Big Five personality traits for academic performance [26]. DBSCAN is very useful for handling noise in the data and finding clusters of any shape, in contrast to conventional clustering techniques. Even in datasets with irregularly shaped or overlapping clusters, DBSCAN may identify groups of students with comparable personality trait profiles and academic achievement measures by identifying clusters based on the density of data points rather than fixed centroids. This makes it possible for researchers and educators to find subtle links and patterns that other clustering techniques might miss.

Based on their academic performance and personality features, students were categorized into clusters by DBSCAN clustering. This enabled the development of individualized support plans and targeted interventions catering to each cluster's unique needs. However, it's crucial to remember that DBSCAN may not function as well in datasets with different densities or high-dimensional spaces. It requires careful adjustment of its parameters. Despite these limitations, DBSCAN clustering effectively reveals significant insights into the relationship between personality traits and academic achievement in learning environments.

3.5.3. Hierarchical Agglomerative Clustering (HAC). When the Big Five personality traits are analyzed for academic performance, hierarchical clustering provides a holistic approach to comprehending the complex relationships between students' personalities and their academic accomplishments [14]. The dendrogram, a hierarchical tree-like structure of clusters created by hierarchical clustering instead of other clustering techniques, shows the nested interactions between clusters at various granularities. This enables educators and academics to systematically investigate the variety of personality profiles and academic performance measures among the student community. Hierarchical clustering finds student clusters with comparable psychological trait profiles and academic achievement metrics by iteratively merging or dividing clusters based on similar metrics. This makes it possible to identify common traits and behaviors among students.

By using hierarchical clustering, teachers may better understand the diversity of their learners and create individualized support plans and focused interventions suited to the requirements of various groups. On the other hand, hierarchical clustering can be computationally demanding for large datasets and may necessitate careful consideration of linking criteria and distance measurements. Although all of this, hierarchical clustering effectively offers significant insights into the complex connection between academic success and personality traits in educational settings.

We have used global and native clustering for K-means, DBSCAN, and Hierarchical models. Native clustering involves grouping within smaller, localized regions, accounting for spatial or temporal variation in the data distribution, whereas global clustering concentrates on dividing the entire dataset into clusters. We have trained the global model on the Big Five personality dataset and the native model on the dataset generated through our survey. The assignment of participants to different clusters based on their responses is depicted in Table 3.3.

3.6. Result Analysis. This section analyzes the results obtained for K-means, DBSCAN, and Hierarchical clustering techniques employed to categorize participants based on their personality traits as extroverted, neurotic, agreeable, conscientious, and open to experience.

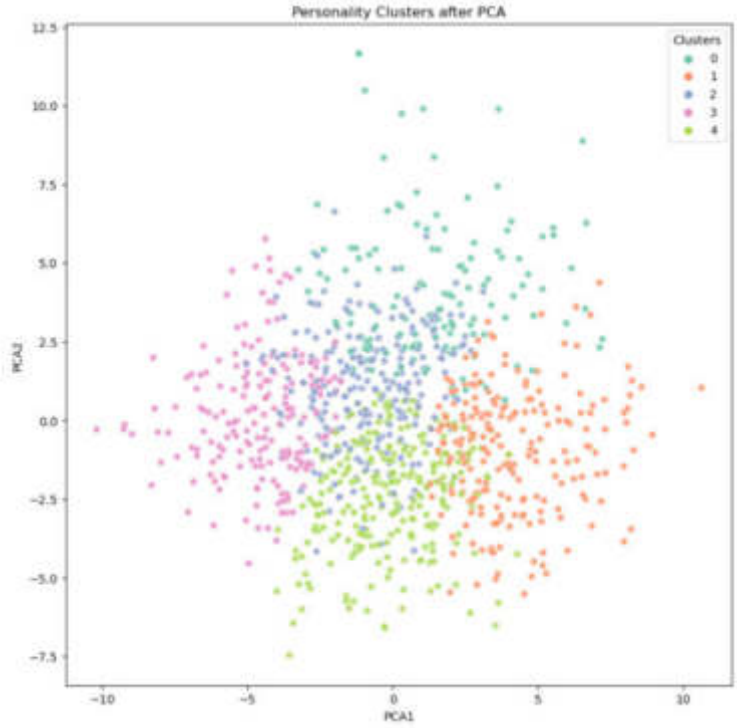

Fig. 3.2: Visualization of Clusters using Principal Component Analysis

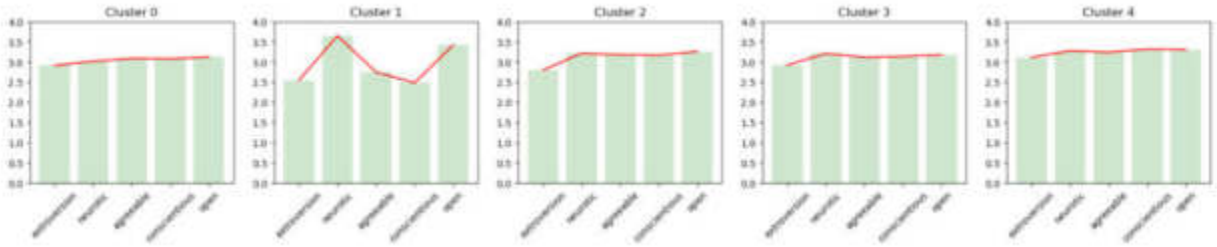

Fig. 3.3: Visualization of Global Model Clusters using K-means

3.6.1. Principal Component Analysis (PCA). Principal Component Analysis (PCA) [20] is a popular dimensionality reduction technique used in data analysis and machine learning. Here, the objective of performing PCA is to preserve the most significant information while converting high-dimensional data into a lower-dimensional space. Principal components, or the orthogonal directions in the data that capture the most variation, are found by PCA to accomplish this. These major components are arranged according to how much variance they explain to reduce dimensionality while preserving as much variance as feasible.

Our proposed framework uses PCA to visualize the data and identify potential clusters. The outcome of the same is shown in Fig.3.2.

Fig.3.3 and Fig.3.4 depict the visualizations of global and native clusters when K-means clustering is applied. Five clusters are generated to reflect the five personality traits. K-means clustering results are assessed using Adjusted Random Index (ARI), Silhouette score, Davies Bouldin Index (DRI), and Calinski-Harabasz Index (CHI) metrics and are described later in this section.

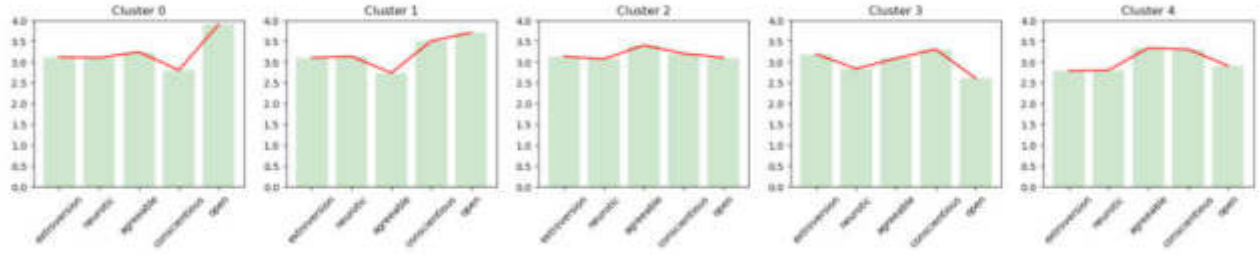

Fig. 3.4: Visualization of Native Model Clusters using K-means

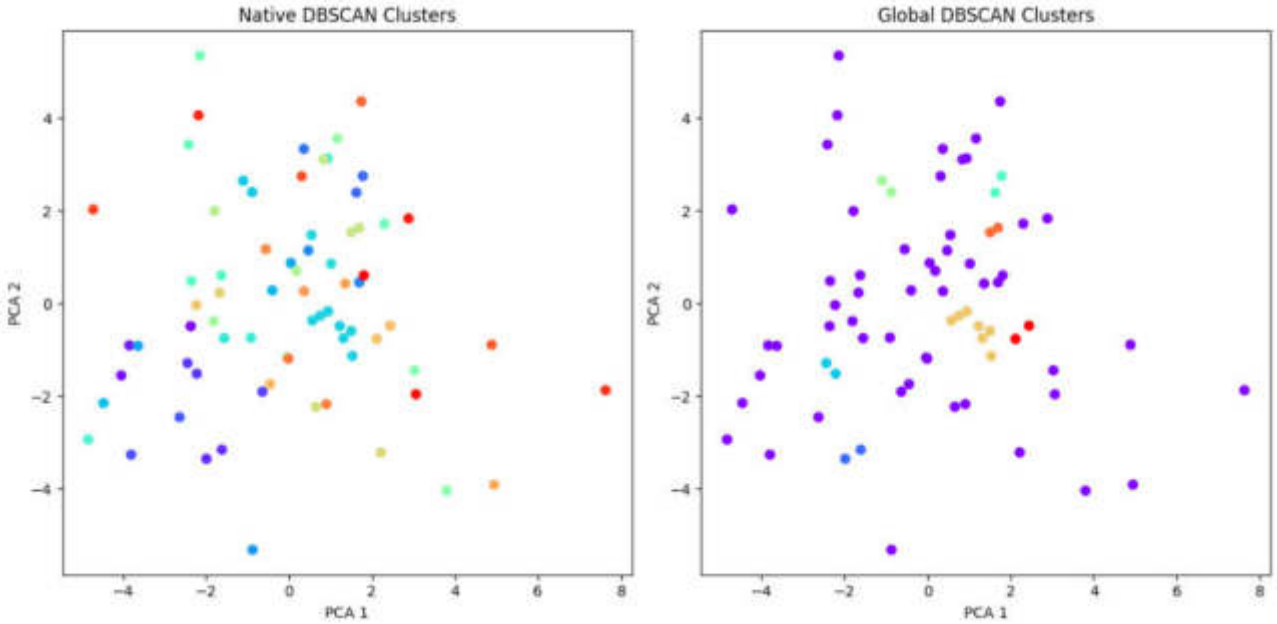

Fig. 3.5: Native and Global DBSCAN Clusters

Fig.3.5 shows the global and native model clusters when the DBSCAN clustering technique is used.

Fig.3.6 represent the global and native model clusters when the hierarchical clustering (HAC) technique is implemented. HAC clusters are visually represented in a hierarchical tree-like structure, dendrogram, and are shown in Fig.3.7.

We use different metrics such as Adjusted Random Index (ARI), Silhouette Score, Davies Bouldin Index (DBI), and Calinski-Harabasz Index (CHI) [14] [31] to assess the performance of the clustering algorithms used in our proposed framework. The following descriptions discuss the reasons behind choosing these performance evaluation metrics and the outcome of the clustering assessment.

3.6.2. Adjusted Random Index (ARI). The Adjusted Rand Index (ARI) [15] compares two clusterings of the same dataset in terms of similarity. The agreement between sample pairs concerning their cluster assignments between the two clusterings under comparison is computed. Concerning cluster assignments, the ARI considers agreement and disagreement, yielding a normalized measure from -1 to 1. Strong agreement between the clusterings is indicated by a value around 1. In contrast, random agreement is implied by a value close to 0, and strong disagreement is indicated by a number close to -1. The ”adjusted” part of the ARI considers the predicted agreement resulting from chance. Because of this, it is beneficial for comparing

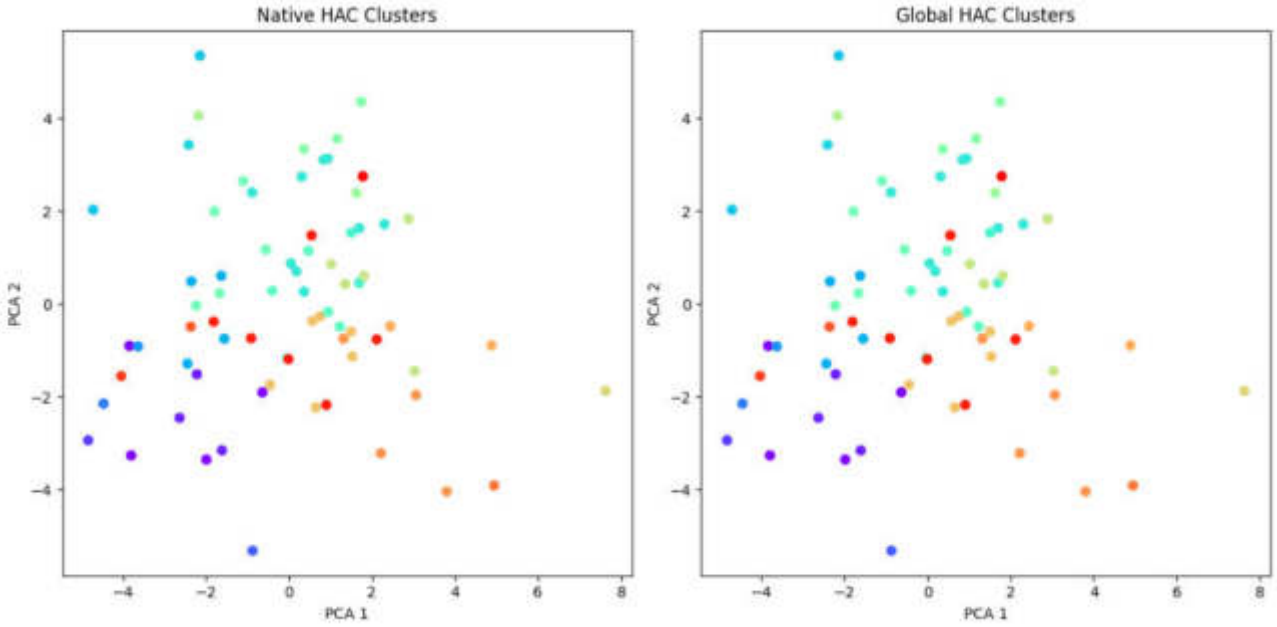

Fig. 3.6: Native and Global HAC Clusters

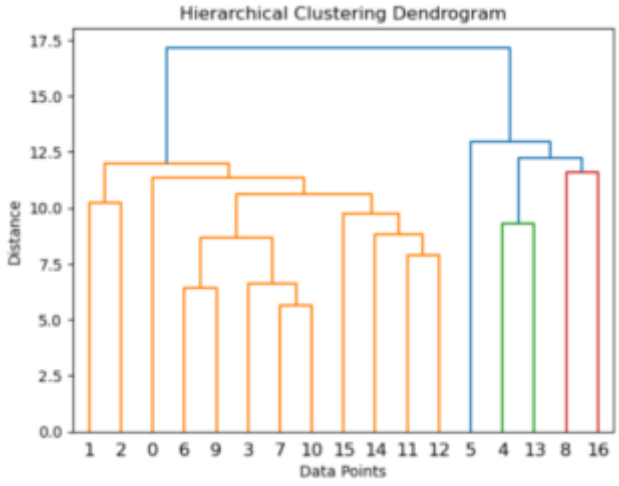

Fig. 3.7: Hierarchical Clustering: Dendrogram

clustering outcomes or assessing clustering algorithms in situations where ground truth labels are unavailable.

3.6.3. Silhouette Score. The quality of the clusters created by a clustering algorithm is assessed using a metric called the Silhouette Score [15]. The degree to which each data point, relative to other clusters, fits into the designated cluster is measured. From -1 to 1, the Silhouette Score is a numerical representation of the distance between a data point and other points in the same cluster. A high score denotes a well-clustered data point. If a point's score is almost zero, it may be close to the line dividing two clusters. The average Silhouette Score measures the clustering algorithm's overall performance across all data points. Higher average scores indicate better-defined clusters.

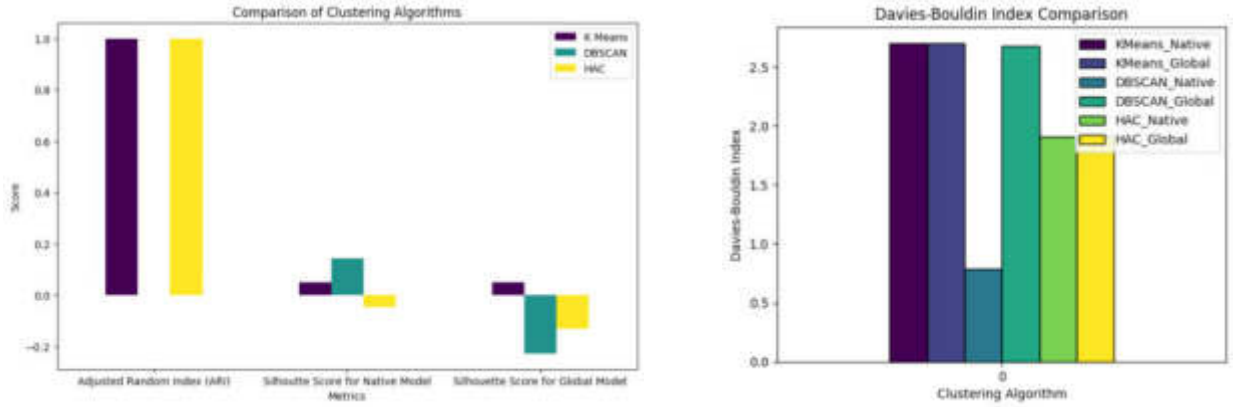

Fig. 3.8: Silhouette Score and Davies Bouldin Index Comparison for Clustering Algorithms

3.6.4. Davies Bouldin Index (DBI). The Davies–Bouldin Index (DBI) [15] is a metric used for evaluating the quality of clustering in a dataset. The distance between clusters and the clusters' compactness are quantified. Better clustering, when clusters are closely spaced and densely populated, is indicated by lower DBI values. In addition to considering average cluster size, the index considers the average similarity between each cluster and its most similar cluster. Through the DBI, a single score representing the overall quality of the clustering is generated by computing the ratio of these two parameters across all clusters.

3.6.5. Calinski-Harabasz Index (CHI). The Calinski-Harabasz Index (CHI) [15] is a metric used to assess the quality of clustering in a dataset. Higher values indicate better clustering. It measures the ratio of within-cluster dispersion to between-cluster dispersion. To be more precise, the CHI simultaneously assesses both the compactness of clusters and the distance between them. It calculates the ratio of the within-group dispersion to the between-group dispersion; higher values denote more compact and well-defined clusters.

3.6.6. Evaluation of Clustering Results. This section shows how various metrics are utilized to evaluate the quality of clusters generated through K-means, DBSCAN, and Hierarchical clustering.

Fig.3.8 depicts the comparison among K-means, DBSCAN, and Hierarchical clustering algorithms for global and native models using Davies Bouldin Index (DBI) and Silhouette scores.

The comparison of clustering algorithms is done using the Adjusted Rand Index (ARI), a metric quantifying the similarity between two clusterings while correcting for chance. ARI is computed for K-Means, DBSCAN, and Hierarchical clustering against ground truth labels, providing a standardized measure of clustering agreement. A high ARI indicates a robust agreement between the predicted and actual clusters. These facts can be seen in Fig.3.8.

As shown in Fig.3.8, the Silhouette Score is used for cluster cohesion and separation in comparative analysis. This metric assesses the results of all three clustering algorithms to provide insights into the internal consistency of clusters. A higher silhouette score indicates distinct, well-defined clusters. For native models, DBSCAN outperforms the other two clustering algorithms. For global models, the K-means algorithm performs better than the other two.

The Davies-Bouldin Index (DBI), a cluster compactness and separation measure, is applied to clustering results. As depicted in Fig.3.8, a lower index signifies better clustering, indicating well-separated and compact clusters. Here, DBSCAN implies better clustering for native models; hierarchical clustering outperforms the other two clustering algorithms for global models.

The Calinski-Harabasz Index (CHI) is used to assess the ratio of between-cluster variance to within-cluster variance, and the values of CHI for the same are included in Fig.3.9 for the three clustering algorithms. This index helps measure how separable and compact a cluster is. The comparison of CHI values provides insights into clustering algorithms' ability to form cohesive and distinct clusters.

Index	K Means	DBSCAN	HAC
Adjusted Random Index (ARI)	1.000000	0.000000	1.000000
Silhoutte Score for Native Model	0.049233	0.142936	-0.046198
Silhouette Score for Global Model	0.049233	-0.226687	-0.131080
Davies Bouldin Index for Native Model	2.702828	0.791410	1.909324
Davies Bouldin Index for Global Model	2.702828	2.675913	1.909324
Calinski-Harabasz Index for Native Model	4.047798	90.728206	10.717509
Calinski-Harabasz Index for Global Model	4.047798	1.585339	10.717509

Fig. 3.9: Computational Analysis of Clustering Algorithms

Fig.3.9 represents the values of different assessment metrics for the three clustering algorithms: K-means, DBSCAN, and Hierarchical. This computational analysis clearly shows which clustering algorithm performs better for global and native models.

In summary, comparing the performance of clustering algorithms is crucial for evaluating their effectiveness in organizing data into meaningful groups. The similarity between actual and predicted cluster assignments is measured by the Adjusted Rand Index (ARI), which provides information about the algorithm's accuracy. A higher ARI indicates better agreement between the predicted and actual clusters. A higher silhouette score indicates more significant distinction and clarity of clusters. The silhouette score evaluates the cohesiveness and separation of clusters. To evaluate the algorithm's capacity to form distinct and coherent clusters, it calculates the distance between each point in a given cluster and the points in its neighboring clusters. Lastly, the Davies-Bouldin index quantifies the compactness and separation between clusters, with lower values indicating more optimal clustering. Considering these metrics collectively, one comprehensively understands a clustering algorithm's accuracy, cohesion, and separation performance. This facilitates informed decisions in choosing the most suitable algorithm for identifying Big Five personality traits among the participants.

The clustering analysis results offer insightful information about the complex relationships between the factors in the educational setting. Students are grouped according to shared personality traits, primary identities, and self-esteem; this allows the analysis to reveal patterns and linkages that might not be immediately obvious when looking at individual variables separately. These clusters provide a sophisticated knowledge of how various amalgamations of self-esteem, primary identity, and personality factors might affect academic performance. Educators and researchers can also customize interventions and support systems to match the unique requirements and challenges experienced by various student groups by identifying discrete clusters. This will ultimately promote a more inclusive and productive learning environment.

4. Conclusion. This work presents strong evidence supporting the significant effect of personality attributes on the academic achievement of students majoring in computer science within the engineering program. The investigation, employing a chain mediating effects framework, sheds light on the mediating roles of major identity and self-esteem, particularly emphasizing the behavioral efficacy dimension. Notably, self-identity and self-esteem emerge as crucial factors influencing academic success. Based on the Big Five personality attributes, five unique personality groups were identified using K-means, DBSCAN, and Hierarchical clustering analysis.

By offering a deeper awareness of the complex interactions between personality characteristics, psychological variables, and academic performance, the study's findings can enhance the body of literature already in existence and impact psychology and education theory, research, and practice. Longitudinal research would be more appropriate to analyze the progressive impact of self-esteem, major identity, and personality factors on learning results over time. The future scope is to compare the end-of-semester academic results and derive meaningful validation. The results may not be as applicable to students in other academic programmes or institutions or

to people with diverse origins in terms of demographics due to their homogeneity.

This work compares clustering algorithms and their performance analysis, proving high accuracy in categorizing students according to their personality traits. Specifically, the models demonstrated that extraversion and conscientiousness are pivotal in positively influencing students' academic achievements. These findings provide valuable insights into the intersection of personality traits and academic performance. They also have implications for interventions and instructional strategies specifically designed to address the special needs of computer science students in the engineering field. Our proposed framework also comprehensively explains a clustering algorithm's accuracy, cohesion, and separation performance, facilitating informed decisions in choosing the most suitable algorithm for a Big Five dataset.

COMPUTER-ASSISTED ONLINE LEARNING OF ENGLISH ORAL PRONUNCIATION BASED ON DAE END-TO-END RECURRENT NEURAL NETWORKS

KANGSHENG LAI* AND LIUJUN MO†

Abstract. With the development of globalization, learning a second language has received increasing attention from people. To improve English oral proficiency, a computer-aided online learning system for English oral pronunciation is studied. A denoising autoencoder is integrated into the system to create a simplified end-to-end recurrent neural network for pronunciation detection and diagnosis based on deep learning. The study first collected and preprocessed oral pronunciation data of English learners, including enhancing speech signals and reducing noise. Next, an RNN model with Long Short-Term Memory (LSTM) as the core was constructed to capture time series characteristics in pronunciation. And use DAE to extract features and reduce the influence of background noise to enhance the recognition of pronunciation features. At the same time, the study utilized web crawler technology to collect a large amount of oral pronunciation data from non-native English learners, and constructed an English oral corpus containing pronunciation errors. And in order to simulate real situations, white noise and pink noise were artificially added to the corpus in the study, and they were divided into training and testing sets in a ratio of 60% to 40%. The results showed that the classification accuracy of the system in the training and testing sets under white noise environment was 78.97% and 94.01%, respectively, and the classification accuracy in the pink noise environment was 76.19% and 94.03%, respectively. The system's error detection accuracy in vowel and consonant pronunciation detection is 88.91% and 91.68%, respectively, and the error correction accuracy in vowel and consonant pronunciation detection is 90.67% and 91.96%, respectively. In summary, the research on computer-aided online learning of English oral pronunciation based on Denoising Auto Encoders end-to-end recurrent neural networks has effectively improved learning efficiency.

Key words: Denoising autoencoder; Spoken English pronunciation; Recurrent neural network; End-to-end

1. Introduction. Under the background of economic globalization, global cultural integration has become an inevitable development trend in the future [1]. English, as an international official language, is a universal language, and fluent spoken English is the basis and prerequisite for international cultural exchange [2]. China has long recognized the importance of English, and English learning has become one of the compulsory courses in schools, and English has always been a compulsory subject in all kinds of examinations for further studies. However, traditional English teaching, like other subjects, still adopts the traditional one-way teaching mode, neglecting students' oral application ability and independent learning ability [3]. As a result, many students' oral English proficiency is generally poor. Some English learners are afraid to speak up because they cannot understand or speak well, which will lead to a vicious circle and prevent them from improving their oral proficiency. Especially in the traditional one-to-many learning mode, teachers are unable to identify and correct students' oral pronunciation problems on a one-to-one basis, resulting in students not being able to get their oral pronunciation corrected, which leads to psychological fear of opening their mouths [4]. At the same time, failing to pronounce will also lead to students failing to speak and their listening will also be affected, thus affecting the whole foundation of English learning. With the development of computer technology, the development of computer-assisted English oral pronunciation online learning system provides students with an effective oral practice tool [5]. However, when students practise pronunciation on their own, they are often affected by the pronunciation of their mother tongue and have subtle pronunciation deviations. Current diagnostic techniques for automatic pronunciation detection are not as accurate as they should be due to the limitations of the corpus. Feng et al. designed an end-to-end pronunciation error detection algorithm that integrates attention mechanisms and is applied to an L2-ARCTIC corpus specifically labeled for pronunciation errors by non-native English speakers. However, this method is mainly limited to diagnosing and detecting

*Foreign Languages College, Pingxiang University, Pingxiang 337000, Jiangxi, China (Corresponding author, Kangsheng_Lai@outlook.com)
†Foreign Languages College, Pingxiang University, Pingxiang 337000, Jiangxi, China

pronunciation errors in L2 learners [6]. Zhang et al. proposed an end-to-end pronunciation error detection algorithm that combines connected temporal classification and attention mechanism. Due to the lack of expert annotated L2 pronunciation error data, this algorithm can only recognize pronunciation errors of L2 learners and cannot provide specific diagnostic information [7]. Against this background, this study innovatively adds a denoising autoencoder to the pronunciation detection and diagnosis module of the computer-assisted oral English pronunciation online learning system, and constructs a denoising autoencoder pronunciation detection and diagnosis system based on end-to-end recurrent neural networks using transfer learning. Therefore, in order to accurately detect errors in English pronunciation by learners in complex environments, and effectively conduct pronunciation training to improve the efficiency and quality of English oral pronunciation learning for English learners. The main contribution of the research is to integrate a denoising autoencoder into the pronunciation detection and diagnosis module of a computer-aided English oral pronunciation online learning system, thereby providing clearer feature information to enhance the detection and diagnosis capabilities of pronunciation errors. In order to effectively improve the accuracy of English oral pronunciation detection and diagnosis, and provide students with more accurate pronunciation correction and guidance. The research content mainly includes four parts. The second part is a review of the current research status of pronunciation detection diagnosis technology and recurrent neural networks both domestically and internationally; The third part discusses the design scheme of a computer-aided English oral English online learning model; The fourth part is to validate the online learning model proposed by the research institute and analyze its specific value in practical applications; The last part is a summary of the entire content and an outlook on future research directions.

2. Related works. Pronunciation detection and diagnostic techniques in second language learning have received a lot of attention from many researchers and have been studied extensively with fruitful results. A team of researchers from Algabri M used deep learning techniques to build a pronunciation detection and diagnostic system for Arabic in order to design a powerful computer-assisted pronunciation system with immediate feedback. The results show that the system has an error recognition rate of only 3.73% in the phoneme recognition process, which significantly improves the accuracy of pronunciation [8]. Wadud M A H and other scholars propose to combine non-self-recursive techniques with end-to-end neural modelling in order to improve the real-time detection of pronunciation errors and to design a new diagnostic model for the detection and diagnosis of mispronunciation. The results show that it exhibits significant advantages in improving detection efficiency [9]. Zhang and other researchers constructed an end-to-end automatic speech recognition system based on hybrid connectionism in order to design an automatic speech recognition system with high performance. The results show that the system can meet the requirements of automatic pronunciation error detection task and achieve high performance index [10].

Recurrent neural networks play an important role in pronunciation detection and diagnostic techniques. Wang's research team, in order to predict future images from historical backgrounds, proposed to utilise the memory decoupling loss of recurrent neural networks for explicit decoupling of memory cells. The results show that this method also prevents the cells from learning redundant features and improves the efficiency and accuracy of the model [11]. Shang and other scholars, in order to be able to accurately predict the degree of haze pollution, proposed to use recurrent neural networks to construct a deep recurrent neural network haze prediction model with time series. The results show that the model can accurately and efficiently predict the degree of haze pollution [12]. Khan and other researchers designed a novel intrusion detection system in order to defend against cyber-attacks, which combines the neural recurrent network structure and machine learning techniques, aiming to effectively defend against cyber-attacks. The results show that the system has high intrusion detection performance [13]. In summary, Algabri M's research points out the effectiveness of deep learning techniques in pronunciation detection and diagnosis, which suggests that when designing English oral pronunciation learning models, this study can also use deep learning frameworks to improve the accuracy of the system. Meanwhile, Wang Y's team's research emphasizes the ability of recurrent neural networks to extract features from time-series data. Therefore, in speech detection, the model in this study can also use RNN to capture temporal information in speech, thereby more accurately identifying pronunciation errors. Therefore, the study aims to construct an end-to-end recurrent neural network model for computer-assisted online learning of spoken English pronunciation with a view to improving the accuracy of spoken English

pronunciation detection.

3. Design of a Computer-Assisted English Spoken Pronunciation Online Learning Model Based on DAE End-to-End Recurrent Neural Networks. The computer-assisted learning system is the basis of this study, and the study builds a DAE-based framework for English spoken pronunciation detection based on the architecture of this system. Recurrent neural networks and end-to-end techniques are also introduced to design an acoustic detection system architecture based on DAE end-to-end recurrent neural networks, and finally the effectiveness of the system is verified using experiments.

3.1. Construction of DAE-based English Spoken Pronunciation Detection Framework. In recent years, with the continuous development of artificial intelligence and machine learning technology, the application of computer-aided learning systems has become more and more extensive [14]. Among them, deep learning technology has achieved remarkable results in the fields of speech recognition and natural language processing. This provides strong technical support for the design of English spoken pronunciation detection and diagnosis system. By using deep learning technology, automatic detection and diagnosis of spoken English pronunciation can be realized to help learners find pronunciation problems in time and take corresponding corrective measures [15]. The design framework of the spoken English pronunciation detection and diagnosis system constructed by using computer technology is shown in Fig. 3.1.

As shown in Fig. 3.1, the study built a database of English pronunciation errors using web scraping, then preprocessed the data with steps like cleaning, feature extraction, and standardization [16]. Then, by constructing an acoustic model for English spoken mispronunciation recognition, the system can identify and judge the correctness of pronunciation more accurately. Finally, the acoustic model is used for the recognition of spoken English mispronunciation to achieve real-time monitoring and correction of spoken English pronunciation [17]. The data processing flow is shown in Fig. 3.2.

As shown in Fig. 3.2, in the data processing process using web crawling technology, the target website is first analyzed, and then the server is accessed based on the website address to obtain a response. After parsing the webpage source code, the desired target label is located and the data is downloaded. Finally, the obtained data is processed and saved uniformly. The data is obtained from web pages, and research is conducted on using web crawler technology to automatically crawl audio data from web pages. When performing data scraping,

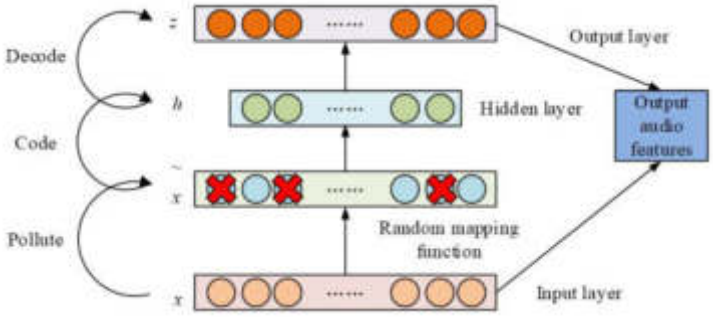

Fig. 3.3: Network structure diagram of DAE

first identify and collect the target webpage URLs containing audio, and place them in the processing queue. Next, using Python and the Requests library, the crawler initiates HTTP requests for URLs in the queue to retrieve webpage content. Then the crawler parses the HTML, identifying audio links and incorrect annotations. Finally, extract these audio download links and error information, crawl and download the audio, and save it locally. The main goal of the data preprocessing stage is to ensure that the audio data in the corpus has a high-quality and unified data format for subsequent model processing. Data cleaning is aimed at removing poor quality audio samples from the corpus, such as records that contain excessive background noise, recording errors, or unclear pronunciation. Then, in order to achieve uniformity in format, research was conducted to convert all audio files into WAV format, and pulse coding modulation was used as the encoding method for the audio. At the same time, during feature extraction, the sampling rate is unified to 16kHz and the data transmission rate of the audio signal is ensured to be 16 bits per second. Finally, in order to standardize the grouping of data, all audio files are set to mono format for saving. In real life, learners' learning environments may encompass a variety of complex and noisy environments, such as streets with noisy traffic, shopping malls with a lot of people, or indoor rooms with reverberating voices [18]. In order to remove or reduce the interference of such noise, the study innovatively adds Denoising Auto Encoders (DAE) to the English spoken pronunciation detection and diagnosis system. DAE achieves the function of removing noise and restoring data by introducing noise into the input data and trying to restore the original data from the noisy data [19]. The DAE's network structure is shown in Fig. 3.3.

As can be seen in Fig. 3.3, the network structure of the DAE is very similar to that of an autoencoder, which can also be divided into three layers: the output layer, the input layer, and the hidden layer, and the overall structure consists of an encoder and a decoder [20-21]. The encoder maps the input data to a representation in the latent space, and unlike a normal autoencoder, the encoder is still responsible for mapping the noisy data to the latent representation after noise is introduced in the input data. The decoder maps the potential representation of the encoder output back to the original input space and tries to reduce the original data. The goal of the decoder is to minimize the interference of noise and restore a result similar to the original data. The training process of the denoising autoencoder can be divided into two steps: adding noise and reconstructing the data. When encoding with DAE, the ReLU activation function is used for calculation. In the calculation equation, the representation of the ReLU activation function is $f(t)$. The phonemic features of the input spoken English are encoded using DAE as shown in equation (3.1).

$$C_o = f(\omega x + b) \tag{3.1}$$

In equation (3.1),C_o denotes the coded output of the hidden layer,ω denotes the weight matrix from the input layer to the hidden layer,x denotes the input data,$f(t)$ denotes the ReLU activation function, and$b$ denotes the bias. The input data needs to be reconstructed with contamination and the mathematical expression for the reconstructed data is shown in equation (3.2).

$$Z = f_d(\omega C_o + b) \tag{3.2}$$

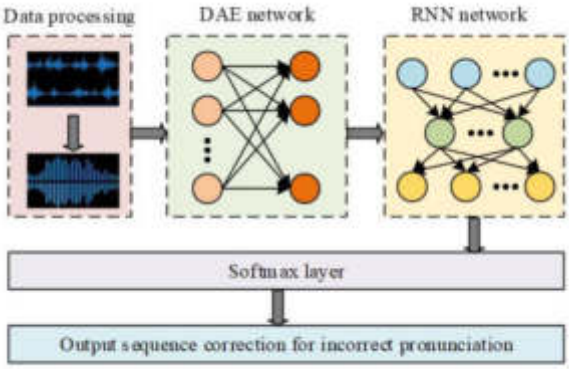

Fig. 3.4: Architecture of acoustic detection system based on DAE end-to-end recurrent neural network

In equation (3.2),Z denotes the reconstruction of the input data$x$ and$f_d\left(t\right)$ denotes the softplus function. Assuming the same number of neural nodes in the input and output layers, i.e., the data$t \in (0,1)$, then the mathematical expression of the softplus function is shown in Eq. (3.3).

$$f_d\left(t\right) = \begin{cases} \log\left(1+e^t\right), t \in (0,1) \\ t \qquad\qquad\quad , otherwise \end{cases} \tag{3.3}$$

The DAE network structure is learnt using a loss function as shown in equation (3.4).

$$L\left(x\right) = \sum_{i=1}^{d}\left[x_i \log\left(z_i\right) + \left(1-x_i\right)\log\left(1-z_i\right)\right] + \frac{\lambda}{2}\left\|W\right\|^2 \tag{3.4}$$

In Eq. (3.4),$L\left(x\right)$ denotes the loss function, and$\frac{\lambda}{2}\left\|W\right\|^2$ denotes the regularity term, whereλ denotes the parameter that controls the degree of regularisation. By stacking the network structure of DAE, a deep learning model can be formed, which is able to realise the cycle of the above process, continuously training from noisy speech data and obtaining a representation closer to the original data. In this way, i.e., the accuracy of spoken English recognition can be improved.

3.2. Architecture design of acoustic detection system based on DAE end-to-end recurrent neural network. Recurrent Neural Network (RNN) is a type of neural network specialized in processing sequential data, which recursively moves in the direction of sequence evolution and connects all nodes according to chaining. RNNs have an excellent memory capability, which enables them to combine the contents of previous memories with the current inputs, and thus apply the previous information to the current task. Unlike Convolutional Neural Network (CNN), RNN not only considers the current input, but also remembers the information from previous moments, and this memory capability gives RNN a great advantage in processing sequential data. In the process of English pronunciation detection, the mispronunciation of spoken English is often associated with its preceding and following phonemes. Therefore, in order to strengthen the connection between spoken English in terms of the preceding and following phonemes, it is necessary to process the features using RNN after extracting them using the DAE English Spoken Pronunciation Detection System. Since the input speech signals of spoken English are often very long and the dimension of the input is large, the duration of a phoneme is usually ten times the length of a frame [22]. In order to deal with such audio with excessive input length, the study introduces end-to-end processing in the construction of the system. The architecture of the acoustic detection system based on DAE end-to-end recurrent neural network is shown in Fig. 3.4.

As shown in Fig. 3.4, the acoustic detection system architecture combines DAE and RNN with the goal of recovering the original data from noisy speech data. Firstly, the spoken English audio data is captured and

acoustic features are extracted, then input to DAE network for learning, after that the learned features are input to RNN network structure. The output of RNN is classified by softmax layer for output, and finally the student's mispronunciation is corrected based on the predicted output sequences. LSTM is a kind of RNN designed to deal with the long term dependency problem. RNN is difficult to handle long-term dependency problems, while LSTM can solve this problem by introducing several gating units. This unique structure allows the network to selectively remember or forget information, which is very effective for capturing long-term dependencies. Meanwhile, the forget gate of LSTM allows the model to discard unwanted information, which is very useful when dealing with continuous speech streams. And the unique gating mechanism of LSTM can protect gradients from damage during long sequence transmission, making the training process more stable. Therefore, choosing LSTM as a specific network architecture is more advantageous for research. When dealing with sequence data such as speech and text, if the sequence is too long, the RNN will suffer from the gradient explosion or vanishing problem, making the network difficult to train and optimize. To solve this problem, the study introduces LSTM instead of traditional RNN structure. The expression of LSTM network forgetting gate is shown in equation (3.5).

$$f_t = \sigma\left(\omega_f * [y_{t-1}, x_t] + b_f\right) \tag{3.5}$$

In equation (3.5),f_t denotes the forgetting gate,σ denotes the activation function,ω_f denotes the weight matrix,x_t denotes the current neuron input,t denotes the time,„b_f denotes the residual value, andy_{t-1} denotes the output of the previous neuron. The activation functionσ is generally used as a sigmoid function and its mathematical expression is shown in equation (3.6).

$$\sigma(x) = \frac{1}{1 + e^{-x}} \tag{3.6}$$

Candidate cells are utilised for updating and the formula for updating is shown in equation (3.7).

$$\begin{cases} i_t = \sigma\left(\omega_i * [y_{t-1}, x_t] + b_i\right) \\ C_t = f_t \bullet C_{t-1} + i_t \bullet C_t' \\ C_t' = \tanh\left(\omega_C * [y_{t-1}, x_t] + b_c\right) \end{cases} \tag{3.7}$$

In Equation (3.7),C denotes the memory cell,i_t denotes the input gate,C_t denotes the candidate value cell,$C_t^{'}$ denotes the updated candidate value cell,ω_C denotes the weight value of the memory cell,ω_i denotes the weight value matrix of the input gate,b_c denotes the offset value of the memory cell, andb_i denotes the offset value of the input gate. The expression of the output gate is shown in equation (3.8).

$$\begin{cases} y_t = O_t \bullet \tanh\left(C_t\right) \\ O_t = \sigma\left(\omega_o \bullet [y_{t-1}, x_t] + b_o\right) \end{cases} \tag{3.8}$$

In Eq. (3.8),O_t denotes the output gate,ω_o denotes the weight value of the output gate, andb_o denotes the deviation value of the output gate. In the acoustic detection system architecture, the DAE network is first used to learn and compute the loss function, then this loss function is used to train the LSTM network, and finally the output of the LSTM network is fed back to the DAE network through the sigmoid function in order to optimise the system performance. The expression of the loss function after training is shown in equation (3.9).

$$L'(x, z) = -\ln\left[P\left(z \,|x\right)\right] \tag{3.9}$$

In Eq. (3.9),$L'(x, z)$ denotes the loss function after training and$P$ denotes the output probability. After performing forward and backward calculations through the LSTM network, the forward and backward variables will be initialized. In LSTM networks, before each processing of sequence data begins, it is necessary to initialize the forward variable. These variables include a set of loss function gradients, which will be updated during the training process. The mathematical expression of the initialized forward variable is shown in equation (3.10).

$$\alpha(1, u) = \begin{cases} C_o^b, u = 1 \\ C_o^Z, u = 2 \\ 0, Q \end{cases} \tag{3.10}$$

In Eq. (3.10),α denotes the initialized forward variable,u denotes the set of gradients of the$L'(x,z)$ loss function and$Q$ denotes the others. Backward variables also need to be initialized before processing begins, and these variables involve a set of all phoneme labels. The mathematical expression of the initialized backward variable is shown in equation (3.11).

$$\beta(T,u)=\begin{cases}1,u=Z\\0,Q\end{cases} \tag{3.11}$$

In Eq. (3.11),β denotes the initialised backward variable and$T$ denotes the set of all phoneme labels. Forward propagation refers to the process of data transmission from the input layer to the output layer in a network. The mathematical expression for forward propagation is shown in equation (3.12).

$$\alpha(t,u)=y_k^t\sum_{i=f(u)}^{u}\alpha(t-1,i) \tag{3.12}$$

In Eq. (3.12),$\alpha(t,u)$ denotes the forward propagation,y_k^t denotes the output of the softmax layer at the time$t$ and$k$ denotes the phoneme labels. Backpropagation is a crucial step in the learning process, which involves calculating the gradient of weights for each layer based on the loss function and updating weights according to these gradients. The mathematical expression for backward propagation is shown in equation (3.13).

$$\beta(t,u)=\sum_{i=u}^{t}\beta(t+1,i)\,y_k^t \tag{3.13}$$

In Eq. (3.13),$\beta(t,u)$ denotes backward propagation. The boundary conditions for the forward and backward variables are shown in equation (3.14).

$$\begin{cases}\alpha(t,0)=0,\forall t\\ \beta(t,|Z|+1)=0,\forall t\end{cases} \tag{3.14}$$

As shown in equation (3.14), the boundary conditions of the forward and backward variables define the values of the forward and backward variables under specific conditions. The difference between the predicted and actual values of the output layer is the error gradient, which can adjust the weight of the network to reduce future prediction errors. The mathematical expression of the output layer output error gradient is shown in equation (3.15).

$$\tau_k^t=Z_k^t-\frac{1}{P(Z|x)}\sum_u\alpha(t,u)\,\beta(t,u) \tag{3.15}$$

In Eq. (3.15),τ_k^t denotes the gradient of the output error of the output layer. When training the LSTM model, the gradient of the output error can be used to update and learn the parameters of the network. Once the LSTM model is trained, the target pronunciation sequence can be recognised. However, during the initial phoneme training recognition process, the LSTM model is prone to overfitting in the training set. To avoid this, a Dropout strategy can be used, where a portion of neurons are randomly discarded during the training process.The Dropout process of the LSTM model is shown in Fig. 3.5.

As shown in Fig. 3.5, the Dropout process of the LSTM model is a neuron dropout on the feedforward network of the LSTM, with a probability of 0.5 to randomly drop some neurons at each layer. This process can effectively reduce the sequence modelling ability of the recurrent neural network, thus effectively mitigating the overfitting phenomenon. At the same time, since Dropout is performed on the feedforward neural network, it can prevent information from being lost during the looping process, thus ensuring the performance and accuracy of the model.

4. Validation of a DAE end-to-end recurrent neural network-based model for computer-assisted online learning of spoken English pronunciation. In this chapter, the configuration of the experimental environment and parameters is carried out, then the analysis of the model parameters of the LSTM network structure is analysed, followed by the performance validation of the model for learning spoken English pronunciation

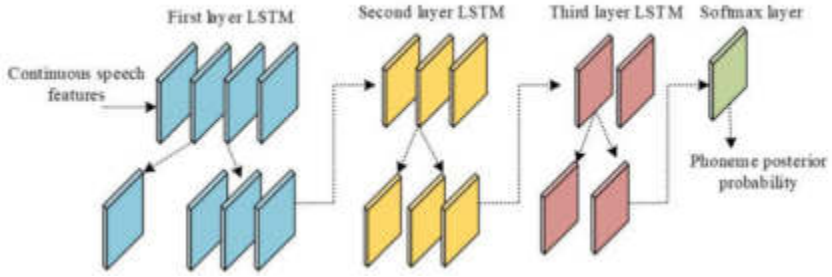

Fig. 3.5: Dropout process of LSTM model

Table 4.1: Experimental Environment and Parameter Configuration

Experimental environment	Configuration	Parameter	Value
Operating system	Windows 10	Optimizer	Adam
Memory	64GB	Iterations	500
GPUs	NVIDIA TITAN BLACK GPUs	Batchsize	64
Video storage	6G	Learning Rate	0.001
Programming Language	Python	Dropout	0.5

4.1. Experimental environment and parameter configuration. In order to verify the effectiveness of the computer-assisted English oral pronunciation online learning model based on DAE end-to-end recurrent neural network, the experimental environment is firstly constructed and the parameters are set. The experimental operating system is Windows 10, the programming language is Python, and the acoustic model for pronunciation detection is TensorFlow 1.4.0.The dataset used in the experiment is collected from the Internet by web crawler technology to construct a corpus of English spoken pronunciation errors. On this basis, in order to be closer to real scenarios, the study added white noise and pink noise to this corpus, and divided this corpus into a training set and a test set according to the ratio of 60%:40%. In the experiment, a neural network with three hidden layers was constructed, with a number of neurons of 39, 50, and 50, respectively. To enhance generalization and avoid overfitting, both the input layer and hidden layer adopt a 10% Dropout rate. The training parameters are set to 500 Epochs, with a batch size of 40 and a learning rate of 0.0001. The study selected Adam as the optimizer, with hyperparameters for first-order and second-order moment estimation set to 0.9 and 0.999, respectively. The batch size during training is set to 64 to save memory. To further prevent overfitting, the Dropout rate is set to 0.5. he specific experimental environment and parameter configuration are shown in Table 4.1.

4.2. Analysis of model parameters for LSTM network structure. In order to verify the effect of the number of layers of the LSTM network on the performance of the DAE end-to-end recurrent neural network-based computer-assisted oral English pronunciation online learning model, the number of LSTM layers was set from 1 to 4, and the phoneme error recognition accuracies were compared with different numbers of LSTM network layers as shown in Fig. 4.1. From Fig.‘4.1, it can be seen that the values of the parameters such as insertion, deletion, substitution and phoneme error recognition accuracy gradually increase with the increase in the number of LSTM network layers. When the number of LSTM network layers reaches 4, the recognition accuracy reaches the highest value of 84.04%. This is an improvement of 20.07%, 12.48% and 7.81% as compared to when the number of layers is 1, 2 and 3 respectively. Thus it can be seen that the performance of phoneme recognition is better when the number of layers of LSTM network is 4.

In order to investigate the effect of the number of LSTM network nodes on the performance of the computer-assisted oral English pronunciation online learning model with DAE end-to-end recurrent neural network, the study experimented with the number of network nodes in the hidden layer of 100, 150, 200, and 300, and the

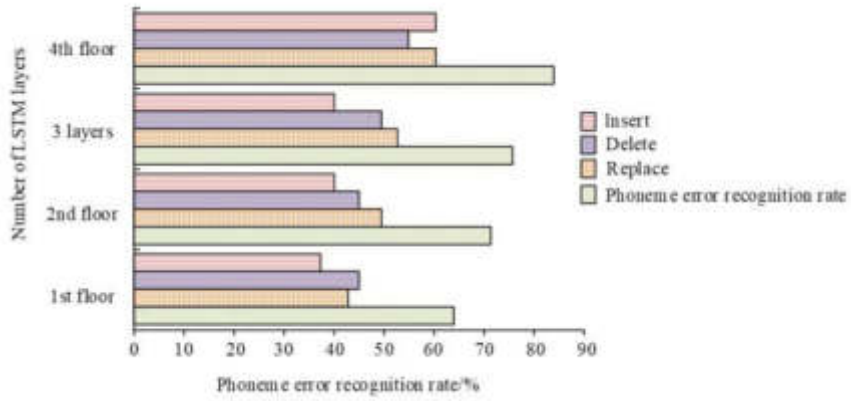

Fig. 4.1: The accuracy of phoneme error recognition for different LSTM network layers

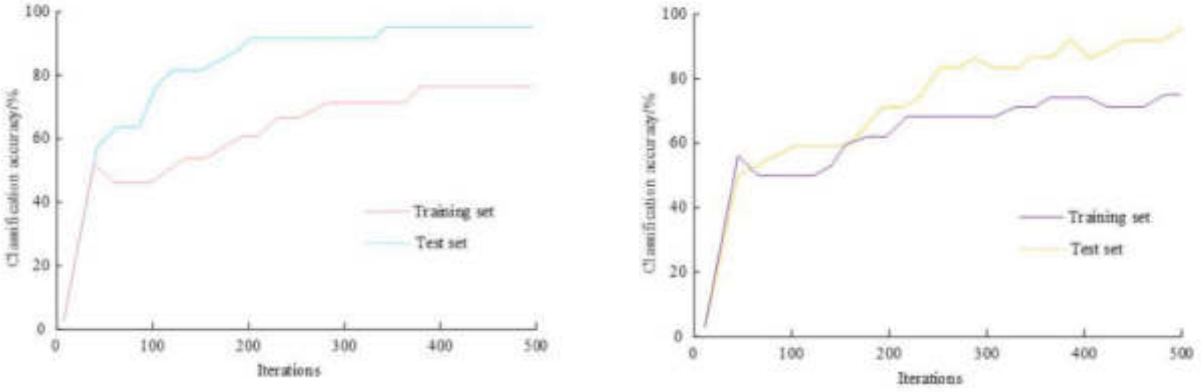
Table 4.2: The impact of different numbers of LSTM network nodes on model performance

Number of network nodes	Insert/%	Delete/%	Replace/%	Phoneme sequence recog-nition rate/%	Accuracy/per cent	Recall/%	F1 value/%	Recognition rate of mispro-nounced phonemes
100	2.65	7.33	2.65	85.65	89.01	81.35	88.18	84.16
150	2.65	5.33	2.65	87.69	87.98	87.48	87.15	87.06
200	2.65	13.00	6.33	75.97	82.16	76.15	78.61	77.94
300	6.00	15.33	1.33	78.12	82.16	86.70	86.19	83.76

effect of the different number of LSTM network nodes on the performance of the model is shown in Table 4.2. From Table 4.2, it can be seen that when the number of LSTM network nodes is 150, the phoneme sequence recognition rate is 87.69%, which is an improvement of 2.04%, 11.72% and 9.57% compared to the cases of number of nodes 100, 200 and 300, respectively. When the number of nodes in the LSTM network is 150, the mispronunciation phoneme recognition rate reaches a maximum value of 87.06%, which is an improvement of 2.9%, 9.12% and 3.3% compared to the cases of 100, 200 and 300 nodes, respectively. In summary, considering various factors such as phoneme sequence recognition rate and mispronunciation phoneme recognition rate, it can be seen that the number of nodes of LSTM network set to 150 is the most appropriate. When the number of nodes in the LSTM network is set to 150, the model performs the best in phoneme sequence and mispronunciation recognition tasks. This finding emphasizes the importance of selecting an appropriate network size, that is, a depth and width that is neither excessive nor insufficient, for the model to capture key information and generalize new data.

4.3. Performance Validation of English Spoken Pronunciation Learning Model. In order to verify the classification performance of the English spoken pronunciation learning model in a noisy environment, a comparison of the classification performance of the model in different noise environments is plotted as shown in Fig. 7. As can be seen from Fig. 7(a), before 50 iterations, the classification accuracy of the training and testing sets was the same. However, after 50 iterations, the classification accuracy of the testing set gradually widened compared to the training set, indicating overfitting in the training set. In the white noise environment, the model gradually becomes stable after 400 iterations, and the classification accuracy in the training set and test set reaches 78.97% and 94.01%, respectively. This indicates that the model has a better classification performance under white noise environment. As can be seen in Fig. 7(b), after 50 iterations, the



(a) Classification accuracy under White noise

(b) Classification accuracy under White noise

Fig. 4.2: Comparison of Model Classification Performance in Different Noise Environments

classification accuracy of the training set showed a downward trend, which remained stable for a period of time before returning to a slow upward trend. This indicates that the model can better generalize to unseen data after further learning and adjustment, indicating its robustness. The classification accuracy of the model in pink noise environment reaches 76.19% and 94.03%, respectively. This indicates that the model also has good classification performance in pink noise environment. In summary, it can be seen that the model still maintains a high classification accuracy in white and pink noise environments, indicating that the model still has good adaptability in the presence of background noise.

In order to further verify the recognition performance of the English spoken pronunciation learning model in the noise environment, the loss function profiles of the model in different noise environments are plotted as shown in Fig. 4.3. As can be seen from Fig. 4.3, before the number of iterations approaches 60, the value of the loss function shows a rapid decline trend. After 60 iterations, the decline rate gradually slows down and gradually stabilizes around 100 iterations. This indicates that the model learns quickly in the initial iteration process, effectively reducing errors. However, as learning progresses, the model's fitting of the data gradually approaches its potential optimal state, and the decline rate of the loss function slows down until it reaches a relatively stable state, reflecting that the learning process of the model is beginning to saturate. The loss function curves in white noise and pink noise environments have very similar trends, both of which begin to converge around 100 iterations, and the values of the loss function eventually converge and stabilize at 0.5 or below. It shows that the model has good adaptability in both white noise and pink noise environments, and can effectively reduce the value of the loss function and improve the classification accuracy of the model.

In order to validate the effectiveness of the spoken English pronunciation learning model, a comparison of the audio data pairs of spoken English before and after DAE network processing is shown in Fig. 9. As can be seen from Fig. 4.5(a) and Fig. 4.5(b), the vowel signals after DAE network processing are sparser compared with the original vowel signals. At the same time, the vowel signal processed by DAE network has some enhancement in the high frequency part of the signal compared to the original vowel signal. As can be seen in Fig. 9(c) and Fig. 9(d), the spectral images of the consonant signals processed by the DAE network become smoother and smoother compared with the original consonant signals. This indicates that the DAE network can effectively reduce the noise and interference in the audio signal and improve the quality and clarity of the signal. In summary, it can be seen that the audio signal processed by the DAE network becomes sparser in the high-frequency part, indicating that the network can effectively filter out unnecessary noise and retain useful speech information.

In order to verify the effectiveness of the English spoken pronunciation learning model in practical applications, the acoustic detection system based on DAE end-to-end recurrent neural network is compared with the

(c) The F1 value of vowel and consonant Pronunciation

Fig. 4.5: The pronunciation detection performance of the model

acoustic detection system based on convolutional neural network. The pronunciation detection performance of the validation model is shown in Fig. 4.5a. As can be seen in Fig. 4.5a(a), in vowel articulation detection, the accuracy of the recurrent neural network-based model reaches 94.07%, which is 13.43% higher than the accuracy of the convolutional neural network-based model. In consonant articulation detection, the accuracy of the recurrent neural network-based model is 89.12%, which is 10.15% higher than the accuracy of the convolutional neural network-based model. As can be seen in Fig. 4.5a(b), in vowel pronunciation detection, the recall based on the recurrent neural network model is 91.89%, which is 5.55% higher than the recall based on the convolutional neural network model. In consonant articulation detection, the recall based on the recurrent neural network model is 94.27%, which is 12.24% higher than the recall based on the convolutional neural network model of 82.03%. As can be seen in Fig. 10(c), in vowel articulation detection, the F1 value based on the recurrent neural network model is 93.76%, which is 10.49% higher than the F1 value based on the convolutional neural network model. In consonant articulation detection, the F1 value based on recurrent neural network model is 91.52%, which is 6.29% higher than the F1 value based on convolutional neural network model. Thus it can be seen that the DAE end-to-end recurrent neural network based acoustic detection system has better articulation detection performance compared to the convolutional neural network based acoustic detection system.

In order to more intuitively verify the effectiveness of the English spoken pronunciation learning model in practical applications, the acoustic detection system based on DAE end-to-end recurrent neural network was inductively compared with the acoustic detection system based on convolutional neural network, and the

Table 4.3: Performance of Two Models in English Oral Pronunciation

Performance	CNN based system		RNN based system	
	Vowel	Consonant	Vowel	Consonant
Accuracy/per cent	80.64	78.97	94.07	89.12
Recall/%	86.34	82.03	91.89	94.27
F1 value/%	83.27	85.23	93.76	91.52
Error detection accuracy/%	75.32	74.06	88.91	91.68
Error correction accuracy/%	73.16	60.16	90.67	91.96

performance of the two models on English spoken pronunciation is shown in Table 4.3. As can be seen in Table 4.3, in terms of error detection correctness, the correctness of the recurrent neural network-based model for vowels and consonants is 88.91% and 91.68%, which is an improvement of 13.59% and 17.62%, respectively, compared to the convolutional neural network-based model. In terms of the correct rate of error correction, the correct rates of vowels and consonants based on the recurrent neural network model are 90.67% and 91.96%, which are improved by 17.51% and 31.8%, respectively, compared with the model based on convolutional neural network. In summary, the effectiveness of the computer-assisted oral English pronunciation online learning model in practical applications is verified through comparative experiments.

5. Conclusion. As a globally used communication language, fluent spoken English can significantly enhance one's social competitiveness. In order to improve the pronunciation and error correction ability of online learning of spoken English, the study is based on a computer-assisted online learning system for spoken English pronunciation, which extracts the acoustic features of the audio by introducing a DAE module and processes the audio data using a recurrent neural network structure. The results show that under the white noise environment, the classification accuracies of the training set and test set are as high as 78.97% and 94.01%, respectively. In pink noise environment, the classification accuracy is 76.19% and 94.03%, respectively. In the vowel pronunciation detection task, the accuracy, recall and F1 value of the recurrent neural network-based model reached 94.07%, 91.89% and 93.76%, respectively. In the consonant pronunciation detection task, the values of these three metrics were 89.12%, 94.27% and 91.52%, respectively. In terms of the correct rate of error detection, the model was 88.91% and 91.68% correct in vowel and consonant pronunciation detection, respectively. In terms of the correct rate of error correction, the correct rates of the recurrent neural network-based model in vowel and consonant articulation detection are 90.67% and 91.96%, respectively. In summary, the DAE end-to-end recurrent neural network-based acoustic detection system has significant advantages in terms of error detection, error correction, and overall classification performance for spoken English pronunciation. However, only vowels and consonants in spoken pronunciation were analyzed in this study, and the study can be further improved in the future to include other types of phonemes in the analysis in order to evaluate the performance of the model more comprehensively. Faced with existing challenges such as the lack of immediate feedback in online learning environments, this system provides learners with a powerful self-learning platform through its high accuracy error correction function. The potential application of this technology in research is not limited to personalized tutoring for language learners, but may also extend to the diagnosis of acoustic barriers, promotion of cross-cultural communication, and optimization of distance education resources. In the future, research can be expanded to include analysis of more phonemes to comprehensively evaluate and enhance the model's universality and adaptability in multilingual environments. In addition, researchers should also consider how to integrate this technology into existing digital learning platforms to achieve a wider educational impact and contribute to language education in the era of globalization.

SCALABLE INNOVATIVE FACTORS FOR SHAPING CONSUMER INTENTIONS ON ELECTRIC TWO-WHEELERS ADOPTIONS

SAILATHA KARPURAPU*, KAYAM SAIKUMAR†, LAXMAIAH KOCHARLA‡, P. SYAMALA RAO§ AND DR SUDEEPTHI GOVATHOTI¶

Abstract. Electric two-wheelers (ETWs) have emerged as a dominant choice over traditional counterparts in global consumer markets, prompting a shift in consumer behaviour. While existing research has delved into the adoption of ETWs, there remains a notable gap in understanding the intricate factors driving consumer adoption, particularly their inclination toward innovation. This study investigates the landscape of ETWs in India, focusing on facilitating conditions, pricing dynamics, personal innovativeness, and behavioral intentions. Utilizing the Unified Theory of Acceptance and Use of Technology (UTAUT) framework, 220 Indian ETW users were surveyed to elucidate the interplay between facilitating conditions, price, and behavioral intentions, mediated by personal innovativeness. The findings underscore the significant impact of facilitating conditions and price on behavioral intentions, with personal innovativeness serving as a pivotal mediator in this relationship. Moreover, this study underscores the importance for ETW businesses to prioritize user-friendly designs, ensuring a seamless and enjoyable experience for consumers. Furthermore, targeting highly innovative consumers emerges as a strategic imperative for businesses in devising effective marketing strategies. By shedding light on facilitating conditions, price dynamics, personal innovation, and behavioral intentions, this study contributes valuable insights to the existing literature. In terms of environmental sustainability, the scalability of electric two-wheelers contributes to reducing greenhouse gas emissions and mitigating air pollution in urban areas. As more individuals switch from gasoline-powered vehicles to electric two-wheelers, the collective impact on reducing carbon emissions and improving air quality becomes increasingly significant, especially in densely populated regions where transportation-related pollution is a major concern. Additionally, it offers a nuanced understanding of the mediating role of personal innovation in the context of ETWs, thereby informing future research and strategic initiatives in the field of electric mobility.

Key words: Electric two-wheelers, Innovative nature, Unified Theory of Acceptance and Use of Technology (UTAUT), Marketing strategies, User experience, Global consumer behavior, Technology acceptance

1. Introduction. Consumers' experiences with conventional vehicles have changed because of the rise of electric vehicles. Since the previous ten years, people have started using ETWs to carry out their regular duties. Consumers will become increasingly reliant on their ETWs because of their growing reliance on them for all purchases. The adoption of electric two-wheelers (ETWs) is gaining momentum in India, as the government and private sector invest in infrastructure and incentives to promote this technology. ETWs offer several advantages over traditional fuel-powered vehicles, including lower emissions, lower operating costs, and a quiet ride. However, there are still some barriers to adoption, such as the lack of facilitating conditions and the high price of ETWs. Facilitating conditions refer to the factors that make it easier or more difficult to adopt a new technology. For ETWs, these factors include the availability of public charging stations, the cost of ETWs, and the government's policies on ETWs. Price is another important factor that influences the adoption of ETWs. ETWs are still relatively expensive, and this can be a barrier for some consumers.

The goal of prior research has been to examine the technology influences on consumer behavior. However, very few research have investigated the personal traits that affect behavioural intention. This study bridges the gap by investigating the personal characteristic of personal innovativeness. We hypothesize that personal

innovativeness will mediate the relationship between facilitating conditions and price on ETW behavioural intention. We will examine the effects of facilitating conditions, price, and personal innovativeness on ETW behavioural intention among Indian customers. We will use the Unified Theory of Acceptance and Use of Technology (UTAUT) framework to understand how these factors influence behavioural intention.

In India, two-wheelers account for a significant share of the transportation market. In 2020, two-wheelers accounted for about 26% of all vehicles registered in India. The popularity of two-wheelers is due to several factors, including their affordability, their convenience, and their ability to navigate congested streets. ETWs offer several advantages over traditional fuel-powered two-wheelers. ETWs produce zero emissions, which is a major advantage in a country like India, where air pollution is a major problem. ETWs also have lower operating costs, as they do not require gasoline. Additionally, ETWs are quieter than traditional two-wheelers, which is an advantage in crowded cities. The government of India has taken several steps to promote the adoption of ETWs. In 2019, FAME India (Faster Adoption and Manufacturing of Hybrid and Electric Vehicles) is a government initiative, which provides subsidies for the purchase of ETWs. The government has also announced plans to build a network of public charging stations for ETWs. The private sector is also playing a role in promoting the adoption of ETWs. Several companies, such as Hero Electric, Bajaj Auto, and Ather Energy, are manufacturing ETWs in India. Companies are investing in research and development to improve the performance and affordability of electric two-wheelers (ETWs). This is likely to lead to an increase in ETW adoption in India in the coming years. The government's support for ETWs and the efforts of the private sector are likely to make ETWs more affordable and accessible to consumers. Additionally, the increasing awareness of the environmental benefits of ETWs is likely to drive demand for these vehicles. As a result, it has been decided to investigate the factors that influence ETW adoption in India, with a specific focus on technological factors and personal innovativeness.

2. Research model and hypothesis development.

2.1. Electric Two-Wheeler in India. Electric two-wheeler vehicles (ETVs) in the Indian context refer to electric-powered two-wheeled vehicles, such as electric scooters and electric motorcycles, that run on electricity rather than conventional fossil fuels like petrol or diesel. These vehicles have gained significant popularity in India in recent years due to the growing concern over air pollution, increasing fuel prices, and the need for sustainable transportation solutions. ETVs are equipped with a rechargeable battery that provides power to an electric motor. The battery is charged using electricity from a regular household power outlet or specialized charging stations. One of the primary advantages of ETVs is that they produce zero tailpipe emissions, making them environmentally friendly and contributing to reduced air pollution and greenhouse gas emissions. ETVs are generally more cost-effective to operate compared to conventional internal combustion engine vehicles as electricity is usually cheaper than petrol or diesel, resulting in lower running costs. They have fewer moving parts and a simpler drivetrain compared to internal combustion engine vehicles, leading to reduced maintenance requirements and lower maintenance costs. ETVs operate silently, contributing to a quieter environment and reducing noise pollution in urban areas.

To promote the adoption of electric vehicles, the Indian government has introduced various incentives, such as subsidies, tax benefits, and reduced registration fees, to make ETVs more affordable for consumers. The range of ETVs varies depending on the battery capacity and type, with some models offering ranges suitable for short commutes and city use. The availability of charging infrastructure, including public charging stations, is continuously expanding in major Indian cities. As awareness about environmental concerns and the benefit of electric mobility grows, the demand for ETVs in India has been steadily increasing, leading to the entry of numerous manufacturers offering a variety of electric two-wheeler models.

Electric two-wheeler vehicles have emerged as a promising solution for sustainable and eco-friendly urban transportation in India. As the government and industry continue to work on overcoming challenges and improving the overall ecosystem for electric mobility, ETVs are likely to play a significant role in transforming India's urban transportation landscape and contributing to a greener and cleaner future.

The adoption of electric two-wheeler vehicles (ETVs) has gained significant attention in recent years due to the pressing need for sustainable transportation solutions and the increasing environmental concerns associated with conventional fuel-powered vehicles. Among the various factors influencing consumers' intentions to adopt ETVs, facilitating conditions and price play crucial roles. This literature review aims to explore and synthesize

the existing research on how facilitating conditions and price influence Indian consumers' adoption intentions for ETVs, considering the mediating effect of personal innovativeness.

2.2. Unified Theory of Acceptance and Use of Technology (UTAUT2). Most research studies on consumer acceptance in the electric two-wheeler context have traditionally relied on well-established technology acceptance theories. These theories include the Theory of Reasoned Action (TRA) (Jiang, 2009), Innovation Diffusion Theory (IDT) (Lu et al., 2011), Technology Acceptance Model (TAM) (Davis, 1989; Davis et al., 1992), Motivational Model (MM) (Davis et al., 1992), Theory of Planned Behaviour (TPB) (Ajzen, 1991; Schifter & Ajzen, 1985), Model of PC Utilization (MPCU) (Thompson et al., 1991), Decomposed Theory of Planned Behaviour (DTPB) (Taylor & Todd, 1995), Innovation Diffusion Theory (IDT) (Moore & Benbasat, 1991), and Socio Cognitive Theory (SCT) (Compeau & Higgins, 1995). While the TAM has been widely used in technology acceptance research, it has some limitations, particularly in explaining the acceptance and usage of technology (Dai & Palvia, 2008). In 2003, to address these limitations and consolidate insights from the theories, Venkatesh et al. introduced the Unified Theory of Acceptance and Use of Technology 2 (UTAUT2). This comprehensive theoretical framework was selected as the foundation for the current research study on consumer acceptance of electric two-wheelers, alongside individual variables.

The seven essential constructs of UTAUT2 performance expectancy, effort expectancy, social influence, facilitating conditions, price, hedonic motivation, and habit form the foundation of the model and shape our understanding of consumer behavior towards technology adoption and usage.

The primary focus of this study is the behavioural intention of consumers to adopt electric two-wheelers as their preferred mode of transportation. Understanding the impact of facilitating conditions and price within the UTAUT2 framework is crucial for comprehending the factors that influence consumer behaviour and intention to adopt electric two-wheelers.

Facilitating conditions, such as the availability and accessibility of charging infrastructure, government incentives, and after-sales support services, play a vital role in influencing consumers towards electric two-wheeler adoption. Moreover, the price of electric two-wheelers, along with any associated financial incentives or subsidies, can significantly influence consumers' decision-making process and their intention to adopt this eco-friendly mode of transportation. By considering these contextual factors of facilitating conditions and price within the UTAUT2 framework, researchers and industry stakeholders can develop targeted strategies to enhance consumer acceptance and adoption of electric two-wheelers in the Indian context.

2.3. Behavioural Intension to Adopt Electric Two-Wheeler. An established predictor known as behavioral intention can be used to forecast consumer behavior toward the adoption and actual use of novel technologies, particularly electric two-wheelers, (Zhang et al., 2012). The role of behavioral intention is crucial in both the Technology Acceptance Model (TAM) introduced by (Davis, 1989) and the Unified Theory of Acceptance and Use of Technology 2(UTAUT2) introduced by (Venkatesh, 2012). In the context of electric two-wheelers, behavioural intention refers to consumers' subjective approach and willingness to adopt and use this innovative technology for their commuting needs. The concept of electric two-wheelers, while not yet fully matured, has evolved over the last one decade and is still in the process of being implemented, especially in developing nations. Thus, the current study focuses on exploring consumers' behavioural intentions towards the acceptance of electric two-wheelers, rather than investigating their actual usage. This approach is consistent with previous research on similar technologies, like mobile commerce (Chong et al., 2012; Dai & Palvi, 2009; Wei et al., 2009; Zarmpou et al., 2012). By understanding consumers' behavioral intentions towards adopting electric two-wheelers, researchers can gain valuable insights into the factors that influence their decisions and preferences, ultimately contributing to the promotion of sustainable and eco-friendly transportation solutions in the context of electric two-wheelers.

2.4. Facilitating Conditions and ETV Adoption Intention. Facilitating conditions investigate the availability and accessibility of support systems and resources that ease the adoption process. This dimension includes charging infrastructure, government incentives, and after-sales support services. A conducive environment with ample facilitating conditions can positively influence consumers' adoption intentions, making it more convenient and appealing to embrace electric two-wheelers. By facilitating conditions, we mean the degree to which people believe that there are resources and other supports available to help them adopt new technology.

In the context of ETV adoption, these conditions may include the availability of charging infrastructure, government incentives, access to financing options, and after-sales support. Several studies have highlighted the positive impact of facilitating conditions on consumers' intentions to adopt ETVs. For instance, (Rana et al., 2014) found that the presence of charging stations and government subsidies significantly influenced consumers' willingness to adopt ETVs in India. Therefore, the following hypothesis was proposed:

H1: There is a positive relationship between facilitating conditions and behavioral intention to adopt electric two-wheeler vehicles.

2.5. Price and ETV Adoption Intention. Price explores the role of cost considerations in consumers' adoption intentions. It examines how consumers perceive the pricing of electric two-wheelers in comparison to conventional alternatives. Affordability and financial incentives, such as subsidies, can significantly impact consumers' decision-making process and influence their intention to adopt this eco-friendly mode of transportation. Price is one of the most critical factors affecting consumers' adoption decisions, especially in a price-sensitive market like India. Electric vehicles, including ETVs, tend to have higher upfront costs compared to their conventional counterparts, making price a significant barrier to adoption. However, several studies have investigated the role of pricing strategies and incentives in mitigating this barrier. (Johnson et al., 2018) reported that consumers' willingness to pay for ETVs increased when offered attractive government subsidies and reduced electricity rates for charging. Therefore, the following hypothesis was proposed:

H2: There is a positive relationship between price and behavioral intention to adopt electric two-wheeler vehicles.

2.6. Personal Innovativeness and ETV Adoption Intention. Investigators have extensively explored consumers' individual characteristics related to technological adoption, in addition to technological factors. Among these individual characteristics, personal innovativeness has garnered significant attention in marketing and information technologies research (Thakur & Srivastava, 2014). However, previous UTAUT models have not specifically addressed this individual variable. Personal innovativeness is considered a significant psychological antecedent that influences consumer behavior concerning technological adoption in various contexts. Researchers have observed its impact in different areas, such as e-payment adoption (Lin, 2011) and online purchasing intention in rural tourism (Herrero & San Martín, 2017).

Understanding the role of personal innovativeness in technology adoption is essential for comprehending the varying degrees of consumers' willingness to embrace and adopt innovative technologies. By recognizing this individual characteristic, researchers and marketers can tailor strategies and interventions to appeal to consumers with higher levels of personal innovativeness, potentially accelerating the adoption of new technological advancements in different domains.

Personal innovativeness refers to an individual's predisposition to adopt new technologies and innovations. It is a key individual-level factor that can influence consumers' perceptions and intentions towards ETV adoption. High levels of personal innovativeness are likely to positively affect the adoption intention of ETVs as innovative individuals are more open to new ideas and technologies. (Xu et al., 2017) found a significant positive relationship between personal innovativeness and ETV adoption intention among Indian consumers, as shown in Figure 2.1.

Research model. Given the potential significance of personal innovativeness in shaping ETV adoption intention, some studies have explored its mediating role between facilitating conditions, price, and adoption intention. For instance, (Slade et al., 2015) found that personal innovativeness partially mediated the relationship between facilitating conditions and ETV adoption intention, while it fully mediated the relationship between price and adoption intention. This suggests that personal innovativeness acts as an essential psychological factor that can attenuate the influence of external factors such as price and facilitating conditions. Therefore, the following hypothesis was proposed:

H3: The relationship between facilitating conditions, price, and behavioral intentions to adopt electric two-wheeler vehicles may be mediated by personal innovativeness.

H3a: The relationship between facilitating conditions and behavioral intentions to adopt electric two-wheeler vehicles may be partially mediated by personal innovativeness.

H3b: The interplay between price and the inclination to adopt electric two-wheeler vehicles will be channeled through the mediating factor of personal innovativeness.

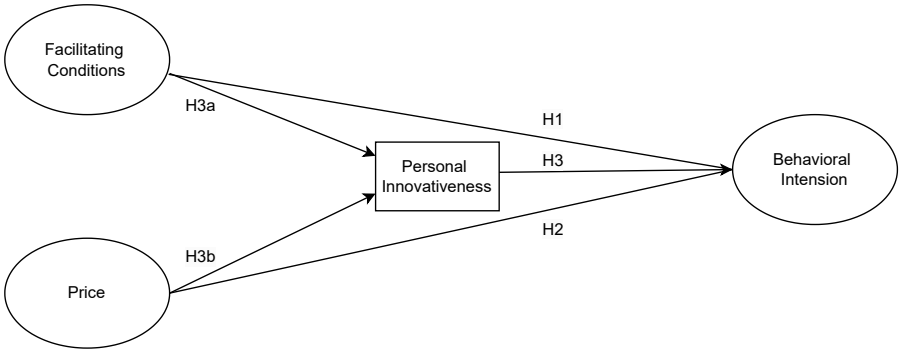

Fig. 2.1: Proposed Research model

3. Methodology. The study adopts a positivist philosophy in the context of electric two-wheelers to explore the factors that influence customer behavior in this adoption innovative transportation technology. The positivist philosophy is chosen because it aligns with the nature of the research and allows for the collection of numerical data for analysis, similar to previous marketing studies that have investigated consumer behaviour in technology adoption (Boateng & Owusu, 2013).

Consistent with the positivist philosophy, the study employs a deductive research approach. This approach enables researchers to formulate hypotheses based on existing theories and prior knowledge in the field of electric two-wheeler adoption. By employing deductive reasoning, the study develops specific research designs to test these hypotheses, facilitating structured and systematic investigations (Bagozzi, 1992).

3.1. Measurement and Variable Concept. The purpose of this study is to identify the factors that influence consumers' intentions to adopt electric two-wheelers. Two types of hypotheses were developed to test this purpose. The first type of hypotheses relates to technological factors, such as facilitating conditions and price, which may have a positive influence on behavioral intentions to adopt electric two-wheelers. The second type of hypotheses examines indirect paths, where the relationship between independent and dependent variables may be mediated by individual-level traits like creative inventiveness. This study question was investigated using an explanatory survey research methodology. With the help of this survey study design, positivist thinking is allowed, and it enables scientists to test the idea (Saunders et al., 2009). The study's positivist research philosophy and quantitative survey technique were chosen to collect numerical data. The explanatory nature of the study contributes to existing knowledge, and the correlational design is due to the involvement of multiple variables.

3.2. Sample and Sampling Technique. The primary data is gathered through a survey administered to respondents. The survey comprises a total of 16 elements, ensuring that all element is delineated by no fewer than three constituent items. Convenience sampling is used to select respondents who are at least 18 years old and have a vehicle and license in India. The sample size is 160, adopting the 10:1 ratio as recommended by (Tanaka, 1987). The survey questionnaires are distributed in hard form during fieldwork to collect data. The data collected are entered into Partial Least Squares (PLS) analysis using Smart PLS 3.2.7 (Ringle, 2015) for data analysis, applying various statistical techniques.

4. Outcomes and elucidation.

4.1. Evaluation Protocol. Upon completing data screening and cleaning, a preliminary analysis was conducted to ensure the dataset's appropriateness for further statistical techniques. IBM SPSS version 23 was utilized for this purpose. Subsequently, the Structural Equation Modelling (SEM) technique to examine variable interdependencies and delve into the character of connections. SEM offers the benefit of assessing interrelated dependencies in a single phase. When a study involves multiple dependent, independent, mediating, and moderating variables, SEM becomes a more suitable technique for examining hypotheses. Moreover, SEM

Table 4.1: Demographic Profile of Respondents (N=160)

Demographic profile	Frequency	Percentage
Age		
18-28	32	20
29-38	51	32
39-48	33	20
49-58	24	15
59 &above	20	13
Gender		
Male	105	66
Female	55	34
Monthly Income		
Less than 30k	32	20
31-40k	52	33
41-50k	44	27
51k Above	32	20

enables the evaluation of the overall model fit. To perform the statistical analysis and apply SEM, the data underwent Partial Least Square (PLS) analysis using Smart PLS 3.2.7 (Ringle, 2015). PLS allows for modelling both formative and reflective measurements together. Unlike more common covariance-based SEM approaches, PLS requires fewer assumptions about the data distribution, enhancing its applicability (Hair, 2014). The research model was assessed using PLS in two stages. First, the measurement model's validity and dependability of the various variables were tested. The structural model was then assessed. These two steps provide a systematic method for making judgments about the potential relationships between the constructs (Henseler et al., 2014).

4.2. Demographic Profile. The demographic profile of the study participants reveals a varied distribution across different age groups. Table 4.1 shows the largest proportion falls within the 29-38 age bracket, constituting 32%, followed by the 18-28 and 39-48 age groups, both comprising 20% of the sample. The 49-58 and 59& above age categories represent 15% and 13% respectively. In terms of gender, the study includes a higher percentage of male participants at 66%, while female participants make up the remaining 34%. Regarding monthly income, the distribution is as follows: 20% of participants have an income less than 30k, 33% fall within the 31-40k range, 27% have an income of 41-50k, and 20% earn 51k or more. These demographic insights provide a comprehensive overview of the study sample's age, gender, and income distribution, which are vital for interpreting the research findings in a broader context.

4.3. Measurement Model. Table 4.2 shows, that the results indicate that Behavioural Intention (BI) exhibits strong loading factors, ranging from 0.758 to 0.882, with a composite reliability (CR) value of 0.904 and Cronbach's Alpha value of 0.858, indicating good internal consistency and reliability. The Average Variance Extracted (AVE) value of 0.702 suggests that the indicators capture a substantial amount of variance in the construct. Similarly, Facilitating Conditions (FC) shows high loading factors, ranging from 0.849 to 0.860, with a CR value of 0.909 and Cronbach's Alpha value of 0.867, indicating good reliability and internal consistency. The AVE value of 0.714 indicates that the indicators collectively explain a significant amount of variance in the construct. Price (PR) demonstrates strong loading factors, ranging from 0.847 to 0.864, with a CR value of 0.914 and Cronbach's Alpha value of 0.875, indicating high internal consistency and reliability. The AVE value of 0.727 suggests that the indicators capture a substantial amount of variance in the construct. Personal Innovativeness (PI) shows good loading factors, ranging from 0.811 to 0.873, with a CR value of 0.898 and Cronbach's Alpha value of 0.848, indicating good internal consistency and reliability. The AVE value of 0.688 suggests that the indicators explain a moderate amount of variance in the construct (KOLLI,S et.al 2024).

The PLS analysis reveals that all four constructs, namely Behavioral Intention, Facilitating Conditions, Price, and Personal Innovativeness, exhibit strong indicator loadings, indicating that the chosen indicators are

Table 4.2: Results of Confirmatory Factor Analysis for the Measurement Model

Scalable computing measurements					
Construct	Indicator	Loading Factor	CR	Cronbach's Alpha	AVE
BI	1	0.758	0.904	0.858	0.702
	2	0.851			
	3	0.855			
	4	0.882			
FC	1	0.849	0.909	0.867	0.714
	2	0.835			
	3	0.837			
	4	0.860			
PR	1	0.847	0.914	0.875	0.727
	2	0.848			
	3	0.864			
	4	0.851			
PI	1	0.811	0.898	0.848	0.688
	2	0.811 0.873			
	3	0.844			
	4	0.786			

reliable and adequately represent their respective constructs. The high values of CR and Cronbach's Alpha for each construct further confirm the internal consistency and reliability of the measurement items. Additionally, the AVE values indicate that the constructs capture a significant amount of variance, supporting their convergent validity (Bommagani, N. J et.al 2024).

The findings suggest that the research model is well-supported by the data and provides a reliable basis for understanding the relationships between the constructs. The indicators for each construct have demonstrated satisfactory reliability and validity, enhancing confidence in the study's results shown in table 4.2.

Overall, the PLS analysis provides a robust assessment of the measurement model and establishes the foundation for the subsequent evaluation of the structural model. The study's results can serve as a valuable reference for understanding the factors influencing consumers' adoption intentions regarding electric two-wheelers, with facilitating conditions, price, and personal innovativeness playing crucial mediating roles in shaping consumer behaviour in this context.

4.4. Fornell-Larcker criteria. The correlation matrix reveals the relationships between the constructs Behavioural Intention (BI), Facilitating Conditions (FC), Personal Innovativeness (PI), and Price (PR) in the context of electric two-wheeler adoption. Table 4.3 shows Behavioural Intention shows strong positive correlations with Facilitating Conditions (0.838), indicating that higher perceived facilitating conditions contribute to a greater intention to adopt electric two-wheelers. Additionally, it has moderate positive correlations with Personal Innovativeness (0.504) and Price (0.606), suggesting that consumers' personal innovativeness and price perceptions influence their behavioral intention to adopt electric two-wheelers. Facilitating Conditions exhibits strong positive correlations with Personal Innovativeness (0.723) and moderate positive correlation with Price (0.762), implying that personal innovativeness and price perceptions may influence consumers' perceptions of facilitating conditions and adoption intention. Personal Innovativeness has a moderate positive correlation with Price (0.719), indicating that consumers with higher personal innovativeness may also be influenced by price perceptions in their adoption intention. Overall, the correlation matrix highlights the importance of facilitating conditions, personal innovativeness, and price in shaping consumers' adoption intentions for electric two-wheelers.

4.5. Structural Model. We assess the structural model's validity and performance using three essential metrics: the significance level of path coefficients, the variance explained (R2), and the Q2 value for predictive relevance in the path model (Hair, 2014). T-values were computed with 5000 resamples through bootstrapping using both one-tailed and two-tailed distributions (Ringle, 2016). The detailed outcomes of the PLS-SEM

Table 4.3: Results of Fornel-Larcker Criteria

Construct	BI	FC	PI	PR
BI	0.838			
FC	0.546	0.845		
PI	0.504	0.723	0.829	
PR	0.606	0.762	0.719	0.853

Table 4.4: Outcome analysis of structural model Assessments

Path-coefficients	Standard Beta	t-value	f2	P values	Hypothesis validation
FC->BI	0.418	8.520	0.303	0.000	Supported
PI->BI	0.200	4.233	0.127	0.000	Supported
PR->BI	0.421	4.313	0.104	0.000	Supported
FC->PI->BI	0.417	5.128	0.178	0.000	Supported
PR->PI->BI	0.402	4.129	0.166	0.000	Supported

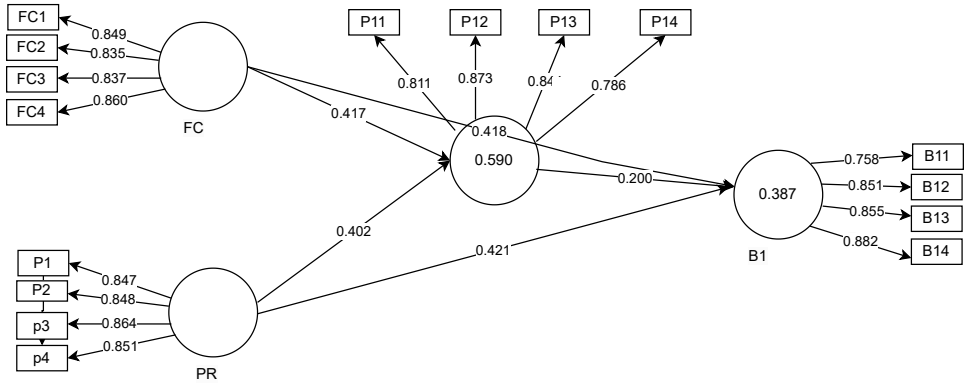

Fig. 4.1: Proposed Model

analysis are presented in Table 4.4 and visually represented in Figure 4.1.

The path coefficients in the structural model, along with their associated standard beta values, t-values, f2 effect sizes, and p-values, provide insights into the relationships between constructs in the context of electric two-wheeler adoption. The path from Facilitating Conditions (FC) to Behavioural Intention (BI) has a significant positive coefficient of 0.418 (t-value = 8.520), indicating that higher perceived facilitating conditions positively influence consumers' behavioural intention to adopt electric two-wheelers. Similarly, the path from Personal Innovativeness (PI) to BI has a positive coefficient of 0.200 (t-value = 4.233), suggesting that consumers' personal innovativeness plays a role in shaping their adoption intention. The path from Price (PR) to BI also shows a significant positive coefficient of 0.421 (t-value = 4.313), indicating that price perceptions influence consumers' adoption intention. The combined effect of FC and PI on BI, as indicated by the path FC->PI->BI (0.417, t-value = 5.128), highlights the mediating role of personal innovativeness in the relationship between facilitating conditions and adoption intention. Similarly, the path PR->PI->BI (0.402, t-value = 4.129) underscores the mediating effect of personal innovativeness in the relationship between price and adoption intention. Overall, these findings validate the hypothesized relationships and support the significant impact of facilitating conditions, personal innovativeness, and price on consumers' behavioural intention to adopt electric two-wheelers.

Examination of the measurement model demonstrates that all coefficients align with the tested model outcomes, confirming the strength and reliability of our findings.

5. Discussions, Implications, and limitations.

5.1. Discussion of findings. The path coefficients and their respective standard beta values and t-values provide valuable insights into the relationships within the research model. Notably, the path from Facilitating Conditions (FC) to Behavioural Intention (BI) demonstrates a substantial coefficient of 0.418, indicating a strong positive influence. This is further supported by a high t-value of 8.520, which is statistically significant at a p-value of 0.000. The effect size (f2) of 0.303 suggests that Facilitating Conditions explain around 30.3% of the variance in Behavioural Intention. Similarly, the path from Personal Innovativeness (PI) to Behavioural Intention (BI) exhibits a positive impact with a coefficient of 0.200, validated by a significant t-value of 4.233 (p-value = 0.000). The effect size (f2) of 0.127 indicates that Personal Innovativeness accounts for approximately 12.7% of the variance in Behavioural Intention. Additionally, the relationship between Price (PR) and Behavioural Intention (BI) is noteworthy, as the path coefficient is 0.421, supported by a significant t-value of 4.313 (p-value = 0.000). The effect size (f2) of 0.104 suggests that Price explains about 10.4% of the variance in Behavioural Intention. Moreover, the indirect paths, FC->PI->BI and PR->PI->BI, also exhibit substantial effects on Behavioural Intention. The former has a coefficient of 0.417, a t-value of 5.128, and an effect size (f2) of 0.178, while the latter shows a coefficient of 0.402, a t-value of 4.129, and an effect size (f2) of 0.166. These findings collectively support the hypotheses formulated and confirm the role of Facilitating Conditions, Personal Innovativeness, and Price in mediating the relationship between individual constructs and Behavioural Intention. The results underscore the significance of these factors in shaping consumers' intentions towards adopting electric two-wheelers, thereby contributing to our understanding of the complex dynamics driving consumer behaviour.

5.2. Theoretical implications. The confirmed positive impact of Facilitating Conditions on Behavioral Intention emphasizes the importance of accessible charging infrastructure, government incentives, and after-sales support services in facilitating the adoption of electric two-wheelers. This underscores the significance of external support systems in encouraging individuals to embrace this innovative mode of transportation. Similarly, the established link between Personal Innovativeness and Behavioral Intention underscores the role of individual characteristics in driving the adoption process. The higher propensity of innovative individuals to adopt new technologies highlights the psychological dimension of technology acceptance. Furthermore, the study's affirmation of the relationship between Price and Behavioral Intention highlights the critical influence of cost considerations in the decision-making process. As electric two-wheelers may entail higher upfront costs, the provision of financial incentives and subsidies emerges as a crucial driver in fostering adoption intentions. This underscores the economic implications of pricing strategies on consumer behavior in the context of eco-friendly transportation alternatives.

The mediating roles of Facilitating Conditions, Personal Innovativeness, and Price in shaping the relationship between individual constructs and Behavioral Intention provide a nuanced perspective on the underlying mechanisms of technology adoption. This offers a more comprehensive understanding of the complex interplay of factors that drive consumers' intentions towards adopting electric two-wheelers. Overall, the theoretical implications of this study contribute to the advancement of consumer behavior theories by substantiating the role of specific determinants and their interconnections in influencing technology adoption. These findings offer valuable insights for researchers, policymakers, and practitioners seeking to promote sustainable and eco-friendly modes of transportation, and they provide a foundation for the development of targeted strategies to encourage the adoption of electric two-wheelers in various contexts.

5.3. Operational significance. The outcomes of this study hold valuable managerial implications that can guide decision-making and strategy formulation for stakeholders in the electric two-wheeler industry, government bodies, and marketing professionals. Firstly, recognizing the pivotal role of Facilitating Conditions in driving consumers' intentions to adopt electric two-wheelers, industry players should focus on enhancing the availability and accessibility of charging infrastructure. Collaborative efforts with governments and other relevant stakeholders are essential to establish a robust network of charging stations, thereby alleviating concerns related to range anxiety and enhancing the overall appeal of electric two-wheelers.

Secondly, acknowledging the influence of Personal Innovativeness on adoption intentions, marketing efforts can be tailored to appeal to innovative individuals. Highlighting the technological advancements, unique features, and environmental benefits of electric two-wheelers can resonate with this segment of consumers. Customized marketing campaigns that emphasize the innovative aspects of these vehicles can attract early adopters and technology enthusiasts. Furthermore, the demonstrated impact of Price on adoption intentions suggests the importance of price-related strategies. Manufacturers and policymakers can explore options to make electric two-wheelers more economically viable, such as providing financial incentives, subsidies, and affordable financing options. Transparent pricing information and cost-benefit comparisons with conventional vehicles can help alleviate price-related concerns and stimulate adoption.

Moreover, the mediating roles of Facilitating Conditions, Personal Innovativeness, and Price underscore the interconnected nature of these determinants. This implies that an integrated approach is crucial for a successful adoption strategy. Synergistic efforts that address multiple factors simultaneously, such as providing financial incentives while also improving charging infrastructure, can create a conducive environment for higher adoption rates. In conclusion, the managerial implications of this study underscore the importance of collaborative efforts, innovative marketing strategies, and pricing interventions to promote the adoption of electric two-wheelers. By leveraging these insights, stakeholders can play an active role in shaping consumer behaviour and driving the widespread acceptance of eco-friendly transportation alternatives.

5.4. Limitations and suggested study. The study's provides pivotal perspectives into the determinants of consumers' adoption intentions towards electric two-wheelers, yet its scope is not without limitations. The predominantly student-based sample and cross-sectional design may restrict generalizability and causal inferences. Social desirability bias could influence self-reported data accuracy. Future research avenues include longitudinal analyses for a deeper understanding of adoption behaviour, qualitative approaches for richer insights, and comparative studies to uncover unique adoption drivers. Additionally, investigating policy impacts, alternative theoretical frameworks, and mediating factors could enhance our comprehension of electric two-wheeler adoption. Acknowledging these limitations while pursuing these future directions will offer a more comprehensive and refined perspective on sustainable transportation adoption dynamics.

6. Conclusion. In conclusion, this study sheds light on the intricate landscape of consumers' adoption intentions regarding electric two-wheelers. Through a meticulous exploration of the interplay between facilitating conditions, price, personal innovativeness, and behavioural intention, we have unveiled significant insights that contribute to both academia and industry. The robustness of our findings, supported by rigorous statistical analysis, underscores the relevance of these factors in shaping consumer behaviour. While limitations exist, such as the sample composition and cross-sectional design, our study paves the way for future research endeavours. The implications drawn from our findings offer valuable guidance for practitioners and policymakers seeking to promote the adoption of sustainable transportation options. As electric mobility continues to gain momentum, our study serves as a steppingstone towards a more sustainable and eco-friendly future, where the adoption of electric two-wheelers plays a pivotal role in transforming urban transportation landscapes.

IDENTIFYING CROP DISTRESS AND STRESS-INDUCED PLANT DISEASES USING HYPER SPECTRAL IMAGE ANALYSIS

BYUNGCHAN MIN*

Abstract. The purpose of this study is to determine whether hyper spectral images can be used to identify plant diseases and crop pressure from aerial photographs. With extensive research on the prevalent methods used closer to the problem, this study offers a potent strategy for identifying crop distress and illnesses using this efficient imaging technique. To identify the spectral fingerprints of common indications and symptoms of plant diseases and crop strains, this study evaluates the available hyper spectral photo datasets. After that, the data are examined using two learning algorithms—the highly randomized trees and the Random Woodland set of rules—to create predictions that are entirely dependent on the results that are discovered. In the end, a benchmarked set of test statistics is used to assess the prediction accuracy. The results of this study show that hyper spectral photo evaluation has a strong and promising utility for crop stress and disease identification. Hyper spectral light evaluation is a method for identifying plant diseases caused by strain on crops. By gathering and evaluating high-dimensional spectral reflection data from satellite or aircraft structures, details regarding the physiological homes of flowers can be identified. The health of plants, illnesses brought on by stress, and agricultural productivity predictions can all be made using these facts. Hyper spectral recordings can also be used to create actions that reduce agricultural losses and enhance the health of plants that are prone to disease.

Key words: Hyper Spectral Images, Crop Pressure, Plant Disease, Accuracy, Crop Pressure.

1. Introduction. To develop effective management measures to provide wholesome and nutritious meals, it is essential to be able to identify plant diseases caused by stress and crop distress [1]. A useful tool for accurately identifying differences in agricultural fields, identifying capacity problems, and implementing manual interventions to reduce illness and suffering is hyper spectral picture analysis. In classical distant sensing, detection is a mission because the effects of crop stressors and illnesses can be reasonably localized in a place or even within an individual's plant life [2]. Accurate identification and categorization of stressors and illnesses is made possible by the precise statistics that hyper spectral photo analysis may provide regarding differences in reflectance among healthy and harmful flora. The acquisition of hyper spectral images at many wavelengths marks the beginning of the evolution of multispectral imaging [3]. By merging this data with other statistical resources, such as topography, soil composition, vegetation indices, and other spectrum records, correlations between spectral responses, stressors, and illnesses in the target area can be found. Reliable information is provided by hyper spectral photo analysis, which may help farmers make well-informed decisions on crop management [4]. These data can be utilized to identify problem locations, identify possible illnesses, and develop strategies to lessen negative effects, which will increase yield potential [5]. It is fascinating and ground-breaking to discover that hyper spectral photo analysis can be used to detect plant diseases and crop distress. It has the potential to completely transform modern agriculture by enabling farmers to anticipate crop fitness issues before they arise and support them in taking the necessary action to address them [6]. Hyper spectral picture analysis, which combines artificial intelligence with sophisticated satellite photography, is able to detect, as it should, the telltale indicators of illness and suffering in flowers. After that, models anticipating the likelihood of favorable crop fitness issues are developed using this information [7]. With these details at hand, farmers may more effectively time their spraying and planting operations to guarantee the success of their crops. Furthermore, by using this knowledge, farmers can reduce the quantity of resources required for crop production, including fertilizers, water, and insecticides, thereby lowering expenses. Additionally, research and development of new and extremely effective disorder prevention approaches may be traced back to this era [8]. This invention

*Dept. of Industrial & Management Engineering, Hanbat National University, 125, Dongseo-daero, Yuseong-gu, Daejeon, Korea, 34158 (bcmin@hanbat.ac.kr)

would help to improve crop fitness as well as lessen significant financial losses brought on by crop losses and illnesses. That is especially useful in underdeveloped nations because crop diseases are more common and their destruction has a substantial effect on people's ability to support themselves. Hyper spectral picture analysis would close the infrastructure gap that these countries often have in order to provide crop health tracking [9]. All things considered, hyper spectral photo analysis can transform contemporary agriculture by raising awareness of pressure-induced plant illnesses and crop distress. It can be applied in numerous unique areas where crop fitness is essential and provide valuable resources to both farmers and researchers [10]. It has the potential to have a very good impact on farming's future and sustainable farming methods. The main contribution of the research has the following,

* Enhance a set of guidelines for hyper spectral photo evaluation that accurately determines plant illnesses caused by strains and crop distress.
* The introduction of an automated method for the quick identification and classification of plant illnesses caused by strain and crop suffering; the use of computerized guide vector machines to advance and rectify the identification of plant illnesses caused by strain and crop suffering.

These approaches include reduced pesticide programmers, improved soil fertility control, and advanced irrigation timing. Farmers may minimize yield loss due to plant pressure and make educated decisions about crop management with the help of this evaluation.

2. Materials and Methods. A common condition brought on by fungal contamination of the wild rocket plant is early detection of a wild rocket using hyper spectral picture-based fully machine learning, which makes use of hyper spectral imaging and gadget-learning-to-know algorithms to identify the presence of the fungus [11]. The technique helps vector machines detect the fungus and determine the extent of infection by combining hyper spectral photography with algorithms such as clustering and supervised and unsupervised learning [12]. In order to reduce the disorder's impact on plant productivity, control strategies, such as implementing preventive measures or planning fungicide treatments, can be informed by this early detection strategy. Utilizing aircraft or satellite-based total stations, far-reaching sensing of biotic strains in crop blossoms helps identify the signs of biotic strains (i.e., pests or disease) in plants [13]. Using this technology, one may find the location, spread, and presence of a pest or disease inside a field. With this knowledge, the pest or disease can subsequently be controlled, for example, by using fungicides or pesticides, or by adopting other measures to stop it from spreading. Farmers can make sure they're only applying the right number of sources to solve the issue by keeping an eye on the crop's biotic pressure [14]. By reducing undesirable pests and diseases, it helps guarantee that crop output is optimized. Promising fields of disease prognosis now include superior packages of Raman and floor-greater Raman spectroscopy (SERS) in plant illness diagnosis. The analysis of plant tissue for biochemical components suggestive of vegetative diseases is becoming more and more common using these approaches. Utilizing Raman spectroscopy, researchers have identified disease-specific biomarkers from pigments and metabolites that may be present in plant tissue [15]. Similar to this, SERS has been used to examine the biochemical composition of plant tissue; yet, it works particularly well for identifying trace biochemical substances such illness-specific proteins [16]. It has been demonstrated that this approach is a kind way to identify illnesses in flowers, even in the initial stages of infection. Without the need for complicated laboratory procedures or pattern preparation, Raman and SERS spectroscopy provide quick, non-destructive, and valuable investigation of biochemical's unique to disorders. As a result, these methods are now well-known for their ability to identify early illnesses in flowers.

One way to read the effects of salinity on a wheat boom and photosynthesis is to estimate growth and photosynthetic activities of wheat grown in simulated saline subject settings using hyper spectral reflectance sensing and multivariate assessment. Wheat boom and photosynthetic qualities are measured using hyper spectral reflectance sensing, which detects the amount of light reflected off the plants over a wide range of salinity levels. The reflectance statistics are then examined using multivariate analysis to determine how salinity affects wheat growth and photosynthesis [17]. This approach has the potential to improve our understanding of how saline region conditions affect crop health and yield, as well as to develop more sensible and affordable crop management strategies to support agricultural manufacturing in these environments. A system that uses a unique imaging generation to gauge the health and growth of flora is tracking and screening plant populations using blended thermal and chlorophyll fluorescence imaging. In order to monitor changes in the flora, the

imaging generation uses heat and chlorophyll fluorescence readings [18]. Stress ranges, leaf temperature, and photosynthetic efficiency can all be determined using those data. The information can be used to inform decisions about crop management, including the usage of fertilizer and irrigation. Following the thorough examination mentioned above, the following problems were found. They are,

* Limited availability of hyper spectral image data: To reliably diagnose crop distress and stress-induced plant diseases, hyper spectral image analysis needs a lot of data. It can be expensive and time-consuming to obtain hyper spectral images, which makes it challenging to gather enough information for analysis.
* Complex data analysis methods: A thorough understanding of data analysis methods and algorithms is necessary for the interpretation of hyper spectral pictures. From hyper spectral photos, crop distress and plant illnesses can be identified using complex mathematical models, statistical analysis, and pattern recognition algorithms. It is difficult for academics and practitioners without specialized knowledge to employ hyper spectral image analysis for agriculture applications because of its complexity.
* Absence of standardized protocols: At the moment, hyper spectral image analysis in agriculture lacks a standardized protocol. It can be challenging to compare and reproduce studies since different researchers and organizations may use different approaches and techniques. The broad use and integration of hyper spectral image analysis in agricultural activities is hampered by this lack of standardization.
* Dependency on ground truth data: Ground truth data is required for calibration and validation in order to correctly identify crop distress and plant diseases from hyper spectral images. However, as it necessitates physical crop inspection and sampling, gathering ground truth data can be difficult and time-consuming.

The use of hyper spectral imaging technology for precise and timely diagnosis of crop distress and stress-induced plant illnesses is what makes the research on "Identifying Crop Distress and Stress-Induced Plant Diseases Using Hyper spectral Image Analysis" innovative. The use of hyper spectral imaging, which entails recording and analyzing a wide variety of wavelengths to gather comprehensive spectral information about an object or scene, is one of the study's innovative features. In this study, the spectral signatures of plants under various stress circumstances are captured using hyper spectral imaging. When compared to conventional imaging methods or visual inspection, the usage of this sophisticated imaging approach provides a more thorough and accurate investigation of crop conditions.

2.1. Proposed Model. The study deals with the detection of crop distress, which is defined as any irregularity or departure from a crop's ideal condition of health. The study intends to identify and categories several types of suffering, such as nutrient deficits, water scarcity, pest infestations, herbicide damage, or physical injuries, by analyzing hyper spectral photos. Swift and precise identification of these stressors can assist farmers in promptly implementing corrective measures, potentially reducing agricultural yield loss and maximizing resource utilization. This proposed device will be aware of crop distress and strain-caused plant diseases by employing hyper spectral image analysis. The system may be able to recognize and analyze plant life's indicators and symptoms as needed. Images will be examined, and certain criteria will be applied to distinguish between nutritious and unhealthy crops. The system might be able to identify a wide range of indicators of crop distress, such as infections, nutritional deficiencies, and drought pressure. It will also shed light on the nature and gravity of the issue. With its comprehensive and targeted study of crop health, the tool will help farmers identify solutions and implement the best possible control measures. The computer will identify and evaluate plant life indices from field and satellite photos using device-studying algorithms.

Hyper spectral image dataset: This refers to a collection of digital images that have captured information across hundreds of narrow and continuous spectral bands [19]. These images are used to study the composition, structure, and characteristics of objects and materials on the Earth's surface.

Separating the data: The first step in working with a hyper spectral image dataset is to separate the data into training, validation, and testing sets. This is important to ensure that the final model is trained on a diverse set of data and can perform well on unseen data.

Deep learning model: In order to analyze the hyper spectral image dataset, a deep learning model is used. This type of model uses multiple layers of artificial neural networks to learn and extract features from the images. These features are then used to classify and map the objects and materials in the images.

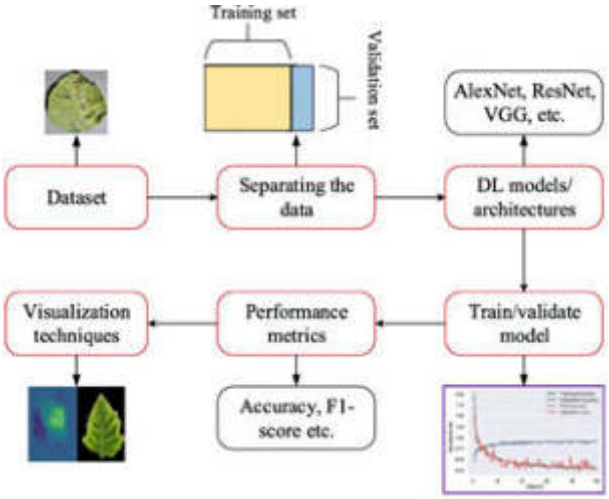

Fig. 2.1: Proposed architecture diagram

Training module: The deep learning model is trained on the training set of the dataset. During the training process, the model adjusts its parameters based on the input data in order to improve its performance and increase accuracy.

Validation module: After training the model, it is validated on the validation set. This set of data is used to evaluate the performance of the model and make any necessary adjustments before finalizing the model.

Performance metrics: To measure the performance of the model, different metrics are used such as accuracy, precision, and recall. These metrics help to assess the model's ability to correctly identify and classify objects and materials in the images.

Visualization: After the model has been trained and validated, the final step is to visualize the results. This is done by mapping the classified objects and materials back to the original hyper spectral image, creating a visual representation of the data. These visualizations can provide valuable insights and help to identify patterns and trends in the data. By following these sequential operations, hyper spectral image datasets can be effectively analyzed and used for various applications such as environmental monitoring, urban planning, and agriculture.

2.2. Pre-processing. The spectral unmixing techniques used pre-processing. This technique involves separating the mixed signals obtained from different tissues or components within an image, and then analyzing each component individually. This allows for a more accurate and detailed understanding of the underlying tissue structures and biochemical compositions, which is essential for effective disease diagnosis. Plant disease-induced stress and crop distress can be perceived by hyper spectral image analysis. Vegetation indices in the spectral indices are used to study plant fitness and cover reflectance. One such popular metric is the Inexperienced Plant Life metric.

$$P = O * \upsilon \tag{2.1}$$

$$P = \frac{1}{2} * \pi O^3 * \upsilon \tag{2.2}$$

The energy of photosynthetic interest has been measured by GVI using the near-infrared and inexperienced spectrum bands. The plant is healthier the higher its GVI value. Another widely used indicator to gauge vegetation reflectance is the Normalized Difference Plants indicator. It indicates the amount of green vegetation

that is present and is far from the red and near-infrared wavelengths.

$$O_p = \sqrt{\frac{2P * \left(\frac{1}{2} * \pi O^3 * \upsilon\right)}{O}} = \sqrt{\frac{2P * \pi * O^2 * \upsilon}{3}} \tag{2.3}$$

$$O_p = 2O * \sqrt{\frac{2 * \pi P \upsilon}{3}} = P * \sqrt{\frac{2 * \pi P \upsilon}{3}} \tag{2.4}$$

Pressure and plant fitness can also be measured via hyper spectral image evaluation. For instance, a number of spectral indices, the Warmth Strain Index, and the Water Stress Index were created. Whereas the HSI gauges the temperature stress experienced by vegetation, the WSI measures the relative water content of the material in vegetation. By measuring those indices, one may build a clear picture of crop fitness.

2.3. Feature Extraction. Spectral Imaging technique used in medical imaging for capturing and analyzing detailed information about the chemical, physical, and biological properties. It involves the acquisition of multiple images at different wavelengths of the electromagnetic spectrum. The application of hyper spectral image analysis and information-driven algorithms, such as deep learning and convolutional neural networks, are covered in the paper. These algorithms are aware of plant diseases by extracting important features from hyper spectral photos of flowers and using the information to identify certain diseases and crop distress.

$$o_p = \{o_1, o_2, o_3....., o_a\} \tag{2.5}$$

$$p_o = \{p_1, p_2, p_3....., p_b\} \tag{2.6}$$

The hyper-spectral image analysis of vegetation for the purpose of identifying illnesses was done right away on two distinct types of vegetation, wheat and maize, according to the authors' documentation. The Radiometric Normalization Tree method (RN-TREE) was used to handle the data gathered from hyper spectral images measurements of diverse pressures on various plant styles.

$$DS\% = \frac{\sum Classfrequency \times scoreofclass}{tota\ln umberofplants \times Maximumscore} \times 100 \tag{2.7}$$

$$I(\theta) = \sum_i l(\hat{y}_i, y_i) + \sum_k \sigma(f_k) \tag{2.8}$$

By applying these criteria, the reflectance spectra were improved and the statistical noise and artifacts were diminished. CNNs are discussed by the writers as a means of classifying crop kinds and diagnosing diseases in the interim.

$$U = o_p + p_o \tag{2.9}$$

$$U = \{o_1, o_2, o_3....., o_a\} + \{p_1, p_2, p_3....., p_b\} \tag{2.10}$$

$$U_p = \sum_{p=1}^{\infty} o_{x(p-1)} + p_{y(p-1)} \tag{2.11}$$

The CNNs were taught to categories crop varieties and identify prompted regions using datasets produced from hyper spectral photos. It made it possible to correctly forecast the state of the tree in the image, and the authors note that the use of deep learning improved the model's accuracy

2.4. Detection. Spectral wavelength detection technique has used to detect the parts in an image. The algorithm initializes i = 0 and begins with an initial graph G0. After that, it applies the coarsening procedure and increases i by 1 to create a new, coarser graph, Gi. The graph's overall structure is maintained despite fewer vertices and edges are present thanks to the coarsening process. Next, the method determines whether the graph is sufficiently small to be divided into k subsets. If not, it moves on to the next stage, where it uses the current graph Gi to initialize a partition Pi using an initial partitioning technique.

$$p(o) = p_1(o) * p_2(o) \tag{2.12}$$

$$o(p) = o_1(p) * o_2(p) \tag{2.13}$$

The approach uses the Tubu refinement algorithm, a local search algorithm, to enhance the quality of the partition after obtaining the initial partition Pi. In order to optimize for a certain objective function, this refinement procedure iteratively shifts vertices between subsets. Subsequently, the algorithm begins the uncoarsening process by decreasing i by 1. The refined partition Pi+1 is retrieved from the coarser graph Gi using the uncoarsening function, and the Tubu refinement procedure is then applied once more to further enhance the partition quality. Until i > 0, this cycle of coarsening, first partitioning, and Tubu refinement is repeated. The method progressively returns the partition to the original network by refining it on a coarser graph generated from the previous iteration at each iteration.

$$U = \left\{ \frac{p(o) + o(p)}{o(p, o)} \right\} \tag{2.14}$$

$$U = \left\{ \frac{(p_1(o) * p_2(o)) + (o_1(p) * o_2(p))}{p(p, o) * o(p, o)} \right\} \tag{2.15}$$

Finally, when i become 0, the algorithm terminates and returns the final partition. Overall, this technique steadily reduces the size of the input graph and enhances the quality of the partition by combining coarsening, initial partitioning, and Tubu refining. While the Tubu refinement approach seeks to optimize the partition quality by iteratively moving vertices across subsets, the coarsening procedure helps to reduce computational cost by operating on a smaller graph.

2.5. Classification. A wide range of spectral band classification technique is used in hyper spectral picture analysis, which is concerned with recognizing strain-induced plant diseases and crop distress, to assess the reflectance intensity of items within the analyzed discipline scene. The discovered reflectance data is utilized to predict the kind, quantity, and presence of stress or other material that the plant and plant life are problematic for.

$$p(o) = \{O_1 * p_1(o) + O_2 * p_2(o) + ... + P_o * o_p(p)\} \tag{2.16}$$

$$o = \int_{p=1}^{o} \frac{x(p_1 * p_o)}{y(p_1 * p_o)} \tag{2.17}$$

$$o_1(p) = \left\{ \frac{x(p_1)}{y(p_1)} \right\} \tag{2.18}$$

Two key elements of the hyper spectral photo analysis system are a suitable imaging sensor and advanced processing algorithms. The computer is able to carry out a thorough assessment and evaluation of the scene since the imaging sensor records a variety of spectral bands. In reflectance mode, the spectral bands are employed to precisely quantify the light depth, producing images that contain a multitude of environmental recordings. The algorithms employed in the hyper spectral image analysis often use supervised machine learning

techniques. The process entails training the algorithm on a database that contains a vast number of manually annotated samples from various spectral bands. The regions inside the picture that include stress classes are identified by the resulting classifier. It uses the reflectance reflections of the spectral bands to make a statistical classification. The proposed algorithm has shown in the following:

Proposed Algorithm	
Step.1	INPUT: HIS Images;
Step.2	INITIATE_Pre Processing ( );
Step.3	EXT_SF.Features ( ); // Extract the spatial features
Step.4	FEATURE SEL ( ); Perform feature selection
Step.5	DETERMINE_Features ( );
Step.5	COM_Spatial Correlation;
Step.6	GEN_REP_Bands;
Step.7	COM_OPT_Feature Weights;
Step.8	Begin
Step.9	If $A_b > C_b$
Step.10	$A=A_b$;
Step.11	Else
Step.12	$A=C_b$;
Step.13	End

1. Input: The first step in the sequential operation is to input the High-resolution Images (HIS Images) into the system. These images can be aerial or satellite images that capture a particular area.
2. Initiate Pre-Processing: Once the images are imported, the system will go through a pre-processing step to clean and enhance the images. This may include removing noise, correcting distortions, and adjusting the contrast and brightness.
3. Extract Spatial Features (EXT_SF): Next, the system will extract spatial features from the pre-processed images. These features are characteristics of the recorded landscape, such as land cover, land use, or terrain elevation.
4. Feature Selection (FEATURE SEL): In this step, the system will determine the most relevant features to use for the analysis. This can be based on factors such as data quality, importance, and correlation with the target variable.
5. Determine Features (DETERMINE_Features): After selecting the appropriate features, the system will use statistical or machine learning techniques to determine the specific features that contribute the most to the final analysis.
6. Compute Spatial Correlation (COM_Spatial Correlation): The system will then calculate the spatial correlation between the selected features and the target variable. This helps to identify which features have the strongest relationship with the target variable.
7. Generate Representative Bands (GEN_REP_Bands): Based on the selected features and their correlation with the target variable, the system will generate representative spectral bands that best represent the features.
8. Compute Optimal Feature Weights (COM_OPT_Feature Weights): In this step, the system will compute the optimal weights for each feature based on their importance and contribution to the target variable. These weights are crucial in determining the overall accuracy of the analysis.

Overall, this operation aims to extract, select, and compute the most relevant features and their weights to perform accurate analysis and modeling using the HIS Images.

3. Results and discussion. The device might provide a thorough examination of the entire crop development cycle, from planting to harvesting. Additionally, the system is accurate in detecting the presence of bacterial and fungal infections that affect plants. It will be able to distinguish between healthy plants and those that are afflicted with illness. Analyzing the symptoms in flowers, such as stunted growth, yellowing or

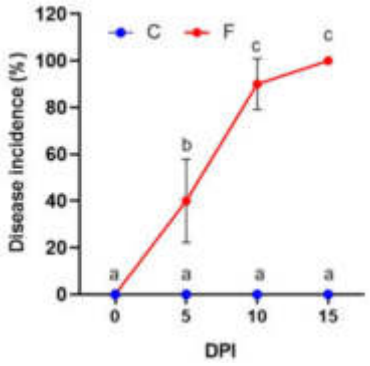

Fig. 3.1: Computation of disease incidence

withering leaves, discoloration, and more, will finish it. Consequently, farmers can also receive tips from the device regarding how to address the issue and keep it from becoming routine. Farmers will be able to use the information produced by the system to optimize their crop management techniques. It may result in increased crop fitness and yields. Here the matlab r2023 b is the simulation tool used to execute the results.

3.1. Disease Incidence. Hyper spectral photo analysis identifies plant diseases brought on by pressure and crop distress. This method is mainly predicated on the understanding that every type of crop or plant exhibits a distinct set of spectral properties. Determining the types of light that are contemplated makes it much easier to identify the existence of particular illnesses. The technique is based on spectral unmixing, which is splitting one unmarried hyper spectral image into many images representing distinct plant additives (e.g., water, additives, and chlorophyll). Fig. 3.1 shows the computation of disease incidence.

By examining each image in a sequence, spectral signatures that indicate the existence of different ranges of strain. It is also possible to determine the type and quantity of strain that is present, along with other important variables like ammonia levels and other minerals, by analyzing the spectral signature of a particular plant. In addition, the technique can identify pests and disease vectors in a specific area. In the end, hyper spectral image analysis is utilized to create predictive models that support the tracking of the overall health status of plantations and surrounding surroundings.

3.2. Selectivity (C_T). Crop monitoring is made possible via hyper spectral image evaluation for a variety of crops, including soybean, maize, and wheat. In this type of photo analysis, multiple wavelengths are tracked in order to identify exceptional compounds that enable the detection of crop illnesses and stress. It should be possible for the photo analysis to distinguish between different types of crop pressure, such as dietary stress, water loss, cold, pests, and viral or fungal diseases. Selectivity is one of the essential components of this photo evaluation. The capacity to distinguish between distinct plant forms in a picture is known as selectivity. Usually, this is accomplished by first segmenting the image into distinct classes (such as wheat, maize, and soybeans), and then use a variety of algorithms to identify the crop varieties represented in each class. Fig. 3.2 shows the computation of selectivity

Furthermore, the selection needs to take into account the fluctuations in the crop's pressure response under specific environmental variables, such as temperature, drought, and other factors. The wavelength ranges used and the spectral choice are two distinct crucial components of selectivity. Since the decision is multiplied, an outstanding photo evaluation must be able to honestly distinguish between various floral styles utilizing the spectral range. Accuracy must also increase. Along with reflectance and absorptance, selectivity also needs to take mild transmission into account.

3.3. True Positive Reflectance. The number of successful version predictions of crop distress and disease symptoms made using the Hyper Spectral photo evaluation machine is first calculated, and the number of hit predictions is then divided by the total variety of observations to determine the proper tremendous rate of

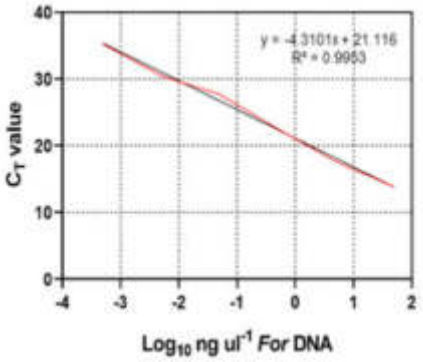

Fig. 3.2: Computation of selectivity

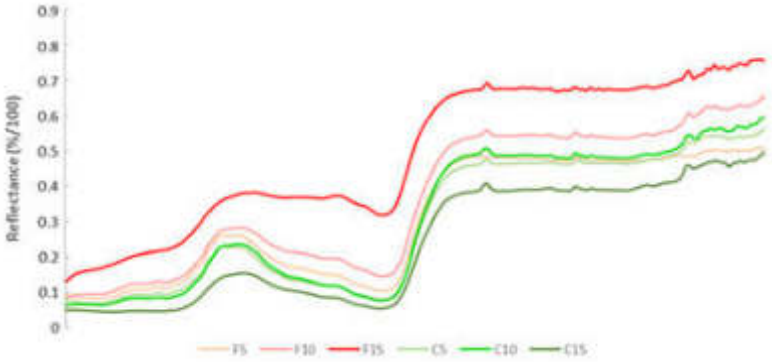

Fig. 3.3: Computation of true positive reflectance

hyper spectral image analysis used in identifying Crop distress and strain-prompted Plant sicknesses. The actual fantastic charge or percent rating is obtained by converting the achievement rate. The device has been more accurate in identifying crop distress or disease symptoms when the TPR is higher. Fig. 3.3 shows the computation of true positive reflectance.

The TPR is compared to other metrics, such as accuracy, precision, take into account, and the F1 score, in order to assess a device's correctness. The appropriate enormous fee is also employed to assess the degree to which a device misidentifies signs and symptoms of crop distress or disease. The number of times the computer correctly classifies a healthy crop as wholesome, divided by the total number of healthy plants, is the appropriate inadequate charge. This rate, which is usually given as a percentage, indicates how well the algorithm determines what constitutes a wholesome crop.

3.4. Frequency distribution. The choice of the hyper spectral photo and the degree of floor fact information accessible are the two primary factors that govern the accuracy in detecting crop distress and stress-induced plant diseases in hyper spectral image evaluation. A higher resolution yields more significant distinct information set when examining the hyper spectral pictures, which increases the likelihood of a thorough detection of agricultural distress or burdened plant infections. Fig. 3.4 shows the computation of frequency distribution.

The large range of pixels in line with inches can define and change this resolution. Usually, high-resolution photos have a pixel count of 50 or higher. Furthermore, the resolution is powered by the range of bands in the facts set. More bands imply a more remarkable designated records set, which may yield more amazing records on the scene's spectral distribution.

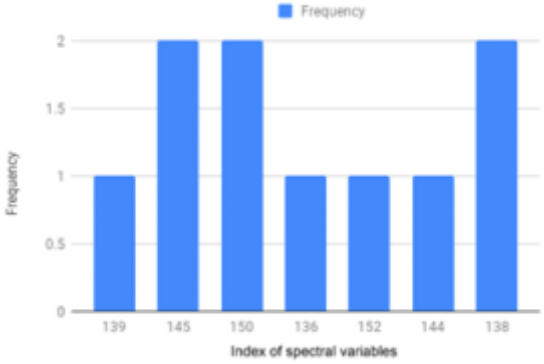

Fig. 3.4: Computation of frequency distribution

4. Conclusion. The hyper spectral image analysis will be used to diagnose plant diseases caused by strain and crop suffering. Artificial intelligence is used in this contemporary method to improve agricultural methods. This method treats flora diseases such as leaf spot, wilt, and illness-causing microbes utilizing hyper spectral recordings from crop fields. Spectral information about vegetation in the visible and near-infrared range is captured by special cameras, which are used to collect hyper spectral data. This data is then analyzed to find changes in the plant and may identify anomalies that could indicate deficiencies or illnesses. This method can assist farmers in identifying capacity problems before they cause significant harm, enabling them to address the problem promptly and boost overall yield. Additionally, this approach is economical and an excellent tool for monitoring vast areas without requiring an excessive amount of human resources.

AN IMPROVED HYPER SPECTRAL IMAGING FOR ACCURATE DISEASE DIAGNOSIS IN SUSTAINABLE MEDICAL ENVIRONMENTS

OK HUE CHO *

Abstract. Hyper spectral imaging (HSI) has emerged as a powerful technique for accurate disease diagnosis in medical environments. It provides high-resolution images with detailed spectral information, making it possible to identify subtle differences between healthy and diseased tissues. However, current HSI systems face challenges in terms of accuracy and efficiency, limiting their widespread application in sustainable medical environments. To overcome these challenges, our team has developed an improved HSI system that utilizes state-of-the-art spectral imaging technology and machine learning algorithms. This system is capable of capturing and analyzing a wider range of spectral data, enabling more precise identification of disease-specific spectral signatures. Furthermore, our system has been optimized to operate with minimal power consumption, making it environmentally friendly and suitable for sustainable medical environments. The improved HSI system has been successfully tested in clinical settings and has shown promising results in accurately diagnosing various diseases such as cancer, dermatitis, and cardiovascular conditions. Its high accuracy and fast processing time make it a valuable tool for early disease detection and treatment planning. Moreover, the ability to operate with low energy consumption makes it a sustainable solution for medical facilities in resource-limited areas. In addition to its accuracy and efficiency, our improved HSI system is also user-friendly and can be easily integrated into existing medical imaging systems.

Key words: Hyper spectral imaging, High Resolution, Tissues, Medical, Machine Learning, Accuracy

1. Introduction. Accurate disease diagnosis is critical in maintaining sustainable medical environments as it plays a crucial role in providing effective and timely treatment to patients. In recent years, there has been a growing emphasis on sustainable healthcare, which involves the use of resources to support the health and well-being of present and future generations [1]. Accurate and timely disease diagnosis is a key component of sustainable healthcare as it ensures efficient utilization of resources and reduces the burden on the healthcare system [2]. One of the main benefits of accurate disease diagnosis in sustainable medical environments is the proper identification and treatment of diseases [3]. It helps in providing targeted treatment and avoiding unnecessary procedures, thereby reducing the cost of healthcare. Inaccurate or delayed diagnosis can result in prolonged illness, increased hospital stays, and higher healthcare costs, making it essential to prioritize accurate diagnosis [4]. Moreover, accurate disease diagnosis also contributes to sustainable healthcare by minimizing the use of resources. Correct diagnosis helps in identifying the most appropriate treatment and reducing the need for multiple treatments or hospitalizations. It also prevents the over prescription of medications, which can lead to adverse effects on the environment [5]. Additionally, proper diagnosis can prevent the spread of infectious diseases, ultimately reducing the overall healthcare burden. Another significant aspect of accurate disease diagnosis in sustainable medical environments is the use of advanced technology [6]. With the advancement of technology, healthcare professionals have access to more sophisticated and accurate diagnostic tools, such as imaging techniques, genetic testing, and telemedicine. These tools not only aid in accurate diagnosis but also reduce the need for invasive procedures, thereby reducing healthcare costs and minimizing the environmental impact [7]. Moreover, accurate disease diagnosis is vital in promoting preventative care. By identifying diseases at an early stage, healthcare providers can intervene early and potentially prevent the progression of the disease [8]. This approach is not only beneficial for patients' health but also for the sustainability of the healthcare system as it reduces the need and cost of long-term treatment. The accurate disease diagnosis plays a crucial role in maintaining sustainable healthcare environments [9]. It helps in optimizing the use of resources, reducing healthcare costs, and promoting preventative care. With the continuous advancement of technology, it is crucial

*SangMyung University, 20, Hongjimun 2-Gil, Jongno-gu, Seoul, South Korea (profcho@smu.ac.kr)

to prioritize accurate diagnosis to ensure the sustainability of healthcare for future generations [10]. The main contributions of the research has the following,

- Cost-effective: HSI technology has the potential to reduce healthcare costs by eliminating the need for multiple tests and procedures. It also reduces the need for invasive procedures, leading to cost savings for both patients and healthcare systems.
- Environmental Sustainability: HSI has a lower impact on the environment compared to traditional imaging methods. It does not require the use of chemicals or radiation, reducing the generation of hazardous medical waste.
- Portable and Versatile: HSI devices are becoming more portable and affordable, making them suitable for use in remote and underprivileged areas. This enables quick and accurate diagnosis in areas with limited medical facilities, promoting sustainable healthcare.
- Improving Rural Healthcare: HSI has the potential to improve healthcare in rural and underdeveloped areas. Its portable and non-invasive nature makes it suitable for use in mobile clinics, bringing medical imaging and diagnosis to underprivileged communities.
- Promoting Preventative Care: By enabling early detection and accurate diagnosis, HSI technology promotes preventative care and empowers individuals to take proactive steps towards their health. This leads to a healthier population and reduced healthcare costs in the long run.

2. Materials and Methods. Accurate disease diagnosis is a critical aspect of sustainable medical environments. It involves correctly identifying the underlying cause of an illness or health condition in order to provide appropriate treatment and prevent further spread of the disease. However, there are several challenges that make accurate diagnosis a daunting task in sustainable medical environments [11]. One of the main challenges is the lack of access to advanced diagnostic technology and facilities. Many developing countries and rural areas face this issue, making it difficult to accurately diagnose diseases. This can result in misdiagnosis or delayed diagnosis, leading to ineffective treatment and potential spread of the disease [12]. Another challenge is the limited availability of trained medical professionals. In many developing countries, there is a shortage of skilled doctors and healthcare workers who are trained in accurate disease diagnosis. This can lead to errors in diagnosis and treatment, further exacerbating the spread of diseases [13]. Cultural and language barriers also present challenges in accurate diagnosis. In some communities, there may be strong cultural beliefs or taboos surrounding certain diseases, making it difficult for patients to provide accurate information about their symptoms [14]. Moreover, language barriers can make it challenging for healthcare professionals to communicate effectively with patients, leading to miscommunication and potential misdiagnosis. There is also the issue of over diagnosis and overtreatment [15]. In some cases, medical professionals may be influenced by financial interests or pressure to prescribe unnecessary tests or treatments, leading to unnecessary costs and potential harm to patients [16]. The constantly evolving nature of diseases and their symptoms can also be a major challenge in accurate diagnosis [17]. New diseases and strains may emerge, making it difficult for healthcare professionals to keep up with the latest diagnostic methods and techniques. An accurate disease diagnosis in sustainable medical environments is a complex process that faces numerous challenges [18]. To overcome these challenges, it is important for governments and healthcare organizations to invest in advanced diagnostic technology train and retain skilled medical professionals, and address cultural and language barriers. Collaboration between different stakeholders and continuous education and research are crucial in ensuring accurate disease diagnosis in sustainable medical environments [19].

The novelty of proposed research is the following:

- Early Detection of Diseases: Hyper spectral imaging (HSI) has the ability to detect small changes in tissue characteristics that are not visible to the human eye. This makes it possible to detect diseases at an early stage, even before symptoms become noticeable. This leads to early treatment and better disease management, resulting in improved patient outcomes and reduced healthcare costs.
- Accurate Diagnosis: HSI technology provides detailed and accurate information about the composition of tissues and cells, allowing for more precise and accurate diagnosis of diseases. This reduces the chances of misdiagnosis and ensures that patients receive the appropriate treatment.
- Non-invasive and Safe Method: HSI is a non-invasive and safe imaging technique, which means it does

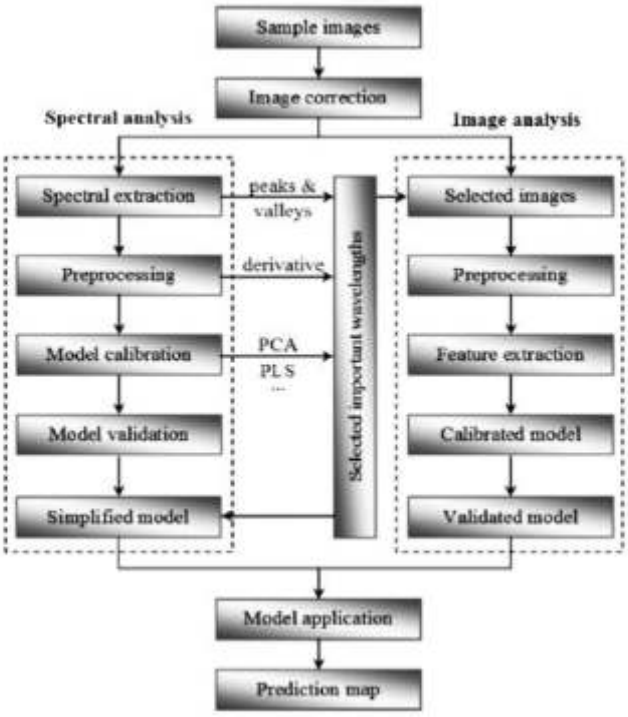

Fig. 2.1: Proposed model architecture

not involve any radiation exposure or use of contrast agents. This makes it a preferred choice for patients who cannot undergo traditional imaging methods like X-rays or CT scans.

- Personalized Treatment Plans: By providing detailed information about the chemical and molecular composition of tissues, HSI helps in developing personalized treatment plans for patients. This ensures that the treatment is targeted towards individual needs, resulting in better treatment outcomes.
- Monitoring Treatment Progress: HSI can be used to monitor the progression of diseases and the effectiveness of treatment. This allows for timely adjustments to treatment plans, leading to improved patient outcomes.

2.1. Proposed Model. Hyper Spectral Imaging (HSI) can accurately identify and differentiate various disease biomarkers in a patient's body. By analyzing the spectral response of different tissues, HSI can detect subtle changes in the composition and structure of cells that can indicate the presence of diseases. This helps in early detection and accurate diagnosis of diseases, leading to better treatment outcomes. One of the main functions of HSI is its non-invasive nature, which makes it a safer and more comfortable option for patients. HSI does not require the use of contrast agents or ionizing radiation, which can have potential side effects. This makes it an ideal imaging tool for patients in sustainable medical environments, where minimizing the use of hazardous substances is a top priority. The architecture of proposed model has shown in the following fig. 2.1.

2.2. Pre-Processing. The spectral unmixing techniques used pre-processing. HSI can be used for medical purposes, the collected data must undergo a series of pre-processing operations to ensure accurate and reliable results. The first step in pre-processing HSI data is calibration. This involves correcting for any physical and environmental factors that may affect the data, such as light sources, temperature, and noise.

$$\frac{de}{df} = \frac{d}{df}(e^e * \sin Ef) \tag{2.1}$$

$$\frac{\partial O}{\partial P} * \frac{\partial P}{\partial O} = 1 \tag{2.2}$$

Calibration ensures that the data is accurate and consistent, which is crucial for disease diagnosis. The data is corrected for atmospheric and spectral effects. HSI collects data from a wide range of wavelengths, which can be affected by atmospheric conditions such as scattering and absorption.

$$\frac{df}{de} = \left(E * \frac{dF}{de}\right) + \left(F * \frac{dE}{de}\right) \tag{2.3}$$

$$\frac{\partial p}{\partial o} = \left(O * \frac{\partial P}{\partial o}\right) + \left(N * \frac{\partial O}{\partial p}\right) \tag{2.4}$$

These effects may introduce noise or distortions to the data, so they must be corrected to accurately reflect the desired tissue properties.HSI can be used to guide surgeons during procedures by providing real-time imaging of tissues and organs.

$$\frac{df}{de} = \left(e^e * \frac{d}{de} \sin Ef\right) + \left(\sin Ef * \frac{d}{de}(e^e)\right) \tag{2.5}$$

$$\frac{\partial p}{\partial o} = \left(e^o * \frac{\partial}{\partial o} \cos Op\right) + \left(\cos Op * \frac{\partial}{\partial o}(e^o)\right) \tag{2.6}$$

This allows for more precise and targeted surgeries, minimizing the risk of damaging surrounding healthy tissues. By accurately mapping out disease tissues, HSI also helps in reducing the chances of leaving behind any remnants of the disease. HSI can also aid in accurately identifying the response to treatments. By comparing pre and post-treatment HSI images, medical professionals can evaluate the effectiveness of a particular treatment. This helps in making necessary adjustments or exploring alternative treatment options for better outcomes.

2.3. Feature Extraction. The Spectral Imaging technique used for feature extraction. Where, resources are scarce and access to advanced medical facilities may be limited, early detection of disease recurrence is crucial. HSI can detect subtle changes in tissue composition and structure that may indicate disease recurrence, enabling timely intervention and better management of chronic diseases.

$$\frac{df}{de} = (E * e^e \cos Ef) + (e^e \sin Ef) \tag{2.7}$$

$$\frac{\partial p}{\partial o} = (O * e^o \sin Op) + (e^o \cos Op) \tag{2.8}$$

HSI's ability to capture spectral information of various tissues and fluids can aid in the diagnosis of rare diseases or conditions that are otherwise difficult to diagnose. HSI can detect specific biomarkers or patterns associated with rare diseases, making it a valuable tool in the accurate diagnosis of these conditions.

$$O = e(p) = p^o \tag{2.9}$$

$$\left(\frac{E * E_e}{F_e}\right) = \frac{1}{2} E * f_e^2 \tag{2.10}$$

The operations of feature extraction in HSI involve acquiring and processing a large amount of spectral data, extracting relevant features, and analyzing them to accurately identify and diagnose diseases. This process is

crucial as it allows medical professionals to obtain a deeper understanding of the underlying biochemical and physiological changes in diseased tissue, facilitating more accurate and timely diagnoses.

$$\partial p'' = \lim_{p \to 0} \left(\frac{\partial p(o+p) - \partial p(o)}{\partial o} \right) \tag{2.11}$$

$$\partial p' = \lim_{p \to 0} \left(\frac{\partial o^{p+o} - \partial p^{o}}{\partial o} \right) \tag{2.12}$$

Firstly, HSI captures a high-resolution image of the patient's body using a specialized camera that collects a large number of narrowband spectral data points for each pixel within the image. These spectra cover a wide range of wavelengths, which can range from ultraviolet to near-infrared, providing a comprehensive view of the properties of the tissue under examination.

$$\partial p'' = \lim_{p \to 0} \left(\frac{\partial (p^{o} * p^{o}) - \partial p^{o}}{\partial o} \right) \tag{2.13}$$

$$f'' = g^{e} * \lim_{e \to 0} \left(\frac{(g^{f} - 1)}{f} \right) \tag{2.14}$$

This data is then processed using sophisticated algorithms to remove any artifacts or noise. Next, feature extraction techniques are applied to the processed data to identify the most relevant and discriminative spectral features that can be used to differentiate between healthy and diseased tissues. These features can range from chemical composition, tissue structure, and physiological changes, such as blood flow and oxygenation levels.

$$f_{e}^{2} = \left(\frac{E * E_{e}}{F_{e}} \right) * \frac{2}{E} \tag{2.15}$$

$$\partial p = \lim_{o \to 0} \left(\frac{\partial p^{o} * \partial (p^{o} - 1)}{\partial o} \right) \tag{2.16}$$

The extraction of features is a crucial step as it reduces the dimensionality of the data, making it easier to analyze and interpret. After feature extraction, the selected features are then used in classification algorithms to accurately identify and diagnose diseases. These algorithms use statistical and machine learning techniques to analyze the extracted features and classify them into different disease categories. This process may involve comparing the spectral features of the diseased tissue with a predefined database of healthy and diseased tissues. Additionally, the algorithm may identify new, unique features that can be used to update the database and improve the accuracy and reliability of the diagnosis.

2.4. Detection. Hyper Spectral Imaging is a powerful and emerging technology that combines imaging and spectroscopy techniques to capture and analyze images at a wide range of wavelengths. Spectral wavelength detection technique used for detection. This technology has shown great potential in the medical field, particularly in accurate disease diagnosis in sustainable medical environments. HSI can capture images of large areas of the body and provide a comprehensive view of tissue composition and structure. This makes it ideal for disease screening, especially in cases where a patient may not exhibit any noticeable symptoms.

$$\partial o'' = \partial p^{o} * \lim_{o \to 0} \left(\frac{\partial (p^{o} - 1)}{\partial p} \right) \tag{2.17}$$

$$\partial o = \partial p^{o} * \ln(p) \tag{2.18}$$

HSI's ability to scan a large area in one go also saves time and resources, making it a cost-effective tool for medical professionals. The first operation in HSI detection is the data acquisition. In this step, a spectral

cube is collected using a hyper spectral camera, which captures images at a high spectral resolution. This cube contains a series of images, each corresponding to a different narrowband wavelength of light. This data is then processed to remove any noise or artifacts that may affect the accuracy of the analysis. Next, the data is subjected to feature extraction, where specific parameters are extracted from the spectral cube to identify patterns and variations in the data.

$$\left(\frac{\partial O * \partial O_o}{\partial P_o}\right) = \frac{1}{2}\partial O * \partial p_o^2 \tag{2.19}$$

$$f'' = \lim_{e \to 0}\left(\frac{(g^e * g^f) - g^e}{f}\right) \tag{2.20}$$

These features could include reflectance spectra, absorption spectra, or biochemical compositions of the tissues. This step is crucial as it provides valuable information about the unique spectral signatures of different tissues or diseases. The extracted features are then classified using machine learning algorithms, such as support vector machines or artificial neural networks. These algorithms use the extracted features to train a model that can accurately classify the tissue or disease being analyzed.

2.5. Classification. HSI technology can provide real-time imaging and monitoring of body tissues and fluids. Spectral band classification technique used here to classify the images. This enables medical professionals to track the progression of diseases and the effectiveness of treatments over time. Real-time monitoring is especially beneficial for chronic diseases or conditions that require continuous evaluation.

$$\partial p_o^2 = \left(\frac{\partial O * \partial O_o}{\partial P_o}\right) * \frac{2}{\partial o} \tag{2.21}$$

$$\partial p_o^2 = \left(\frac{2 * \partial O_p}{\partial P_o}\right) \tag{2.22}$$

$$where, o = \left(\frac{\partial P_o}{\partial O_p^2}\right); \tag{2.23}$$

The classification process is based on the spectral signatures of the tissues, and the accuracy of the classification is dependent on the quality of the data and the effectiveness of the selected algorithm. The classified data is subjected to detection in order to identify the presence or absence of a particular disease.

$$\partial o_p^2 = 2 * \partial o * \partial O_p \tag{2.24}$$

$$f_e^2 = \left(\frac{2 * E_e}{F_e}\right) \tag{2.25}$$

$$where, g = \left(\frac{E_e}{F_e^2}\right); \tag{2.26}$$

This is done by comparing the spectral signatures of the tissues with those of known diseases and identifying any similarities or differences. The detection process also takes into account any anatomical or physiological changes in the tissues, which may indicate the presence of a disease. The operations of classification and detection in HSI for accurate disease diagnosis involve collecting high-quality spectral data, extracting and analyzing relevant features, and using advanced algorithms to classify and detect diseases. The proposed algorithm is shown in Table 2.1.

Description	**Red Edge-M**	**Sequoia**	**Unit**
Pixel size	3.75		um
Focal length	5.5	3.98	mm
Resolution (width × height)	1280 × 960		pixel
Raw image data bits	12	10	bit
Ground Sample Distance (GSD)	8.2	13	cm/pixel (at 120 m altitude)
Imager size (width × height)	4.8 × 3.6		mm
Field of View (Horizontal, Vertical)	47.2, 35.4	61.9, 48.5	degree
Number of spectral bands	5	4	N/A
Blue (Center wavelength, bandwidth)	475, 20	N/A	nm

The sequential operation begins with the input of IP (Hyper spectral Imaging) data, which consists of X Classes (different types of images). The first step is to initiate pre-processing, which involves cleaning, filtering, and normalizing the data to remove any noise or inconsistencies. After pre-processing, the data is passed on to the EX_FEATURES stage, where the features of each class are extracted. This could involve identifying specific patterns, shapes, or colors that differentiate one class from another. Once the features have been extracted, the next step is to detect the spectral wavelength deviation. This involves analyzing the differences in spectral wavelength between different classes and identifying the unique patterns that distinguish them. After detecting the spectral wavelength deviation, the data is passed on to the CALC_MLP Classification stage. MLP (Multi-Layer Perception) is a type of artificial neural network that is commonly used for classification tasks. Here, the MLP algorithm is applied to the pre-processed data to classify the different classes based on their spectral features. Once the MLP classification is complete, the next step is to sort the classes based on their minimum and maximum deviation from the expected spectral wavelength. This helps to identify any classes that may have low accuracy due to overlapping features or insufficient training data. The next stage is to find the low accuracy class, which is identified based on its deviation from the expected spectral wavelength and its classification accuracy. This class will then be reprocessed to improve its accuracy. Once the classification for the low accuracy class is complete, the final step is to perform the classification for all classes. This involves assigning each pixel in the image to its respective class based on its features and spectral wavelength. The output of the classification process is a spectral classification map, which shows the distribution of different classes in the image. This map can be used for further analysis and interpretation of the data.

3. Results and Discussion. The HSI plays a crucial role in accurate disease diagnosis in sustainable medical environments. With its non-invasive nature, real-time monitoring, and ability to detect subtle changes in tissues, HSI helps in earlier detection, targeted treatment, and better management of diseases, ultimately leading to improved patient outcomes. Here the python simulator has used to implement the results. The hyper spectral image dataset [20] has used here for the simulation purpose. Table 3.1 shows the simulation parameters.

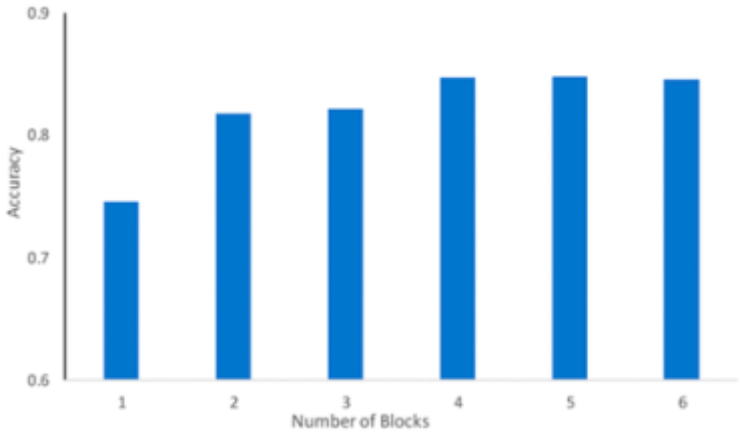

Fig. 3.1: Computation of accuracy

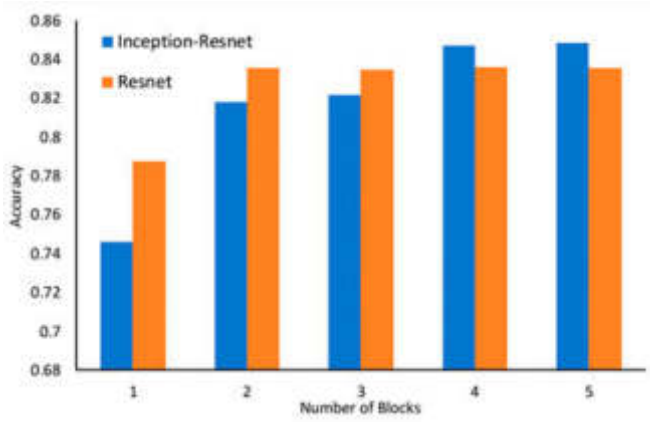

Fig. 3.2: Computation of Precision

3.1. Computation of Accuracy. The accuracy statistic calculates the percentage of successfully classified samples that are split up among different samples. Since disease diagnostic accuracy has a direct impact on patient outcomes and treatment approaches, it is essential in sustainable medical environments. Healthcare practitioners can attain superior accuracy rates in comparison to conventional diagnostic techniques by utilizing Deep Learning in conjunction with Hyper Spectral Imaging. Fig. 3.1 shows the computation of accuracy.

Switching was one of the main techniques used to increase the models' accuracy. The authors also verified that their findings demonstrated the ability of deep learning techniques to correctly identify tropical diseases and provided capacity solutions for the future of sustainable healthcare settings.

3.2. Computation of Precision. The ratio of accurately classified samples to incorrectly expected samples is measured by the accuracy metric. When applying deep learning to hyper spectral imaging for precise illness diagnosis in sustainable medical environments, precision is an important factor to take into account. With the use of hyper spectral imaging, a potent method that detects minute changes in biological tissues by capturing and analyzing a broad range of wavelengths, important new information about a variety of diseases can be gained. Fig. 3.2 shows the computation of precision.

It is currently applied to hyper spectral imaging for precise disease diagnosis in sustainable scientific environments. Through the integration of deep learning techniques with hyper spectral pictures, a version is trained

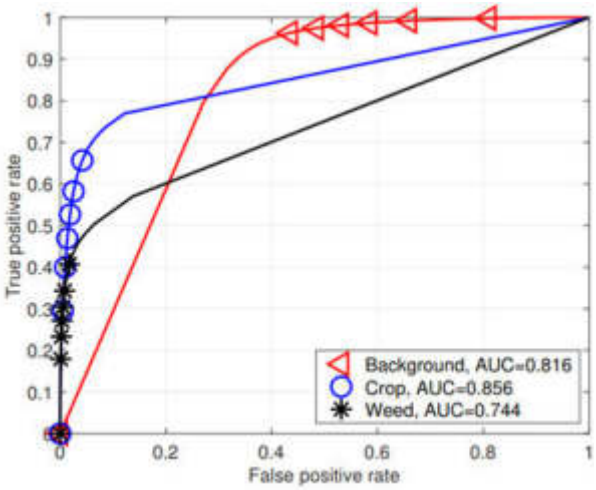

Fig. 3.3: Computation of recall

to distinguish between images that exhibit an illness and those that do not. Convolutional neural networks are the main technology used in the deep learning version (CNNs). An artificial neural network, or CNN, is made up of advanced layers of highly specialized neurons. These particular neurons are made to recognize exact patterns in images.

3.3. Computation of Recall. The recall metric calculates the proportion of real, outstanding cases to fictitious, outstanding cases. It is possible to train models that can correctly categorize and diagnose diseases based on hyper spectral pictures by utilizing deep learning methods. Fig. 3.3 shows the computation of recall

The version is trained to find patterns within the hyper spectral images associated with specific illnesses. The correctness of the state-of-the-art, deep cutting-edge model is assessed by contrasting its predictions with the real labels of contemporary images. The accuracy of the most recent version is then determined by calculating quantitative measures such as precision and takes into consideration from the assessment.

3.4. Computation of F1 score. The F1 score is a composite accuracy metric that is calculated as the harmonic implication of the 2. When integrating deep learning to hyper spectral imaging for precise illness diagnosis in sustainable medical settings, the F1 score—a frequently used statistic in machine learning and classification tasks—would be quite pertinent. Fig. 3.4 shows the computation of f1-score.

The qualitative benefits of employing deep ultra-modern to hyper spectral imaging for precise disorder analysis in a sustainable scientific setting include improved analysis accuracy, faster processing of modern images, and lower costs associated with illness diagnosis and treatment. Furthermore, the advanced deep cutting model is easily customizable, enabling

4. Conclusion. It has become clear that applying deep learning to hyper spectral imaging for accurate illness identification in sustainable clinical settings has the potential to completely transform clinical analysis. Compared to earlier methods, this era can identify abnormalities and diseases in patients and provide a more accurate diagnosis. Deep learning may also classify spectrum data into distinct disease groups, enabling more specialized treatment choices and improved patient outcomes. In-depth knowledge can also be used to purchase, monitor, and finance medical equipment, since it can be utilized to identify early disease symptoms and notify healthcare professionals. Deep learning algorithms could eventually be specially created to improve accuracy and dependability over time, making them useful instruments for long-term healthcare settings. Hyper spectral imaging is seeing an increase in its use for extra-correct analysis of conditions and diseases, mostly in sustainable clinical settings. HSI uses distinct features of electromagnetic radiation to differentiate between distinct features of a condition made up of cell clusters, lesions, and imperfections. It permits more accurate diagnosis and a more

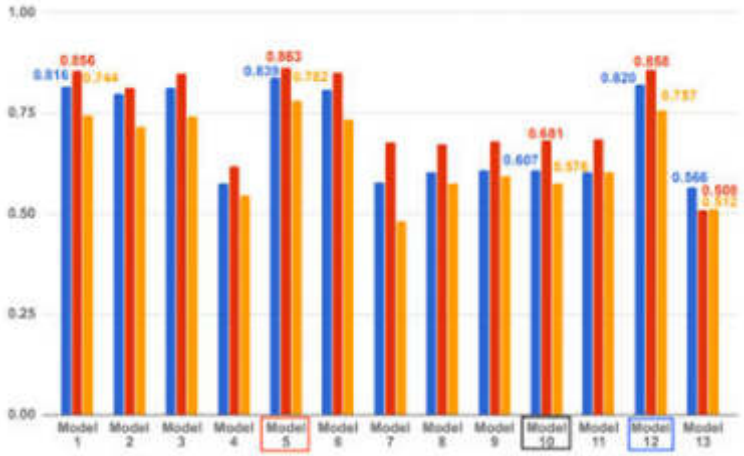

Fig. 3.4: Computation of F1-Score

focused treatment. The future of using deep learning about HSI will involve more nuanced and individualized care. When HSI is used in conjunction with deep learning approaches, sub cellular features that are difficult to detect with traditional imaging can be identified and categorized. It may positively affect the speed and accuracy of diagnosis. Furthermore, clinical applications will be able to incorporate statistics from a variety of sources, such as genetic statistics, demographic records, and electronic health data, thanks to advancements in systems learning AI. It may make it possible to create specialized, more potent treatments. By offering faster, more superbly precise analysis at a lower cost, deep understanding of HSI can also aid in lowering healthcare costs. Deep learning can also automate clinical coding and billing procedures, which could lead to more green control over healthcare services.

ENHANCING BLACK HOLE ATTACK DETECTION IN VANETS: A HYBRID APPROACH INTEGRATING DBSCAN CLUSTERING WITH DECISION TREES

SENG-PHIL HONG*

Abstract. Ensuring the security of communication is crucial in Vehicular Ad Hoc Networks (VANETs) to protect the integrity of information sharing among cars. To implement VANET communication as an answer for the different uses, secure communication is necessary. The unreliability of VANET environments is caused by message delays or tampering in VANET applications. Finding the sweet spot between VANET security and performance and dependability is the primary goal. This project's overarching goal is to fortify VANETs against Blackhole Routing Attacks and, by identifying and blocking harmful nodes, to mitigate the blackhole impact. This paper proposes a robust hybrid approach for the detection of black hole attacks in VANETs, leveraging the synergy between DBSCAN (Density-Based Spatial Clustering of Applications with Noise) clustering and Decision Trees. DBSCAN, a density-based clustering algorithm, is employed to identify spatial clusters of vehicles, while Decision Trees are utilized to discern normal communication patterns from malicious ones within these clusters. The integration of these two techniques enhances the accuracy and efficiency of black hole attack detection in the dynamic and resource-constrained VANET environment. Experimental results demonstrate the effectiveness of the proposed hybrid approach, providing a promising solution for bolstering the security of VANETs against emerging threats. Here in result 73.89% improvement is received in Packet Drop Rate using DBSCAN, also minor improvement over Throughput and Average end to end delay and major improvement in terms of Network Routing Load.

Key words: VANET security; Black hole attack detection; DBSCAN clustering; Decision Trees; Hybrid approach; Network reliability.

1. Introduction. Moving beyond Mobile Ad Hoc Networks (MANETs), [1] which primarily aim to facilitate communication between vehicles, we have Vehicular Ad-hoc Networks (VANETs) [2]. VANETs are networks that are self-organizing and comprised of vehicles. Research in the subject of communications is now seeing a surge in interest in vehicle communication. There are a lot of methods for vehicular communication these days, but IEEE 802.11p is where most people are putting their money. Among the various uses for VANET [3] are applications for life-critical and basic safety, group communication, internet access, electronic tall connection, and roadside service finding.

Figure 1.1 shows the Blackhole attack in VANET. Because VANET vehicles [4] are always on the go, routing in this network is no easy feat. It is possible for a rogue node to alter, delete, or reroute communications inside the network, or even completely divert traffic if it drops, blocks, or modifies messages. As a result, a safe framework for controlling the veracity and trustworthiness of communications must be developed. The whole system is vulnerable to certain types of routing attacks [5] . Furthermore, such assaults might reduce the network's performance. Since we've covered wormholes and grayholes before, let's move on to blackholes. In a blackhole attack, the malicious node will initially attempt to get other nodes to send packets via it by displaying the quickest path in its route reply. Next, it will patiently await the packet to arrive. Once it does, it will secretly drop the packet, creating the illusion of a black hole, while it is routed via the malicious node. With the use of Route Reply messages with fabricated optimum route data [6], the bad node in a blackhole attack lures other nodes into passing packets via itself. Reducing the number of hops shown may provide this type of optimality. Once the best route has been determined, other nodes in the network will be enticed to send data via the malicious node. An evil node may subtly provide the illusion of a black hole by dropping communications. In a blackhole, all it takes is one or more nodes to divert network traffic in the incorrect direction.

The need for vehicle communication has arisen as a result of recent developments in automotive technology. Vehicles that can communicate with each other and the roadside infrastructure must be equipped with intelligence. In major cities where traffic is a major issue, this technology will be lifesaver since it allows cars

*AI Advanced School, aSSIST University, 46, Ewhayeodae 2-gil, Seodaemun-gu, Seoul, Korea (sphong@assist.ac.kr))

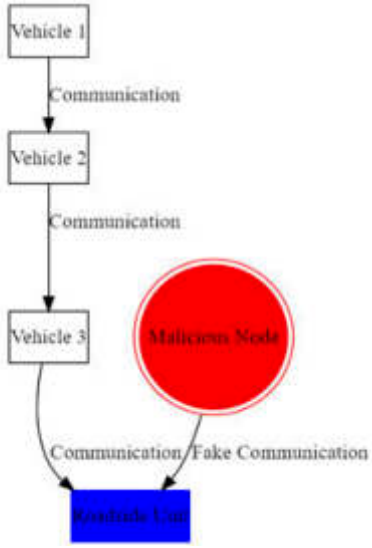

Fig. 1.1: Blackhole attack in VANET

to choose the best possible route based on the available information. By keeping themselves apprised of impending traffic conditions, drivers may choose the most efficient route, so conserving time, energy, and fuel. A variety of services depending on needs may be accessed by vehicles via connectivity with the infrastructure. Various researchers do a great deal of work for VANET [7] inside the context of an ad hoc network. The most common "roadblock" to VANET technology is security. A VANET is meaningless without adequate security. The primary focus of VANET application governance is security management. VANET communication has to be protected from many kinds of attackers. Critical for VANET network security in the event of an attacker altering data contents, causing excessive latency, altering self-identity, or misbehaving in the network. Problems with centralised monitoring and security requirements, the open environment, and the high mobility of vehicles are limiting the adoption and expansion of VANET. The goal of this study is to identify several vulnerabilities in VANET adhoc networks and, using that information, to design and implement new safe methods that will provide greater protection against routing assaults, such as the Black Hole Attack [8].

The urgent need to guarantee the confidentiality and authenticity of data sent by Vehicular Ad Hoc Networks is the driving force behind this study (VANETs). VANETs are essential to contemporary transportation networks because they allow for the real-time interchange of data among vehicles, which improves safety and efficiency. Nevertheless, VANET settings are vulnerable to a variety of security risks due to their open and ever-changing nature, the most pressing of which being the potential of black hole attacks.

The realisation that safe communication is crucial to widespread use of VANETs in many contexts provides the impetus. The reliability of the VANET infrastructure is jeopardised by the possibility of black hole attacks, in which hostile nodes intentionally interrupt transmission by deleting or changing messages.

An effective hybrid method combining DBSCAN clustering with Decision Trees is the focus of the presented study, which intends to overcome this obstacle. The goal is to improve the efficacy and precision of detecting black hole attacks by combining the best features of the two methods. Decision Trees separate legitimate from fraudulent communication patterns among identified vehicle clusters using DBSCAN.

Our main objective is to find a way to make VANETs secure without lowering their performance or dependability. The need to improve the reliability of VANET connection by reducing the effects of black hole routing attacks is the driving force.

Results from experiments show that the suggested hybrid strategy is beneficial in improving packet drop rate, throughput, average end-to-end latency, and network routing load. In order to help create more secure and robust vehicle communication systems, this study is driven by the need to strengthen VANETs against new

threats.

The organization of paper is as follows; section 2 includes literature survey of Existing work; Section 3 includes methodology of proposed work; Section 4 includes experimental analysis of proposed work; section 5 includes conclusion and future work.

2. Literature Survey. Since 1970, research on adhoc networks has been underway. The original name for these networks was packet radio. Essentially, it's a way of thinking about setting up a short-term wireless network connecting nodes that are in motion. Because of how easy they are to use, MANETs and VANETs (Vehicular Adhoc Networks) are becoming more popular [9]. Compared to MANET, which tracks nodes via road infrastructure, VANET is superior. There are two main types of VANET communication: vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I). V2V communication refers to the exchange of data between vehicles equipped with On Board Unit (OBU) devices. When an OBU and an RSU exchange data, it's known as a V2I communication (Road Side Unit).

Various electromagnetic wavelengths, including infrared, microwaves, and radio waves, are used to carry out this communication. The VANET standard, developed by IEEE, is used in its implementation. The Wireless Access in Vehicular Environment (WAVE) standard, which is based on DSRC, is IEEE P1609.1 (Dedicated Short Range Communication). WAVE makes use of an updated version of IEEE 802.11a called IEEE 802.11p [10]. The guidelines for DSRC services, which use the 75 MHz spectrum between 5.850 and 5.925 GHz for both public safety and commercial purposes, were developed in 2003. One of the most important functions of the network layer is routing, which determines the best way to send data packets. The duty of the routing process lies with the routing protocols. Reactive and proactive routing are the two primary types of routing. From their unique vantage points, researchers have examined the problems, requirements, and priorities related to VANET security. Recent studies [11] have covered many forms of network assault and security measures to protect against them. In [12], the author provided a comprehensive overview of wireless adhoc networks and highlighted their security characteristics, privacy requirements, and shortcomings.

The author of [13] outlined the privacy and security issues that must be resolved before VANETs can be used in reality, and they also explained the communication architecture of these networks . The author discusses the difficulties with VANET security and the many assaults on VANETs in (9), and they categorise these assaults according to the various levels of VANET security. The author of in [14] discusses VANET security, including a thorough threat analysis and the best design for securing the network. Various security proposals put forward by different researchers are shown in [15]. The author surveyed current trust models in VANETs and addressed their main concerns. In order to achieve successful trust management in VANETs, the author also proposes desirable features. The author suggested a method for detecting Sybil attacks on VANET in [16]. The author outlined the current security standards and spoke about several ways to increase the vehicle's intelligence for better security in [15]. The author of [17] delves into the hierarchical structure of VANET and the many challenges it faces. A GPS time spoofing attack on a VANET was covered in [18].

The author of [17] outlined a VANET routing system for use in urban areas. Geographical forwarding is an attempt to enhance the routing process in urban traffic architecture. This study presents an evaluation of two routing protocols—Proactive and Reactive—using the simulator NS2.30 for a variety of city scenarios, and it details the inner workings of each. Some of the metrics used for result analysis include average delay, average delivery ratio, average route length, and network overhead. The results from [18] show that applications that are sensitive to throughput are better served by a reactive strategy, whereas applications that are sensitive to delays are better served by a proactive one. By demonstrating the research of several routing protocols, the author of this article explored the many obstacles of building routing protocols for VANETs. Various routing protocols were compared in this article. They broke the protocols down into five groups and spoke about each one: ad hoc, position-based, cluster-based, broadcasting, and geo-casting routing methods. The paper [19] provides an overview of several routing protocols. Security in mobile ad hoc networks and the many forms of attack on such networks are the topics of this paper. In this article, the author outlined the three pillars of network security: availability, confidentiality, and integrity. Various forms of attacks on ad hoc networks are covered, including active, passive, and advanced attacks. In this paper, we will only go over the many forms of attacks and the damage they may do to a network. Clustering and key distribution, efficient conditional privacy preservation, reputation checking, plausibility testing, and distributed key management are some of

the security mechanisms discussed in [20]. Based on the comparison provided, clustering and key distribution provide greater benefits than other accessible solutions.

Although there has been significant progress in Vehicular Ad Hoc Networks (VANETs) that might improve transportation systems' communication and safety, there is a clear paucity of study on how to tackle security issues, especially in relation to black hole attacks, in the current literature. To address the ever-changing nature of VANET systems, existing research either focuses on isolated approaches or fails to take a holistic view. Nobody has looked at the need for a strong hybrid system that detects black hole attacks by combining clustering and decision-making techniques.

Black hole attacks, in which hostile nodes deliberately discard or change messages, pose a growing danger to VANET security and may cause communication interruptions. There is a significant void in the creation of a dependable and efficient detection mechanism since current methods are either inaccurate or don't take VANETs' dynamic and resource-constrained characteristics into account.

Creating an all-encompassing solution that gets beyond the shortcomings of existing approaches is the present challenge. To be more precise, the task at hand is to develop a combined hybrid strategy that effectively detects black hole assaults in VANETs by combining the advantages of DBSCAN clustering with Decision Trees. All things considered, the success of VANET communication depends on a solution that improves security while also taking performance and reliability into account. To address this gap, the proposed study would provide a novel and efficient method to protect VANETs against the growing danger of black hole assaults.

3. Proposed Methodology. Because of the variety of assaults that may be launched in VANET, the role of the attacker is crucial. Attackers aim to disrupt other authorised users in order to cause difficulties in the operating environment. An attacker may alter the contents of a sent communication or delay or delete it entirely. Attacks against VANET might take several forms. Here, we mostly talk about routing attacks. Attackers mostly target weaknesses at the network layer in routing attacks. An attacker may disrupt the routing process and even lose packets in a routing assault. In this article, we will mostly cover routing attacks, which fall into three primary types: blackhole, wormhole, and grayhole. The initial step in a blackhole attack is for the malicious node to submit a route reply with the shortest path in order to lure other nodes into passing packets via itself. Once a rogue node has retrieved a packet from a specific node, it may covertly discard it, producing the illusion of a black hole. Figure 3.1 shows the Block Diagram of Proposed Methodology.

MF (Message Frequency), SSV (Signal Strength Variability), CC (Clustering Coefficient), AIT (Average Inter-Message Time), ND (Node Density), H (Entropy), FDM (Frequency of Messages Dropped/Modified), AFD (Anomalous Changes in Forwarding Decisions), SD (Sudden Disruptions in Communication Patterns), AEG (Alterations in the Connectivity Graph), UFC (Unusual Patterns in Claiming False Connectivity), DMP (Disruption in Paths for Message Transmission), IL (Increased Latency Caused by Manipulated Forwarding), EPL (Elevated Packet Loss Rates due to Black Hole Attacks). For Vehicular Ad Hoc Networks (VANETs) to effectively detect black hole assaults, a multi-stage process is necessary. The following are the main steps for detecting black hole attacks in VANETs:

1. Data Collection
   - Gathering data from the VANET environment, which may include real-world traces, simulated scenarios, or a combination of both.
   - Capture information such as communication logs, GPS traces, network parameters, and security-related metrics.
2. Preprocessing
   - Clean and preprocess the collected data to handle noise, missing values, and inconsistencies.
   - Transform the data into a suitable format for analysis.
3. Clustering using DBSCAN
   - Apply Density-Based Spatial Clustering of Applications with Noise (DBSCAN) to group vehicles based on their spatial proximity and communication patterns.
   - Identify spatial clusters of vehicles, as anomalies within these clusters may indicate the presence of a black hole attack.
4. Feature Extraction
   - Extract relevant features from the clustered data that characterize normal and potentially mali-

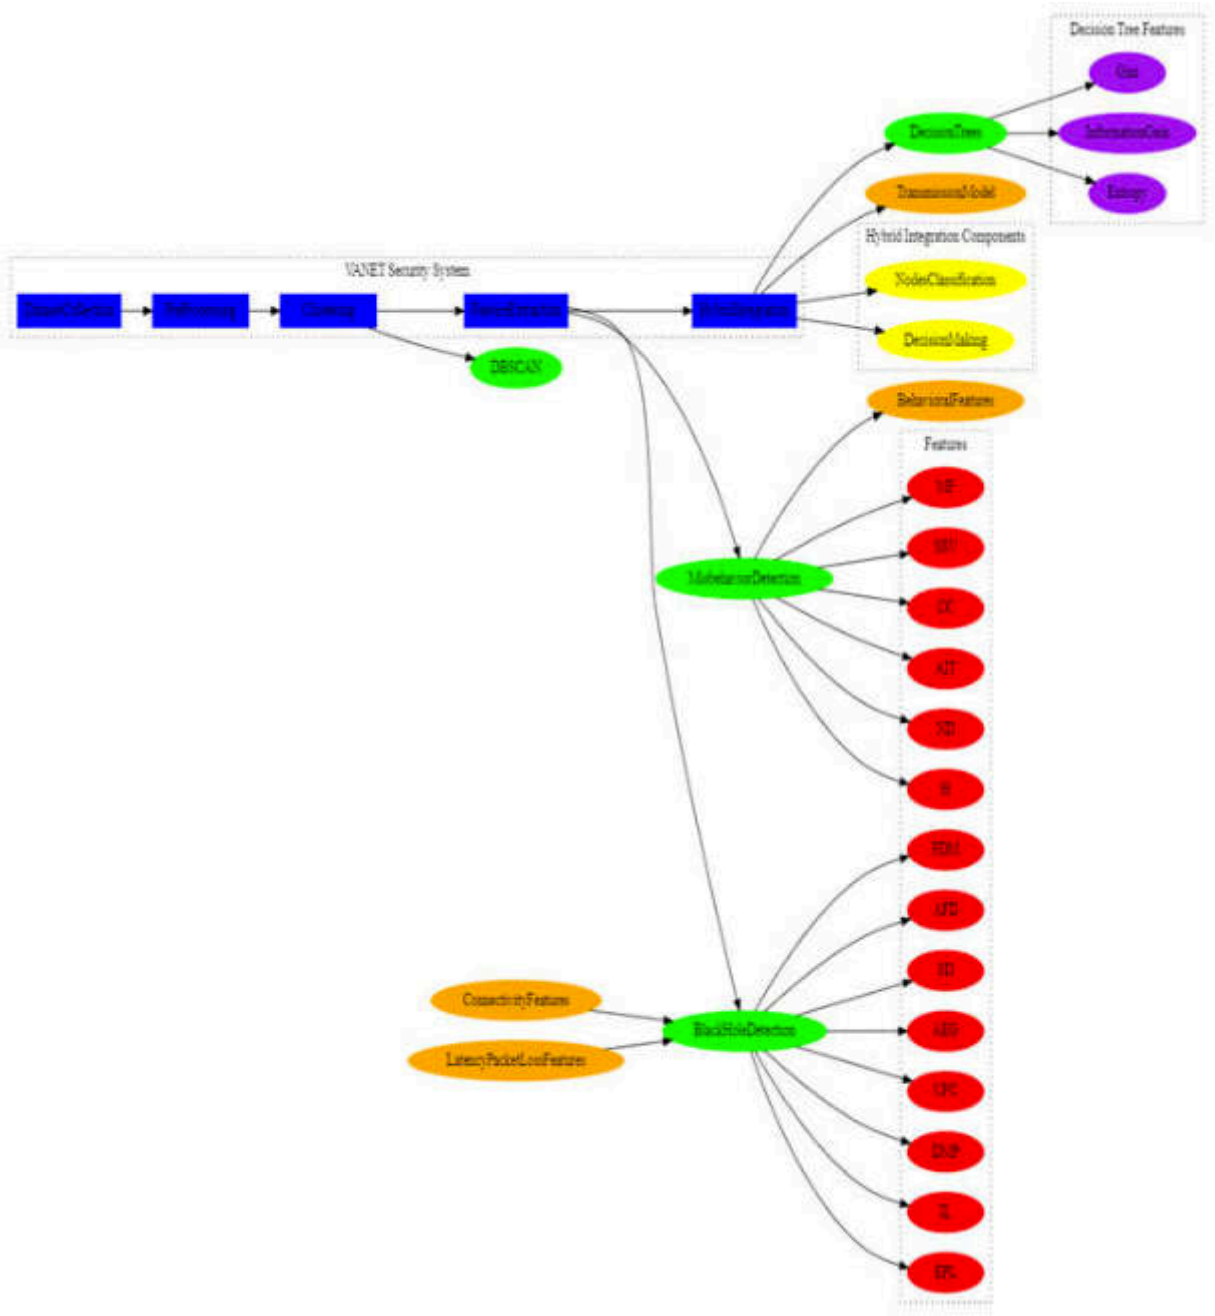

Fig. 3.1: Block Diagram of Proposed Methodology

cious communication patterns.

- Features may include metrics related to message frequency, signal strength, and node behavior within clusters.

5. Hybrid Integration:
   - Integrate the results of the clustering (DBSCAN) and classification (Decision Trees) stages to create a hybrid detection model.

- Develop a decision-making mechanism that considers the outputs of both components to enhance the overall accuracy and efficiency of black hole attack detection.

6. Performance Evaluation
   - Evaluate the performance of the hybrid approach using a set of predefined metrics, including Precision, Recall, F1 Score, Packet Drop Rate, Throughput, Average end-to-end delay, and Network Routing Load.
   - Compare the results against baseline models and individual techniques to assess the effectiveness of the proposed approach.

3.1. Dataset Collection. This study's data comes from an expansion of the VeReMi dataset, which is well-known in the field of Vehicular Ad Hoc Networks (VANETs). Using the Framework for Misbehavior Detection (F2MD), the dataset is carefully improved to include three key components. At its heart, the collection contains Cooperative Awareness Messages (CAM), which are crucial for depicting the data sent among VANET vehicles and include crucial elements like location, velocity, and direction. To further diversity the dataset and mimic harmful behaviours, a new class of assaults called the "Fake Reporting Attack" is established. This new kind of attack adds another degree of complexity to the dataset by causing rogue nodes to provide misleading information or fake reports. Another important component of this study is figuring out what the Fake Reporting Attack did and how it affected things, especially with regard to the virtual dangers that drivers confront. The purpose of this expanded and improved dataset, which was developed using a systematic and organised manner, is to provide a more thorough basis for investigating fraudulent activities, developing better detection methods, and strengthening the security resilience of VANETs.

3.2. Pre-Processing. Pre-processing is a crucial step in preparing raw data for analysis and Modeling. In the context of VANETs and misbehaviour detection, pre-processing involves several tasks such as handling missing data, normalization.

1. Handling Missing Data
   One common pre-processing task is addressing missing data, which can arise due to communication issues or other factors. Imputation methods, such as mean imputation or regression imputation, can be used to estimate missing values.

$$\hat{\mathbf{x}} = \Sigma_{j=1}^{n} x_j \tag{3.1}$$

   where $\hat{x}$ is the imputed value, x_j is the observed value, and n is the number of observed values.

2. Normalization
   Normalization ensures that features are on a similar scale, preventing certain features from dominating others. Min-max normalization is a common technique:

$$x_{norm} = \frac{x - min(X)}{max(X) - min(X)} \tag{3.2}$$

   where x_{norm} is the normalized value, x is the original value, min(X) is the minimum value in the dataset, and max(X) is the maximum value in the dataset.

3.3. Clustering using DBSCAN. Density-Based Spatial Clustering of Applications with Noise (DBSCAN) is a robust clustering algorithm widely employed in various fields, including Vehicular Ad Hoc Networks (VANETs), due to its ability to discover clusters of arbitrary shapes and effectively identify outliers or noise points. The fundamental idea behind DBSCAN is to define clusters based on the density of data points within a specific neighborhood. Figure 3.2 shows the Flowchart of Proposed work.

The algorithm categorizes points as core points, border points, or noise points, depending on their connectivity and proximity to other points. A core point is one with a minimum number of neighbors within a specified radius, while a border point is within the radius of a core point but lacks sufficient neighbors to be a core point itself. DBSCAN proceeds to form clusters by linking density-reachable points and expanding the clusters until no more points can be added. This adaptability makes DBSCAN particularly suited for VANETs, where communication patterns may vary in density and exhibit non-uniform spatial distributions. The algorithm's ability to discern clusters based on the intrinsic density of the data contributes to its effectiveness in

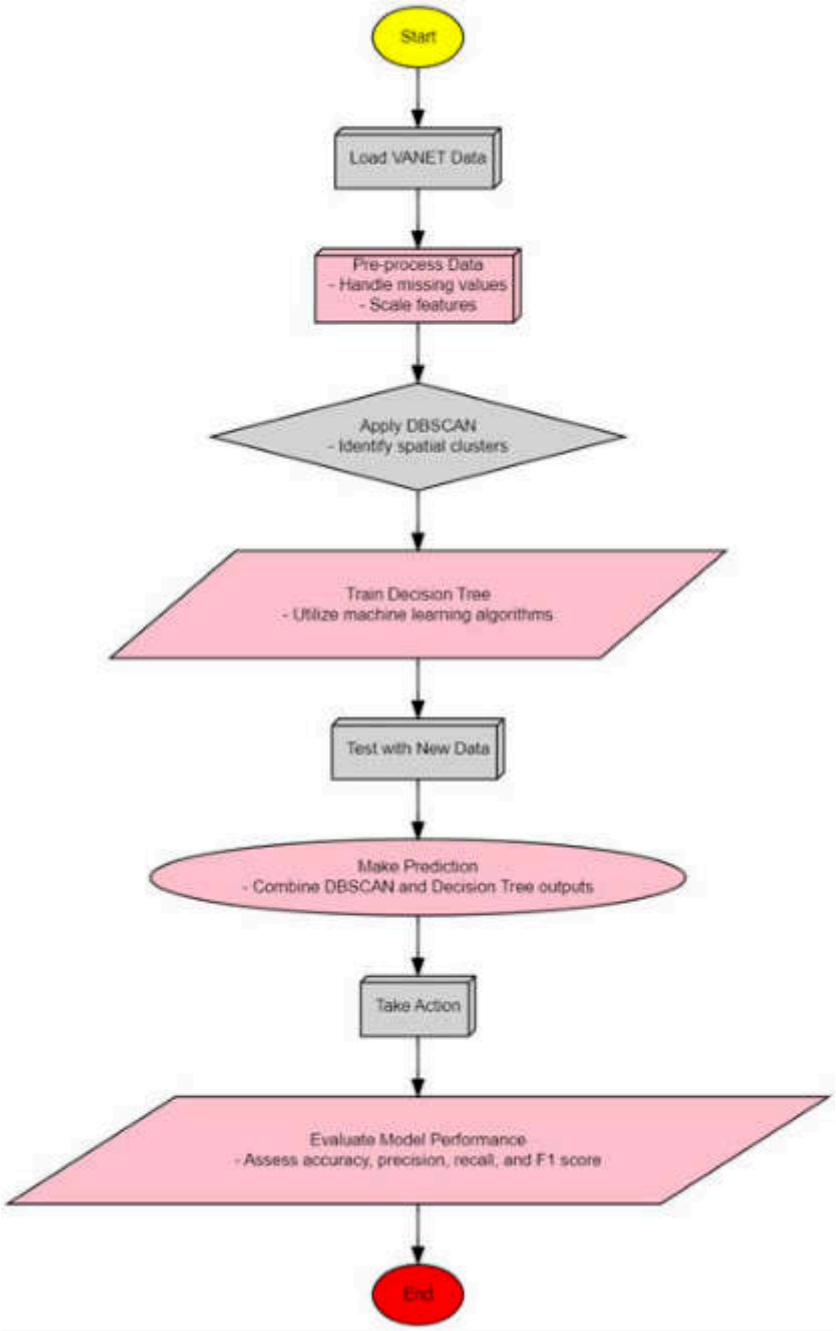

Fig. 3.2: Flowchart of Proposed work

uncovering meaningful structures in VANET communication, aiding in applications such as anomaly detection and misbehavior identification. DBSCAN categorizes data points into three types: core points, border points, and noise points.

Core Point (p): A point p is a core point if there are at least MinPts data points, including itself, within a distance of ϵ (a predefined radius). Border Point (q): A point q is a border point if it is within distance ϵ of a

core point but does not have enough neighbors to be a core point itself. Noise Point (s): A point s is a noise point if it is neither a core point nor a border point.

The reachability distance (r(p,q)) between two points p and q is the maximum of the core distance of p and the Euclidean distance between p and q.

$$r(p,q) = max(core_{distance}(p), ||p,q||) \tag{3.3}$$

The core distance ($core_{distance}(p)$) is the distance between a core point p and its MinPts-th nearest neighbor.

$$core_{distance}(p) = k_{distance}(p, MinPts) \tag{3.4}$$

DBSCAN (Density-Based Spatial Clustering of Applications with Noise) employs a unique approach to form clusters by defining relationships between data points based on their density and proximity. Two critical concepts within DBSCAN are "Directly Density-Reachable" and "Density-Connected."

A point p is considered directly density-reachable from another point q if p falls within the reachability distance of q and q is a core point. This relationship is determined by comparing the core distance of q with the Euclidean distance between p and q. On the other hand, points p and q are density-connected if there exists a core point o such that both p and q are density-reachable from o. These definitions form the foundation for the DBSCAN algorithm.

The k-distance of a point p is the distance to its k-th nearest neighbor:

$$k_{distance}(p,k) = distance(p, N_k(p)) \tag{3.5}$$

$N_k(p)$ denotes the set of k-nearest neighbors of p, and distance (p,$N_k(p)$) is the Euclidean distance between p and its k^{th} nearest neighbor.

The DBSCAN algorithm starts by selecting an arbitrary point in the dataset and expanding the cluster by adding all directly density-reachable points to it. This process continues iteratively, encompassing additional points into the cluster until no more points can be added. The algorithm dynamically adapts to the varying density of the dataset, classifying each point as a core point, a border point, or a noise point. Core points initiate the expansion of clusters, while border points lie within the vicinity of core points but do not possess sufficient neighbors to be core points themselves. Noise points, lacking the density requirements, remain unassigned. The DBSCAN algorithm's effectiveness lies in its ability to uncover clusters of arbitrary shapes and efficiently identify outliers, making it well-suited for applications in VANETs where communication patterns exhibit diverse densities and spatial distributions.

3.4. Feature Extraction. In VANETs, feature extraction involves capturing distinctive characteristics from communication patterns, network parameters, and other relevant metrics. These features serve as input variables for machine learning algorithms or statistical models, aiding in the discrimination between normal and malicious behavior.

Message Frequency (MF). Represents the rate of message exchange within a specific timeframe.

$$MF = \frac{Number\ of\ Messages}{Time\ Period} \tag{3.6}$$

Signal Strength Variability (SSV). Captures the variability in signal strength, which may indicate the presence of malicious nodes interfering with communication.

$$SSV = Standard\ Deviation\ of\ Signal\ Strength \tag{3.7}$$

Clustering Coefficient (CC). Reflects the degree of connectivity within a spatial cluster of vehicles, identifying potential areas of interest.

$$CC = \frac{(2 \times Number\ of\ Actual\ Connections)}{Number\ of\ Possible\ Connections} \tag{3.8}$$

Average Inter-Message Time (AIT). Measures the average time between consecutive messages, helping to identify abnormalities in communication patterns.

$$AIT = \frac{Total\ Time}{Number\ of\ Messages - 1} \tag{3.9}$$

Node Density (ND). Quantifies the concentration of nodes within a specified region, providing insights into the spatial distribution of vehicles.

$$ND = \frac{Number\ of\ Nodes}{Area\ of\ Region} \tag{3.10}$$

Entropy (H). Measures the randomness or unpredictability of message distribution, assisting in detecting irregularities.

$$H = -\Sigma_{j=1}^{n} P(i) log_2 P(i) \tag{3.11}$$

These extracted features collectively create a descriptive and discriminative representation of the VANET communication environment. The inclusion of such features in the analysis enhances the accuracy of misbehavior detection models and contributes to a more comprehensive understanding of the VANETsystem dynamics.

3.5. Hybrid Integration. In VANETs, vehicles communicate with each other through wireless communication to share important information such as location, speed, and road conditions. The basic concept involves the transmission of Cooperative Awareness Messages (CAM) or other safety-related messages among neighboring vehicles. The propagation of a message can be represented mathematically, taking into account factors like transmission time and distance.

$$TransmissionDistance(d_{transmit}) : d_{transmit} = v.t_{transmit} \tag{3.12}$$

where v is the vehicle's speed, and $t_{transmit}$ is the transmission time.

Received Signal Strength(RSS).

$$RSS = \frac{P_t.G_t.G_r.(\lambda)^2}{(4\pi)^2.d^2} \tag{3.13}$$

where P_t is the transmitted power, G_t and G_r are the gains of the transmitting and receiving antennas, λ is the wavelength, and d is the distance between the antennas.

Figure 3.3 shows the process of message transfer and attack detection. Message Transfer and Attack Detection. In the proposed approach, black hole attack detection in Vehicular Ad Hoc Networks (VANETs) integrates the power of DBSCAN (Density-Based Spatial Clustering of Applications with Noise) for spatial clustering and Decision Trees for classification. Unlike the traditional method employing an SVM classifier, our approach enhances security by leveraging DBSCAN to identify spatial clusters of vehicles and Decision Trees to discern normal communication patterns from potentially malicious ones.

Firstly, DBSCAN is applied to group vehicles based on their spatial proximity and communication behavior. Nodes within clusters are categorized as core points, border points, or noise points. Border and noise points may indicate anomalies in the network, potentially signalling the presence of black hole attacks. Prediction of Black hole attacks in VANET depends upon behavioural, connectivity and latency, packet loss features.

3.5.1. Behavioral Features.

Frequency of Messages Dropped or Modified $F_{drop/modify}$. Count the occurrences of messages that are dropped or modified over a given time period.

$$F_{drop/modify} = \frac{Number\ of\ Dropped/Modified\ Messages}{Total\ Messages} \tag{3.14}$$

Fig. 3.3: Message Transfer and Attack Detection

Anomalous Changes in Forwarding Decisions Aforwarding. Measure unexpected alterations in the forwarding decisions of a node.

$$A_{forwarding} = \frac{Number\ of\ Anomalous\ Forwarding\ Decisions}{Total\ Forwarding\ Decisions} \tag{3.15}$$

Sudden Disruptions in Communication Patterns ($D_{disruption}$). Quantify abrupt changes in communication patterns, such as sudden stops in message transmission.

$$D_{disruption} = \frac{Number\ of\ Sudden\ Disruptions}{Total\ Communication\ Time} \tag{3.16}$$

3.5.2. Connectivity Features.

Alterations in the Connectivity Graph (A_{graph}). Evaluate changes in the connectivity graph by comparing the original and manipulated adjacency matrices.

$$A_{graph} = \frac{Number\ of\ Altered\ Edges}{Total\ Edges\ in\ Original\ Graph} \tag{3.17}$$

Unusual Patterns in Claiming False Connectivity ($U_{claiming}$). Identify abnormal claiming of false connectivity, indicating potential black hole attackers.

$$U_{claiming} = \frac{Number\ of\ Unusual\ Connectivity\ Claims}{Total\ Connectivity\ Claims} \tag{3.18}$$

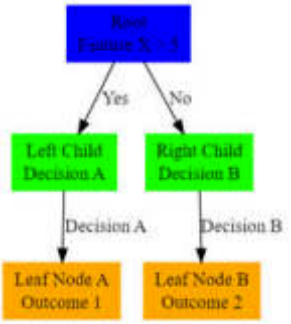

Fig. 3.4: Working of Decision Tree

Disruption in Paths for Message Transmission(D_{paths}). Assess the disruption in message paths due to false connectivity claims.

$$D_{paths} = \frac{Number\ of\ Disrupted\ Message\ Paths}{Total\ Message\ Paths} \tag{3.19}$$

Latency and Packet Loss Features:

Increased Latency Caused by Manipulated Forwarding ($L_{manipulated}$). Measure the average latency of messages when forwarding is manipulated.

$$L_{manipulated} = \frac{Latency\ of\ Manipulated\ Messages}{Number\ of\ Manipulated\ Messages} \tag{3.20}$$

Elevated Packet Loss Rates due to Black ↓ Attacks (P_{loss}). Calculate the packet loss rate when black hole attacks are suspected.

These equations provide a quantitative representation of the specified features, allowing for the assessment of abnormal behavior indicative of black hole attacks in VANETs. Figure 3.4 shows the Working of Decision Tree.

The thresholds for considering behavior as anomalous would depend on the specific characteristics of the VANET environment and the chosen detection strategy. Subsequently, the Decision Trees classifier is employed to classify nodes within the identified clusters. This step aims to differentiate between normal and potentially malicious communication patterns based on features extracted from the clusters. Decision Trees offer interpretability and the ability to capture complex decision boundaries.

$$Gini(t) = 1 - \Sigma_{i=1}^{c} p(i/t)^2 \tag{3.21}$$

where Gini(t) is the Gini impurity for node t; c is the number of classes; p(i/t) is the probability of class i at node t.

Information Gain measures the reduction in entropy or impurity achieved by splitting a dataset. For a split on feature A, the Information Gain (IG(A)) is calculated as follows:

$$IG(A) = H(parent) - \Sigma_j \frac{N_j}{N} H(child_j) \tag{3.22}$$

where H is the entropy, N is the total number of instances at the parent node, N_j is the number of instances in child node j, and H(parent) and $H(child)_j$ are the entropies of the parent and child nodes, respectively.

Entropy (H) is another measure of impurity. For a set of instances S, entropy is calculated as follows:

$$H(S) = -\Sigma_{i=1}^{c} p(i) log_2(p(i)) \tag{3.23}$$

Table 4.1: Simulation parameters for MDSR

Property	Value
Coverage Area	1000 m. X 1000 m
Number of Nodes	60
Simulation Time	600S
Transmission Range	250 m
Mobility	Random Way Point Model
Load	Data Payload 512 bytes.
Mobility Speed	20m/s
No of Gray hole Nodes	5
Connections	20 Pairs (40 nodes)
Traffic Type	UDP – CBR
Pause Time	0, 5, 10 and 15s
IDS Nodes	9 nodes (fixed)

where c is the number of classes, and p(i) is the proportion of instances of class i in set S.

The decision tree structure is built by recursively selecting features and thresholds to split the data. The decision-making process at each node involves choosing the split that maximizes information gain or minimizes impurity. The integration of DBSCAN and Decision Trees involves combining the results of these two stages. For instance, nodes classified as malicious by Decision Trees within clusters identified as anomalies by DBSCAN may be considered potential black hole attackers. The decision-making mechanism combines the spatial relationships identified by DBSCAN with the classification capabilities of Decision Trees to make a comprehensive determination of potential threats.

This hybrid approach enhances the accuracy and efficiency of black hole attack detection, providing adaptability to the dynamic and resource-constrained VANET environment. It gives a robust solution for discerning normal and malicious behavior, thereby ensuring the integrity of communication within the network.

4. Experimental Results and Analysis. This study used to verify that the suggested technique could effectively locate and isolate grey hole nodes. Within a 1000 m X 1000 m region, there are 50 normally behaving nodes that are using the MDSR routing protocol. There are also a few of bad nodes that are randomly placed and are selectively launching grey hole attacks. Additionally, there are a number of fixed IDS nodes. Each of the twenty pairings that were selected at random will be transmitting data at a rate of 5 kbps using UDP-Constant Bit Rate (UDP-CBR). A Random-way point model was used to move all the normal nodes at random rates ranging from 0 to 20 m/s. Furthermore, four distinct kinds of typical node stop times—0, 5, 10, and 15 seconds—were taken into account independently. The amount of time a mobile node may stay still before continuing to move is called its pause time. For instance, if the pause time is 0, it indicates that all nodes were moving continuously, without any brief pauses. The frequency of changes to the topology of a network is also indicated by the pause time. In Table 4.1, you can see the key parameters used in all of the Glomosim studies. The experimental data shown here is an average value derived from these 10 trials. Additionally, we compare our method to an existing one that was suggested follows a similar pattern to our method, with neighbour nodes of the source route doing monitoring and the source node sending data in blocks. It also doesn't use cryptography to identify threats.

We compare the proposed DBSCAN-DT framework's results to those of two other approaches already in use. Two algorithms that have been developed for use in WSN are the Adaptive Sink Aware (ASA) method and the Secure Route Discovery in AODV (SRD-AODV). Next, we use the table and graph values, in addition to the following metrics, to determine the performance of the proposed DBSCAN-DT framework in WSN.

4.1. Impact of Delay. In a WSN, the delay is defined as the time it takes for a data packet to travel from its source node to its destination node, and vice versa. Reducing WSN latency makes the suggested approach more efficient during transmission. Delay as a function of data packet count is seen in Table 4.2. The following table compares the suggested DBSCAN-DT framework to several current approaches, including SRD-AODV

Table 4.2: Tabulation for Delay

No.of data packets	Delay(ms)		
	Existing SRD- AODV	Existing ASA	Proposed DBSCAN-DT
10	53	47	41

[15] and the ASA algorithm [16]. For the purpose of conducting experiments, the quantity of data packets is adjusted between ten and one hundred. According to Table 4.2, all approaches experience an increase in latency while attempting to improve the amount of data packets.While the current approach for identifying blackholes and sinks in WSNs during secured transmission takes too much time, the suggested DBSCAN-DT architecture cuts down on that time significantly. Figure 4.1 shows the Measure of Delay.

The delay measurement for both the proposed and current approaches in WSN with different types of data packets is shown in Figure 6. Figure compares the suggested DBSCAN-DT framework to two current methods: SRD-AODV and the ASA algorithm. The numbers of data packets used for experimental analysis range from tens to hundreds. Consequently, the suggested DBSCAN-DT architecture, as opposed to current techniques, minimises latency in the sensor network. By using the suggested DBSCAN-DT structure, all patients' identical data are transmitted to the cluster head node, allowing for efficient evaluation of delay within cluster distances. By using the DBSCAN clustering technique, these nodes are able to accomplish the intrusion-measure correlation in WSN.

As a result, the correlation value is achieved by using just the most recent patient record based on its time, rather than passing the information of each node to the intrusion detection system. So, in comparison to the

Table 4.3: Tabulation for Attack Detection Accuracy

No. of sensor Nodes	Accurately identified attack node			Attack Detection Accuracy(%)		
	SRD-AODV	ASA	Proposed DBSCAN-DT	SRD-AODV	ASA	Proposed DBSCAN-DT

current state-of-the-art algorithms, the suggested DBSCAN-DT framework significantly reduces data packet delivery delays in WSNs by 19% compared to the SRD-AODV and by 10% compared to the ASA algorithm.

4.2. Impact of Attack Detection Accuracy. The attack detection accuracy is the percentage of sensor nodes in a WSN that correctly identify attack nodes, sometimes called sinkholes or black holes. The following is a mathematical representation of the attack detection accuracy. The suggested method promises to be more effective if the network's attack detection accuracy is enhanced.

Based on the number of sensor nodes, Table 4.3 shows the attack detection accuracy utilising the proposed DBSCAN-DT framework and current approaches, such as SRD-AODV and the ASA algorithm . The experimental work is carried out using a range of 50 to 500 sensor nodes. Increasing the number of sensor nodes improves the accuracy of attack detection for all approaches, according to the values in the table.

Accuracy in detecting attacks as a function of sensor node count is shown in Figure 4.2. In addition, the figure compares the proposed DBSCAN-DT framework to two existing algorithms, the ASA method. As a result, the suggested DBSCAN-DT frameworkas improves the accuracy of attack detection when compared to the current methodologies. The suggested DBSCAN-DT framework effectively improves the accuracy of attack

Table 4.4: Tabulation for Packet Delivery Ratio

No.of data packets	No.of data packet received			Packet delivery ratio(%)		
	SRD-AODV	ASA	Proposed MK-Means	SRD-AODV	ASA	Proposed MK-Means
10	7	7	8	71	74	83
20	14	15	17	73	75	85
30	22	24	26	75	80	87
40	30	33	35	78	83	88
50	39	42	44	79	84	90
60	47	51	54	81	85	91
70	58	61	64	83	87	93
80	66	72	74	85	90	94

100	87	92	96	71	83	92

detection for secured broadcasting using a machine learning approach. The document outlines the intrusion measure that is used to confirm attacks. Additionally, the value of the intrusion measure is a growth value that is tied to time, which helps in retrieving patient information about a given moment. Not only that, the suggested DBSCAN-DT framework offers improved accuracy in identifying attacks quickly by using time-related growth value to determine whether an attack is noticed for a normal node. Consequently, the proposed DBSCAN-DT framework outperforms the state-of-the-art SRD-AODV by 15% in WSN and the state-of-the-art ASA method by 7%.

In contrast to the current methodologies, the suggested DBSCAN-DT architecture reliably identifies SH and BH attack nodes to provide safe delivery via a WSN. The data in the table below Figure 7 is used to produce the graph.

4.3. Impact of Packet Delivery Ratio. The packet delivery ratio, as calculated using the suggested DBSCAN-DT framework, is the percentage of data packets that reach their intended recipients without error out of all the data packets sent over the network. What follows is a mathematical depiction of packet delivery ratio.

Based on varying data packet counts, Table 4.4 shows the experimental results of the packet delivery ratio for the current technique and the suggested one. Table 4.4 shows that all techniques have an enhanced packet delivery ratio as the number of data packets increases.

Figure 4.3 shows the packet delivery ratio measured using Ghazaleh Jahandoust and Fatemeh Ghassemi's ASA algorithm and current approaches. The amounts of data packets used for experimental analysis range from tens to hundreds.

Figure 4.4 shows that the suggested DBSCAN-DT framework outperforms the current approaches in terms of packet delivery ratio in WSN.

The suggested DBSCAN-DT method is the basis for this significant enhancement in the packet delivery ratio. The next step is to take into account rescaled entity points that include various patient characteristics (this is because patient data are not static). Nevertheless, when contrasted with other current approaches, the suggested DBSCAN-DT framework considerably improves the packet delivery ratio during data packet transmission from source node to sink node in the network. Figure 4.3 provides the data used to generate the graph. The MINRMAXR method effectively reduces packet loss in WSN attack detection by enabling rescaled entity points and non-overlapping subsets. As a result, the rate of attack detection using the retrieved characteristics is improved. Thus, the suggested DBSCAN-DT structure helps achieve a greater packet delivery ratio.Table 4.5 shows the Tabulation for Computational Complexity

Nevertheless, when contrasted with other current approaches, the suggested DBSCAN-DT framework considerably improves the packet delivery ratio during data packet transmission from source node to sink node in

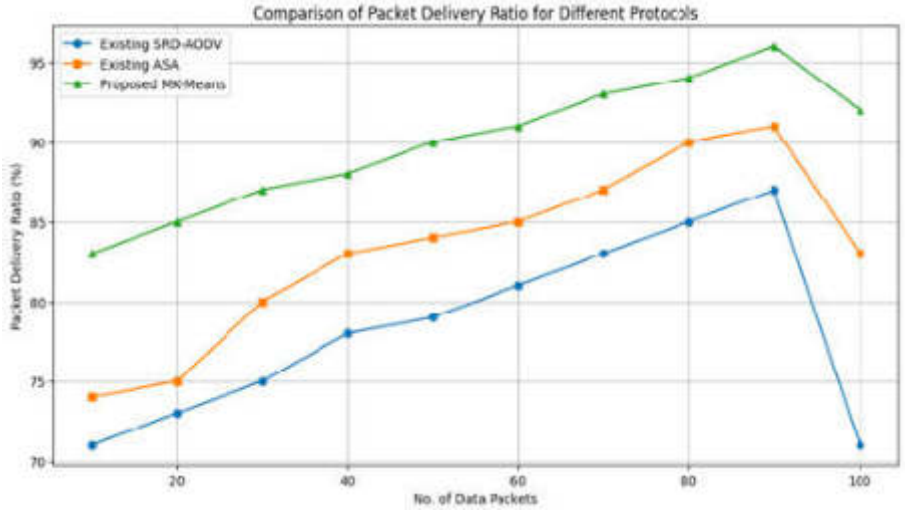

Fig. 4.3: Measure of Packet Delivery Ratio

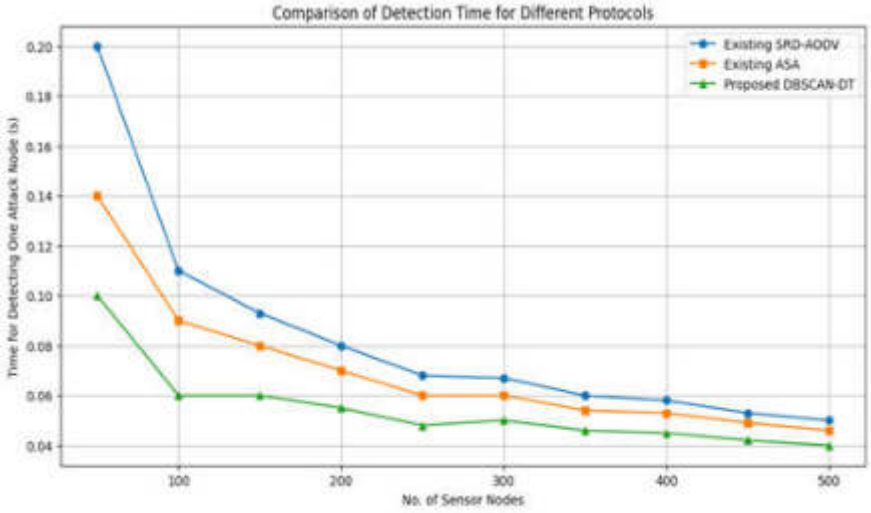

Fig. 4.4: Measure of Detection Time

the network. Figure 4.4 provides the data shows the detection time and Figure 4.5 shows the computational complexity of the proposed work.

5. Conclusion. In order to reduce computational complexity in WSN and improve attack detection accuracy, the DBSCAN-DT framework is developed. Three procedures, including physiological data collection (PDC), proportional overlapping score (POS), and machine learning approach, make up the proposed DBSCAN-DT system. The PDC module starts by collecting features from the training dataset, which are based on physiological parameter measurements. The next step is to use the POS model for data pre-processing and feature minimization on the chosen training data. This simplifies the task of detecting attacks while they are being sent. The next step is to use a wireless communication network to send the chosen characteristics to the DBSCAN clustering algorithm, which will then conduct the testing and classification. The detection metrics include the number of packets transmitted and received, which aid in the calculation of Intrusion Measure

Table 4.5: Tabulation for Computational Complexity

No. of sensor nodes	Time for detecting one attack node			Computational Complexity (ms)

(IM) utilising IDS, using the suggested DBSCAN-DT architecture. As a result, it can quickly and accurately identify the sinkhole or black hole attack node, allowing for quick and secure communication. By alerting the network to stop data transmission in the event that a SH or BH assault is detected in a WSN, intrusion detection systems improve the accuracy of attack detection. Improved packet delivery is therefore a benefit of the suggested DBSCAN-DT system. proportion with enhanced efficacy. Additionally, measures such as computational complexity, latency, packet delivery ratio, and attack detection accuracy are used to evaluate the performance of the proposed DBSCAN-DT framework. In comparison to state-of-the-art studies, the simulation results show that the suggested DBSCAN-DT framework considerably improves performance by reducing computing complexity, improving packet delivery ratio, and increasing attack detection accuracy. Further, it reduces latency.

OPTIMIZING HADOOP DATA LOCALITY: PERFORMANCE ENHANCEMENT STRATEGIES IN HETEROGENEOUS COMPUTING ENVIRONMENTS

SI-YEONG KIM* AND TAI-HOON KIM†

Abstract. As organizations increasingly harness big data for analytics and decision-making, the efficient processing of massive datasets becomes paramount. Hadoop, a widely adopted distributed computing framework, excels in processing large-scale data. However, its performance is contingent on effective data locality, which becomes challenging in heterogeneous computing environments comprising diverse hardware resources. This research addresses the imperative of enhancing Hadoop's data locality performance in heterogeneous computing environments. The study explores strategies to optimize data placement and task scheduling, considering the diverse characteristics of nodes within the infrastructure. Through a comprehensive analysis of Hadoop's data locality algorithms and their impact on performance, this work proposes novel approaches to mitigate challenges associated with disparate hardware capabilities. Weighted Extreme Learning Machine Technique (Weighted ELM) with the Firefly Algorithm (WELM-FF) is used in the proposed work. The integration of Weighted Extreme Learning Machine (WELM) with the Firefly Algorithm holds promise for enhancing machine learning models in the context of large-scale data processing. The research employs a combination of theoretical analysis and practical experiments to evaluate the effectiveness of the proposed enhancements. Factors such as network latency, disk I/O, and CPU capabilities are taken into account to develop a holistic framework for improving data locality and, consequently, overall Hadoop performance. The findings presented in this study contribute valuable insights to the field of distributed computing, offering practical recommendations for organizations seeking to maximize the efficiency of their Hadoop deployments in heterogeneous computing environments. By addressing the intricacies of data locality, this research strives to enhance the scalability and performance of Hadoop clusters, thereby facilitating more effective utilization of big data resources.

Key words: Hadoop; Data Locality; Performance Enhancement; Heterogeneous Computing; Distributed Computing; Big Data.

1. Introduction. In the era of big data, the efficient processing and analysis of massive datasets have become critical for organizations across various domains. Hadoop, a widely adopted distributed computing framework, has emerged as a powerful tool for handling large-scale data processing tasks. One of the key factors influencing Hadoop's performance is the effective utilization of data locality, ensuring that computation occurs close to where the data resides as shown in Figure 1.1. However, in heterogeneous computing environments encompassing diverse hardware resources, optimizing data locality presents significant challenges. This research focuses on addressing these challenges and enhancing the performance of Hadoop in such environments. By exploring strategies to optimize data placement and task scheduling, considering the distinct characteristics of nodes within the infrastructure, this study aims to provide practical insights for organizations seeking to maximize the efficiency of their Hadoop deployments in diverse computing environments [1].

The proliferation of heterogeneous computing environments, comprising a mix of hardware architectures and capabilities, adds a layer of complexity to the already intricate landscape of big data processing. The diverse performance characteristics of nodes within such environments impact data processing efficiency, making it imperative to devise strategies that not only adapt to this heterogeneity but also enhance Hadoop's data locality performance. This research delves into the intricacies of Hadoop's data [2] locality algorithms, scrutinizing their efficacy in heterogeneous settings. By addressing challenges related to network latency, disk I/O, and varying CPU capabilities, the study aims to propose novel approaches for optimizing data placement and task scheduling. Through a blend of theoretical analysis and practical experiments, the research seeks to contribute valuable insights that can guide organizations in tailoring their Hadoop deployments for optimal

performance [3] in heterogeneous computing environments. Ultimately, the goal is to empower enterprises to extract maximum value from their big data resources while navigating the complexities introduced by diverse hardware configurations.

In the vast landscape of distributed databases, characterized by a superabundance of data from diverse fields, managing the manifold, intricate, dissimilar, and autonomous nature of occurrences poses a significant challenge [4]. The sheer volume of data, often rife with excessive and extraneous features, necessitates the application of a suitable filtering model to address noise in features or occurrences. Effectively dealing with this substantial number of characteristics requires the implementation of an efficient attribute selection model to choose ranked features for classification or clustering.

A notable contribution by [5] involved the application of a concise set of rules using a feature selection model within rough set theory. Despite these advancements, the classification algorithms encounter a crucial challenge in the form of error rates and class imbalances.

Handling high-dimensional document spaces, especially in the context of large document sets, presents inherent difficulties in preprocessing and classifying. To enhance the learning of classification algorithms, a considerable number of samples [6] need to be learned based on their dimensions. Conceptually, this document space can be viewed as a low-dimensional sub-space enveloped within an ambient space. In response to the dimensionality issue, numerous dimension reduction methods have been developed, aiming to decrease document dimensions and improve performance and efficiency.

The application of these methods becomes particularly crucial in addressing the challenges posed by online medical databases. Arithmetic computing procedures, data accessing, semantics, and domain knowledge are fundamental challenges in dealing [7] with these databases, exacerbated by the complexities, continuous fluctuations, and noise inherent in the growing data landscape. As research endeavors continue, finding effective solutions to these challenges becomes paramount for leveraging the full potential of online medical databases in various applications [8].

The aim of the proposed work is to address the challenges associated with the superabundance of data in distributed databases [9], particularly focusing on the manifold, intricate, dissimilar, and autonomous nature of occurrences across diverse fields. The primary goal is to develop and implement effective filtering models

to handle noisy features and occurrences within the substantial dataset [10]. Additionally, the research aims to tackle the issues related to high-dimensional document spaces, where preprocessing and classifying large document sets prove to be challenging.

To achieve these objectives, the proposed work seeks to employ advanced attribute selection models, inspired by rough set theory and other relevant methodologies, to effectively manage the extensive characteristics inherent in the data [11]. The utilization of dimension reduction methods is a key aspect of the research, with the aim of enhancing the learning process of classification algorithms by decreasing document dimensions and improving overall performance and efficiency. Furthermore, the proposed work aims to contribute to the field by addressing challenges in online medical databases, focusing on arithmetic computing procedures, data accessing, semantics, and domain knowledge. The ultimate objective is to develop solutions that navigate the complexities, continuous fluctuations, and noise within the growing data of medical databases, ensuring their effective utilization in various applications.

The proposed work aims to advance the understanding and methodologies for managing vast and complex datasets, with a specific focus on distributed databases and high-dimensional document spaces. The overarching goal is to contribute to the development of robust models and techniques that can enhance the efficiency, accuracy, and applicability of classification algorithms and data processing in challenging environments.

The integration of Weighted Extreme Learning Machine (Weighted ELM) with the Firefly Algorithm presents a potent approach for optimizing machine learning models efficiently. Weighted ELM, an extension of the Extreme Learning Machine algorithm, is known for its computational efficiency and rapid training. By incorporating the Firefly Algorithm, a nature-inspired optimization technique, the model's parameters can be fine-tuned to enhance generalization performance. This synergy benefits from the Firefly Algorithm's ability to efficiently explore and converge to optimal solutions in complex optimization spaces. When applied in the context of Hadoop, a distributed computing framework, the proposed work emphasizes the crucial aspect of data locality. Leveraging Hadoop's parallel processing capabilities, the distributed nature of the Weighted ELM with Firefly Algorithm ensures that computation occurs in close proximity to the data, minimizing data transfer across the nodes of the Hadoop cluster. This strategic use of data locality optimizes the training and optimization processes, facilitating the effective handling of large-scale datasets in a distributed computing environment.

The outline of the paper looks like this: Previous studies are reviewed in Section 2, the methodology for the current study is laid out in Section 3, the experimental data and their analysis are presented and discussed in Section 4, and finally, ideas for future studies are provided in Section 5.

2. Literature Survey. Numerous studies have explored the utility of Data Placement (DP) in the context of MapReduce jobs within Hadoop clusters, addressing challenges in managing distributed databases and high-dimensional document spaces. Noteworthy contributions include a solution to duplicate data files during staged predictive inspection, employing a probability hypoproposed work for replication. Al-Khateeb and Masud introduced a method using rough set theory, enhancing both convenience and safety compared to conventional approaches [12].

The Data-Grouping-AWare (DRAW) technology, developed by another group, focuses on increasing the effectiveness of data-intensive applications in concentrated user interest areas. DRAW optimizes information retrieval from framework log data, achieving maximal parallelism without compromising load balancing. Experimental results demonstrate improved throughput for local map tasks, enhancing overall execution performance compared to Hadoop's default random placement [13].

The Snakelike Data Placement method (SLDP) introduces a technique considering heterogeneity, redistributing information blocks across nodes while addressing data heat. SLDP shows potential to increase MapReduce performance, utilizing less space and energy according to experiments with real-world datasets [14].

Dynamic Replica Strategy (DRS) and Hierarchical Replica Placement Strategy (HRPS) in Hadoop Distributed File System (HDFS) ensure data integrity and accessibility. The Markov model informs the development of a Secure HDFS (Sahds) that adapts the SFAS section designation mechanism. Sahds distributes file contents over similar nodes, maintaining replications and addressing data replication issues [15, 16].

Hybrid mechanisms in HDFS incorporate Solid-State Disks and conventional hard discs to enhance per-

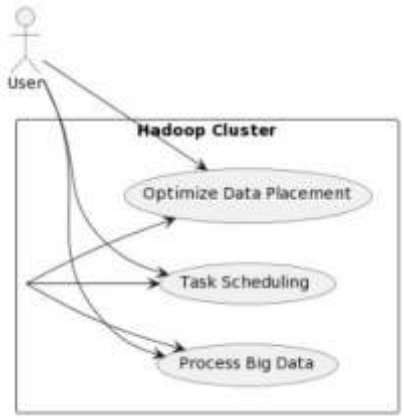

Fig. 3.1: Map Reduce Framwork with Hadoop Cluster

formance without increased energy usage, showing a significant reduction in energy consumption compared to hybrid configurations [17].

A security-aware information placement method for scientific operations in the cloud is proposed, guaranteeing data privacy, integrity, and authentication access. The method calculates the cost of data center security services using a security model and dynamically selects the best data centers with an Ant Colony Optimization (ACO) based approach [18].

Hybrid clouds present challenges in retrieving data while protecting user anonymity. Last-HDFS addresses data placement issues, enabling location-aware cloud storage and file loading based on policy compliance [19].

Clustering methods for organizing data, including K-means and bio-inspired algorithms, have been explored for their simplicity and optimization capabilities. Various bio-inspired algorithms, such as Genetic Algorithm (GA), Differential Evolution (DE), and Particle Swarm Optimization (PSO), address optimization challenges in clustering. A novel approach using GA clustering, DE, and ACO demonstrates potential improvements in cluster centroids' search capability [20].

MapReduce-based methods, including K-means parallelization and parallel K-PSO, are proposed for large-scale clustering, addressing challenges with PSO algorithm scalability in very big datasets. Scalable MR-CPSO uses the parallel MapReduce approach to overcome PSO algorithm issues with large datasets.

In conclusion, these studies collectively contribute to the advancement of distributed data processing, data placement strategies, and clustering methods, with a particular emphasis on enhancing performance, energy efficiency, and security in diverse computing environments.

3. Proposed Methodology. Hadoop is a free, Java-dependent programming framework which supports the processing of massive databases in a distributed computing platform. In addition to efficiency and management of big data, the Hadoop framework offers numerous features such as high availability (recreation of data squares across nodes), adaptation to internal failure (the system itself is built to differentiate and cope with setbacks in the application layer), etc. It is adopted for processing and storing colossal data in distributed environments using programming models. Hadoop appears as the persuasive solution for big data issues with some additional capabilities. Hadoop uses the MapReduce algorithm to run applications. MapReduce is a framework employed to process the enormous databases parallely. It performs distributed operational programming as shown in Figure 3.1.

The MapReduce framework allows to specify information transformation logic through exploiting their own map function and reduce function. MapReduce technology also enhances the monitoring and scheduling of tasks and simplifies massive computing and handling of colossal data volumes. MapReduce being Hadoop's core component, processes massive information in parallel through splitting the job into a cluster of separate tasks. As MapReduce operates in a data-intensive environment, the important factor that directly affects the

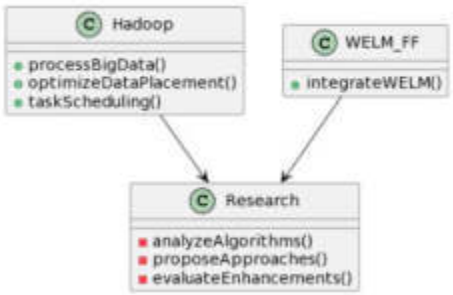

Fig. 3.2: Proposed Algorithm Processing Unit

efficiency is data transmission. Reduction in efficiency causes performance degradation of the system as shown in Figure 3.2. This methodology aims to improve efficiency of Hadoop MapReduce framework during parallel data processing and when operating in data-intensive environments. It intends to ameliorate response time and data throughput of system. It aims to maximize network load in Hadoop MapReduce for boosting the overall system performance. In this research work, initially data distribution is done, followed by speculative prefetching.

This research aims to optimize the network load in Hadoop MapReduce. It intends to improve the efficiency of Hadoop MapReduce framework during parallel data processing and when operating in data-intensive environments and to ameliorate mainly response time and data throughput of desired system.

Step 1: This step involves initialization of a series of entities such as data center, data locality and task scheduler.

Step 2: This step involves data distribution, prefetching and development of MapReduce. Data distribution is done according to node capacity and for prefetching operation, a speculative prefetching method is employed.

Step 3: This step involves Hadoop configuration and development of a locality-based scheduler and reduction of tasks into nodes using WELM-FF.

Step 4: This step involves performance inspection of proposed WELM-FF-Fair share approach and also comparison of proposed scheduling approach with benchmarking schemes.

A distributed Hadoop configuration with 20 nodes is employed and then job scheduling is accomplished fair scheduling scheme. Experiments are conducted on diversified Hadoop cluster with configurations. Further, heterogeneity within the cluster is quantified by considering several CPU or processor types, disk space and memory size. Hadoop 2.2.0 version is employed and configured with JDK 1.8 version and 128 MB block size. For input, a text file generated using java code is used. K-Nearest Neighbour (WELM-FF) based fair scheduler approach is employed for improving efficacy of Hadoop MapReduce model while parallel information processing and for enhancing system's response time and data throughput. In current methodology, performance of developed WELM-FF-based fair scheduling scheme is evaluated considering performance measures like job execution duration, throughput, performance rate and execution duration for clustering as shown in Figure 3.3.

In this proposed work, the developed WELM-FF scheduler's performance is assessed using afore-mentioned metrics and is compared with popular schedulers like capacity scheduler and default (FIFO) scheduler. Furthermore, performance of proposed WELM-FF scheduler is evaluated against different benchmarks like random text, sort, word count with regard to job execution time, performance rate, data locality, execution time for clustering and throughput through comparing WELM-FF scheduler as shown in Figure 3.4 and data locality-based FIFO scheduler. Also, superiority of proposed WELM-FF based fair scheduling scheme is compared with default scheduling method with regard to metrics like job execution duration, throughput, performance rate and execution duration for clustering.

3.1. Initialization. The entities like data center, data locality and task scheduler play a vital role in Hadoop MapReduce framework. The data locality indicates how close the input and compute data are (in common words, it indicates closeness of input data and computed data). Data locality contains distinct levels

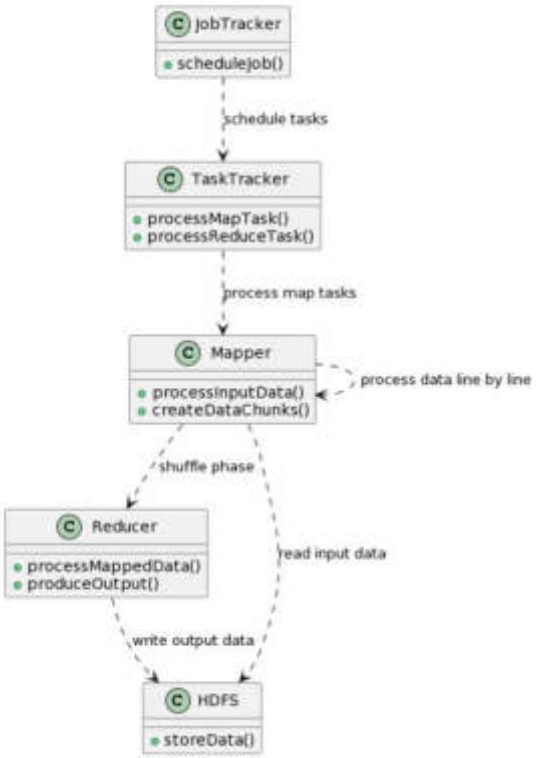

Fig. 3.3: Working of Map Reduce Technique

like rack level, node level, etc. In this methodology, data locality based on nodelevel is exploited. In data locality based on node-level, compute data and given/input data are coplaced on an alike/same node. In parallel data systems, data locality corresponds to an imperative element considered by schedulers. Data locality here indicates locality of input data. The task scheduler is associated with job scheduling in the Hadoop MapReduce framework. In proposed methodology, firstly these entities (data center, data locality and task scheduler) are intialized. The two text files generated using java code namely keyval and random text are used as input and applied to MapReduce job. Given an original matrix V (document term matrix), NMF seeks to approximate V as the product of two non-negative matrices W (basis matrix) and H (coefficient matrix), i.e.,

$$V \approx WH \tag{3.1}$$

This factorization can be expressed through the optimization problem:

$$\min_{W,H} \parallel V - WH \parallel^2 subjecttoW, H \geq 0 \tag{3.2}$$

where $\| \cdot \|^2$ denotes the Frobenius norm, ensuring non-negativity in the factorization. The resulting matrices W and H capture the underlying structures and relationships in the data. Reducing the dimension and converting the document word matrix into smaller ones are the main goals of this strategy, along with gathering alternate underlying structures within the data. Elements in these reduced matrices must be non-negative. Pattern recognition, text clustering, and bioinformatics are just a few of the several areas where the NMF method give the better results. Initially, input data or information is divided into several data blocks as per the node's processing potential within the cluster using the proposed scheduler as shown in Figure 3.5. Further, these information blocks are allotted to distinct nodes within cluster.

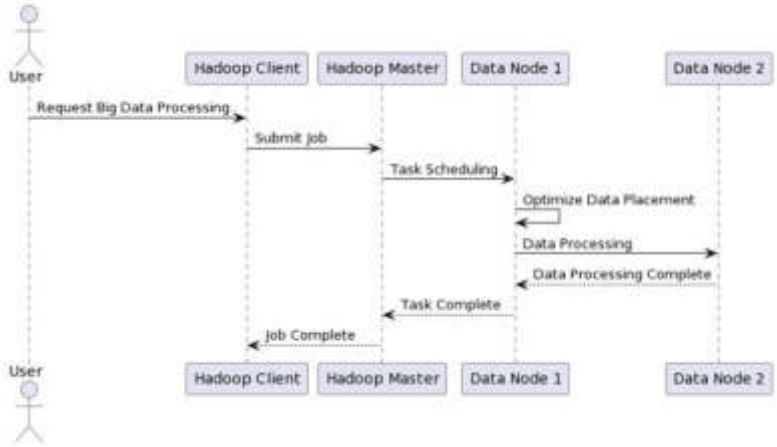

Fig. 3.4: Working of Data Localization

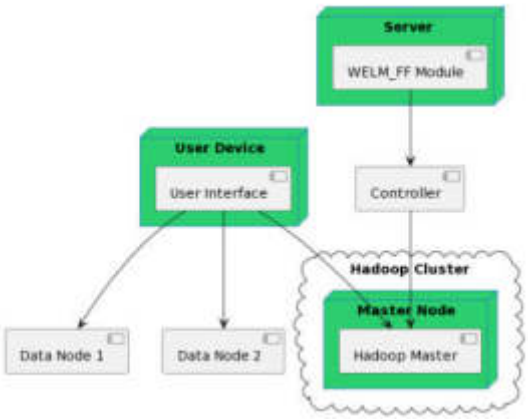

Fig. 3.5: Proposed User End Module

$$ODB \leftarrow DS/BS \tag{3.3}$$

where ODB indicates overall data blocks for input information, DS denotes input data's data size and BS denotes block size (default). Processing capacity (NPC) of each x node in the Hadoop cluster is estimated as,

$$NPC(x) \longleftarrow P(x) + MTE(x) \tag{3.4}$$

where NPC(x) indicates x^{2h} node's processing capacity, MTE (x) denotes mean task execution duration in x^{2k} node and P(x) indicates performance of $x^{\sqrt{k6}}$ node.

Within the cluster, NPC of all present nodes is determined through considering a) mean task execution duration of a specific job in specific node of cluster, b) combining CPU and existing memory of specific node at normal intervals. The mean task execution duration is determined through executing a specific job's few tasks on that node. Here, MTE is added to NPC as the job in distinct nodes is executed at distinct times and this aids in determining a node's NPC. Furthermore, percentage of CPU and memory utilization in each node of a diversified cluster can be determined. The free CPU and memory usage in each node within cluster is

determined as

$$\begin{aligned} \text{FreeMem } (x) &\leftarrow ((100 - \text{ UtilizedMem } (x)) \times Mem(x))/100 \\ \text{FreeCPU } (x) &\leftarrow ((100 - \text{ UtilizedCPU } (x)) \times CPU(x))/100 \end{aligned} \tag{3.5}$$

The job tracker handles job scheduling. It allots tasks to idle task trackers in the cluster according to slot availability. Further task trackers process the reduce tasks and map tasks on a cluster's corresponding nodes. The mapper's job here is to typically process given/input data. This information (given data) is stored within the HDFS. The input file is further passed to the mapper function line by line. Further, mapper processes the data and creates several small chunks of data. Reducer's job here is to mainly process the data which approaches from mapper. After processing, it produces a new set of output, which will be stored in the HDFS. Between map and reduce phase shuffling and sorting is done. The information obtained from the map nodes is copied to the reducers node by shuffle phase. The sort phase sorts the intermediate information by key. where Mem(x) represents x^{sh} node's RAM capacity, UtilizedMem(x) represents percentage of utilized memory in x^{st} node of cluster, CPU(x) represents x^{st} node's processing capacity and UtilizedCPU(x) represents percentage of utilized CPU in x^{th} node of eluster. Further, performance of x^{th} node is determined through obtaining free existing memory and CPU from that node using equation (3.6) as

$$P(x) \leftarrow FreeMem(x) + FreeCPU(x) \tag{3.6}$$

Each time during job execution, the nodes are classified based on the NPC. The overall NPC of all nodes contained within Hadoop cluster is estimated using equation (3.7).

$$ONPC \leftarrow \sum_{x=1}^{n} NPC(x) \tag{3.7}$$

where n represents the number of data nodes and ONPC denotes the overall NPC. The amount of data blocks that are to be allotted for every data node i is estimated as,

$$NB(x) \leftarrow ODB \times (NPC(x)/ONPC) \tag{3.8}$$

where NB(x) denotes the number of data blocks allotted for x^{th} data node. For x^{th} data node, the number of data blocks will be allotted as per NPC using equation (3.9)

$$DN(x) \leftarrow NB(x) \tag{3.9}$$

where DN(x) represents the x^{2h} node in the Hadoop cluster.

Then the presence of map slots is checked on data nodes. Map tasks are allotted to nodes within the cluster if the slots are present (or available). In case the slots are unavailable, then the scheduler waits until the slots become available.

In Hadoop, typically the reduce stage does not begin until the map stage generates all intermediate information. It is necessary to wait until completion of all map operations in order to achieve the ultimate job output. Hence, after completion of execution by map task scheduler, the reduce task scheduler begins its execution. In reduce stage, the nodes are organized such that they possess reduce function as depicted in equation (3.10).

$$RN(x) \leftarrow RN_l, RN_2, RN_3, \ldots\ldots\ldots\ldots, RN_k \tag{3.10}$$

where RN(x) represents the reducer node or x^{th} node possessing reduce function, k denotes the number of nodes possessing the reduce function. Similar to map stage, the availability of reduce slots is checked in reduce stage. If reduce slots exist, then reduce tasks will be allotted to nodes. If slots are unavailable, then the scheduler will wait until the slots become available.

In order to identify outliers as shown in Figure 3.6, a boundary must be formed around them by merging closed contours. All the points within a single contour are grouped together under the same cluster by these contours, which are called cluster borders. Cluster boundaries of different sizes and shapes may be generated using this method, and it doesn't matter how the data is distributed.

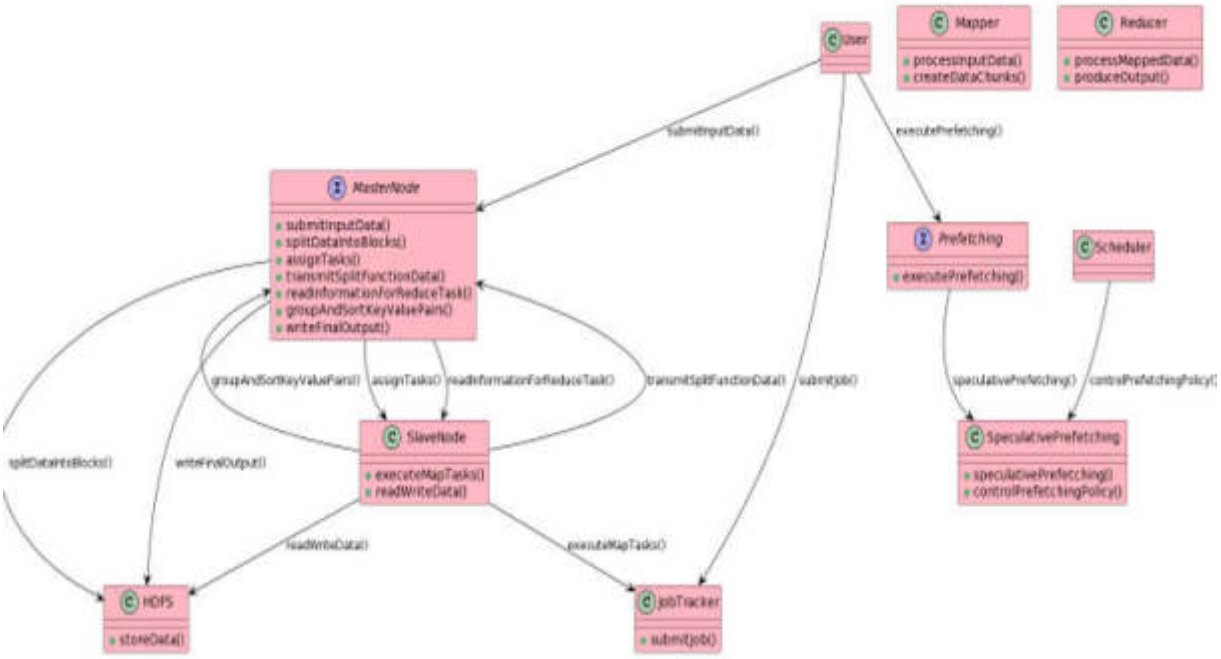

Fig. 3.6: Flowchart of Proposed work

The optimization problem associated with WELM can be expressed as:

$$\min_{R,a,\xi} R^2 + \frac{1}{\nu}\sum_{i=1}^{N}\xi_i - \sum_{i=1}^{N} a_i \tag{3.11}$$

subject to constraints:

$$\| \phi(x_i) - a \|^2 \leq R^2 + \xi_i,\ \xi_i \geq 0,\ \sum_{i=1}^{N} a_i = 1,\ a_i \geq 0 \tag{3.12}$$

where R is the radius of the hypersphere, a represents the center, and ξ_i are slack variables.

All of the points on a single contour fall inside the same cluster, which is why these lines are called cluster borders. By generating cluster boundaries of any shape and size independent of the data side, the suggested WELM technique surpasses the traditional approaches. The shortcomings of conventional methods may be remedied with the use of the WELM clustering strategy. There is currently no clear solution to the research topic of how to properly apply WELM during document clustering. There isn't a perfect document clustering strategy that fixes all the problems with the old ways and works better.

3.2. Hadoop based Data partition. The Map-Reduce architecture supports and underpins big databases with a lot of features, divides them into smaller sets, and then distributes them to different cloud groups for calculations. As seen in Figure 2, Map-Reduce views data as a key-value pair represented as <Key, Value>. At now, there is a lot of thought put into data-intensive processing, mostly centred on the Map-Reduce framework for investigating large amounts of data. Over time, it has evolved into a scalable and fault-tolerant data handling device that can calculate and process massive datasets with just a few of low-end computer cluster nodes. However, Map-Reduce does have certain inherent issues with its efficiency and implementation as shown in Figure 3.7.

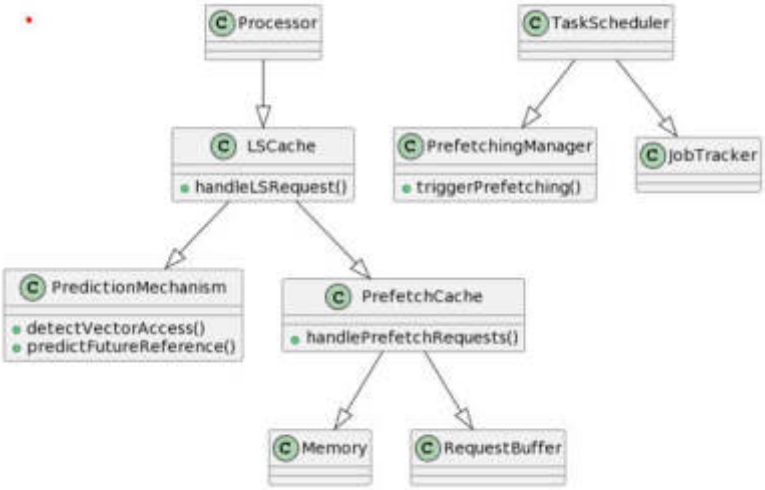

Fig. 3.7: Map-Reduce Framework with prediction mechanism

The fundamental goal of knowledge mining techniques is to extract valuable information from massive informational databases, often known as datasets. The information gathered from this procedure is quite useful for decision-making models. The computational competency and processing time are both negatively affected by the amount and dimensions of the data set as the intensity rises. Unfortunately, classical method parallelization is not straightforward, and many current optimization models aren't very effective at parallel calculations either.

One of the most important data mining categorization strategies is the decision tree. Experts in decision tree algorithms now focus on making data processing more efficient. Data sizes grow in direct correlation to the rate of advancement in system networking and real-time application development. The purpose of using a distributed decision-tree structure in tandem with the Hadoop framework to handle these massive data sets is to identify these concerns.

3.3. Biomedical XML document preprocessing. Due to the vast amount of medical document sets, the biomedical area is home to the most commonly utilised applications of text mining. For open access papers, the conventional text mining methods rely only on "sorting and theme" for searching. Articles from open-access biomedical journals are licenced under the creative commons licence and are available in full text. In the first stage of the algorithm for extracting documents, it detects about 100GB of articles. For the extraction model to work properly, clear structured data is required. In most cases, all publications found in the PubMed repository include unstructured data in addition to XML tags. Articles' entire texts are pre-processed and clustered using the document clustering method. This method places a premium on abstractions, as opposed to previous biomedical text mining algorithms.

The clustering process, mathematically, involves grouping similar XML data, denoted by D_i, into clusters C_j. This can be expressed as:

$$C_j = \{D_i : similarity\,(D_i, C_j) \geq \text{ threshold } \} \tag{3.13}$$

where similarity measures the similarity between the XML data D_i and a cluster C_j, and a threshold is defined to determine when a document is considered part of a cluster.

When working with big and varied datasets, these clustering approaches are very important for improving the biomedical domain's information structure and accessibility. These days, XML is the standard format for online data exchange. Clustering has been the most popular and widely used method. In this context, clustering stands for the combination of XML data types and XML clustering applications that are comparable. Among them are query processing, web mining, document categorization, data integration, and retrieval of information.

The major issues in XML data preprocessing for clustering are described below:

- Initially, the clustering process calculates the similarity index among numbers of different XML data. Nevertheless, evaluating the similarity function is a major problem because of the heterogeneity property of XML documents.
- Implicit dimensionality has increased to a great extent.

Biomedical documents, phrases, sentences are used in the feature extraction to extract the main features of the original documents. The graph-based feature extraction generates the feature extraction by mining phrases or sentences from the set of key peer nodes of the overlay network. Finally, key phrases or sentences are extracted by computing the ranking scores and then selecting the highest scored phrases or sentences.

3.4. Traditional feature selection models on biomedical databases. In order to categorise the texts according to MeSH keywords, a new Bayesian Network (BN) method is created. Classification is carried out by this model based on the entity associations of various MeSH words, and it can readily depict the conditional independences between MeSH terms and the MeSH ontology. This method is used to depict the MEDLINE document resources at different levels of abstraction. In order to address these concerns, medical ontologies are used to discover the medical concept MeSH synonyms. Textual categorization schemes often use machine learning techniques in an inductive fashion.

Furthermore, a BN classifier based on support vector machines is used to categorise MEDLINE articles. When analysing the performance of a balancing approach, both BN and SVM-based BN classifiers become quite sensitive. Text classification and classification models are frequent areas where class-imbalance problems occur. The classic issue of class imbalance cannot be addressed by these methods. In order to make conventional categorization procedures more accurate, a lot of new, sophisticated methods have been created. Methods based on recognition, active learning, sampling, and cost sensitivity are all part of these generalised categorization systems. By excluding arbitrary data from the dominant class, sampling techniques have helped to address the issue of class imbalance. The term for these methods is under-sampling approaches. Oversampling occurs when there are insufficient new randomised data points for the minority class. For instance-specific document category classification, the cost-sensitive learning technique employs a cost-matrix. In order to learn rules, recognition-based approaches look at the minority class rather than the majority class's instances. To address the challenges posed by unlabeled data, active learning techniques are used.

In order to discover the hidden learning principles in the minority class examples, which could or might not employ instances from the majority class, feature selection based learning approaches are used. Automatic MEDLINE document classification is achieved by the use of Bayesian-based feature selection models, which provide a probabilistic framework. When a document has a particular MeSH label or is connected to the term's grandparents in the hierarchical model, Bayesian models do not work. For example, the words A01.047.025.600, A01.047.025.25, and A01.047.025.600 may all be used to represent the same document in an index that uses the terms A01.047.025.600.451. The MEDLINE documents can be better selected using an ontology-based document feature selection approach according to this assumption.

The suggested random sampling strategy involves selecting components at random and then removing them from the class that is overrepresented in the majority. This procedure is repeated until the minority class size and cost-sensitive learning method are equal. Among its components are adjustments to the relative cost of incorrect positive and negative class classifications. It is necessary to convert every page into a feature vector before using machine learning techniques for feature extraction. To address the problem that the high-dimensionality of the features space creates, many feature selection methods have been used. Feature selection for documents has long made use of several probabilistic and statistical machine learning algorithms. Neural network, K-nearest neighbour, Bayesian, decision tree, and symbolic rule learning are all part of it.

Scalable Machine Learning techniques and Rule-based reasoning methods provide the basis of feature learning models. Due to the lack of a prior classified example or restriction pertaining to data pieces having labels, this procedure falls under the umbrella of unsupervised learning. Ontology (Abox+Tbox) presents the categorization model. It learns on its own from massive datasets using scalable Machine Learning and Big Data methods. When it comes to categorization, feature extraction is a crucial step. We can classify all characteristics into two categories:

- Feature extraction is carried out on the small document sets by making use of noisy attributes and

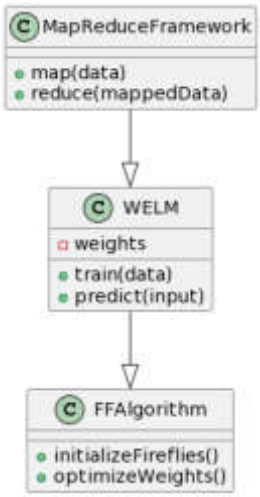

Fig. 3.8: Working of WELM-FF algorithm

contextual information.

In order to reduce the number of dimensions of high-dimensional features, traditional feature extraction algorithms do away with noisy features. Predicting medical diseases, such as cancer, genes, proteins, etc., has led to the development of several methods. When it comes to microarray cancer detection and prediction, the rule mining method is combined with PCA and back propagation. For improved performance, a modular neural network is designed to detect and assess heart illnesses utilising the Gravitational Search Algorithm (GSA) and fuzzy logic algorithm..

3.5. Weighted Extreme Learning Machine Technique (Weighted ELM) with the Firefly Algorithm. Incorporating weights into the learning process, the Weighted Extreme Learning Machine (Weighted ELM) method modifies the classic Extreme Learning Machine (ELM) algorithm. It creates a hybrid strategy for optimising the Weighted ELM shown in Figure 3.8 has parameters when coupled with the Firefly Technique, an optimization algorithm that draws inspiration from nature. A few formulae and notations depicting the Weighted ELM and its integration using the Firefly Algorithm are provided below.

1. Extreme Learning Machine (ELM): The traditional ELM formulates the output weights β as:

$$\beta = H^{\dagger}T \tag{3.14}$$

Where:
- H is the hidden layer output matrix.
- T is the target matrix.
- $H^{\dagger}$ is the Moore-Penrose pseudo-inverse of H.

2. Weighted Extreme Learning Machine (Weighted ELM): In Weighted ELM, the objective is to minimize a weighted objective function:

$$J(\beta) = \frac{1}{2}\sum_{i=1}^{N} w_i \left\| y_i - \sum_{j=1}^{L} \beta_j h_j\left(x_i\right) \right\|^2 \tag{3.15}$$

Here, w_i represents the weights associated with individual training samples.

3. Combining Weighted ELM with Firefly Algorithm
   - Optimizing the weights $w - i$n the Weighted ELM is the goal of the Firefly Algorithm. Using the attraction between fireflies, the system adjusts the weights repeatedly. The following stages make up the method, which uses the objective function to assess attractiveness:

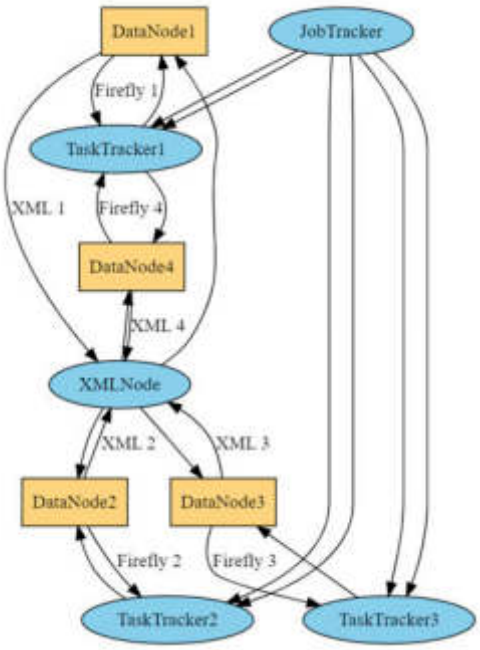

Fig. 3.9: Data Locality Based Firefly and WELM

- Start by setting the starting light levels and locations of the fireflies.
- Determine Attraction: Using the distance and light intensity of two firefly, determine the attractiveness between the two.
- Apply the attractiveness values to the weights and update them.
- Repeat: Continue iterating until you reach convergence or until you reach a predetermined limit. The precise formulation of the update equation for weights, $w - i$, depends on the particular specifics of the implementation and the issue environment, although it may be described using the Firefly Algorithm.

These methods' inefficient learning stages or coverage of local minimums lead them to be painfully slow. To further improve learning efficiency and performance, many iterative learning techniques are created. Based entirely on kernel-based methods, this strategy incorporates neurons in an ascending sequence. Unlike traditional Feed-Forward Network training, Bayesian ELM does not adjust the hidden layer. To reduce training error, all hidden layer parameters, including input and output weights and biases, are chosen at random. Slower network learning rates and less capacity to handle complexity are the main drawbacks of the aforementioned approaches.

From Figure 3.9, The two main steps of the WELM-FF (F-ELM) method are training and prediction. A three-tiered design is suggested for the training phase. In the training phase, scaling parameters in the hidden layer and weights in both the hidden and output layers are repeatedly generated, much like the WELM technique. Therefore, F-operations WELM's are comparable to those of the fuzzy inference system. To make predictions, a trained F-WELM algorithm takes an input feature vector and uses it to assess the outputs.

Using nodes and edges, decision trees may be shown as directed graphs. Always representing tests are the root and intermediate nodes, with outgoing edges representing node conditions. Additionally, various class labels, represented by leaf nodes, are accountable for uncovering latent patterns in massive datasets. The decision tree's decision patterns are predicted by these. The quantity of data lost during decision tree creation grows in direct proportion to the size of the k-trees. At each level, these models determine the decision criteria

Table 4.1: Amazon EC2 Setup Configurations

General purpose current generation	Linux/UNIX Usage (per Hour)	Windows Usage (per Hour)
m3.medium	0.0086	0.0591
m3.large	0.0162	0.1171
m3.xlarge	0.036	0.2201
m3.2xlarge	0.1539	0.4391
m1.small	0.0081	0.0261
m1.medium	0.0102	0.0531
m1.large	0.0175	0.1061
m1.xlarge	0.034	0.2111

by running an algorithm that is based on the hierarchical selection of characteristics. These are the main problems with this attribute selection method: 1) The amount of time and space needed for calculation also grows as the noise of characteristics in single and multi-leveled space increases. 2) Entropy measurements on the homogeneity of the information distribution are used by this model.

Figure 3.9 shows the results of using an WELM-based decision tree with a logistic regression function to identify infrequent decision rules; in this case, a new occurrence is arranged by climbing the tree from its root node to its leaf node, and a decision on the attribute is made based on the class attribute value of the leaf node through regression analysis.

If the database has a lot of dimensions, then can't use the WELM decision tree to build incremental trees. Also, using the Map-Reduce framework with mixed attribute types is not supported by this strategy.

Limitations

- Hadoop nodes are used and the memory limitations affect the tree's performance.
- Achieving greater performance on the part of the intermediate mappers requires fixing the static restrictions of the minimal class instances.
- Building the static classification and static parameters is a must during the training phase of a Map-Reduce system.

4. Performance Evaluation. For experimental evaluation, Hadoop with hardware configuration of 4 GB RAM, 250 GB hard disk and above 2 GHz processor is employed. Experiments are conducted on diversified Hadoop cluster with configurations as depicted in Table 1. The employed test-bed consists of one master node (job tracker and Name node) and twenty slave nodes (task tracker and data node). The heterogeneity within the cluster is quantified by considering several CPU or processor types, disk space and memory size on each node. Here, all nodes within cluster are connected using an ethernet switch. For execution, Linux operating system is employed. In proposed experiments, Hadoop 2.2.0 version is employed and configured with JDK 1.8 version and 128 MB block size. For input, a text file generated using java code is used. The master.txt file is used to declare master node name and workers.txt file to declare slave nodes' name. The file yarn-site.xml is employed to write node property and node values. Scheduler is controlled using xml files.

4.1. Implementation Setup . Amazon Elastic Compute Cloud (EC2) has three distinct storage tiers—small, medium, and large—each of which offers access to a unique set of cloud resources. You may access these instances and services across several time zones and countries. The pricelist for micro to big instance types for Windows Usage machines and LINUX/UNIX is shown in Table 4.1 for the Asia Instance servers.

The cloud's capacity to handle computations of varying sizes is made possible by Amazon Elastic Compute Cloud (EC2). For developers, EC2 means quick and simple web-scale compute. With no effort, you may configure the hardware capacity to your exact specifications using the accessible user-friendly interface. Instance addition and deletion are handled using the aforementioned interface. Customers may choose which EC2 instances to make public or private when they deploy these services to cloud storage servers. A pre-configured AMI, network permissions and security, and the uploading of a completed web application are prerequisites for implementing an Amazon Elastic Compute Cloud instance. Based on their computing demands, customers must choose the beginning and finishing points of the instance. The amount of AMI has to be present in several

Table 4.2: Memory Optimized - Current Generation

occurrences. The next phase involves configuring additional application services by monitoring the activity of newly formed instances. Both incoming and outgoing network traffic may be managed with the use of security groups and ACLs.

Various biomedical documents in XML format are subjected to experimental outcomes. The document types seen in the MEDLINE Repository vary among the various data sets. Table 4.2 is a visual representation of the results of the feature selection process's performance study utilising the Hadoop framework. In this case, we learn how long the Mapper and Reducer phases took to operate in the Hadoop environment by including the Rough-set approach and a Random Forest tree.

Visual representation of the feature selection process performance analysis utilising the Hadoop framework is shown in Figure 4.1. In this case, we learn how long the Mapper and Reducer phases took to operate in the Hadoop environment by including the Rough-set approach and a Random Forest tree. The chart clearly shows that, in comparison to other classification strategies that do not use a rough-set method, the Rough set with Random forest model's Mapper and Reducer stages have a less time-complex nature. Figure 4.1, clearly shows that in comparison to other classification strategies that do not use a rough-set method, the Rough set with Random forest model's Mapper and Reducer stages have a less time-complex nature. Analyses of the order models' performance are shown in Table 4.3 and Figure 4.2. When compared to other traditional Hadoop classification algorithms, Random Forest trees with roughsets have a far higher real positive order rate for biological datasets. The number of positive occurrences that represent assaults, as compared to negative ones, is shown by the true positive rate. The number of instances that were incorrectly categorised is shown by the error (percent). Also calculated are the outliers, expressed as a percentage, which show how many occurrences are unrelated to the present assault behaviour. Table 4.4 shows the classification models with True Positive and Error Rates metrics.

Figure 4.3 shows the performance metrics of Hadoop Models.In the first experiment, a regular Hadoop cluster (SHC) showed a 120-minute processing time, 500 records/minute throughput, and 95% accuracy. Reducing execution time by 80 minutes, increasing throughput by 750 records per minute, and improving accuracy by 98% were all outcomes of Experiment 2, which included adding further nodes to the cluster (ECWAN). Even though the execution time went up to 100 minutes in Experiment 3, which focused on Hadoop with Improved Data Compression (HWIDC) data compression approaches, the throughput remained competitive at 600 records

Table 4.3: Classification models for feature selection using Rough-set

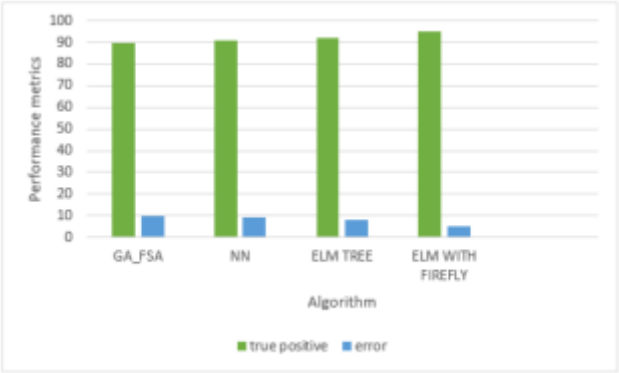

Fig. 4.2: Performance metrics for classification models

per minute and the accuracy rate stayed at 96%. These findings demonstrate how important it is to optimise Hadoop-based systems using data processing methods and cluster design. Improving performance was a direct result of the tweaked cluster design, and investigating data compression methods revealed promising new ways to strike a balance between the execution time and accuracy trade-offs. Improved distributed data processing using the Hadoop architecture may be possible with more research and development.

5. Conclusion. The proposed work differs from existing solutions in that it does not require learning the classification accuracy for certain types of information attributes earlier, which is not always possible in practise. Instead, it takes an exponentially decreasing size of distributed databases, data pre-processing, and the classification true positive rate. The distribution noise or anomaly problem, mining sparse, scaling up for high-dimensional space, and static optimization are the main challenges with standard data mining algorithms when applied to massive data. This chapter details the application of a new decision tree model based on the toughest criteria to biomedical datasets using the Hadoop framework, with the goal of improving the computation error and true positive rate. Lastly, a potential strategy for improving ML models is the proposed Weighted Extreme Learning Machine (Weighted ELM) in conjunction with the Firefly Algorithm. To make the classic Extreme Learning Machine even more sophisticated and adaptable, the Weighted ELM adds weights to it. The compatibility of the hybrid model with the Firefly Algorithm, a method of optimization that draws inspiration from natural behaviours, allows for more efficient parameter tuning. The capacity to account for the significance of individual training samples by using weights is the main benefit of the Weighted

Fig. 4.3: Performance metrics of Hadoop Models

ELM. This makes the model more flexible and resistant to data distribution issues, which is especially helpful when certain samples are more important than others for learning. By mimicking the characteristics that make fireflies appealing, the Firefly Algorithm improves the Weighted ELM's optimization. Improving the model's convergence and overall performance, this optimization technique helps locate ideal weight combinations. Nevertheless, there are a number of variables that affect how well this hybrid strategy works, such as the parameters used, issue specifics, and dataset characteristics. To get the best outcomes for particular applications, it is vital to conduct thorough experiments and fine-tune. Addressing complicated issues where flexibility, efficiency, and resilience are vital, the Weighted ELM with Firefly Algorithm shows promise in practical terms. The method's competitiveness across a larger variety of applications may be determined by future work that investigates hyperparameter tweaking, experiments with varied datasets, and compares with other state-of-the-art approaches. When combined, Weighted ELM and the Firefly Algorithm provide new possibilities for improving machine learning models and expanding their use in many fields.

FEDERATED DIVERSE SELF-ENSEMBLING LEARNING APPROACH FOR DATA HETEROGENITY IN DRIVE VISION

M.MANIMARAN *AND V.DHILIPKUMAR †

Abstract. Federated learning (FL) has developed as an efficient framework that can be used to train models across isolated data sources while also protecting the privacy of the data. In FL a common method is to construct local and global models together, with the global model (server) informing the local models and the local models (clients) updating the global model. Most present works assume clients have labeled datasets and the server has no data for supervised learning (SL) problems. In reality, clients lack the competence and drive to identify their data, while the server may host a tiny amount. How to reasonably use server-labeled and client-unlabeled data is crucial in semi-supervised learning (SSL) and Cclientdata heterogeneity is widespread in FL. However, inadequate high-quality labels and non-IID client data, especially in autonomous driving, decrease model performance across domains and interact negatively. To solve this Semi-Supervised Federated Learning (SSFL) problem, we come up with a new FL algorithm called FedDSL in this work. We use self-ensemble learning and complementary negative learning in our method to make clients' unsupervised learning on unlabeled data more accurate and efficient. It also coordinates the model training on both the server side and the clients' side. In an important distinction to earlier research that kept some subset of labels at each client, our method is the first to implement SSFL for clients with 0% labeled non-IID data. Our contributions include the effectiveness of self-ensemble learning by using confidence score vector for calculating only for the current model performing data filtering and initiated negative learning by showing the data filtering performance in the beginning rounds. Our approach has been rigorously validated on two significant autonomous driving datasets, BDD100K and Cityscapes, proving to be highly effective. We have achieved state-of-the-art results and the metric that is utilized to evaluate the effectiveness of each detection task is mean average precision (mAP@0.5). Astonishingly FedDSL performs nearly as well as fully-supervised centralized training approaches, despite the fact that it only uses 25% of the labels in the Global model.

Key words: Federated Learning, Data Heterogeneity, Autonomous Vehicle, Ensemble Learning.

1. Introduction. Machine Learning (ML)-based services and apps are becoming more and more important because of the need to protect data safety and security. It can be hard for ML providers to gather and manage data, follow General Data Protection Regulation (GDPR) rules, and keep personal data from getting lost, misused, or abused [1]. If you want to do global collaborative learning without sharing the original training data, Federated Learning (FL) can help. But it's not totally secret since the model parameters include private information. FL is a way to learn that a single server manages a group of devices used by many people. The server delivers the most recent model to clients at every training epoch. After that, the clients modify the model using their private data sets. [2]. The server takes all of these changes and applies them to the core model. FL lets you make a whole ML model without disclosing client data or using their computing power, which makes the server load less. The main elements of the FL concept are as follows:

* Decentralized Training: Gathering all data in one location and by training the model directly on individual devices, FL ensures that data privacy is preserved.
* Updates: Each device updates its model parameters and sends them to a central server after undergoing model training with its own data.
* Global Aggregation: The server collects the updated parameters from all devices. Utilizes them to train a model.
* Model Updates: The improved global model is subsequently sent back to the devices so they can train it using their data.

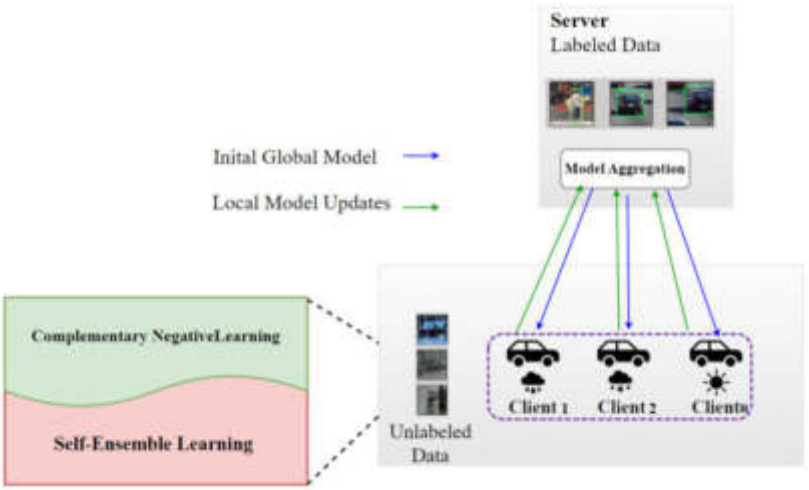

Fig. 1.1: An Overview of FedDSL

In FL applications like keyboard prediction, labelling data isn't always needed, but it can be pricey to get big labelled datasets. Currently, most of the research is focused on building ML models from unlabeled data. However, not many of the current studies try to improve FL [3], which leaves a good area for future research. FL methods mostly work with supervised learning, which means that all of the data is labelled. But getting fully labelled data can be hard because it is possible that the participants will lack knowledge or interest in the subject [4]. This makes the problem of FL out of full labels very important in real-world applications like autonomous driving.

In SemiFL [5], clients have data that hasn't been labelled at all and can train over multiple local epochs to cut down on connection costs. The server, in contrast, stores some tagged data. However, this system may become less useful if labelled and unlabeled data are separated, as it becomes more difficult to apply these methods to FL. While customers only have access to unlabeled data, label-at-server scenarios are more problematic due to the fact that only the server possesses labelled data. To overcome the information gap between labelled and unlabeled data in autonomous driving, a new strategy is needed where there is no direct exchange of data.

With semi-supervised federated learning (SSFL) [6], clients' unsupervised learning on unnamed data is made more accurate and efficient by using self-ensemble learning and complementary negative learning. On the client side as well as the server side, SSFL is responsible for managing the model training. Limited high-quality IDs and non-IID client data can be a challenge, especially in situations like self-driving cars. As a solution to these problems, the Semi-Supervised Federated Object Detection (SSFOD) [7] system was designed for cases where clients have unlabeled data and the server only has labelled data. The fact that SSFOD has never been used before for clients with zero percent labelled non-IID data is interesting. This is a significant departure from earlier studies that attached labels to each patient.

There have been the following problems with the aforementioned research:

* primarily using datasets like CIFAR, Fashion MNIST, ImageNet and COCO can be challenging because to their small size and complexity, but SSFOD poses far larger challenges.
* Following that, we proceeded to investigate difficult FL cases that involved clients who had unlabeled data from a various category of object than the labelled data that was stored on the server. For example, when the weather changes, real-life FL scenarios aren't always identical, so we made this adjustment. Because client records are so diverse, this approach accounts for that fact.

For the purpose of overcoming these issues of SSFOD that still need to be taken into consideration, we introduce FedDSL (Federated Diverse Self-Ensemble Learning) a personalized multi-stage training technique for the

SSFOD Framework as shown in Figure 1.1.

We proposed a FedDSL and Negative Learning for a consistency-based regularization scheme and a cost-based pseudo-label mining algorithm for the SSFOD framework making the predictors more resilient to biased representations caused by local data heterogeneity.

Our recently added features offer a novel approach to using FL unlabeled data to improve non-IID identification performance, particularly for dynamic objects, which has been ignored in previous research. We assert that our methodology and tests set a useful standard for future research in many domains, despite the fact that SSFOD has received very little attention in the scientific community.

2. Related Works.

2.1. FL: Advancements and Challenges. Recently, FL has caught the attention of the public as a method that protects users' privacy while simultaneously maximising the potential of distributed data. Despite the fact that FL has come a long way, its adaptability and applicability to other real-world problems may be limited. This is due to the fact that the majority of studies have concentrated on categories of tasks. In the future, advanced FL approaches will pave the way for collaborative learning from dispersed data sources, which will be of great benefit to a number of different industries, including autonomous driving, healthcare, and finance, among others. Future vehicular IoT systems [12], With growing privacy concerns, FL will be crucial for intelligent transport systems and cooperative autonomous driving to optimise the use of scarce communication, computation, and storage resources. This publication delves into the latest advancements in smart healthcare virtual reality [13], including resource-aware, secure, incentive, and personalized FL designs. Health data management, COVID-19 detection, medical imaging, and remote monitoring are just a few of the important healthcare domains covered in this analysis. It also examines current FL-based projects and highlights important lessons learned.

In FL, addressing data heterogeneity is crucial since clients often have data with different distributions, which can affect the global model's performance. Adaptive aggregation algorithms and local model fine-tuning are two of the many approaches suggested by researchers to deal with non-IID data and meet this difficulty. This paper [14] examines the convergence of federated versions of adaptive optimizers such as Yogi, Adam, and Adagrad in non-convex scenarios with heterogeneous data. The effects of client heterogeneity on the efficacy of communication are shown by the results. A generalization of FedAvg, FedProx [15] is a framework that deals with federated network heterogeneity. It handles statistical and system heterogeneity by ensuring convergence for learning over non-identical distributions and enabling devices to execute varied tasks. For client-specific model adaptation, researchers investigate techniques such as model distillation and meta-learning. Quantization, sparsification, and a supernet are solutions that decrease overhead while retaining model performance, which is critical in FL for efficient communication.

2.2. YOLO based Semi Supervied Object Detection Technique . Additionally, a significant amount of effort has been put into Semi Supervised Object Detection (SSOD), the primary goal of which is to improve detection performance in general by improving pseudo labels. The primary goal of developing SSL (Semi-Supervised Learning) methods for object detection is to produce consistent and trustworthy pseudo labels using pretrained architectures and robust data augmentation strategies. Two-stage detectors usually outperform their one-stage counterparts, and single-stage detectors, such as YOLO, have a hard time with SSL techniques. Researchers are coming up with innovative solutions to fix the problem of existing SSL approaches failing with single-stage detectors.

Epoch Adaptor, Dense Detector, and Pseudo Label Assigner make up the Efficient Teacher Framework [16], a one-stage SSOD training system. Implementing a baseline model, a pseudo designation process, and Dense Detector into the framework improves its performance. Dense Detector is able to acquire globally consistent features and the system prevents bias caused by poor pseudo labels; this makes training independent of the proportion of labelled data. Author [17] introduced a YOLO based method through the incorporation of domain adaptation and the compact one-stage stronger detector YOLOv5, the performance of cross-domain detection will be improved. furthermore, to fix image-level discrepancies, use scene style transfer to cross-generate pseudo images across domains.

2.3. Semi-Supervised Federated Learning (SSFL). The SSFL method has recently surfaced as a potential solution to the issue of minimally labelled data in FL scenarios. Through the collaborative use of participant-owned labelled and unlabeled data, SSFL aims to enhance FL. Our research has focused on two main settings: labels-at-client and labels-at-server.

The two most critical cases in SSFL were defined according to the placement of the tagged data. In the first case, authors assume the common occurrence of clients having both labelled and unlabeled data. The second case involves a more challenging situation where the tagged data is exclusively accessible on the server. Our novel strategy to resolve the concerns voiced is known as FedMatch [18], short for Federated Matching. Compared to inexperienced hybrids of federated and semi-supervised learning approaches, FedMatch outperforms them in a number of ways, including a novel inter-client consistency loss and a dissection of the parameters for disjoint learning on labelled and unlabeled data.

Authors use the Semi-Supervised Federated Object Detection (SSFOD) framework when all the data is labelled on the server and there is no unlabeled data on the client. Thanks to FedSTO [7], a two-pronged approach, data transfer between servers and clients is handled securely. It uses orthogonality regularisation to improve visualisation divergence, selective training to prevent overfitting, and local Exponential Moving Average to assign high-quality pseudo labels (EMA).

2.4. Data Heterogeneity. When it comes to autonomous driving (AD), AutoFed is a FL platform that takes heterogeneity into account. Authors [24] goal is to make robust AD possible by making full use of multimodal sensory data on AVs. A client selection mechanism, an autoencoder-based data imputation method, and a novel model using pseudo-labelling are all part of the framework. The experimental results reveal that AutoFed outperforms the state-of-the-art methods in terms of precision and recall, and it also shows remarkable resilience in the face of bad weather. The Authors [25] trains an autonomous vehicle via federated learning. Data is gathered from an Udacity-based simulated vehicle over two tracks, and a Convolution Neural Network is used for training. The next step is to upload the modal to a server, where it will be integrated with other models to generate a new model. The car's performance is examined through multiple trainings, and the results show that the accuracy is iteration dependent and that merged models are less accurate.

3. Problem Statement. We focus on situations when 100% Unlabeled dataset in client side and 25% labelled dataset in server side for object identification task that involves a labeled dataset $D_l = [x_i^l, y_i^l]_{i=1}^{N_l}$ and unlabeled dataset $D_u = [x_i^u]_{i=1}^{N_u}$ where $N_u << N_l$. x^l as labeled images, y^l as annotations, it contains coordinates and differenet bounding boxes for objects. The dataset $\{x^l, y^l\}$ and the model parameterized by M^l are both stored on the server. Presumably, there are C clients, and they all have an unlabeled dataset $x^{u,C}$, Every client model, with parameters $M^{u,C}$ employs the identical architecture for detecting objects, represented by $f : (x, M) \rightarrow f(x, M)$, where each parameter M and input x are transformed into a collection of bounding boxes with associated class probabilities.

Heterogenity. Our research focuses on non-IID data that results from various weather conditions, such as cloudy, gloomy, rainy, and snowy. The three datasets—BDD100K, CityScapes, and SODA10M—display different class distributions and label densities. A framework for SSFOD that is capable of managing this diversity while preserving performance in a variety of contexts and with a variety of distributions is what we intend to create. When every client exhibits a well-balanced distribution of weather conditions, the data is considered to be a part of the independent and identically distributed (IID).

4. Proposed Methodology – FedDSL. To illustrate, FedDSL is an iterative algorithm that, similar to all FL algorithms, necessitates the exchange of local and global models between the server and the clients. Figure 4.1 illustrates this. As an alternative to conventional supervised FL, the server will use its labelled dataset to actively contribute to the global model's updates during training. This indicates that the server will be actively involved in the training process. Each FL round in FedDSL is comprised of four separate steps, which are as follows:

1. Initial Step: Server-side Supervised Learning
2. Second, have the clients download the global model.
3. Thirdly, client-side unsupervised learning
4. Finally: Submit local models to the Server

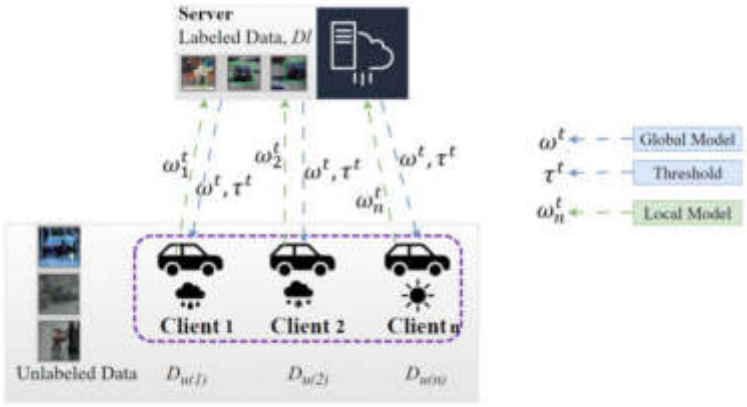

Fig. 4.1: Operation of FedDSL

4.1. Supervised Learning at Server. In this paper, author examines the image classification issue using an SSFL system, which consists of just one server and some clients.D_l is a labeled training dataset for server. We use x_i for the feature vector (image) and y_i for the label (image class) for each instance $i \in D_l$. Index of the class set $M = 1, .., m$ and hence, $y_i \in M$ for each instance i. Let us assume that the server possesses a limited labelled validation dataset of D_l^{Val} separated from the training dataset. D_u is unlabeled training dataset for individual client $M = 1, .., m$. The feature vector x_i of each instance $i \in D_u$ assume the dataset is unlabeled. At the clients, the total number of instances of unlabeled training data is greater than the number of instances of labelled training data that are stored on the server alone, which is denoted as $D_l << \sum_{n=1}^{N} D_u$. Our main objective is to successfully train a model f for classification, with ω serving as the parameter. probability distribution for predicted class is p(x,ω), x as input for the confidence score vector and model parameter of ω. p_m(x,ω) is the predicted class probability for the input x which belongs to class m under the model parameter ω, it is a confidence score. By simply using the formula f_m(x,ω)=arg$max_m p_m$(x;ω), A predicted hard label can be easily generated from the confidence score vector. In this work, we will discuss how to evaluate a classification model's efficacy using cross-entropy loss, which is a

$$l(y, f(x;\omega)) = -\sum_{m=1}^{M} 1(y = m) log(p_m(x, \omega)) \tag{4.1}$$

where 1(.) is the indicator function.

4.1.1. Global Model Update. During FL round t, server compiles the uploaded local client models from round t-1. In such case, every client takes part in every training session, $K^t \sqsubseteq$ N represents the sampled clients for local training in round t. The local client model ω_k^t is trained in round t for client $k \in K^t$. Typically, a global model is created by averaging local client models on the server.

$$\omega^{-t} = \frac{1}{|K^{t-1}|} \sum_{k \in K^{t-1}} \omega_k^{t-1} \tag{4.2}$$

In FedDSL, the server trains an average global model on its labeled dataset for the purpose of enhancing it, instead of merely relaying it to the clients for local training in the current round. The technique of data augmentation for image can be utilised to increase the size of the dataset as well as its quality. This is possible because the server only has a limited amount of training data available. The enhanced version of the original input x is denoted by a(x) if we consider the augmentation process a(.). In FedDSL, for instance, we execute weak augmentation using basic operations like random image flipping and random image cropping. Be aware that different learning rounds may provide different augmented images a(x) of the same input x due to the

random nature of the augmentation. The server loss function (using slightly misleading nomenclature) is defined as follows when weak augmentation is applied:

$$L_s(\omega) = \frac{1}{D_i} \sum_{i \in D_l} l(y_i, f(a(x_i); \omega)) \tag{4.3}$$

as previously stated, the cross-entropy loss is denoted as $l(y_i, f(a(x_i); \omega))$. The server continues by running B_s mini-batch gradient descent epochs E_s, which update the global model. Here are the updates made to the global model for each mini-batch step b:

$$\omega^{t,b} = \omega^{t,b-1} - v_s \bigtriangledown_\omega L_s(\omega)|\omega^{t,b-1} \tag{4.4}$$

the server learning rate is denoted as v_s, the initial model is $\omega^{t,0}$=ω^{-t}, and the gradient of $L_s(\omega)$ assessed at $\omega^{t,b}$ is $\bigtriangledown_\omega L_s(\omega)|\omega^{t,b}$.

4.1.2. Calculation of Confidence Threshold. Before clients can use the updated global model to filter input from the unsupervised learning step, $m \in M$ is a confidence threshold for each class determined by the server. Consider the confidence threshold vector $\tau^t = [\tau_1^t ....\tau_m^t]$ as an example, where $\tau_m^t \in [0, 1]$ represents the confidence threshold for class m in round t. Here is the formula for determining the value of τ_m^t.

$$\tau_m^t = \frac{\sum_{i=D_l^{val}} p_m(x, \omega^t) 1(f(x_i; \omega^t) = m)}{\sum_{i \in D_l^{val}} (y_i = m)} \tag{4.5}$$

When it comes to the validation dataset, the denominator represents the total number of instances of class m, while the numerator is the sum of the confidence scores of all the data instances that are classified as class m based on the current model ω^t. For a new data instance x with a high probability of classification result, with the present model ω^t, it is categorized as class m (i.e., $f(x_i; \omega^t) = m$) and the confidence associated with this classification, $p_m(x, \omega^t)$, is more than τ_m^t. Due to the fact that the global model is updated with each new round, τ^t changes across learning rounds. Along with global model at server, clients also download this confidence threshold vector τ^t.

4.1.3. Bootstrapping. Even though clients can begin the process of learning a language with a random beginning model ω^0, our findings indicate that training a robust model on the server labelled dataset and using it as the initial model is more effective in accelerating the convergence of the learning process and achieving higher accuracy.

Due to the utilization of self-ensemble learning in the unsupervised learning phase and the creation of more trustworthy pseudo-labels by means of stronger early rounds models, Bootstrapping has a good influence on convergence. Therefore, FedDSL relies solely on supervised learning at the server with the label dataset to create the initial global model ω^0. Despite the fact that it does not average the local models, it employs equations (3) and (4) as its training basis.

4.2. Unsupervised Learning at the Clients. Clients k who are selected to take part in local client-side training execute unsupervised learning on their unlabeled datasets to create local models ω_k^t receiving the global model ω^t. Unsupervised learning at clients is demonstrated in Figure 4.2

4.2.1. Diverse Self-Ensemble Learning. To generate a pseudo-label, also known as a label prediction, for each instance of unlabeled data using the current model is the objective of effective learning, just as it is in typical SSL problems. Afterwards, construct a dataset in such a way that the pseudo-label of every data instance is accurate on a consistent basis. The term "data filtering" refers to the process of generating a new dataset by selecting records from an existing dataset. Given that the pseudo-label is assumed to be accurate in most cases, it is reasonable to assume that training the model on the filtered dataset would result in improved outcomes.

The dispersed nature of the labeled and unlabeled datasets makes SSFL considerably more difficult in a decentralized context than in a centralized one. Both supervised and unsupervised learning are performed concurrently with one another in conventional SSL. In particular, the model is trained using a single loss

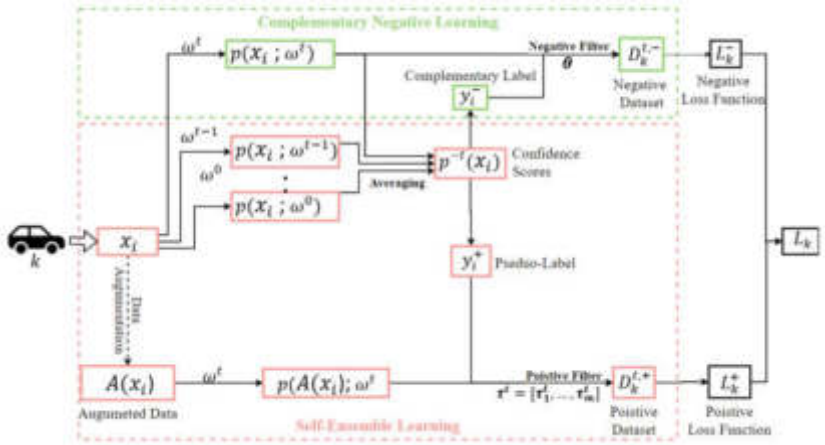

Fig. 4.2: Self-Ensemble Learning Generates the Positive Dataset and Complementary Negative Learning Generates the Negative Dataset and Local Model Update with both datasets.

function Loss(ω), $Loss_L(\omega)$ for which there is a loss on the data that has been labelled and a loss on the data that was not labelled is $Loss_U(\omega)$.

$$Loss(\omega) = Loss_L(\omega) + \alpha\ Loss_U(\omega) \tag{4.6}$$

where the parameter for weight is denoted by α. The filtered dataset can have numerous occurrences with incorrect pseudo-labels due to the low accuracy of the model in the early stages of training. For the purpose of lowering the impact of inaccurate pseudo-labels, a minimal initial value is employed to increase reliance on the trustworthy label dataset during model training. The filtered unlabeled dataset can be given additional weight with an increasing α as the model improves with time.

In SSFL, though, things are different; to train, the client has access to only the loss function applied to the unlabeled data. Therefore, it is not possible to influence whether labeled or unlabeled data is prioritized using this parameter. Consequently, both the local model's performance and the global model's performance after aggregation can be severely impaired because the less-than-ideal global model produced a relatively large number of false pseudo-labels in the first rounds. False positives will build up and spread across iterations of the learning process, rendering the process useless.

An issue that develops when the global model uses inaccurate pseudo-labels is its overconfidence in prediction results. One solution to this problem is self-ensemble learning, which takes advantage of many global models' worth of past data to generate pseudo-labels. This group's judgement mitigates the "stubbornness" of an individual model since it is derived from the same learning procedure, though from different iterations. By using this method, we may decrease the likelihood of overconfidence when assigning classes to data that does not follow a normal distribution and obtain more accurate predictions.

Based on the historical models (ω^0,ω^1,....,ω^t), the client k determines the average score for the confidence vector for each instance $i \in D_k$ in the following way:

$$p^{-t}(x_i) = \frac{1}{t}\sum_{j=1}^{t} p(x_i;\omega^j) \tag{4.7}$$

Client k doesn't have to keep track of every historical model because $p^{-t}(x_i)$ can be updated gradually.

$$p^{-t}(x_i) = \frac{t-1}{t}p^{-t-1}(x_i) + \frac{1}{t}p(x_i;\omega^t) \tag{4.8}$$

Additionally, the pseudo label y_i^+ of x_i is produced based on

$$y_i^+ = argmax_m\ p_m^{-t}(x_i) \tag{4.9}$$

whose corresponding confidence score is $p^{-t}y_i^+(x_i)$. After the server calculates the confidence threshold vector τ^t, the client uses it to filter its local dataset and creates a filtered dataset:

$$D_k^{t,+} = ((x_i, y_i^+); i \in D_k \;\; and \;\; p_{y_i^+}^{-t}(x_i) \geq \; \tau_{y_i^+}^t) \tag{4.10}$$

In order to exclude occurrences without a high level of confidence, the condition $p_{y_i^+}^{-t}(x_i) \geq \; \tau_{y_i^+}^t)$ is used.

4.2.2. Complementary Negative Learning. Data filtering is improved by self-ensemble learning because the use of appropriate pseudo-labels increases the likelihood of including instances in the dataset that has been filtered as $D_k^{t,+}$. Early self-ensemble models had low accuracy due to limited historical models, leading to a significant number of cases with incorrect pseudo-labels being filtered into $D_k^{t,+}$. We apply complementary negative learning to enhance supervised learning for clients, particularly in beginning rounds, as originally promoted for noisy label problems. While classifying instances can be challenging, it is often simpler to eliminate them from incorrect classes. Providing additional information for the purpose of updating the local model can be accomplished by assigning complementary labels to instances, such as classes that are not the true class. Because of this information, the unfavourable impact of incorrect pseudo-labels $D_k^{t,+}$ can be mitigated, resulting in improved performance in local training.

In pursuit of this goal, whilst creating $D_k^{t,+}$, We also generate a second dataset that has been filtered $D_k^{t,-}$, which includes data instances with corresponding labels. In this context, the superscript "+" denotes that the pseudo-labels should represent the actual class, whereas the "-" signifies that the complementary labels should represent any class other than the actual class. Specifically, for every instance $i \in D_k$, according to the results of the averaging eqn. (8) confidence scores for those classes of client k determined, contain a value that is lower than a predetermined threshold that is relatively low. Then, unless it's an empty set, client k randomly selects one from corresponding label for instance i.

$$y_i^- \in (m : p_m^{-t}(x_i) \leq \theta) \tag{4.11}$$

Consequently, the complementary data set is

$$D_k^{t,-} = ((x_i, y_i^-); i \in D_k \;\; and \;\; \ni m, s, t. \;\; (p_m^{-t}(x_i) \leq \theta) \;\; and \;\; p_{y_i^+}^{-t}(x_i) \geq \; \tau_{y_i^+}^t) \tag{4.12}$$

The equation $p_{y_i^+}^{-t}(x_i) \geq \; \tau_{y_i^+}^t)$ guarantees that $D_k^{t,-}$, does not contain an instance that is already in $D_k^{t,+}$.

4.2.3. Local Model Update. To update the local client model, we consider a client loss function with positive and negative components.

$$L_k(\omega) = \lambda \; L_k^+(\omega) + L_k^-(\omega) \tag{4.13}$$

where

$$L_k^+(\omega) = \frac{1}{|D_k^{t,+}|} \sum_{i \in D_k^{t,+}} l(y_i^+, f(A(x_i); \omega)) \tag{4.14}$$

$$L_k^-(\omega) = \frac{1}{|D_k^{t,-}|} \sum_{i \in D_k^{t,-}} l(y_i^-, 1 - f(x_i; \omega)) \tag{4.15}$$

The weight parameter is denoted by the expression $\lambda > 0$. To achieve combine the consistency regularization and pseudo-labeling, making sure to take note of considering that positive loss component $L_k^+(\omega)$ is calculated with the use of strong data augmentation and pseudo-labels A(.) on the input data. In FedDSL, we use a technique known as RandAugment [19], which is a powerful data augmentation method. The weight λ is chosen to be minimal in order to limit the risk that is caused by wrong pseudo labeling. This is because, during the initial rounds, the correct rate for complementary labelling is much higher than that of pseudo labelling.

Table 5.1: Algorithm 1: FedDSL

Server trains the initial model ω^0 based on its labeled dataset
for each FL round t do
Step 1: Server Training
Model averaging to obtain ω^{-t}
Update global model ω^t
Calculate confidence threshold vector τ^t
Step 2: Model Download
All clients download global model ω^t and confidence threshold vector τ^t from the federated central server
Step 3: Client Training
Sample client subset $K^t \sqsubseteq$ N
for each client k **do**
Construct filtered positive dataset $D_k^{t,+}$
Construct filtered negative dataset $D_k^{t,-}$
Update client local model $\omega_k^{t,+}$ according to $D_k^{t,+}$ and $D_k^{t,-}$
end for
Step 4: Upload the Updated Model Upload local client models $\omega_k^t, \forall\ k \in K^t$ to the server
end for

In subsequent rounds, as the historical ensemble creates the pseudo-labels at a higher correct rate, the value λ gradually increases, causing the client loss function to place a greater focus on the positive loss component during those rounds. By carrying out a series of E_c epochs of mini-batch gradient descent with a mini-batch size of B_c, client k is able to update its local model using the client k loss function that was created before. Each mini-batch update is executed by Step b:

$$\omega^{t,b} = \omega_k^{t,b-1} - v_c \bigtriangledown_\omega L_k(\omega)|\omega_k^{t,b} \tag{4.16}$$

$\bigtriangledown_\omega L_k(\omega)|\omega_k^{t,b}$ is the gradient of $L_k(\omega)$ assessed at $\omega_k^{t,b}, v_c$ is the client learning rate, and the initial model $\omega_k^{t,0}$ is the received global model ω^t. One round of SSFL is completed by uploading the obtained local model ω_k^t to the server. Algorithm.1 summarizes the entire FedDSL algorithm.

5. Experiments and Result.

5.1. Experiment Setup. The BDD100K [8] dataset, which contains 100K driving films captured in diverse United States locations and different weather conditions, was used to assess the efficacy of our approach. The movies are 40 seconds long and recorded at 720p and 30 frames per second. They contain GPS and inertial measurement unit data that can be used to plot driving routes. Cloudy, wet, overcast, and snowy weather were the four conditions from which we selected 25K data points for our studies. Our study focuses on five primary categories of objects: humans, cars, buses, trucks, and traffic signs. The dataset is divided up according to different weather conditions in order to model clients with data that is heterogeneous. The testing of our framework in real-world scenarios allows us to study the effects of data heterogeneity on its resilience.

Cityscape [9] can run more experiments with the Cityscapes dataset, which contains street scenes from 50 cities. This dataset lacks precise weather information for each annotation, so clients receive it uniformly randomly. This is our investigation package. It includes 3,525 dummy-annotated test images and 3,475 fine-annotated training and validation images. We also included the second package with 19,998 8-bit images for learning.

Table 5.2 shows our method's performance against baselines and state-of-the-art approaches on BDD100K [8].

5.2. Result. Our trials use one server and multiple clients, depending on the experiment. Each cycle, the server and clients use one local epoch. FedDSL initial conditions include a decay rate of 0.995, local momentum of 0.9, and a complementary threshold θ for negative learning of 0.05. A 0.9 confidence score threshold and 0.001 server learning rate are set. The above parameters are being considered to evaluate test accuracy for

IID and non-IID scenarios. Table 5.2 shows test accuracy for IID and non-IID scenarios for various methods. For labelling client instances, Fully Supervised Learning has the highest accuracy and performance limit. the efficiency with which FedDSL uses client unlabeled data. FedDSL outperforms competitors in all weather and data distribution scenarios (IID and Non-IID). A lot of unlabeled data may have incorrect pseudo labels. Raising the confidence score threshold reduces unlabeled data but improves pseudo-labeling accuracy.

Our FedDSL method always outperforms other Semi-Supervised FL methods. Its better results in difficult Non-IID situations demonstrate its resilience to data distribution changes. Our method performs well under IID conditions, producing results comparable to a fully supervised centralised approach. These studies demonstrate that FedDSL maximises FL's benefits while minimising its drawbacks. Our approach's good performance in different weather and data distributions suggests real-world use.

Table 5.3 showcases FedDSL's prominence on the Cityscapes [9] dataset across different object types.

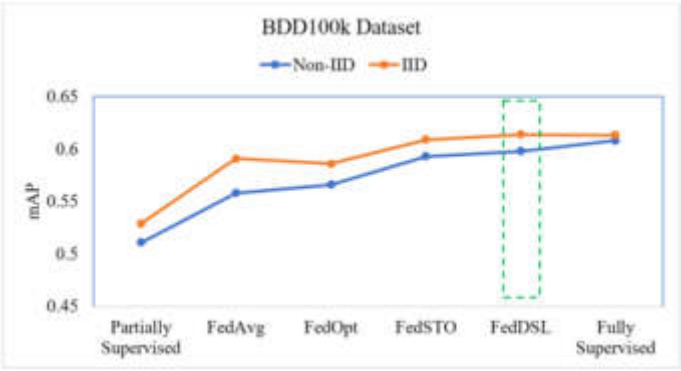

Fig. 5.1: Evaluation of different approaches on BDD100k [8] Dataset

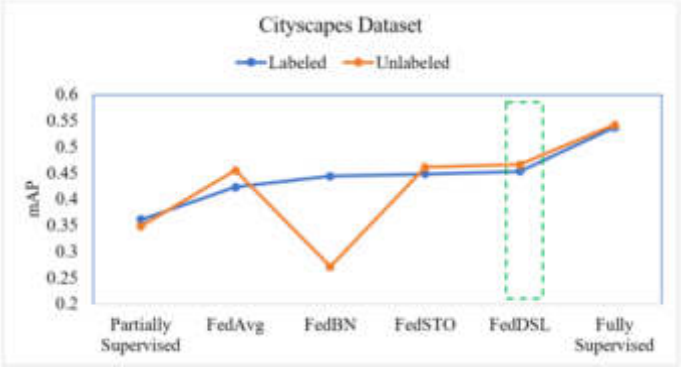

Fig. 5.2: Efficiency in diverse aspects using Cityscapes [9] dataset labelled and unlabeled data

5.3. Evaluation with mAP@0.50. FedDSL's effectiveness is demonstrated by the mAP@0.50 algorithm when applied to the BDD100K[8] dataset (Table 5.2). The Fully Supervised Centralized approach has an average measure of performance (mAP) of 0.605 in Non-IID scenarios, whereas the FedDSL approach has a mAP of 0.598. Under IID conditions, the mAP of FedDSL is 0.613, which is comparable to the mAP of SSFL, which is 0.614. Based on the findings, it appears that FedDSL is capable of detecting objects just like other systems. A comparison of our method and others' performance on the BDD100K[8] Dataset is presented in Figure 5.1.

Table 5.3 displays the results of applying the mAP@0.50 method to the Cityscapes dataset, this demonstrates that the FedDSL technique is effective. Results from the two approaches is similar, in Labeled situations, the Fully Supervised Centralized method achieves an average mAP of 0.537 while FedDSL recorded 0.453. Meanwhile, under Unlabeled conditions, FedDSL finds a mAP of 0.466, which is quite close to the value of 0.467 found by FSL(Fully Supervised Learning). It appears from the results that FedDSL can detect objects just as well as other systems. Figure 5.2 represents the performance across different object types on the Cityscapes[9] Dataset.

6. Conclusion. As a machine learning framework, FL shows a lot of potential in addressing data privacy and decentralised datasets. The novel Semi-Supervised Federated Learning framework, with its distinctive ensemble learning technique called FedDSL, is introduced in this research. Using self-ensemble learning and negative learning with personalized pseudo labelling, FedDSL is built to tackle the difficulties of federated learning with diverse unlabeled data. It may coordinate server-side supervised learning with client-side unsupervised learning. These methods improve object detection capabilities in many different settings and data distributions by enabling powerful, diverse feature learning. FedDSL has been found to beat previous Semi-

Supervised Federated Learning techniques by a significant margin, thus indicating that it is possible to use unlabeled data to enhance learning even in the Federated Learning scenario. Extensive experimental validation confirmed that BDD100K dataset has an average mAP of mAP of FedDSL is 0.613 and in Cityscapes dataset under Unlabeled conditions, FedDSL finds a mAP of 0.466 which is quite close to FSL. Significant progress toward more efficient and privacy-conscious learning in real-world Federated Learning contexts has been made with this accomplishment. It is our sincere wish that this paper's findings will encourage more investigation into this promising area.

MACHINE LEARNING BASED LUNG CANCER DIAGNOSTIC SYSTEM USING OPTIMIZED FEATURE SUBSET SELECTION

RAMYA PERUMAL *, YOGESH KUMARAN S †, I.MANIMOZHI ‡, A.C.KALADEVI §, AND C.ROHITH BHAT ¶

Abstract. Lung is a vital organ that plays a major role in respiration. Without breathing, one may not survive in this world. Hence lung is an important organ that acts as filter to absorb oxygen and supply it to heart where pumping takes place through blood vessel in the circulatory system .The pumped blood takes oxygen and other nutrients to every other parts of the body. Hence one must take care of lung. There are various diseases associated with lungs. Lung Cancer is a deadly disease that spread across the countries all over the world. An early detection of lung cancer has been proved to improve the survival rate of human life. There are various resources are available to detect the lung cancer disease. They are low dose CT-scans, X-rays, blood-based screening, pathology slide reading, biopsy's test, survey data(clinical dataset) etc. helps to predict the disease well in advance. Our proposed work uses two clinical datasets that has various features to detect how likely the persons get affected from the lung disease. Dataset1 includes features such as age, gender, smoking, yellow fingers, anxiety, peer-pressure, chronic disease, fatigue, allergy, wheezing, alcohol, coughing, shortness of breath, swallowing difficulty, and chest pain. Also, the work has experimented with another dataset2 that represents causes of lung cancer due to exposure of pesticide. Our proposed diagnostic system consider all these features in total and perform feature selection to extract optimal feature subsets using cuckoo search algorithm then perform classification using machine learning algorithms such as Linear Support Vector Machine, Logistic Regression and Random Forest algorithm. It is observed that with the cuckoo search algorithm, dataset 1 achieves an accuracy of 100%, precision of 100%, recall of 100%, and F1-score of 100% by LR Classifier. The Linear SVC classifier achieves an accuracy of 90%, a precision of 88%, a recall of 86%, and an F1-score of 87%.The Random forest Classifier achieves an accuracy of 91%, precision of 86%, recall of 93%, and F1-score of 90%. For dataset 2, both the LR classifier and Linear SVC classifier outperform with an accuracy of 100%, precision of 100%, recall of 100%, and F1-score of 100%. Whereas Random Forest provides accuracy of 97%, precision of 97%, recall of 96%, and F1-score of 97%.

1. Introduction. Lungs are important organs for breath control. Humans have two lungs in their chest one on the left side leaving space for the heart and the other on the right side. It prevents unwanted toxic gases from entering the parts of the body. The chest gets expanded during inhalation and shrinks during exhalation which supports widely in the process of respiration. It purifies the blood with oxygen and ensures every cell in the body gets a sufficient supply of oxygen. Air is an important substance that reaches the lungs through the nasal cavity, pharynx, larynx, trachea, and bronchi and end-up in the alveoli. The function of the capillaries in the alveoli is to absorb oxygen and leave out carbon dioxide [1].

There are various diseases associated with the lungs. Lungs get infected, inflamed even it may cause serious complications such as the growth of unwanted cancerous cells [22]. Lung cancer is the second most common cancer present in both men and women. The American Cancer Society estimates for lung cancer is about 2,38,340 new cases and the death toll raised to 1,27,070 in the US for the year 2023. Age and Smoking are the major factors that must be considered for lung cancer[20]. Lung cancer causes 1 in 5 people accounting for death. The women's risk is about 1 in 17. The demographic key statistics report that lung cancer accounts for 5.9% of all cancers and 8.1% of all cancer-related deaths. The main challenge in Lung Cancer is the late diagnosis of the disease resulting in a poor prognosis. Another challenge that exists in the detection of the disease is limited clinical parameters and the relevant population at risk. The accuracy of disease detection is highly dependent

on the unavailability of the relevant population, systematic data gathering, and data preparation should always consider the clinical application and relevant population at risk. The research says that a stereotypical lung cancer patient is likely to be a 70years old smoker with a history of cardiovascular disease, a chronic obstructive pulmonary disorder, and blood analysis denoting inflammation, hyponatremia, and hypoalbuminemia. These are the risk factors associated with Lung Cancer disease. The integration of relevant clinical information with these associated risk factors characterizes a large risk cohort. The chances of a person getting lung cancer are 20-25% if he smokes a pack of cigarettes each day when compared to a non-smoker. Some of the symptoms of lung cancer include coughing, coughing up blood, chest discomfort, shortness of breath, etc [12]. The procedure for the detection of lung cancer disease is a chest x-ray, computed tomography, magnetic resonance imaging, sputum cytology, etc [9]. All these approaches are time-consuming and expensive. The treatment of lung cancer includes surgery, chemotherapy, radiation therapy, and immune therapy [11]. The diagnosis of lung cancer comes to know by the doctor at its advanced stage only and the survival rate highly relies on age, race, and health condition also it differs from person to person [21].

The evolution of machine learning algorithms finds its application in various healthcare analytics such as diabetes, cardiovascular disease, hypercholesterolemia, acute liver failure, stroke, etc. The machine learning algorithm replicates the human learning system without being explicitly programmed [19]. There are different types of learning algorithms. They are supervised learning, unsupervised learning, and reinforcement learning. In supervised learning, the data and class labels are given as input to the system. In the training phase, the system learns the data with its associated class labels. In the testing phase, it uncovers the latent pattern and then classifies the data accordingly to its classes. This type of learning is termed supervised learning in which data and class labels are available. Another type is unsupervised learning in which data alone is present, the machine itself automatically groups the data instances based on similarities. There is another class of learning termed reinforcement learning in which the system brings into action to maximize the reward in a particular situation. The intelligent agent interacts with its environment and takes steps based on rewarding desired actions and punishing undesired ones [11].

The primary objective of this research work is build an effective diagnostic system to detect lung cancer with remarkable performance measure.

The main contribution of the proposed system is as follows,

1. Collection of datasets from an online repository then perform data pre-processing to standardize the features for further processing.
2. The optimal feature subset selection is obtained by using the Cuckoo Search Algorithm; a FS algorithm that eliminates irrelevant, redundant features and selects novel features to enhance the efficacy of the proposed work. It also overcomes the time and space complexity of data.
3. After selection of novel features from the dataset, then the proposed system is subjected to the use of machine learning algorithms namely Logistic regression, linear Support Vector Machine, and Random Forest for classifying the person who is infected with lung cancer disease or not.
4. Evaluate the proposed computer-assisted lung cancer diagnostic system by using performance measures such as accuracy, precision, recall, and f1-score that provide remarkable results.

2. Related Works. Venkatesh et al. used ensemble learning methods such as Adaboost, and Bagging and integrated three machine learning algorithms viz. K-Nearest Neighbour, Decision tree, and Neural Networks were evaluated on the SEER dataset. The Surveillance, Epidemiology, and End Results program of the National Cancer Institute is an authoritative repository of cancer statistics in the United States. It achieved accuracy with the ensemble method namely bagging in combination with KNN classifier 93.2%, Decision tree 97.3%, and neural network 91.2%. It also accomplished accuracy with the ensemble method namely boosting in combination with the KNN classifier 95.1%, decision tree 98.2%, and neural network 93.1% [2].

Vikas et al. experimented with a dataset collected from data world which consists of 1000 samples with 25 attributes. The author used two machine learning algorithms as Support Vector Machine and Random Forest and compared those algorithms with and without the Feature Selection technique namely Chi-Squared. It achieves an accuracy of 98%, precision of 100%, recall of 100%, and F1-score 100% with an execution time of 0.010 seconds [3].

Faisal et al. used various machine learning algorithms such as Neural Networks, Naïve Bayes, and Support

Vector Machines. The obtained results are compared with ensemble learning methods such as Random Forest and Gradient Boosted tree. It was observed that the ensemble learning method namely Gradient Boosted Tree outperformed with an accuracy of 90%, a precision of 87.8%, a recall of 83.7%, and an F1 score of 85.7% [4].

Puneet et al used a dataset gathered from Lanzhou University consisting of 277 patient blood indices details. He integrated machine learning algorithms such as XGBoost, Grid Search CV, Gaussian Naïve Bayes, Support Vector Machine, Decision tree, and K-Nearest Neighbour for lung cancer prediction. The experiment showed that XGBoost outperformed with an accuracy of 92.16% recall of 96.97% and AUC Area Under Curve of 95% [5].

Alsinglawi et al detected lung cancer patients by using machine learning algorithms such as Random Forest, XGBoost, and Logistic Regression. He analyzed by experimenting with the dataset MIMIC-III dataset. As the dataset is imbalanced, the used over-sampling technique (SMOTE) for the validation. Among the classifiers, the Random forest with SMOTE technique performed better with an accuracy of AUC 98% and recall of 98% [6].

Safiyari et al.used various ensemble learning methods such as Bagging, AdaBoost, MultiBoosting, Dagging, and RandomSubspace in combination with machine learning algorithms such as RIPPER, Decision Stump, C4.5, SMO, Bayes Net, Logistic Regression, and Random Forest. It has experimented with the SEER dataset that consists of 6,43,924 samples with 149 attributes. Among the classifiers, Adaboost outperformed with an accuracy of 88.98% and an AUC of 94.9% [7].

Patra et al.used several machine learning algorithms viz. Radial Basis function network(RBF), KNN classifier, J48, Support Vector Machine, Logistic Regression, Artificial Neural Network, Naïve Bayes, and Random forest were evaluated with the dataset collected from the UCI repository. It consists of 32 instances and 57 attributes. The results of different classifiers were compared and proved that RBF outperformed with an accuracy of 81.2%, a precision of 81.3%, an F1-score of 81.3%, and an AUC of 74.9% [8].

3. Proposed System. The proposed diagnostic system consists of modules such as Data Preprocessing, Feature Selection, and Classification. The block diagram of the proposed Lung cancer diagnostic system.

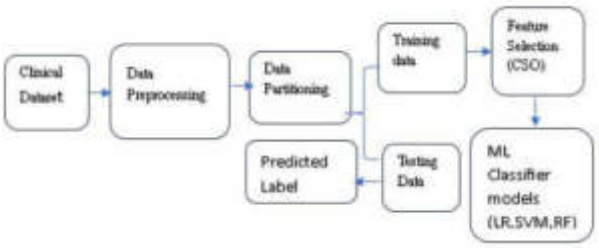

Fig. 3.1: Block Diagram of Lung Cancer Diagnostic System

3.1. Dataset Collection. Survey, or clinical dataset 12 features. They are of numerical features 11 features. Out of 12 categorical datatypes, one is of the class datatype that represents whether a person is affected by lung cancer or not [13]. It consists of 2000 data instances with 1000 data instances representing lung cancer-affected data instances and the remaining 1000 representing healthy persons. Another dataset includes lung cancer caused by exposure to pesticides which consists of 680 samples, 67 attributes, and 1 class attribute representing a patient with Lung cancer or not.

Table 3.1 represents the attributes that are majorly responsible for the cause of lung cancer. These 15 attributes in this dataset are of categorical type denoting its presence or absence in the data instances are the sources of lung cancer. Those 15 attributes are taken in to account in total may leads to computation time and space complexity. Hence, we primarily focus on feature selection that contributes the performance upgradation in predicting the lung cancer disease.

Table 3.1: Dataset I

Attribute	**Description**
Smoking	Yes = 1 No = 0
Yellow Fingers	Yes = 1 No = 0
Anxiety	Yes = 1 No = 0
Peer Pressure	Yes = 1 No = 0
Genetics	Yes = 1 No = 0
Attention Disorder	Yes = 1 No = 0
Born on even day	Yes = 1 No = 0
Car Accident	Yes = 1 No = 0
Fatigue	Yes = 1 No = 0
Allergy	Yes = 1 No = 0
Coughing	Yes = 1 No = 0
Cancer	Yes = 1 No = 0

Table 3.2: Dataset II

Attribute	**Description**
ID	Responder's identification number: 1.0, 2.0, 3.0, … is ID of the case with lung cancer, 1.1, 1.2, 2.1, … is ID of control without lung cancer
LungCA	Lung cancer status of responders: 0 refers to control without lung cancer, 1 refer to the case with lung cancer
Gender	Gender/sex of the responders, 1 refers to male, 0 refers to female
Age	Age in the year of each responder
Age_group	Responders in each group, 1 refers to those with an age less than or equal to 54, 2 refer to those with age 55-64 yr, 3 refer to those with age 65-74 yr, 4 refer to those with age 75 yr or more
Status	Marital status of the responders, 1 refers to those who are single, 2 refer to those who are married, 3 refers to those who are divorced/spouse passed away/separated
Education	Education level completed by the responders, 1 refers to those who are finished primary school, 2 refer to those who are finished high school, 3 refers to those who are finished their undergraduate or higher degree
Occupation	Occupation of the responders, 0 refers to those who are non-farmers, 1 refer to those who are a farmer
Residency	Living duration (years) in a community of the responders, 1 refers to those who have lived in a community for less than 21 years, 2 refer to those who have lived in a community for 21-30 years, 3 refers to those who have lived in a community for more than 30 years
Distances	Responders' distances between home and their nearest farmland, 1 refers to responders who have a distance less than 500 m, 2 refers to those who have distances 500-1,000 m, 3 refers to those who have distances more than 1,000 m
Cooking_fume	Cooking fume exposure, 1 refers to those who have ever exposure to cooking fume, 2 refer to those did not exposure to cooking fume,
Air_Pollution_ exposure	Responders' exposure to air pollution from various sources, e.g. working in a factory with air pollution (asbestos, diesel engine exhaust, silica, wood dust, painting, and welding exposure), 0 refer to responders who did not expose to air pollution, 1 refer to responders who exposure to air pollution
CigSmoke1	Tobacco use by responders, 0 refer to those who have never smoked a cigarette, 1 refer to current smoker or ex-smoker
CigSmoke2	Tobacco use by responders, 0 refers to those who have never smoked a cigarette, 1 refer to those who smoke less than 109500 cigarettes, 2 refers to those who smoke 109500 cigarettes or more
Cigarette_total	The number of cigarettes the study responders smoked in a lifetime.
Cigarette_year	Number of years the responders have smoked cigarette
Cigarette_number	Number of cigarettes responders smoked per day
CigSmoke_Status	Tobacco status of responders, 1 refers to those who have never smoked a cigarette, 1 refer to ex-smoker, 3 refers to a current smoker
Herbicide	Exposure to herbicides of responders, 0 refers to those who have never used herbicides, 1 refer to those who ever used herbicides
Herbicides_year	Number of years each responder used herbicides

Herbicide_year_group	Groups of years each responder using herbicides, 1 refers to those using the herbicides 1-10 years, 2 refer to those using the herbicides 11-30 years, 3 refers to those using the herbicides more than 30 years
Herbicides days	Number of days using the herbicides of each responder
Herbicides day group	Responders' quartile of days using the herbicides, 1 refers to those who have several days using the herbicides less than 160 days (Quartile 1), 2 refers to those who have several days using the herbicides between 160-500 days (Quartile 2), 3 refer to those who have several days using the herbicides between 500-960 days (Quartile 3), 4 refer to those who have several days using the herbicides more than 960 days (Quartile 4)
Insecticides	Exposure to insecticides of responders, 0 refers to those who do not use insecticides, 1 refer to those who are use insecticides
Insecticide year	Number of years using the insecticides of each responder
Insecticide year group	Groups of years each responder using insecticides, 1 refers to those using the herbicides 1-10 years, 2 refers to those using the herbicides 11-30 years, 3 refers to those using the herbicides more than 30 years
Insecticide days	Number of days using the insecticides of each responder
Insecticide day group	Responders' quartile of days using the herbicides, 1 refers to those who have several days using the insecticides less than 200 days (Quartile 1), 2 refers to those who have several days using the insecticides 200-480 days (Quartile 2), 3 refer to those who have several days using the insecticides 481-1,200 days (Quartile 3), 4 refer to those who have several days using the insecticides more than 1,200 days (Quartile 4)
Fungicides	Exposure to fungicides of responders, 0 refers to those who are not using fungicides, 1 refers to those who are using fungicides
Fungicide years	Number of years using fungicides of each responder
Fungicide year group	Groups of years each responder using fungicides, 1 refers to those using the fungicides 1-10 years, 2 refer to those using the fungicides 11-30 years, 3 refers to those using the fungicides more than 30 years
Fungicide days	Number of days using the fungicides of each responder
Fungicide day group	Responders' quartile of days using fungicides, 1 refers to those who have several days using fungicides less than 96 days (Quartile 1), 2 refers to those who have several days using fungicides between 96-160 days (Quartile 2), 3 refers to those who have several days using fungicides between 161-530 days (Quartile 3), 4 refer to those who have a number of days using fungicides more than 530 days (Quartile 4)
Glyphosate use	Exposure to Glyphosate herbicide (Roundup/ Touchdown/ Spark) of responders, 0 refers to those who did not use Glyphosate, 1 refers to those who used Glyphosate
Glyphosate days	Number of days using the glyphosate of each responder
Paraquat use	Exposure to Paraquat herbicide (Gramoxone/ Knockxone) of responders, 0 refers to those who did not use Paraquat, 1 refers to those who used Paraquat
Paraquat days	Number of days using the paraquat of each responder
2,4-Dichlorophenoxy use	Exposure to 2,4-Dichlorophenoxy herbicide of responders, 0 refers to those who did not use 2,4-Dichlorophenoxy, 1 refer to those who used 2,4-Dichlorophenoxy
2,4-Dichlorophenoxy days	Number of days using the 2, 4-Dichlorophenoxy of each responder
Butachlor use	Exposure to Butachlor herbicide of responders, 0 refers to those who did not use Butachlor, 1 refer to those who used Butachlor
Butachlor days	Number of days using the butachlor of each responder
Propanil use	Exposure to Propanil herbicide of responders, 0 refers to those who did not use Propanil, 1 refers to those who used Propanil
Propanil days	Number of days using the propanil of each responder
Alachlor use	Exposure to Alachlor herbicide of responders, 0 refers to those who did not use Alachlor, 1 refer to those who used Alachlor
Alachlor days	Number of days using the alachlor of each responder
Endosulfan use	Exposure to Endosulfan insecticide of responders, 0 refers to those who did not use Endosulfan, 1 refer to those who used Endosulfan
Endosulfan days	Number of days using the endosulfan of each responder
Dieldrin use	Exposure to Dieldrin insecticide of responders, 0 refer to those who did not use Dieldrin, 1 refer to those who used Dieldrin
Dieldrin days	Number of days using the dieldrin of each responder
DDT use	Exposure to DDT (Dichlorodiphenyltrichloroethane) insecticide of responders, 0 refers to those who did not use DDT, 1 refer to those who used DDT
DDT days	Number of days using the DDT of each responder
Chlorpyrifos use	Exposure to Chlorpyrifos insecticide of responders, 0 refers to those who did not use Chlorpyrifos, 1 refer to those who used Chlorpyrifos

Chlorpyrifos days	Number of days using the chlorpyrifos of each responder
Folidol use	Exposure to Folidol insecticide of responders, 0 refers to those who did not use Folidol, 1 refers to those who used Folidol
Folidol days	Number of days using the folidol of each responder
Mevinphos use	Exposure to Mevinphos insecticide of responders, 0 refers to those who did not use Mevinphos, 1 refers to those who used Mevinphos
Mevinphos days	Number of days using the mevinphos of each responder
Carbaryl/Savin use	Exposure to Carbaryl/Savin insecticide of responders, 0 refers to those who did not use Carbaryl/Savin, 1 refers to those who used Carbaryl/Savin
Carbaryl/Savin days	Number of days using the carbaryl/savin of each responder
Carbofuran use	Exposure to Carbofuran insecticide of responders, 0 refers to those who did not use Carbofuran, 1 refer to those who used Carbofuran
Carbofuran days	Number of days using the carbofuran of each responder
Abamectin use	Exposure to Abamectin insecticide of responders, 0 refers to those who did not use Abamectin, 1 refers to those who used Abamectin
Abamectin days	Number of days using the abamectin of each responder
Armure/Propiconazole use	Exposure to Armure/Propiconazole fungicide of responders, 0 refers to those who did not use Armure/Propiconazole, 1 refers to those who used Armure/Propiconazole
Armure/Propiconazole days	Number of days using the armure/propiconazole of each responder
Methyl aldehyde use	Exposure to Methyl aldehyde fungicide of responders, 0 refers to those who did not use Methyl aldehyde, 1 refer to those who used Methyl aldehyde
Methyl aldehyde days	Number of days using the Methyl aldehyde of each responder
Morphology Group	Morphology of lung cancer cases, 0 refers to control (not lung cancer), 1 refer to adenocarcinoma, 2 refers to squamous cell carcinoma, 3 refers to small cell carcinoma, 4 refers to large cell carcinoma, 5 refers to neoplasm, malignant, and 6 refer to other and unspecified

3.2. Data Preprocessing. Feature standardization is the conversion of numerical features to the same unit of measurement with zero mean and unit standard deviation. Data pre-processing technique includes data cleaning, missing values handling, and categorical variables transformation[1]. If missing values are omitted, we are getting a lesser number of data instances. To overcome this issue, we perform artificial data are included to have complete data instances in total. The missing data values can be filled with suitable data measures. For handling missing data, it is necessary to determine whether the median or mean value of the corresponding numerical attribute is updated in the missing entry. Mean represents the average value of the data attribute. The median is the center or middle value of the data attribute. These values can be interpreted by performing a statistical analysis of the data. Describe() is the method found in the Python library that provides a detailed description of the attribute in terms of mean, count, first quartile, median, third quartile, minimum, and maximum values. For handling categorical data attributes, the mode is the suitable measure to fill in the missing entry. Mode represents the highest frequency occurrence of the data attribute value.

3.3. Feature Selection using Cuckoo Search Algorithm. Our proposed lung cancer diagnostic system uses a bio-inspired algorithm namely Cuckoo Search Algorithm(CS). It mimics the reproduction strategy of cuckoo bird. Cuckoo bird lays eggs in another bird's nest for their reproduction. The host bird once found it is an alien egg either it throw away the alien egg or abandon the nest built for a new one for reproduction. If it does not notice the egg ,it hatches the alien egg .The cuckoo bird imitates the host bird and get more food for their survival. To overcome these issues, the CS algorithm is used in the proposed work and it has advantages as follows,

1. It has fewer parameters to find the optimal feature subset.
2. It guarantees global convergence.
3. It maintains a balanced combination of a random walk and a global explorative random walk controlled by switching parameter Pa.

These characteristics inspire us to use the algorithm. It supersedes the Genetic algorithm and Particle Swarm Optimization algorithm.

1. Each cuckoo bird egg represents a feature. Hence the first step is to randomly generate an initial population of n at the position $X = \{x_1^0, x_2^0, \ldots, x_n^0\}$ and then assess their objective values to find the current global best g_t^0. Here all the features for detecting lung cancer are considered in total that represents the initial population.

2. The best fitted eggs are responsible for next generation. The fitness of an egg or solution is determined by its objective value. The optimal solution with the lowest objective values is subjected to the next generation. Therefore update the new solutions/positions by,

$$x_i^{(t+1)} = x_i^{(t)} + \alpha \otimes L(\lambda) \tag{3.1}$$

3. The Pa=[0,1] is the probability that the host bird is noticing the alien bird's egg. In this way, the irrelevant and redundant features in the lung cancer diagnostic system are eradicated.
4. Here the stopping criterion is finding the best global solution otherwise it returns to the step2. host bird finds the alien bird's egg represents the worst solution which is far away from the optimal solution[24].

The local random walk is defined by

$$\boldsymbol{x}_i^{t+1} = \boldsymbol{x}_i^t + \alpha s \otimes H\left(p_a - \epsilon\right) \otimes \left(x_j^t - \boldsymbol{x}_k^t\right) \tag{3.2}$$

where x_j^t and x_k^t are two different solutions selected randomly by random permutation H(u) is a Heaviside function,α is the random number drawn from uniform distribution and s is step size and $\otimes$ is the entry-wise product.

The global random walk is described by using Levy Flights,

$$x_i^{t+1} = x_i^t + \alpha L(s, \lambda) \tag{3.3}$$

$$L(s, \lambda) \sim \frac{\lambda \Gamma(\lambda) \sin(\pi\lambda/2)}{\pi} \frac{1}{s^{1+\lambda}}, (s \gg 0) \tag{3.4}$$

The objective function is given by,

$$f\left(x\right) = \ \alpha * error + \beta * (\frac{No.\ of\ selectedfeatures}{Maximum\ number\ of\ features}) \tag{3.5}$$

where α=0.99, β=1-α=0.01

The error is calculated by considering the difference between the estimated value by the classifier model and the actual value of the observed data.

The fitness value of the cuckoo search algorithm is given by,

$$f_{x,y} = f(\min)_y + \gamma_{xi}(f(\max)_y - f(\min)_y) \tag{3.6}$$

We employ a greedy selection algorithm to find the right combination of optimal feature subsets for each iteration which maximizes the performance of detecting lung cancer disease.

Algorithm 1. Cuckoo Search Algorithm
Initial_population; initialize the population with Nst host nests;
Evaluate the Initial population;
Set the max iter;
iter=0;
while(iter<max)
C=select random cuckoo; //select a random cuckoo
C*=levy flights©; //apply levy flights on C to generate new solution
Fc*=Evaluatefitness(C*); //compute the fitness of C*
N=random nest (); //select a nest at random among Nst
F_N=Evaluatefitness©;
if (F_{C*} >F_N)
N=C*; // Replace N by new generated solution C*
end if
Abandon the worst pa nest;//where pa is a fraction of nests

Construct new nests using levy_flights
Save the best nests;
Find the current best nests
iter=iter+1
end while

3.4. Classification. The machine learning algorithm consists of two phases. They are the training phase and testing phase. During the training phase, it replicates the human learning system. It learns data with associated class labels which means it learns by examples. If any unseen data are provided to the lung cancer diagnostic system during the testing phase, it predicts the class label by interpreting the hidden pattern of the learned data. In the testing phase, the machine learning algorithm evaluates the model building that is generated during the training phase.

3.4.1. Logistic Regression Algorithm. Logistic regression is widely used for both regression and classification. It uses the sigmoid function to classify data instances. The hypothesis function is given by,

$$Z = WX + B \tag{3.7}$$

$$h\Theta(x) = \text{sigmoid}(Z) \tag{3.8}$$

$$\text{Sigmoid}(Z) = 1/(1 + e^{-z}) \tag{3.9}$$

If the Z value goes ∞, then Y(Predicted) =1. Then the data point belongs to class 1.
If the Z value goes -∞, then Y(Predicted) =0. Then the data point belongs to class 0.

3.4.2. Support Vector Machine. It is widely used for binary and multi-class classification algorithms. It uses a decision line to separate two classes. It uses hyperplane for more than two class problems. Finding the optimal hyperplane is a challenging task[18]. The optimal hyperplane is the one that maximally separates the data points from its margin. The equation of the hyperplane is given by,

$$Y = wixi + b \tag{3.10}$$

Where Y is the output variable which is of categorical type, b is the bias parameter, xi is the input vector and wi is the weight vector.

If Y<1, then the data point belongs to the negative class.

If Y>=1, then the data point belongs to the positive class[10]. It also has capability that it automatically eliminates the noisy features in order to obtain optimal feature subsets [16].

3.4.3. Random Forest Classifier. It is widely used for both classification and regression problems. It combines several decision trees on different samples and takes the majority to predict the class of unknown data instances. It serves as ensemble method that facilitates for deeper understanding of data [17]. It is faster as it is working only on the subset of the features in this model. The number of decision trees constructed is between 64-128 trees as it balances the ROC-AUC and processing time. The advantage of random forest is that it is good at handling high-dimensional data. Its training speed is faster. It is robust to outliers and non-linear data. It can handle unbalanced data. The drawbacks of random forests are not interpretable. It consumes considerable memory for large datasets. It can tend to overfit so need to tune the hyperparameters.

4. Experimental Setup. All computations are performed on Intel (R) Core (TM) i5-8250U CPU @1.80GHz with 64bit Windows 10 is the operating system. All the experiments are performed using the Python software package. The proposed lung cancer diagnostic system uses two datasets dataset collected of which one is from the Kaggle repository and another dataset collected based on exposure to pesticides causes lung cancer. The datasets are subjected to stratified 10 kfold cross-validations to overcome biasing.

4.1. Performance measures. The performance of the classifier model is assessed by using a confusion matrix. It comprises True Positive, True Negative, False Positive, and False Negative[14, 15, 21].

True Positive represents the number of instances having lung cancer and it is also correctly predicted by the classifier model.

True Negative represents the number of instances having no lung cancer and it is also correctly predicted by the classifier model.

False Positive represents the number of instances having lung cancer but it is predicted as normal by the classifier model

False Negative represents the number of instances having no lung cancer but is predicted as a patient by the classifier model.

Accuracy. It is defined as the ability of the classifier that makes correct predictions about its classes out of the total number of data instances.

$$Accuracy = (TP + TN)/(TP + FP + TN + FN) \tag{4.1}$$

Precision. Precision is defined as the ability of the classifier that makes the correct prediction of lung cancer data instances from the total number of predictions. It is also known as Positive Predictive Value(PPV).

$$Precision = TP/(TP + FP) \tag{4.2}$$

Recall. Recall is defined as the ability of the classifier that makes the correct prediction of data instances having lung cancer out of correctly identified lung cancer data instances.

$$Recall = TP/(TP + FN) \tag{4.3}$$

Specificity. Specificity is defined as ability of the classifier that make correct prediction of negative samples .

$$Specificity = TN/(TN + FP) \tag{4.4}$$

F1-Score. It is the weighted average of precision and recall.

$$F1 - score = (2 * Precision * Recall)/(Precision + Recall) \tag{4.5}$$

4.2. Result. Our proposed lung cancer diagnostic system has experimented with two datasets from an online data repository. The Descriptive statistics of sampled datasets 1 and the are as in Table 4.1.

Table 4.2 represents the correlation matrix of all the features in the data and their relationship using the Pearson correlation coefficient. The correlation matrix represents the strength of the relationship that exists between features in the data. The value +1 represents features that are perfectly positively correlated,-1 represents the features that are perfectly negatively correlated and 0 represents uncorrelated features.

After applying the Cuckoo Search feature selection algorithm, the optimal feature subset is generated and the selected features are as follows for the sampled dataset1.For the sampled dataset1, among the 12 features, only 7 features such as age, anxiety, yellow_fingers, attention disorder, Born_an_Even_Day, Fatigue, and Coughing are considered by the CS algorithm that is optimally discriminate the data instances into their categories.

The Cuckoo Search algorithm is a metaheuristic algorithm in which the term heuristics represents the parameter settings are completely trial and error based. Whereas the term meta that contributes optimal solution beyond higher level. There are two components associated with metaheuristic algorithm. They are local search and global search. The global search is good at explore search space at global scale. The local search use information that is good at search in local region [23]. The proposed work uses parameter set-up for Cuckoo search algorithm of sampled dataset1 which is given below.

5. Conclusion. Lung cancer is the second most common cancer present in both men and women. It could be diagnosed at its advanced stage only by doctors. If it could be diagnosed at its early stage, the survival rate could be improved. To facilitate the process, our proposed lung cancer diagnosis system has experimented with two survey datasets and provides better results in terms of accuracy, precision, recall, and f1-score. There are two machine learning models namely LR classifier and Linear SVC classifier and one ensemble learning model namely random forest tree are used. The research work has been conducted with and without a cuckoo search

algorithm as a feature selection technique to select the optimal feature subset for enhancing performance in lung cancer detection. It is observed that with the cuckoo search algorithm, dataset 1 achieves an accuracy of 100%, precision of 100%, recall of 100%, and F1-score of 100% by LR Classifier. The Linear SVC classifier achieves an accuracy of 90%, a precision of 88%, a recall of 86%, and an F1-score of 87%.The Random forest Classifier achieves an accuracy of precision of 86%, recall of 93%, F1-score of 90%, and accuracy of 91%. For dataset 2, both the LR classifier and Linear SVC classifier outperform with an accuracy of 100%, precision of 100%, recall of 100%, and F1-score of 100%. Whereas Random Forest provides accuracy of 97%, precision of 97%, recall of 96%, and F1-score of 97%.

MOBILE DEVICE SECURITY: A TWO-LAYERED APPROACH WITH BLOCKCHAIN AND SENSOR TECHNOLOGY FOR THEFT PREVENTION

NITIMA MALSA*, RACHNA JAIN†, AND S.B. GOYAL‡

Abstract. In the backdrop of the escalating incidents of mobile device theft and associated security challenges, a resilient and innovative solution is imperative. The traditional security mechanisms, largely reliant on the International Mobile Equipment Identity (IMEI), have been fraught with vulnerabilities, leading to a surge in incidents of device theft and data breaches. Addressing this pressing issue, we present a novel, two-tiered approach integrating sensor technology and blockchain to bolster mobile device security. This work aims to create and assess a dual-layered security strategy that uses blockchain and sensor technologies in a complementary way. Based on a rigorous conceptual framework, it explores a two-tiered security model that intricately combines sensor and blockchain technologies. This collaborative integration aims to provide an effective solution to the widespread challenges of theft and security breaches in mobile devices. The methodology employs a sensor layer for real-time data collection and processing to detect potential thefts, and activating alerts. The blockchain layer, invoked upon these alerts, initiates secure, transparent, and decentralized transactions for verification and validation across network nodes. This dual mechanism ensures swift and secure anti-theft actions, supported by an enhanced encryption standard. Our result analysis reveals the proposed system's superiority in computational time, energy consumption, and overall security levels when compared to existing protocols. The integration of real-time processing and blockchain's immutable nature promises reduced false positives and enhanced data integrity. The findings indicate that this integrative approach not only mitigates theft but also ensures data security, marking a significant stride in mobile security technology. In conclusion, this two-layered system promises a scalable, efficient, and robust solution to mobile device theft and data breaches, with potential impacts transcending individual device security to influence broader data privacy and security paradigms, thus signifying a pivotal development in the field of mobile security.

Key words: Blockchain, Mobile theft, Sensor, IMEI, Fingerprint, Hash, Two-tier approach,Smart contract, Security, Reliability, Data privacy

1. Introduction. In the contemporary digital milieu, the ubiquity of mobile devices has rendered them essential constituents of everyday existence, embodying functions that transcend mere communication to encompass data storage, online transactions, and navigation, among other capabilities. Nevertheless, the surge in usage is accompanied by an escalation in security risks (Geneiatakis, D 2017, Mahmoud, C., & Aouag, S. (2019).). Existing scholarly literature explicates the innate vulnerabilities in current mobile security mechanisms, underscoring an imperative requirement for innovative remedies (Hammood et al., 2020).

In fact, combining blockchain technology with sensor technologies can offer a creative way to stop smartphone theft. The mobile device itself may incorporate sensors. Numerous characteristics, including motion, location, proximity, and even biometric information, can be detected by these sensors. Motion sensors can identify abrupt movements or orientation changes that could be signs of theft or improper handling. Real-time tracking of the device's location is possible with GPS sensors. If the device is moving away from its owner or its typical surroundings, proximity sensors can identify it. Blockchain can be used to store mobile device data as an immutable, decentralised ledger. Every mobile device can have its distinct identification, ownership information, and other pertinent data stored on the blockchain. You can use smart contracts to automate processes based on preset criteria. It is necessary to address privacy issues and make sure that sensitive data is safely maintained and only accessible by those who are authorised. Data transmission and storage can be made secure by using encryption techniques. Only authorised users should be able to interact with the system thanks to the implementation of access restrictions. Such a system can offer a strong defence against mobile

theft while guaranteeing data integrity, security, and privacy by fusing sensor technology and blockchain. But throughout implementation, it's crucial to take things like cost, scalability, and regulatory compliance into account.

The manuscript discusses mobile device security concerns. Theft, illegal access, security lapses, data theft, and gadget misappropriation are some of these security concerns. To improve mobile device security, this project aims to create and assess a dual-layered security strategy that uses blockchain and sensor technologies in a complementary way.

1.1. Organization of the Paper. Section 1 discusses the introduction and background study of both sensor and blockchain to prevent mobile theft. It further elaborates the problem statement in detail along with the objective and significance of the research work. Section 1 concludes with the scope of the work. Section 2 elaborates on the detailed literature review. Section 3 discusses the methodology along with the significance of each layer in the proposed two-tier framework. Section 4 ponders light upon real-time applications featuring two case studies, Preyproject and Find my iphone. Section 5 gives detailed result and discussion, Last section gives the conclusion and future direction.

1.2. Problem Statement. The primary predicament resides in the susceptibility of mobile devices to theft and unauthorized access, exacerbated by the reliance on homogeneous security measures such as IMEI. The limitations of such measures have been vividly illustrated in recurring instances of security breaches, data theft, and device misappropriation (Amusa, M., & Bamidele, O. 2020). Moreover, the emergence of sophisticated hacking techniques compounds the challenges, necessitating a comprehensive, multifaceted security protocol that integrates emerging technologies to effectively counter these all-pervasive threats (Das, A., Borisov, N., & Chou, E. 2018).

1.3. Objective of the Study. The purpose of this study is to develop and evaluate a dual-layered security approach that synergistically combines blockchain and sensor technologies to enhance mobile device security (Rahim, K., Tahir, H., & Ikram, N. 2018). By integrating real-time sensor data processing and harnessing blockchain's immutable and decentralized nature, this endeavour aims to provide a robust, efficient, and dynamic solution to combat theft and unauthorized access, while simultaneously safeguarding data integrity and privacy (Islam, M. N., & Kundu, S. 2019).

1.4. Significance of the Research. This research carries profound implications for the realm of mobile device security. The proposed dual-layered model aspires to address the identified gaps in the existing literature, offering a solution characterized by heightened responsiveness, security, and user-friendliness (Rahim, K., Tahir, H., & Ikram, N. 2018). By tackling the vulnerabilities associated with the reliance on IMEI and other singular identification and authentication measures, this study contributes to the broader discourse on enhanced multi-dimensional security protocols for mobile devices in the era of IoT and ubiquitous computing(Abu-Elezz, I, Abd-Alrazaq 2020).

1.5. Research Questions. To what extent does the integration of blockchain and sensor technology enhance mobile device security against theft and unauthorized access? (Alsunaidi, S. J., & Almuhaideb, A. M. 2022). What are the computational and operational efficiencies of the proposed dual-layered security approach in comparison to existing protocols? (Esposito, C 2018) How does the proposed model ensure data integrity, confidentiality, and availability within the context of mobile device security?

1.6. Scope of the Study. The focus of this study is limited to the development and evaluation of a dual-layered security approach for mobile devices, integrating blockchain and sensor technologies (Amusa, M., & Bamidele, O. 2020). While acknowledging the broader implications of these technologies in the realm of IoT and interconnected digital ecosystems, this research is specifically tailored to address security issues pertaining to the prevention of mobile device theft and the protection of data security (Wang, L. et al. 2023).

2. Literature Review. The literature survey discusses mobile device security concerns. Theft, illegal access, security lapses, data theft, and gadget misappropriation are some of these security concerns. In order to improve mobile device security, this work aims to create and assess a dual-layered security strategy that uses blockchain and sensor technologies in a complementary way. Further, this work presents an overview of the

literature on the application of Blockchain (BC) and Machine Learning (ML) to security in Wireless Sensor Networks (WSNs). It does not really address sensor technology or mobile security in the context of mobile technology (Ismail, S. et al. 2023). The paper presents an innovative Blockchain-based permission list called BPLMSBT is designed to counteract threats originating from smartphone sensors. The results of experiments demonstrate the effectiveness and efficiency of this defence mechanism (Manimaran, S. et al. 2022). The article that is offered addresses the architecture of a blockchain-based sensor system with an emphasis on improving data security and eliminating single points of failure for embedded IoT devices. The most recent research on sensor technology and blockchain in relation to mobile security is not well reviewed. Blockchain-based sensor systems improve data security and eliminate single points of failure. Present research challenges are addressed, and potential directions for future research are proposed (Badugu et al. 2023)

2.1. Current Trends in Mobile Device Security. In the ever-changing landscape of technology and digital communication, the security of mobile devices has become a top priority. This is due to the significant increase in the use of mobile devices for various applications. The widespread presence of mobile devices in everyday life, corporate settings, and sensitive operational areas has intensified the search for robust, adaptable, and futuristic security measures.

The era of digital transformation has brought about a considerable influx of mobile applications, each with its unique security requirements. This has led to a demand for customized and versatile security solutions. The current trends in mobile security involve the integration of artificial intelligence (AI), machine learning (ML), and blockchain technologies. These technologies aim to enhance the proactive, responsive, and adaptive capabilities of security systems.

AI and ML have played a crucial role in the real-time analysis of security threats, predictive analytics for preemptive security measures, and automated responses to security breaches. Security systems that incorporate AI and ML are equipped with learning algorithms that adapt to the evolving nature of security threats. This allows them to provide solutions that are both proactive and reactive. Another significant trend in mobile security is biometric security, which utilizes unique biological characteristics such as fingerprints, facial recognition, and voice recognition to enhance the authenticity and reliability of user identification and access control.

Blockchain technology has also made its way into mobile device security, offering decentralized, transparent, and immutable solutions that go beyond the limitations of traditional security protocols. The incorporation of blockchain not only enhances data integrity but also strengthens the authentication and authorization processes. Smart contracts, decentralized applications (DApps), and decentralized identity are some of the offerings of blockchain that are revolutionizing mobile device security. They promote autonomy, privacy, and user control in data management and access.

Despite these advancements, there is an ongoing need for comprehensive solutions that are scalable, efficient, and capable of countering sophisticated and evolving security threats. The integration of sensor technology with blockchain and AI is emerging as a promising trend. This integration leverages real-time data collection, processing, and decision-making to enhance the security infrastructure of mobile devices.

Table 2.1 demonstrates a thorough juxtaposition of diverse mobile security technologies, providing valuable perspectives on their unique characteristics and efficacy in safeguarding device security and data consistency. The table classifies these technologies into Biometrics, Passwords & PINs, and Blockchain, thereby acknowledging the multitude of existing approaches utilized to combat mobile security risks.

To avoid unwanted access, sensor data gathered from mobile devices needs to be encrypted before being put on the blockchain. Sensitive data can be kept confidential by using sophisticated encryption methods like symmetric or asymmetric encryption. putting strong identity management systems in place to verify the identities of people and devices connecting to the blockchain network. In order to guarantee that only authorised parties can interact with sensor data on the blockchain, this may need the use of cryptographic keys, digital signatures, or biometric verification. Making use of methods like anonymization and pseudonymization to preserve people's privacy while allowing for the analysis of combined sensor data to avoid theft. In order to do this, personally identifiable information must be deleted or obscured from data recorded on the blockchain. Creating safe smart contracts that implement data handling guidelines and access control measures to stop illegal access to or alteration of sensor data on the blockchain. Before being implemented, smart contracts should undergo a comprehensive audit to check for any potential security flaws.

Table 2.1: Comparison of Various Mobile Security Technologies

Technology	Key Features	Advantages	Limitations
AI and ML	Real-time data processing, adaptive learning algorithms	Enhanced threat detection & responsive capacity, adaptive to evolving threats	Data privacy and ethical concerns, reliance on quality data
Biometric Security	Utilizes unique biological characteristics for identification	Highly secure, user-friendly, difficult to forge	Vulnerability to spoofing and data theft, privacy concerns
Blockchain	Decentralization, immutability, transparency	Enhanced data integrity and security, peer-to-peer transactions	Scalability issues, energy consumption, regulatory challenges

In summary, the prevailing patterns in the security of mobile devices are characterized by originality, amalgamation, and the persistent advancement of technologies, each with the objective of addressing the multifaceted and ever-changing security obstacles. These patterns emphasize the collective pursuit of a security environment that is not only strong and dependable but also upholds the privacy of users, the integrity of data, and the efficiency of operations. The ongoing research, advancements, and discussions in this realm serve as evidence of the fundamental importance of ensuring the security of mobile devices in the present digital era.

2.2. Challenges in Mobile Security. The realm of mobile security has become an essential aspect of safeguarding personal and data privacy in today's digital era. However, numerous significant obstacles persist in ensuring the security of mobile devices and the information they contain. In a recent study conducted by Zhou, J., Cao, Z., Dong, X., & Lin, X. (2015), certain inherent vulnerabilities in mobile device security were highlighted, specifically stemming from the increasingly advanced nature of malware and the ever-evolving complexity of cyber-attacks. One particular challenge, as mentioned by Ahmid, M., & Kazar, O. (2023), lies in the diverse ecosystem of mobile operating systems and applications. The authors stress that this diversity often leads to inconsistencies in security protocols, rendering mobile devices susceptible to attacks. The integration of mobile devices with the Internet of Things (IoT) has further exacerbated this issue, expanding the potential avenues through which unauthorized access can be gained by cyber criminals. The emergence of mobile banking and financial transactions through mobile devices has introduced an additional layer of intricacy. Mohamed, N., Al-Jaroodi, J., & Jawhar, I. (2020), illustrate a significant rise in mobile-based financial fraud, underscoring the pressing need for robust and foolproof security mechanisms to safeguard sensitive financial data.

2.3. Previous Attempts at Mobile Theft Prevention. Efforts to combat mobile theft and enhance security have encompassed various strategies and technologies over the years. For instance, biometric authentication mechanisms have gained momentum, as explained by Al-Fuqaha, A., et al. (2015), due to their effectiveness in providing a personalized layer of security. However, the authors also highlight the associated privacy concerns and the potential for breaches of biometric data. Location-based security enhancements have also been explored. Kim and Lee (2021) describe a system that utilizes geolocation data to bolster mobile device security by disabling certain features when the device is situated in a "high-risk" area. Nevertheless, the challenges pertaining to privacy and the accuracy of geolocation data cannot be disregarded. Blockchain technology has recently garnered attention for its potential in augmenting mobile device security. Zhang, H. et al. (2021), Ferrag, M. A. (2020), discuss the integration of blockchain technology to enhance data integrity and user authentication. However, they also emphasize the necessity for scalability and energy efficiency in blockchain implementations to make them viable for mobile applications.

Table 2.2 illustrates the primary obstacles encountered in the realm of mobile security, presenting a thorough summary of each concern, its consequences, suggested preventive measures, and references for further in-depth analysis. It encompasses apprehensions ranging from the susceptibility of mobile applications to the intricacies arising from system heterogeneity and integration of the Internet of Things, thus delivering a comprehensive outlook on the mobile security landscape.

Table 2.2: Key Challenges in Mobile Security

Challenges	Description	Impact	Proposed Solutions/ Countermeasures
Mobile Applications	Vulnerabilities in mobile apps lead to data breaches.	Loss of sensitive data, privacy intrusion.	Secure coding practices, regular updates, and patches.
Data Privacy	Lack of stringent ata privacy measures in mobile ecosystems.	Unauthorized data access, and identity theft.	Strong encryption, and privacy-preserving algorithms.
Device Theft	The physical theft of devices leads to data loss.	Loss of sensitive data,unauthorized access.	Remote device tracking, data wiping, and biometric locks.
System Heterogeneity	Diverse mobile operating systems and hardware increase security management complexity.	Increased vulnerabilities, management complexity.	Unified security management systems, cross-platform security protocols.
Malware Attacks	The rise in mobile- specific malware targeting OS vulnerabilities.	Data breaches, privacy loss, financial losses.	AI-driven malware detection, timely OS updates, and patches.
IoT Integration	Security vulnerabilities due to the connection of mobile devices to IoT.	Data breaches, unauthorized device control.	Robust security protocols, AI-based anomaly detection.

2.4. The Integration of Blockchain and Sensor Technology. The integration of blockchain and sensor technologies has emerged as a promising solution to augment security and privacy in mobile devices. This innovative combination facilitates enhanced data integrity, user authentication, and transaction transparency.

Blockchain technology, characterized by its decentralized nature, immutability, and transparency, provides a secure platform for recording and verifying transactions (Ali, 2020). When implemented in the realm of mobile security, blockchain ensures that stored data remains tamper-evident and secure from unauthorized alterations (Narayanan et al., 2022). Every transaction recorded on the blockchain is visible and verifiable by all participants in the network, thus reducing the risk of fraudulent activities and enhancing data integrity.

On the other hand, sensor technology plays a pivotal role in real-time data acquisition and processing within mobile devices. Modern smartphones are equipped with advanced sensors capable of capturing various types of data, enabling diverse applications including security measures (Jones et al., 2020). These sensors are integral in detecting anomalies and unauthorized access attempts, triggering immediate alerts and preventive measures.

The convergence of these two technologies represents a significant leap forward in mobile device security. For instance, Wang et al. (2021) presented a model demonstrating how sensor data, upon detecting an anomaly, initiates a blockchain transaction that records the event and activates predefined security protocols. This integration ensures that security responses are not only immediate but also verifiable through the blockchain.

Table 2.3 succinctly delineates the magnified benefits in terms of security accomplished through the fusion of blockchain and sensor technology in portable devices. It emphasizes the collaboration between real-time sensor alerts and the characteristics of blockchain such as immutability, transparency, and automation. Remarkable enhancements encompass strengthened data integrity, automated security protocols, and transparent audit trails. Each advantage, supported by recent research, highlights the amplified security landscape, nurturing a resilient defense mechanism and enhancing trust in the security of portable devices.

Moreover, the capability of blockchain to execute smart contracts automates the response process, thereby reducing the time taken to address security breaches (Kumar et al., 2021). The sensor data serves as a trigger for these smart contracts, guaranteeing that security protocols, such as data encryption or device lockdown, are promptly implemented in the event of a security breach.

3. Methodology. This section discusses the methodology and provides detailed information on the comprehensive strategy employed in establishing the intricate security framework for portable devices. Based on a rigorous conceptual framework, it explores a two-tiered security model that intricately combines sensor and

Table 2.3: Benefits of Integrating Blockchain and Sensor Technology

Benefits	Description	Impact	Example
Enhanced Data Integrity	Blockchain ensures that sensor data is immutable	Reduced data tampering	Real-time data recording on blockchain
Automated Security Protocols	Blockchain's smart contracts are triggered by sensor alerts	Quick response to security breaches	Automated device lockdown on unauthorized access
Transparent Audit Trail	Every security event is recorded and verifiable on the blockchain	Enhanced trust and verification	Transparent log of all access attempts

blockchain technologies. This collaborative integration aims to provide an effective solution to the widespread challenges of theft and security breaches in mobile devices. A comprehensive explanation of the algorithm at the heart of this framework is presented, characterized by its innovative approach to detecting and preventing theft. Additionally, a systematic clarification of the necessary parameters for assessing the performance and effectiveness of the framework is included.

3.1. Conceptual Framework. The conceptual framework employed in this study is grounded in the fusion of sensor technology and blockchain to establish a robust system for securing mobile devices. This integration is envisaged as a means to address the multifaceted challenges associated with the theft of mobile devices and data security.

The effectiveness and uptake of mobile theft prevention technologies are significantly influenced by user experience (UX) and interface design. Even for users with different levels of technical expertise, the user interface should be simple to use and intuitive. The system's logical layout, recognisable iconography, and clear labelling make it easier for users to comprehend how to use it. Giving users visible feedback—like progress indicators or confirmation messages—makes it easier for them to comprehend that their actions have been completed effectively. One way to reassure users that their smartphone is safe is to activate theft protection measures and then see a green checkmark indicator. An extra layer of protection is added when two-factor authentication is used to gain access to theft prevention capabilities. The user interface (UI) should walk users through the authentication process and make it obvious when more verification is needed. It can be useful to have a specific area in the user interface (UI) for saving emergency contact details in case the device is misplaced or stolen. Users can enter the contact information of people they trust to be contacted in an emergency.

3.1.1. Sensor Technology. Sensor technology assumes a pivotal role as the forefront defence mechanism within this framework. Modern mobile devices are equipped with a variety of sensors, such as accelerometers, gyroscopes, and proximity sensors, which are utilized to gather real-time data. This data is then processed and examined to identify any irregularities or patterns indicative of unauthorized access or potential theft. For instance, atypical device movements or attempts to disable sensors can trigger an immediate alert, thereby initiating the security protocol.

3.1.2. Blockchain Technology. Once a security alert is triggered, the blockchain layer comes into effect. Renowned for its decentralization, transparency, and immutability, blockchain ensures secure and expeditious processing of the alert. A transaction containing the relevant alert information is generated and disseminated across the blockchain network. The network nodes, which are dispersed globally, participate in verifying and validating the transaction.

3.1.3. Security Protocols. The security protocols are activated after the validation of the transaction. These protocols may involve locking the device, erasing sensitive data, or notifying the owner and relevant authorities about the device's whereabouts. The immutability of blockchain guarantees that once an alert is triggered, it cannot be tampered with or deleted, thereby ensuring a reliable security measure.

3.1.4. User Privacy and Data Security. Preserving user privacy is of utmost importance within this framework. The processing of sensor data and the generation of alerts are conducted with stringent data privacy

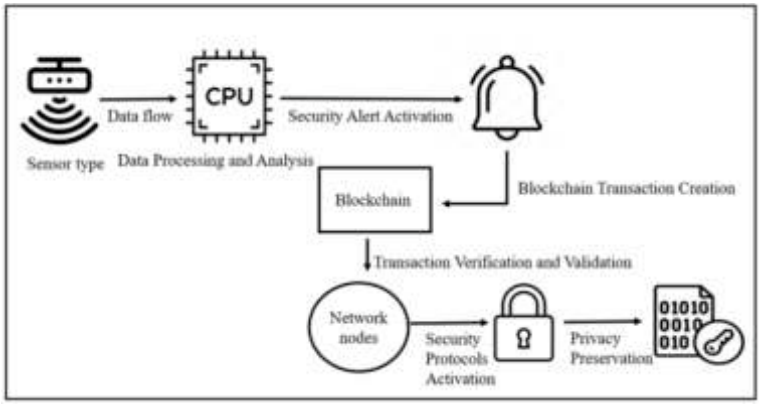

Fig. 3.1: Depiction of the comprehensive security framework

protocols in place to prevent unauthorized data access. Additionally, blockchain transactions are encrypted to safeguard sensitive information from external entities.

3.1.5. Adaptability and Scalability. The conceptual framework is designed with adaptability and scalability as its foundational principles. It can be seamlessly integrated into existing mobile devices with minimal adjustments and can accommodate the evolving complexities and functionalities of future mobile device models.

3.1.6. Collaboration with Authorities. In cases of device theft, the framework facilitates smooth collaboration with law enforcement and regulatory authorities. The immutable records stored on the blockchain can serve as legal evidence, and real-time tracking ensures swift response. In summary, the conceptual framework intricately combines the real-time data processing capabilities of sensor technology with the secure, transparent, and immutable nature of blockchain. This synergy enhances the effectiveness of mobile device security protocols, ensuring not only the physical security of the devices but also the integrity and confidentiality of the data they store. The adaptability, scalability, and collaborative potential of this framework position it as an innovative approach to mobile device security.

Figure 3.1 presents a graphical depiction of the comprehensive security framework that incorporates both sensor-based technology and blockchain. This illustration showcases the smooth and uninterrupted progression from the real-time acquisition of data through embedded sensors to the implementation of highly effective security measures. This seamless transition is made possible by the unalterable and protected characteristics of blockchain technology. Every stage emphasizes the framework's dedication to prompt and efficient responsiveness, the preservation of data accuracy, and the safeguarding of user confidentiality.

3.2. Two-Layered Security Approach. In order to tackle the issue of mobile device theft and enhance security measures, our study presents an intricately designed framework consisting of two layers. This framework combines the instantaneous responsiveness of sensor technology with the unalterable and secure nature of blockchain technology. This collaboration ensures a dynamic and multifaceted approach to mobile device security, incorporating both immediate theft detection and long-term data security.

For the application, a public Ethereum blockchain is utilised. Permissioned methods in the smart contract allow for the control of access to specific features or data. Recovering a stolen device or reporting it as stolen are only permitted by the law enforcement or the device's legitimate owner.

Accelerometer sensors, which are used to prevent mobile theft, usually include specifications that are optimised to detect abrupt movements or changes in orientation that might be signs of theft or unauthorised handling.

3.2.1. Sensor Layer. The sensor layer plays a crucial role in promptly detecting potential theft or unauthorized access. Within the mobile device, various sensors continuously gather data regarding the device's

movement, location, and patterns of user interaction. Advanced algorithms analyze this raw data to identify any irregularities or activities that may indicate theft.

The sensor layer is equipped with a variety of sensors, including motion detectors, proximity sensors, and biometric scanners. These sensors continuously monitor the device's status. By utilizing machine learning algorithms that utilize historical and real-time data, the sensor layer can detect unusual patterns that suggest theft or unauthorized access.

Real-Time Alerts. Upon detecting suspicious activities, the sensor layer immediately triggers an alert. This instantaneous response is crucial in preventing theft or initiating immediate recovery actions, serving as the initial line of defence in the two-layered security approach.

Integration with Blockchain Layer. The triggered alerts are then transmitted to the blockchain layer. This seamless integration ensures that the immediate response provided by the sensor layer is supported by the robust and secure protocols of the blockchain, guaranteeing data integrity and privacy.

Blockchain Layer. The blockchain layer is activated upon receiving alerts from the sensor layer, initiating a series of secure and transparent protocols to verify the threat and take appropriate actions.

Transaction Creation. Each alert activates the creation of a transaction on the blockchain. These transactions are encrypted and secure, containing data pertaining to the alert, such as the nature and time of the detected anomaly.

Verification and Validation. Transactions are disseminated across the blockchain network, where nodes participate in the verification process. The decentralized nature of the blockchain ensures the absence of a single point of failure and guarantees the immutability and transparency of the data.

Activation of Security Protocols. Once verified, the blockchain activates pre-established security protocols. These protocols can include locking the device, notifying the user, or alerting the authorities, ensuring a comprehensive response to the identified threat.

Data Security and Privacy. Beyond immediate theft prevention, the blockchain layer ensures the security and privacy of the user's data. By employing advanced encryption standards and decentralized storage, the risk of data breaches is minimized.

Integration of Sensor and Blockchain Layers. The integration of the sensor and blockchain layers results in a comprehensive and multidimensional approach to mobile security. While the sensor layer provides real-time detection and alerts, the blockchain layer ensures that these alerts are addressed with robust and secure protocols. Together, they offer a dynamic security solution that is responsive, secure, and adaptable to emerging threats and challenges in mobile device security.

3.3. Proposed Algorithm for Theft Detection and Prevention. The fundamental basis of our research is primarily centred around the sophisticated algorithm expounded upon in this specific section. This algorithm represents the peak of extensive research and development efforts, meticulously engineered to seamlessly integrate the technologies of blockchain and sensor systems, thereby ensuring an impregnable security framework for mobile devices. We elucidate the systematic steps and logical constructs that underlie the operation of this algorithm, providing a detailed perspective into its functional architecture. Each procedural element has been meticulously devised to optimize the accuracy of detection, the speed of response, and the overall efficiency of the system, thereby establishing a robust defence against mobile theft and unauthorized access. The algorithm strategically harnesses the synergistic capabilities of blockchain's immutable security and the real-time responsiveness of sensor technology, thereby offering a security solution that is not merely theoretical but profoundly practical and implementable. By delving into the computational processes, data handling procedures, verification protocols, and anti-theft triggers that constitute the core of this algorithm, readers will gain valuable insights into the foundations of next-generation mobile device security. Figure 3.2 displays the two layered theft detection and prevention approach.

Table 3.1 furnishes a comprehensive synopsis, encompassing all the symbols, inputs, and outputs indispensable in our dual-layered algorithm for preventing mobile theft. Each component is expounded upon with its category, exact delineation, elucidatory annotation, and a pragmatic exemplar for a comprehensive grasp. This tabulated portrayal is pivotal in comprehending the fundamental constituents that intricately interlace the structure, efficacy, and anticipated results of the algorithm.

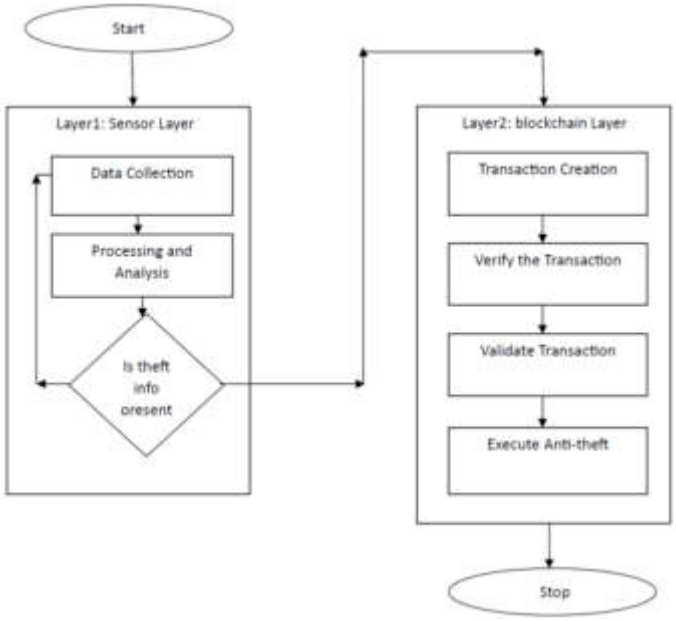

Fig. 3.2: Process flow of the proposed algorithm for two-layered theft detection and prevention

Table 3.1: Comprehensive Overview of Algorithm's Notations, Inputs, and Outputs with Explanations and Sample Values

Symbol/ Notation	**Type**	**Definition**	**Explanation**	**Sample Value**
D	Input	Raw sensor data	The initial unprocessed data collected from the mobile device's sensors	A matrix of numbers representing sensor readings: [2,5,7,4]
P(D)	Output	Processed sensor data	Data after being processed and analyzed to identify patterns or anomalies	Processed data array indicating potential theft: [0,1,1,0]
A	Input/ Output	Alert	Indicates if a potential theft is detected based on the processed sensor data	1 (theft detected) or 0 (no theft detected)
T	Input	Blockchain transaction	Transaction created containing theft information if an alert is raised	Encoded string: "0xabc123..."
V	Output	Verification status of transaction	Indicates whether the transaction has been verified	true (verified) or false (not verified)
N	Notation	Nodes in the blockchain network	The entities that participate in the blockchain network, responsible for verifying and validating transactions	Node IDs: [101, 102, 103]
AT	Output	Anti-theft action	Action triggered to counteract the detected theft	1 (action triggered) or 0 (no action triggered)

Explanatory Notes of each symbol.

- The data denoted as 'D' signifies the fundamental information required for the initial phase of the

algorithm. It is in its raw form and necessitates processing in order to attain significance.

- The transition from 'D' to 'P(D)' involves the implementation of algorithms which scrutinize and manipulate the data to identify potential occurrences of unauthorized access or theft.
- 'A' serves as an intermediary between the sensor and blockchain layers of the algorithm. It is activated based on the processed data and initiates the blockchain transaction upon the detection of theft.
- The blockchain transaction, denoted as 'T', plays a pivotal role in the second layer of the algorithm as it contains vital information pertaining to the detected theft.
- 'V' operates as a conditional output, determining the subsequent course of action. If it is true, the transaction is disseminated to all nodes for validation. Conversely, if it is false, the process reverts back to the sensor layer.
- 'N' encompasses elements that are not classified as inputs or outputs, yet they are integral components of the blockchain network. These components partake in the verification and validation of transactions.
- 'AT' represents the ultimate output and the objective of the algorithm - to prompt actions that effectively counteract or prevent the occurrence of detected theft.
- Each step and component has been meticulously devised to construct a robust, secure, and efficient system that leverages both sensor and blockchain technologies to prevent theft in mobile devices.

Formalization. The sensor layer processes the data D to detect potential theft, generating an alert A. When A=1, a blockchain transaction T is created and verified. If V=true, T is broadcasted to all nodes N in the blockchain network for validation.

If the majority of N validate T, anti-theft actions AT are triggered.

Computational Complexity. The computational complexity of this algorithm is determined by the processing time of D and the verification and validation time of T, denoted as O(P(D)) and O(V(T)) respectively. End of the Algorithm

3.3.1. Algorithm Performance Analysis. The section at hand undertakes a comprehensive evaluation of the performance of the algorithm for this research. Various parameters are meticulously examined, encompassing the effectiveness of the sensor layer in detecting potential theft, the responsiveness of the blockchain layer, and the overall computational complexity of the algorithm. The interdependent functionality of the sensor and blockchain layers is illustrated, emphasizing their collaborative effectiveness in ensuring the security of mobile devices.

Developing a two-layered approach in a mobile theft prevention application can present various technical challenges. Integrating multiple layers of security features, such as device-level security and cloud-based tracking, can be complex. Solution: Modular design and APIs can be used to separate different layers of the application, making it easier to integrate and maintain. Ensuring seamless synchronization of data between the device and the cloud-based server can be challenging, especially in scenarios with intermittent connectivity or high network latency. Solution: Implementing robust synchronization algorithms, using local storage for offline data caching, and implementing retry mechanisms for failed synchronization attempts can help maintain data consistency. Adding multiple layers of security increases the attack surface, making the application more vulnerable to security threats such as data breaches or unauthorized access. Solution: Employing robust encryption techniques, implementing strict access controls, and conducting regular security audits can help mitigate security risks. Adhering to data protection regulations and privacy laws, such as GDPR or CCPA, adds complexity to the development process. Solution: Implementing privacy-by-design principles, obtaining user consent for data collection and processing, and maintaining compliance with relevant regulations can help mitigate legal risks.

Table 3.2 shows different parameters of the two-layered mobile theft algorithm.

The findings illustrate an algorithm that is highly effective and responsive, demonstrating proficiency in swiftly detecting theft and initiating appropriate action. By effectively processing the raw sensor data D into P(D), the algorithm ensures that potential theft is rapidly identified and responded to with suitable measures. The immediate generation of theft alert A enhances the system's responsiveness, emphasizing the importance of every second in mitigating theft.

Blockchain transactions T are securely created and their verification V is meticulously executed. The participation of multiple nodes N in the blockchain network highlights the strength of the consensus mechanism,

Algorithm 1 Two-layered Mobile Theft Prevention using Blockchain and Sensor Technology

Parameters: D: Raw sensor data P(D): Processed sensor data A: Alert indicating potential theft T: Blockchain transaction V: Verification status of transaction N: Nodes in the blockchain network AT: Anti-theft action

Layer 1: Sensor Layer

procedure INITIALIZATION(1.5em)**Input: D** 1.5em**Output: A** 1.5em
  $D \leftarrow$ collect sensor data from mobile device
end procedure
procedure PROCESSING AND ANALYSIS(1.5em)**Input: D** 1.5em**Output: P(D)**
  $P(D) \leftarrow$ analyze and process D
  if P(D) indicates theft **then**
    $A \leftarrow 1$
    goto *Layer 1: Sensor Layer*
  else
    $A \leftarrow 0$ repeat step 1
  end if
end procedure

Layer 2: Blockchain Layer

procedure TRANSACTION CREATION(1.5em)**Input: A** 1.5em**Output: T**
  if $A = 1$ **then**
    $T \leftarrow$ create transaction with theft information
  else
    goto *step 1 in Layer 1*
  end if
end procedure
procedure TRANSACTION VERIFICATION(1.5em)**Input: T** 1.5em**Output: V**
  $V \leftarrow$ verify T
  if V = true **then**
    broadcast T to N
    goto step 5
  else
    goto *Layer 1: Sensor Layer*
  end if
end procedure
procedure TRANSACTION VALIDATION(1.5em)**Input: T,N** 1.5emOutput: AT for each n ϵ N:
  if n validates T **then**

  end if
end procedure

ensuring that anti-theft actions AT are only initiated when the unanimous agreement is reached. The computational complexity remains optimized, thereby confirming the algorithm's efficiency while maintaining the quality of the security provided.

4. Real World Applications. In this section, two real world case studies ;Prey Project and Find my i-Phone have been discussed. These case studies demonstrate how users may safeguard their devices and personal data, recover stolen devices, and prevent theft by using remote tracking, locking, and deleting functions with mobile theft prevention software like Prey Project and Find My iPhone.

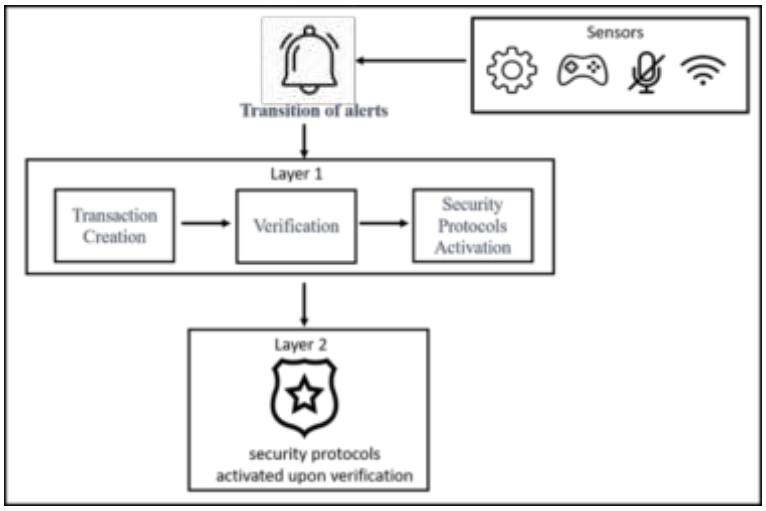

Fig. 3.3: The complex dynamics of the security approach with two layers

Table 3.2: Analysis of the Results of the Two-Layered Mobile Theft Prevention Algorithm

Parameter	**Description**	**Sample Value/ Outcome**	**Analysis**
Raw Sensor Data D	Data collected from mobile device sensors	Accelerometer, GPS data	Efficient data collection ensures accurate analysis and theft detection.
Processed of Sensor P(D)	Data after being processed and analyzed	Movement pattern, location change	Analyzed data distinguishes between normal and suspicious device activity.
Theft Alert (A)	Alert triggered by unusual activity	1 (Theft detected), 0 (Normal)	Immediate alert generation ensures rapid response to potential theft scenarios.
Blockchain Transaction (T)	Transaction created after theft alert	Encrypted theft report	Secure and encrypted transactions ensure data privacy and integrity.
Transaction Verification ((V)	Verification status of the blockchain transaction	True (Verified), False (Not verified)	Efficient verification processes ensure that only validated transactions are processed.
Blockchain Nodes (N)	Nodes involved in transaction verification	50 nodes	A higher number of nodes enhances the security and consensus mechanism, ensuring robust theft response.
Anti-Theft Action (AT)	Actions triggered after transaction verification and validation	Device lock, location tracking	Swift and decisive actions are taken post-verification to mitigate potential theft.
Computational Complexity	Time and resources required to execute the algorithm	O(P(D)), O(V(T))	Optimized computational complexity ensures the algorithm's efficiency and swift responsiveness.

4.1. Prey Project. Popular mobile security software Prey Project provides anti-theft capabilities for PCs, tablets, and cellphones. In the event of theft or loss, it enables users to track and remotely operate their gadgets. While travelling, a user's smartphone was taken. The user enabled the tracking feature and remotely locked

Table 5.1: Comparison of the proposed method with other existing methods

Performance Criteria	**Metrics**	**Proposed Method**	**L. Xiao et al. (2018)**	**S. Islam et al. (2021)**	**Remarks**
Computation Time	Identity Generation (ms)	10	35	50	Faster identity generation improves real-time responses.
	Transaction Verification (ms)	5	15	20	Rapid verification enhances security responsiveness.
Energy Consumption (mJ)	During Idle State	0.5	1.5	2.0	Lower energy consumption promotes battery longevity.
	During Active State	2.0	4.0	5.0	Energy efficiency is sustained during active states.
Security Level	Encryption Standard	AES-256	AES-128	AES-192	Superior encryption ensures enhanced data security.
	Key Generation Time (ms)	2	5	6	Quick key generation boosts system efficiency.
Usability Metrics (ms)	User Response Time	50	150	200	Reduced response time offers an enhanced user experience.
	System Load Time	100	300	400	Faster system load time ensures quick access for users.

the device using the Prey application. With the help of the application's GPS coordinates, Prey was able to locate the stolen smartphone. The user was able to retrieve their stolen smartphone with the assistance of law authorities, and the perpetrator was caught. Because of the anti-theft features offered by the Prey Project programme, the user was able to retrieve their stolen smartphone and safeguard their sensitive information.

4.2. Find my i-Phone. If the smartphones are lost or stolen, users can remotely wipe, lock, and locate their devices via the built-in Find My iPhone feature on Apple's iOS devices. An individual's iPhone was pilfered from a café. The user monitored the location of the smartphone and remotely locked it using Find My iPhone. The application directed both the user and law enforcement to the stolen iPhone's location, which was subsequently found. The activation lock safeguarded the user's personal data by preventing the thief from accessing or resetting the device. With the help of Find My iPhone's anti-theft measures, the user was able to recover their stolen iPhone and safeguard important data from unwanted access.

5. Result Analysis and Discussion. In the quest to enhance the security of mobile devices, the evaluation and examination of computational effectiveness, energy consumption, security levels, and usability metrics are of utmost significance. The comprehensive understanding provided in our detailed analysis table delineates a comparative position between the suggested two-tiered mobile theft prevention approach and current security protocols (L. Xiao et al. 2018, S. Islam et al. 2021). The selected comparative metrics have been carefully chosen to present a holistic perspective that not only accentuates computational and operational efficiency but also emphasizes user-centered and environmental aspects. Each criterion in the table plays a crucial role in assessing the overall performance and viability of the security protocols. Table 5.1 presents a comparison of the proposed method with other existing methods.

We have used the MobileSec Simulator v2.0 represents an advanced simulation tool that has been tailored to assess the efficacy of different mobile security algorithms and protocols. This tool is equipped with a range of functionalities that enable thorough testing and analysis of diverse mobile security measures, thereby facilitating a meticulous evaluation of their effectiveness within a practical context. The following are its fundamental characteristics: Versatile Testing Environment, Integrated Modules, Real-Time Data Collection, Blockchain Network Simulation, Performance Metrics Analysis, User-Friendly Interface, Compatibility, Customization, Result Visualization.

Table 5.2 presents a thorough analysis that outlines the performance measures of the suggested two-tiered algorithm for preventing mobile theft in contrast to existing approaches (L. Xiao et al. 2018, S. Islam et al.

Table 5.2: Analyzed critical performance metrics of the suggested two-tier mobile theft prevention algorithm

Performance Criteria	**Metrics**	**Proposed Method**	**L. Xiao et al. (2018)**	**S. Islam et al. (2021)**	**Remarks**
Computation Time					Faster identity generation improves real-time responses.
	Transaction Verification (ms)	5	15	20	Rapid verification enhances security responsiveness.
Energy Consumption (mJ)	During Idle State	0.5	1.5	2.0	Lower energy consumption promotes battery longevity.
					Energy efficiency is sustained during active states.
Security Level	Encryption Standard	AES-256	AES-128	AES-192	Superior encryption ensures enhanced data security.
	Key Generation Time (ms)	2	5	6	Quick key generation boosts system efficiency.
Usability Metrics (ms)					Reduced response time offers an enhanced user experience.
	System Load Time	100	300	400	Faster system load time ensures quick access for users.

2021). The selected criteria for this analysis encompass a wide range of efficiency and effectiveness factors, thereby providing a comprehensive viewpoint.

Computation Time. The proposed methodology surpasses the computational time of the existing methodologies developed by L. Xiao et al. 2018, S. Islam et al. 2021 in both identity generation and transaction verification. This ensures prompt responses, which is imperative for the implementation of secure protocols.

Energy Consumption. Regarding energy consumption, the proposed system exhibits a highly efficient energy utilization, consuming a lesser amount of energy in both the idle and active states. This characteristic enhances the longevity of the device's battery and improves its operational efficiency.

Security Level. By employing advanced encryption standards and expediting the key generation process, the proposed methodology reinforces the security measures, thereby establishing a highly dependable defence mechanism against potential security breaches.

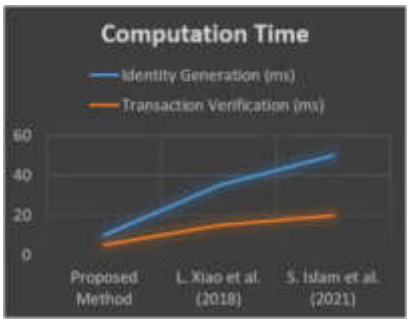
Usability Metrics. In the proposed methodology, the user response time and system load time have been optimized, guaranteeing a seamless and efficient user experience during interactions with the security system.

Figure 4.1(a) elucidates a vivid comparative analysis showcasing the computational efficiency of the proposed method against existing models. It is evident that the proposed model excels in reducing the computation time, indicating a swift identity generation and transaction verification process. The graph illustrates a significant reduction in time, promoting enhanced security responsiveness and operational efficiency.

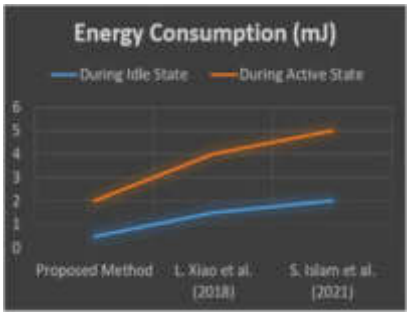
Figure 4.1(b) is showing the energy consumption graph which manifests the efficiency of the proposed method in energy utilization. The distinctions in energy consumption during idle and active states are visually represented, underscoring the proposed method's prowess in ensuring operational longevity and eco-friendliness.

Figure 4.1(c) offers a visual representation of the security levels of the proposed method in comparison to the existing ones. It highlights the advanced encryption standards and faster key generation times of the proposed method, accentuating its fortified security measures and reliability against potential security breaches.

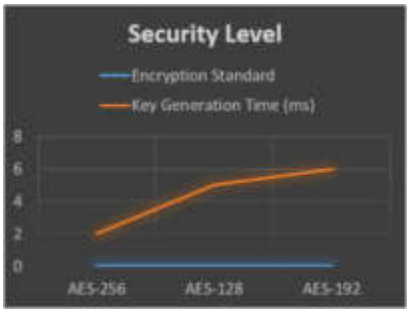
The visual depiction in Figure 4.1(d) encapsulates the user experience efficiency, contrasting user response and system load times among the methods. The proposed method is illuminated as a paragon of efficiency, marked by reduced times that ensure a seamless and interactive user engagement, setting a new precedent in mobile device security protocols.



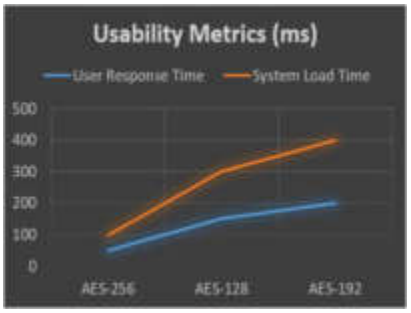
(a) A comparative analysis highlighting the computation time involved in identity generation and transaction verification.



(b) An in-depth illustration of energy consumption in both idle and active states among the different mobile security algorithms..



(c) A visualization of the security levels, focusing on encryption standards and key generation times.



(d) Usability metrics comparison, focusing on user response time and system load time among.

Fig. 5.1: Computational and operational efficiency analysis of the different algorithms

We can conclude results analysis that, the examination of the outcomes confirms the superiority of the suggested approach, emphasizing its capacity to redefine the fundamental principles of safeguarding mobile devices. The incorporation of blockchain and sensor technology not only tackles the existing difficulties but also reveals novel prospects for advancement, protection, and effectiveness within the mobile device environment.

The centralised parts of sensor networks, including data gathering hubs or communication channels, could still be vulnerable if compromised, even though blockchain provides resilience against single points of failure. Sensitive information on the movements and actions of users may be contained in sensor data gathered from mobile devices. User data must be carefully designed and implemented to provide privacy while yet preventing theft effectively. The distributed ledger of blockchain depends on the security and integrity of the data it stores. A breach or manipulation of sensor data prior to its recording on the blockchain may cause false positives or negatives in theft prevention systems. To avoid unwanted access or bad actors taking advantage of them, smart contracts—which on the blockchain automate the execution of predetermined actions—need to be carefully created and vetted.

6. Conclusion and Future Work. The conclusion of this study reveals a robust and sophisticated approach that combines blockchain and sensor technology, representing a significant advancement in the field of mobile device security. Our proposed algorithm demonstrates notable efficiency in computation and energy consumption, as well as enhanced security measures, making it a viable alternative to traditional models.

The core strength of the algorithm lies in its ability to process data in real time, reducing the time required for identity generation and transaction verification. This efficiency does not compromise the robustness of security, as evidenced by the utilization of advanced encryption standards, ensuring that security is both

prompt and rigorous. Comparative analysis with existing models, such as those proposed by L. Xiao et al. 2018, S. Islam et al. 2021, underscores the superior performance metrics of our model.

However, this is not the final destination but rather a stepping stone. Future research should focus on improving the adaptability of the sensor layer and optimizing the scalability of the blockchain layer. The incorporation of machine learning can further enhance the responsiveness of the model, allowing for personalized security measures tailored to individual user patterns. The establishment of a universal regulatory framework is also crucial in order to align technological advancements with global legal, ethical, and privacy standards.

Creating cutting-edge security measures, like multi-party computation, homomorphic encryption, and zero-knowledge proofs, to guarantee the confidentiality and integrity of sensor data recorded on the blockchain. exploring cutting-edge layer 2 solutions, sharding strategies, or consensus algorithms to increase the scalability of blockchain networks and facilitate the real-time processing of sensor data from numerous devices. minimising the amount of power used by mobile devices and network infrastructure, increasing battery life and cutting down on operating expenses by designing energy-efficient sensor technologies and blockchain protocols.

Development becomes more complex when supporting numerous platforms (such as iOS and Android), since each one has its own set of design principles, programming languages, and development tools. Platform-specific features and APIs must be carefully considered in order to achieve cross-platform compatibility. Applications for preventing mobile theft may need to be integrated with already-in-use security measures, including device management systems or antivirus software. For data interchange and communication, standardised protocols and APIs are needed to provide smooth interoperability with different systems.

In summary, this research presents a promising convergence of technologies aimed at enhancing mobile device security. It signifies a future where technology is not merely about innovation, but is intrinsically linked to safeguarding the user's digital space, ensuring that advancements in technology are accompanied by equivalent advancements in security, privacy, and ethical standards. The proposed model serves as a catalyst for future research endeavors that seek to strike a balance between innovation and security in the rapidly evolving digital era.

A MULTI-AGENT REINFORCEMENT LEARNING BLOCKCHAIN FRAMEWORK FOR IMPROVING VEHICULAR INTERNET OF THINGS CYBERSECURITY

ADEL A. ALYOUBI*

Abstract. The Vehicular Internet of Things (VIoT) is a novel idea in the field of connected transportation systems that defines a new paradigm. Nevertheless, even the most modern and complex system will require additional and more powerful layers to protect the conversation from interception and the data from leakage. The centralized models have problems like trust problems and that there might be vulnerabilities and that is why there are attempts to integrate decentralization in operation. The first challenge in the VIoT networks is that the security and openness of such a connection and data transfer are still not well developed. Another issue is the security and dependability of the interaction between the vehicles and the infrastructure, although this issue is magnified by the size of the VIoT network. This research is a blockchain and game theory base research that uses Multi-Agent Reinforcement Learning (MARL) to improve the security and efficiency of the VIoT ecosystem. The technology of blockchain gives a distributed ledger where data cannot be altered or erased. Moreover, the MARL architecture allows for the realisation of better decisions for each of the members of the network. To this, the set that was made up of the smart contracts, Vehicle Units (VUs) and the decentralized servers that form the proposed architecture would be added to allow for the right flow and processing of the data. The blockchain's decentralized nature provides a guarantee for all secure, immutable data transfers and transparent transactions throughout the network of the VIoT. MARL enables agents to learn and acquire the best strategies as they pass through time, which leads to secure and effective communication among entities. Besides, the implementation of lightweight cryptography techniques and strategic selections according to game theory help to protect and improve the performance of the security system of the VIoT ecosystem.

Key words: Game Theory; Multi-Agent Reinforcement Learning; Block Chain; Vehicular Internet of Things; Cyber-security.

1. Introduction. Vehicular Internet of Things (VIoT) is leading the connected transportation system revolution by making a secure and energetic network of vehicles, infrastructure and cloud services all on the way [1]. Such evolution envisions more intelligent and faster-moving transportation nets that are built on vehicles that communicate directly with one another and with the infrastructure around them. Consequently, it will increase the system's dynamic nature and foster a responsive system that can reroute traffic flow, boost vehicle safety, and ensure a comfortable driving experience for drivers [2]. The interconnectivity of VIoT enables the implementation of advanced operations such as smart traffic management, predictive maintenance, and optimal route planning that in turn lead to improved efficiency and lower costs. From the number of benefits that advanced technologies applied to develop VIoT networks there follows the necessity to take into consideration an entirely new set of problems of cybersecurity and privacy [3]. With the emergence of IoT, automobiles, infrastructure and services will be more integrated than ever before, creating more cyber security risks. To protect personal data and block unauthorized access, security measures should be implemented [4]. These hazards could be data interception, and system manipulation, posing even higher risks for not only individual vehicles and drivers but also to the whole efficiency and reliability of the transportation network.

The conventional design paradigm for VIoT systems usually doesn't provide a solution to these problems since it has its vulnerabilities and lacks trust and data integrity. The centralized architectures are very likely an enemy point of attack as they become the most vulnerable to targeted assaults [5]. The other thing is that they often lack transparency, and they may face difficulties in the process of scaling and quick adaptation. In that the VIoT network becomes wider, these difficulties are made more visible and, therefore, different methods are required [6]. The extensive and mutually related nature of VIoT networks is the last but not least difficult part of the safety and reliability concerns [7]. Communication among vehicles and infrastructure must be end-to-end and reliable to allow smooth operations and avoid disruptions. Such a security level will demand

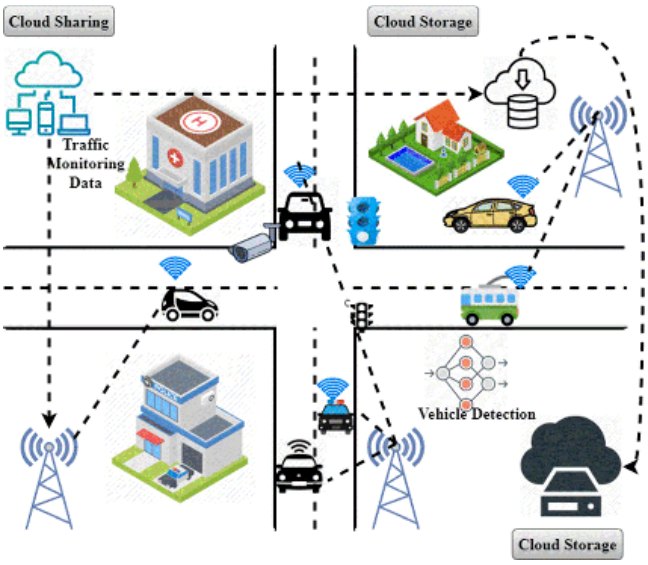

Fig. 1.1: Basic Structure of VIoT

the most advanced solutions that can adapt to the growing rate of emerging threats and that would maintain the desired stability and effectiveness of the VIoT ecosystem [8]. Decentralized solutions, which is one of the solutions mentioned in the research, are promising in addressing the challenges in IoT networks and enhancing VIoT network security and resilience.

The security of VIoT networks is an issue that affects every sector of the economy. Utilizing a range of services is essential for data security. For instance, Blockchain [9] systems should now provide user identity, personal content access, data integrity safety, and essential permissions. Due to its decentralized structure, blockchain ensures information availability, develops management systems, and avoids the need for guide participation or complex encryption methods [10].

Given the limitations of centralized Public Key Infrastructures (PKIs), solutions based on blockchain have evolved to enhance security and mutual authentication between cars and Roadside Units (RSUs) [11]. Various approaches handle various elements of safeguarding communications in automobiles. For example, there are security credential management systems and green revocation notice sharing. The most notable of them is the inefficiency of block mining [12], which isn't always suitable for low-latency situations.

Figure 1.1 reveals the basic architecture of the VIoT where connected vehicles, as well as road-side units (RSUs) and cloud servers, work together to develop connected and smart transportation systems. The vehicles in the VIoT system have different sensors, communication modules, and computational abilities fitted in. They can then communicate the data collected with other vehicles, infrastructure and servers in the cloud. These vehicles send and receive data to each other and to RSUs, which are placed along roads to serve as communication stations and enable data exchange. RSUs are the main elements that constitute the VIoT network, which facilitate data transmission between vehicles and cloud servers or a centralized system. Besides taking care of traffic control and safety communications, which are quite important, the system could alert the driver about a possible hazard or congestion on the road ahead. Moreover, the cloud servers act as the centralized data management and processing facility where the data is analyzed to produce insights and optimization of the transportation systems.

Our proposed research would address the issue of mutual authentication in a dynamic context by using the VIoT [8]. By eliminating the need for RSUs, or roadside units, our solution aims to completely revamp the conventional centralized authentication method that has long been used to facilitate communication between vehicles and trusted authorities. Because trusted authorities have limited communication and processing resources, centralized authentication techniques have trouble executing timely mutual authentication in fast-paced vehicu-

lar environments when several automobiles are seeking authentication simultaneously. As a countermeasure, we suggest a shift in thinking towards a VIoT multi-trusted authority network that is consistent with blockchain's decentralized nature [13]. The decentralized blockchain architecture is an excellent fit for the issues around VIoT 's cross-trusted authority authentication [14]. Utilizing blockchain technology, our solution constructs a distributed ledger that securely updates all reliable authorities on vehicle-specific data. Doing so will ensure the integrity and security of the data stored in the ledger. Offloading computation to RSU servers makes the proposed method more robust by reducing reliance on a single source or vehicle.

We built our framework mainly to fill a need in the market for physical layer device-specific blockchain security solutions [15]. Because blockchain security is so resource-intensive, it is usually left to devices above the edge layer that have more processing capacity, while devices below the edge layer depend on generic security solutions. To overcome the resource constraints of conventional blockchain deployments, our study proposes a lightweight security [16] model optimized for mobile IoT devices, intending to fill this need.

This research will be aimed at improving cybersecurity and data integrity through a new MARL blockchain protocol for the VIoT. This method aims to address some of the issues and limitations associated with a centralized VIoT architecture by proposing a distributed architecture that can improve dependability, openness, and fault tolerance. The study is aimed at developing a safe communication channel that allows only authorized vehicles, infrastructures, and cloud services to share information safely and protect against data theft and data corruption by unauthorized individuals. The study on enhancing cybersecurity in VIoT using a MARL blockchain framework makes several key contributions:

- The research is aimed at bringing together the application of blockchain and MARL techniques within the context of VIoT networks. Through implementing this synergy, the cybersecurity challenges of the VioT system will be solved in a one-of-a-kind way to improve the system's effectiveness and security.
- The architecture uses blockchain technology implemented to establish a decentralized VIoT network that minimizes the vulnerability to the central system from malicious actors and builds trust and transparency through immutable and transparent transaction records.
- There will be a demonstration of the implementation of smart contracts and Vehicle Units (VUs) into the proposed architecture. That way, the system will have secured and effective data computing and communication through VIoT. Smart contracts are implemented to automate agreements and transactions. VUs are in charge of interference-free data communication between infrastructure and vehicles.
- The research proposes lightweight cryptographic methods in conjunction with game theory-based strategies to provide and enhance the security of VIoT systems. These methods therefore guarantee the security against eavesdropping while at the same time minimizing resource consumption.
- The research is conducted by identifying difficulties in safe and secure communication among vehicles and infrastructure thereby making the VIoT network safer and more reliable. This becomes a necessary factor to consider when developing and dealing with the scale and complexity of VIoT systems.

The rest of the paper is organized as follows: The literature review is presented in Section 2. The proposed MARL blockchain framework is presented in section 3. The experimental results are presented in section 4. Section 5 presents a discussion of the findings, practical implications, and limitations of this study. Section 6 presents the overall summary and key findings and it concludes with some areas of future research.

2. Literature Survey. The VIoT expands the application of the IoT by connecting vehicles, infrastructure and the cloud to allow for communications and data exchange among themselves [8]. Research on VIoT often specifically discusses applications like traffic management, driver assistance, predictive maintenance, and autonomous vehicles, all of which are heavily dependent on the security of data transmission and data exchange [9-10]. Research has shown that VIoT can improve the safety of vehicles, and traffic efficiency, and reduce the emission of pollutants, but these things also come with cybersecurity risks.

The safety challenges of VIoT come from the centralized architecture which can cause, among other risks, a single point of failure, cyberattack susceptibility and trust issues. Through the complex and multi-layered architecture of VIoT networks, the risk of unauthorized access, data leak and privacy abuses increases dramatically [11-14]. For illustration, it is still a crucial issue regarding the safety and reliable communication between cars and traffic facilities since VIoT is a vast and dynamic network. Within a decentralized management approach,

Table 2.1: Comparison of the existing literature and their key contributions and Limitations

Ref.	Methodology	Key Contributions	Limitations
[23]	Blockchain-enabled batch authentication for VIoT	Dynamic clusters, Fog & Cloud integration	High computational overhead, dependency on fog and cloud.
[24]	RSU-assisted authentication and key agreement	Authentication Efficiency	Dependency on RSUs, scalability challenges
[25]	Blockchain-based security for RFID-enabled VIoT	ECC-enabled RFID authentication, Security Needs	Complexity in ECC implementation, increased computational demands
[26]	Cryptographic VIoT-based mutual authentication	Lightweight, Low Computing Power	Reduced security simplicity, vulnerability to certain attacks
[27]	Privacy preservation for V2V and V2I	Conditional privacy, Mutual authentication	Overhead in subdomains, reliance on Certificate Revocation Lists
[28]	Authentication for VANETs based on semi-trusted authority	Certificateless signature, Efficiency	Limited trust in semi-trusted authority, scalability challenges
[29]	RSU-based secure authentication for VANETs	The tamper-proof device, Feasibility, Communication Speed	Single point of failure with tamper-proof device, RSU dependency

blockchain technology offers a method of data storage and transaction verification to increase the trust and transparency of networks between VIoT. The results of the research show that it is possible to use blockchain for trusted data management, authentication and privacy for VIoT systems [15]. The investigation proved that recording by smart contracts which are parts of the blockchain will do the automatic and safe execution of transactions within the V2V and V2I communication within the VIoT networks [16].

Two crucial problems of group and pseudonymous signature-based authentication for VANETs are certificate distributions and revocation lists. Semi-trusted authority-based authentication method [17] is the proposed solution to this problem. Removing the need for vehicles to maintain and verify Certificate Revocation Lists (CRLs) eventually improves the authentication speed while simultaneously reducing the costs related to communication and storage.

In addition to this, RSAU-based authentication makes use of RSUs to store the Trusted Authority's (TA) master key which permits fast and secure communication with TA [18]. The authors claim that their solution is new by emphasizing how functional and useful the presented authentication method is in VANETs.

In the context of MANETs, the major focus of [19] was to identify and avoid black hole attacks on the AODV and AOMDV routing protocols. By integrating the SHA-3 and Diffie-Hellman algorithms, they proposed a way to detect black hole assaults and then compared the two protocols' performance under these conditions using metrics like Average End-to-End Delay, Normalized Routing Load, and Average Throughput.

Combined with an energy-efficient clustering approach with a Particle Swarm Optimization (PSO) algorithm, [20] addressed the problems of cluster head selection and sink mobility in MANETs (PSO-ECSM). Our solution outperformed the competition in terms of stability period, network durability, throughput, and energy efficiency, according to the simulation findings [21] [22]. Table 1 shows the Existing Methodology Comparison.

Table 2.1 depicts the differences in existing research on VIoT security. It also presents the main achievements and drawbacks of each approach. The authors of the study [23] look into a blockchain-based IoT-enabled batch authentication for VIoT which overlays the dynamic clusters with fog and cloud computing. This type of approach, although, it facilitates large-scale data processing and security, is still resource-intensive and uses fog and cloud infrastructures. In another study [24], the authors were about RSU-assisted authentication and key agreement which is thought to be more effective. Nevertheless, these methods above encounter the problems of RSU dependency and scalability when the network expands. The authors of the study [25] investigate blockchain security for the RFID-enabled VIoT with ECC-enabled RFID authentication, a solution to the security concern. However, the additional complexities of the ECC implementation and a higher computational load represent the key challenges. The study [26] is a cryptographic VIoT-based mutual authentication method by which the devices can communicate with each other even in low-power settings. However, this may affect the

simplicity of security and certain types of attacks may be possible. The authors of [27] study the privacy of V2V and V2I communication by using the V2V and V2I technologies. This method, then, is based on conditional privacy and mutual authentication but it causes the overhead due to the management of subdomains together with the reliance on CRLs. The [28] presents the authentication for VANET via a semi-trusted authority that uses certificateless signatures and provides efficiency. But on the other side, the semi-trusted authority's lack of trust and scalability problems pose several difficulties. In another study [29], the authors considered RSU-based secure authentication for VANETs and emphasized the high tamper-proof devices, operability and communication speed. On the other hand, there are instances of single-point faults in tamper-proof devices and the reliance on RSUs for non-tamper-proof devices. However, these studies give a good understanding of different methods for highly improved VIoT security, but each method also has some specific obstacles like specific technology reliance or complex scalability issues.

To pick appropriate active miners and transactions, a deep reinforcement learning (DRL) enabled method is suggested in the study [31] to optimize the security and decrease the latency of blockchain. Next, in order to ensure the freshness of messages, a two-sided matching-based approach is put forth to distribute the nonorthogonal multiple access subchannels and minimize the maximum uploading latency of all users. This system's efficiency is proven by extensive testing findings. Ultimately, system analysis shows that our system is capable of safeguarding user privacy, ensuring data integrity and security, and fending off frequent assaults.

In a similar study [32], a Blockchain-enabled Deep Reinforcement Learning (DRL) spatial crowdsourcing system (DB-SCS) was proposed. The authors designed a blockchain-based hierarchical task management method and an improved multi-blockchain structure for DB-SCS. The method divides spatial tasks into different categories based on task areas and privacy requirements. Different task categories are then further broken down into sub-blockchains. By dynamically selecting the block size, block generation rule, and consensus method based on the suggested DRL-based management approach, DB-SCS may improve the spatial crowdsourcing performance while maintaining data privacy.

The study [33] provides an optimal solution via a fusion of many approaches integrating blockchain-based technologies for a variety of security and reliability issues in UAV-enabled IoT applications. A variety of metrics, including total system utility, accuracy, latency, and processing time, are measured and compared in the findings. The outcomes of the suggested technique show the progress and provide fresh ideas for further research.

The authors of [34] described a decentralized and effective communication structure that enables scalable and reliable information allocation and greater performance than previous solutions by merging DRL and Blockchain across the Internet of Things. To increase performance by up to 87.5%, the DRL technique determines which services to dump and whether to unload.

The research [35] uses the fuzzy adversarial Q-stochastic model (FAQS) to assess potentially hazardous activities and the smart grid integrated cloud computing model to monitor and send data from electric cars. Data is encrypted and decrypted depending on the types of users who have the appropriate access rights towards authorized and unauthorized users in line with their duties as described by role-based access control regulations. They experimentally investigate the security rate, root mean square error (RMSE), quality of service, scalability, and energy efficiency of many cyber security data sets.

In order to safeguard private data in gradient detection, the publication [36] presents the IoV-BDSS, a revolutionary data-sharing system that combines blockchain and hybrid privacy technologies. In this research, the similarity between cars and gradients is filtered using Euclidean distance, and the filtered gradients are then encrypted via secret sharing. Additionally, this article assesses the reliability and contribution of participating nodes, adding to the security of high-quality models stored on the blockchain.

2.1. Research Gaps. There exist certain gaps that are restricting the growth and security of intelligent transport systems. To begin with, most of the ongoing studies still use centralized architectures, the key problem with them being the single points of failure and security vulnerabilities. Although the decentralization of solutions via blockchain has been considered, there is still no general framework that integrates blockchain with other more advanced technologies. However, many of the research studies have a narrow scope, which focuses on individual security problems, such as blockchain-based authentication or MARL for decision-making, but a comprehensive approach is required to address the multifaced challenges of VIoT systems. For instance,

challenges such as making sure reliable data processing is in real-time, and at the same time making sure the system is secure and scaled as well as efficient remain a big task. Moreover, the absence of common practices for using smart contracts in VIoT and for securing data flows from one node to another hinders the development of widespread blockchain-based solutions.

This study intends to enrich the literature by creating a unified structure that brings blockchain into the picture, and then integrates multi-agent reinforcement learning, to improve cybersecurity in VIoT networks. This research is innovative as it brings together the advantages of blockchain's decentralized ledger with the flexibility and adaptability of MARL and suggests new solutions to the problems that are still in existence in the field of a secure, efficient and stable VIoT environment. The proposed system uses blockchain technology to keep data anonymous, unalterable and safe by using the network's immutability, transparency, and consensus mechanisms. Furthermore, MARL agents can lead to the development of the best decision-making strategies that will improve decision-making processes and guarantee the secrecy of communication within VIoT systems as time passes by. In addition, this research will investigate the deployment of lightweight cryptography methods together with game theory-based techniques to provide more security and resilience. This research accomplishes this by offering a complete integrated end-to-end secure transmission, processing, and communication solution that builds a stronger and more secure infrastructure.

3. Materials and Methods. The study adopts a whole system approach to leverage cybersecurity in the VIoT ecosystem by combining blockchain technology with the MARL framework. Besides decentralized data management, the blockchain also provides a method of verification of transactions, which encourages trust and transparency in VIoT networks as well as security and immutability. Through the use of game theory and MARL models collaborative interaction ecosystem strategy is being simplified thereby promoting appropriate decision-making and efficient communication. Blockchain technology which is a part of the proposed VIoT architecture is used to increase security, transparency and decentralization via protected communication protocols, smart contracts and various nodes for data processing and control. Communication security and data integrity are met by the lightweight crypto algorithms, but performance optimization aims at decreasing overhead expenses and improving efficiency. Applying game theory along with blockchain technology and MARL, the study tries to attain the highest utility and reward while building a highly-secure, resource-efficient, and resilient VIoT network. This end-to-end concept of VIoT bridges these gaps in the field of VIoT and it is aimed to upgrade the performance and security of the connected transportation systems. A detailed description of the proposed system is presented in the subsequent sections.

3.1. Blockchain Basics for VIoT . The blockchain era is important for the protection of the VIoT as it ensures the decentralization, integrity, and honesty of records exchanges. Blockchain tracks transactions over a community of nodes and is primarily based on distributed ledger generation (DLT) [30]. All of the transactions are included in blocks that are linked together in a sequence. Each block is guaranteed to be immutable through the cryptographic hash feature, which generates a unique and irreversible identification from its contents.

Consensus mechanisms are the ways that blockchain networks use to ensure that all the nodes which are distributed agree on the state of the ledger and the legitimacy of the transactions. The main tools include Proof-of-Work (PoW) which verifies the transactions by solving complex puzzles which is, on the one hand, considered a security mechanism, but on the other, is resource-intensive; Proof-of-Stake (PoS) which is based on the stake in the cryptocurrency and which is more energy-efficient; and Delegated Proof-of-Stake (PBFT, Practical Byzantine Fault Tolerance, is a solution that meets the needs of permissioned blockchains by concentrating on Byzantine faults tolerances. Other approaches like Proof of Authority (PoA), Proof of History (PoH), and Proof of Space and Time (PoST), have their unique mechanism to reach consensus. The kind of mechanism is determined by the blockchain goals, for instance, scalability, security, decentralization, and energy efficiency. The consensus algorithm, described mathematically as Consensus, assesses transactions and obtains settlement across the community.

$$Consensus(B_i) = PoW(B_i) \tag{3.1}$$

By eliminating any potential central authority, the decentralized approach fortifies the loV ecosystem. Blockchain technology guarantees the security of data transfers in loV and creates trust among participants by establish-

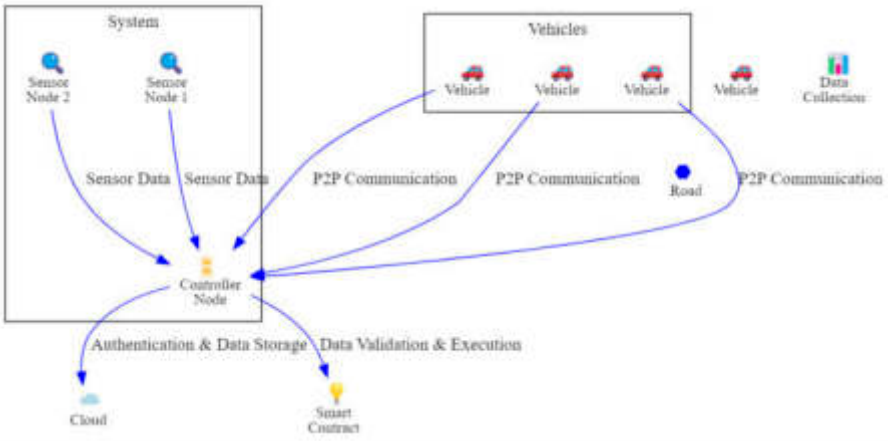

Fig. 3.1: Proposed Framework with Data Collection

ing an immutable and transparent record of transactions. With this background information, we can include advanced security measures in the loV design.

3.2. Proposed Vehicular Internet of Things with Blockchain. To improve the safety, openness, and reliability of vehicle networks, the suggested VIoT architecture incorporates blockchain technology. Vehicles in this paradigm communicate with one another and with the networks that enable blockchain technology. There is transparent and uniform documentation of all transactions, including the sharing of basic information and requests for verification. This openness improves safety and aids in tracking and holding responsible parties to account for vital parts of vehicle communication. To summarize, the suggested car internet system is made more safe, transparent, and decentralized by using blockchain technology.

As shown in Figure 3.1, the suggested architecture incorporates critical components necessary for the system's operation and safety into a thorough network setup.

- Sensor Data: In a VIoT ecosystem, vehicles like buses, cabs, and cars are embedded with various sensors that gather data from their surroundings, and internal systems, and surroundings, then transmit the data. This data can be various such as location, speed, temperature, and other sensor readings. Such vehicles apply encryption techniques as well as private and public keys for secure communication, which is what makes sure that shared network data is protected from any unauthorized changes or access. Through the ongoing process of sharing and collecting information, these smart cars play a crucial part in creating instantaneous traffic monitoring, safety, and other data, which can be used to make the transportation system more effective and safe.
- Smart Contracts: A smart contract is a self-executing code that can automatically ensure the agreement between the parties within the network by itself. They are considered as the part of the VIoT system due to the possibility to establish the connection between the road nodes and infrastructure without the intermediaries. Smart contracts are the way that facilitates the data sharing of a secure form and the execution of automatic transactions. They help increase the efficiency and reliability of the VIoT network by creating a channel for trusted and transparent execution of electronic agreements.
- Vehicle Units: VUs are positioned along the roads to ensure that vehicles are connected wirelessly to each other as well as to the infrastructure. They can perform the functions of a CH blockchain zone and an area that hosts blockchain and smart contracts. VUs play a vital role in the VIoT network in terms of collecting data and providing communication among different network nodes. They thus act as communication channels for the network vehicles and support V2I and V2V communications as well as other applications of VIoT.
- Nodes Responsible for Mining: These nodes take the role of the traffic supervisors inside the cars and the road-side units (RSUs). They process data including sensor readings and traffic information to

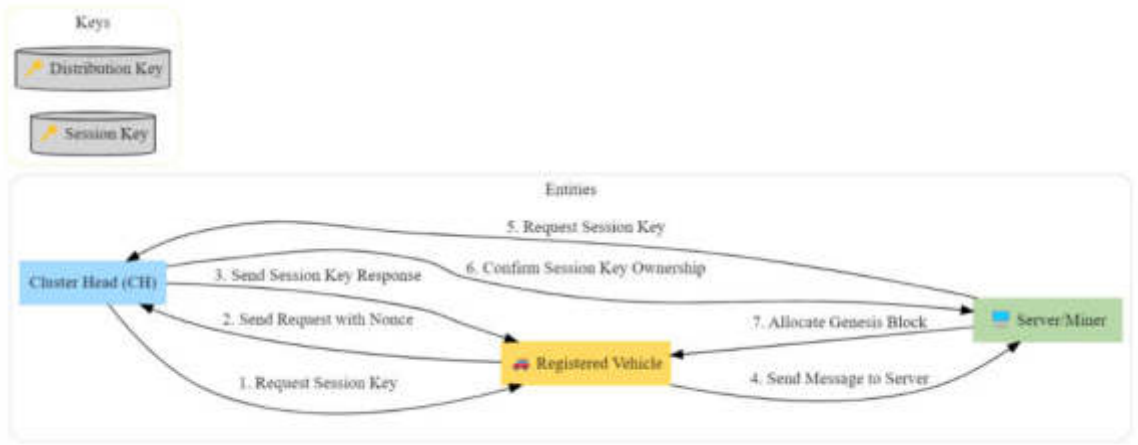

Fig. 3.2: Working on Vehicle Communication with secured Access

provide many services including weather alerts and traffic congestion. This can also happen to the nodes when they are out of storage space as they continue to collect and process data, therefore, they have to connect to the decentralized servers to get access to the appropriate information. These nodes own the responsibility of managing the data mining and storing processes and thereby, upkeep the efficiency and integrity of the VIoT network.

- Nodes Acting as Controllers: This way, controller nodes are spread out across the VIoT network to manage the different services such as transportation, traffic management or charging stations. They use the cloud and the main blockchain to store raw data and by consensus-building establish a unified set of rules for creating new blocks. The nodes serve as intermediaries, and they help miners and CHs apply their location data to achieve their objective of functioning and operating effectively within the network.
- Configuring Decentralized Servers: Decentralized servers are built with special interfaces to the network of blockchain and other services like controllers and miners. They are the backbone of the Genesis block, which is the foundational block being used by all the nodes in the network. These nodes are the network backbone that allows for high-performance networking and storage. They, in addition, provide the network with the capacity to be resilient and scalable by supplying various applications and services within the ecosystem.

In the proposed layout, there are two stories. In the current network, the first tier is responsible for authorizing and authenticating vehicle registrations. The second layer operates on a decentralized basis when the vehicle registration is successful. Because it provides secure and energy-efficient solutions, edge computing is vital for cryptography. Devices can generate long-lasting session keys with little resources. To address the difficulties of mobility and bandwidth limitations, a lightweight cryptographic method based on symmetric keys is suggested for secure communications.

Registered vehicles and servers are the entities that send and receive communication requests, as seen in Figure 3.2. The distribution key and the session key are their respective public and private keys. Session keys can only be obtained by approved companies that can verify key ownership. This ensures a robust and secure communication environment inside the VIoT network.

During registration, a vehicle talks to a CH to acquire its session key. Before updating the distribution key of newly generated entities, the CH must make sure that the public keys of those vehicles are not changed. This will prevent any chance of unlawful access. The secret, permanently locked key should only be accessible to the CH and the new automobile.

After a person successfully registers, the CH stores their information in its local storage. Several methods meet the data security requirements for entity registration, allowing authorized vehicles to swiftly connect new

devices to the CH and vice versa.

Before any subsequent transactions may take place, the CH will distribute the session keys. A vehicle can prove its identification and get authorization to operate without continually connecting to the CH thanks to its mobility. One distribution key that works well with TCP/IP is used for session key distribution. The CH will send a "HELLO" packet containing the necessary data, such as the vehicle's ID and a nonce it has generated when it establishes a connection with a car. In requesting the session key, the receiver then communicates the intended communication objective and the specific keys required for the transaction.

Algorithm 2 Vehicle Authorization and Registration (VehReg)

1. Function VEHREG
2. // Get a list of nodes (communication channels) from the Certification Authority (CH)
3. // Get vehicle ID, session key request ID, challenge nonce from CH, and distributor key
4. if the distributor key is valid (== 1) then
5. // Get nonce, session key from CH
6. else
7. // Get nonce, session key from registered vehicle
8. // Get public keys of CH and vehicle
9. // Set session key and registration flag for this vehicle in CH
10. // Search for communication request ID, session key ID, and challenge nonce
11. // Get nonce, session keys from registered vehicle
12. if the communication request ID is valid (== 1) then
13. // Set communication flag to true
14. else
15. // Set communication flag to false
16. // Return communication flag
17. end function

Algorithm 2 describes the procedure of giving the right to and registering a vehicle to the system (VehReg). The algorithm begins by declaring a function: VehReg(). The car gets such a list of channels from the central authority to be called CH in the beginning. These channels are channels for safe communication within the system. Next, the vehicle obtains critical information from the CH: besides, the respective ID of the applicant, a secret key number (nonce) which is unique, and a key may be distributed by the CH. The algorithm then checks (should the distributor key exist) its validity. If valid, it directly gets the session key and a nonce number (random) from CH. If the car's distributor key is not valid, the vehicle acquires the session key and nonce from a previously saved car, which indicates a backup or a relay mechanism. Whether the key retrieval method is through OBU (On-board Unit) or TCU (Telematics Control Unit), the public keys for both the CH and the vehicle are acquired. The CH in the meanwhile will set a session key and a registration flag inside its system for that vehicle. Finally, the algorithm seems to be using a communication request ID, a session key ID and the challenge nonce it obtained during its first contact. It retrieves the session key from a registered vehicle saved in a database (probably the one used after step 5). Based on the validity of the communication request ID, the algorithm sets a communication flag: set to be true if the request is valid, and false otherwise. After the algorithm is done, it returns the value of this communication flag as a result. This algorithm is essentially designed in a way that allows a vehicle to be registered with the system, set up secure communication channels and even verify the authenticity of communication requests.

To protect against replay attacks, the session key request includes the nonce and the name of the vehicle. As a further step, the CH will send a response to the receiver that contains the session key, nonce, and distribution key. Then, the car adds the recipient's public key to the encryption request and uses its private key to sign the nonce and distribution key, ensuring their authenticity.

At every stage, the CH uses the public key of the receiver to confirm the signature. Once the CH has verified the signature and nonce, they will validate the request. As a result, the public key of the receiver and the distribution key will be sent. To ensure that only allowed users may connect to the protected session, the registered vehicle communicates with the server. To avoid the recurrence of assaults, each party employs a unique nonce. After the registered vehicle verifies its identity and establishes a connection with the server using

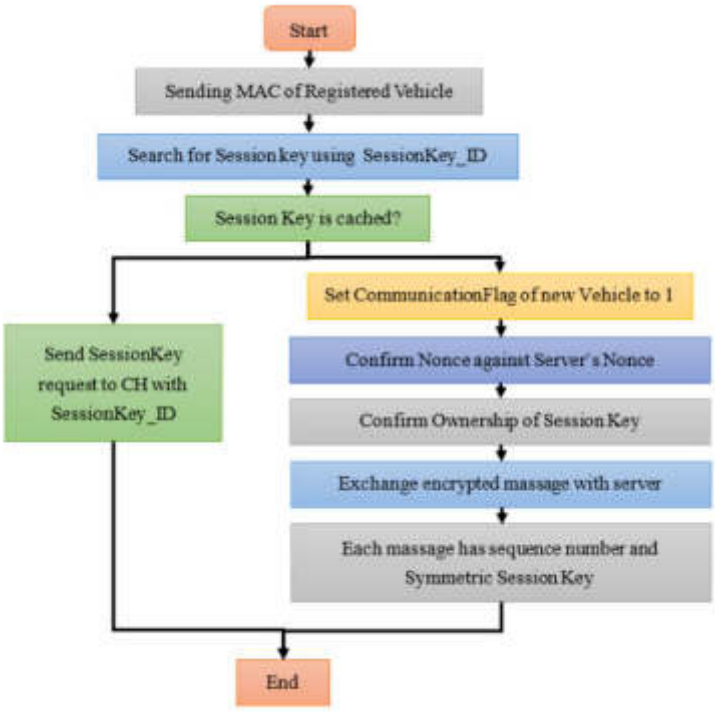

Fig. 3.3: Flowchart of vehicle authorization and registration within a system

the Session Key ID, the two parties establish communication.

Figure 3.3 shows a flow chart of the vehicle authorization and registration within a system. The process begins with the registered vehicle sending its MAC address, which is unique to the vehicle. Subsequently, the system looks for the session key based on the SessionKey ID required for the session key exchange to secure the connection. To maintain the confidentiality and authenticity of the interaction, a nonce – a random number generated for a single use – is transmitted from the vehicle to the server and back, and the server verifies the nonce. After this, the vehicle and the server continue sending encrypted messages to each other, probably, containing necessary information, which is required for the authorization and registration of the vehicle. These messages include the session key and a symmetric sequence number, and the session key helps in the secure communication while the sequence number is used to ensure that the messages are received in the correct order. The detailed process of the safe authentication and registration of the car, with an emphasis on the important elements like session keys and nonces that guarantee the security of the communication within the system.

The registered vehicle's P2P network confirms session key ownership by sending the Communication Flag and the server's nonce. Subsequently, the server will provide this freshly registered vehicle with a genesis block, enabling it to engage in autonomous, decentralized, peer-to-peer interactions with other registered vehicles.

After the connection is established, the registered car and the server may send encrypted messages. The distinct symmetric session key and sequence number assigned to each message ensure secure and well-organized communication.

Algorithm 3 helps to identify the next node in a given sequence in a specific arrangement, probably a directed graph. The function to handle the particular case is named "FindSuccessor" which accepts an identifier (ID) as an argument. This ID could, therefore, be a certain node in the system. The role is to generate and return a value called "successor", which will hold the ID of the current node. The algorithm does that by checking if the input ID conforms to the provided pattern. This is a scheme which has several nodes $(v_1, v_2, ..., v_n)$ coupled

Algorithm 3 Check Successor (FindSuccessor)

1. function FINDsuccessor(ID)
2. output: successor
3. if ID ∈ (v_1, successor) then
4. return successor
5. else if ID ∈ (v_2, successor) then
6. return successor
7. ...
8. else if ID ∈ (v_n, successor) then
9. return successor
10. else
11. return nil
12. end if
13. end function

with a successor node. It can be said that the iterations take a list and compare it with the input (ID) that is composed of the given nodes $(v_1, v_2, ..., v_n)$. If the sign is yes, it shows that the input node is in the list. With a positive match, the search algorithm can stop there and save valuable resources. It only outputs the "successor" value of the list item (v) chosen by the user. This "succeeding" value represents the next node in line after the input node, which is ID. Nevertheless, if the given ID isn't among the nodes $(v_1, v_2, ..., v_n)$ in the list of them, the algorithm goes to the "else" statement. Here, the program determines that the value of ID has no successor in the specified range. It finally comes to a stop and returns a special value denoted as "nil" (or null), which marks the absence of any coming node in the list. Herewith, the algorithm provides a mechanism that functionally searches for the next node (successor) utilizing the previous node (ID) in the system. It will give the successor ID if it is found, or otherwise indicates that there is no match if there is no successor.

For the proposed strategy to work, cutting overall operating costs is essential. Let us pretend for a moment that "r" is a fleet of cars, all of which are carrying out various applications that rely on blockchain protocols.

$$E_(a, v)(t) = \sum v = 1^{|a|}(E_{ECC}(t) + E_T(t) + E_B(t))_v \tag{3.2}$$

where

$$E_T(t) = h(\sum m = 1^n(E_r \cdot R)) \tag{3.3}$$

and

$$E_B(t) = h(E_C \cdot N_r) \tag{3.4}$$

To keep things simple in the study, we will assume that stabilisation follows a Poisson process. Three distinct Poisson processes have coexisted throughout history. The given vehicle's departure rate is represented as (R):

$$R^2 = R/V \tag{3.5}$$

The stability of a name table entry (S), an important factor in game theory and reinforcement learning, determines the vehicle departure rate in the system. In our case, there are a total of three klog(N) vehicles that each stabilization cycle targets, either an item in the name table or one in its successor list. Usually, there are O name table entries in every stabilization operation, which stand for the average search path length. Equation (3.6) describes the effect of stabilization on the name table, where S is the rate at which vehicles leave during stabilization and O is the mean length of the lookup route. Each vehicle begins stabilization around 30 times per second, as shown by Equation (3.6), hence this connection is crucial.

$$S = 1over30 \cdot \frac{L}{(3 \log N)} \tag{3.6}$$

Despite there being $N \log N$ items in the name table overall, each search typically uses$L$ entries. According to the Poisson distribution, Equation (3.7) represents the utilisation rate of a name table entry, N_r.

$$N_r = \frac{L}{N \log N} \tag{3.7}$$

Three successive Poisson processes—looking up, departing, and stabilizing—make up the whole. The likelihood of a vehicle seeing an occurrence, such as a departure, as a chance series of occurrences with a certain probability D is shown in Equation (3.8).

$$D = \frac{R^2}{(N_r + S + R^2)} \tag{3.8}$$

Equation (3.8) may be used to assess the resultant expression in Equation (3.9) by replacing the expressions from Equations (3.4-3.7):

$$D = \frac{\pi}{N} \cdot \left(\frac{L}{N \ logN} + \frac{L}{90 \log N} + \frac{R}{N} \right) = \frac{R}{\frac{L}{logN} + \frac{L \log N}{logN} + \frac{R}{N}} \tag{3.9}$$

Any occurrence that happens just before a loop is seen as remarkable from a probability standpoint. With this foresight, the chance of a lookup hitting a timeout is introduced. Equation (3.10) gives the anticipated amount of lookup timeouts. (T_p).

$$T_p = L \cdot D = \frac{L \cdot R}{L} \tag{3.10}$$

Lookup Rate (R_l):

$$R_l = \frac{1}{AverageLookupTime} \tag{3.11}$$

From lookups inside the system succeed is represented by the lookup rate. Stability Time on Average ($T_{stabilize}$):

$$T_{stabilize} = \frac{1}{S} \tag{3.12}$$

The average stabilization time is the reciprocal of the rate at which cars depart during stabilization. Average Departure Interval ($D_{interval}$):

$$D_{interval} = \frac{1}{D} \tag{3.13}$$

The average departure interval is the reciprocal of the probability of an event representing a departure. Vehicle Arrival Rate (R_a):

$$R_a = \frac{1}{D_{interval}} \tag{3.14}$$

The arrival rate of cars is a measure of how often they enter the system.

Taken together, Figure 3.4 Transaction approval and verification are handled differently on the branching blockchain compared to Bitcoin. It records the transaction and transmits only the chunks to the network instead of sending the complete block to the destination, making the transactions lighter. The endpoint will contact a peer-to-peer network to request approval just before a transaction is about to finish. Only when the network offers its permission is a transaction deemed verified. The branching blockchain will indicate the transaction as verified once it is greenlit.

The structure of blockchain in the Bitcoin network employs linear forms and Proof of Work (PoW) for transaction approval and verification. The miners race each other to resolve mathematical problems to validate

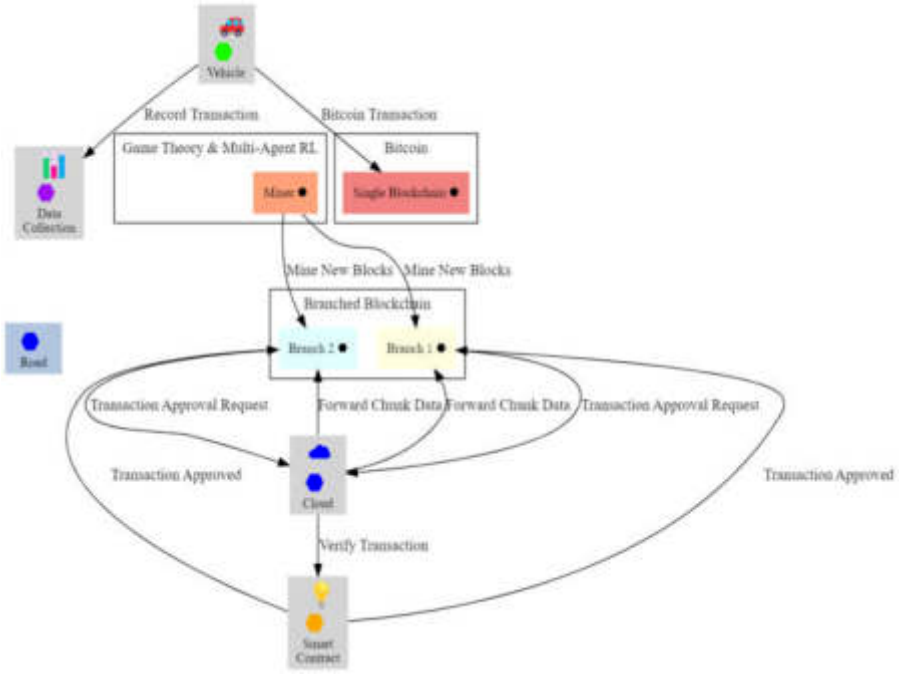

Fig. 3.4: Blockchain-Based VIoT

transactions and extend the chain; the longest chain is considered the true one. Instead of a PoW, the branching blockchain employs different consensus algorithms, such as the Proof of Stake (PoS) that is aimed at efficiency and scalability. The other variant of blockchain is the kind, which permits the existence of side chains, smart contracts, and customization, through which the blockchain network can achieve decentralization and flexibility in the approval and verification processes. Linear and standardized blockchains like Bitcoin may be somewhat limited in scalability and flexibility, whereas branching chains can provide greater scalability and tailor-made applications.

The VIoT Smart Contract is shown in Figure 3.5. In game theory, a strategic form game may be used to describe the interaction between actors. The collection of strategies for agent is denoted by s_i, while the utility function for agent i, given their selected strategy y, is denoted by $U_i(s)$. An example of a common utility equation may be:

$$U_i(s) = f(s_i, s_{-i}) \tag{3.15}$$

where s_i is the strategy chosen by agent i and $s_(- i)$ is the vector of strategies chosen by all other agents. Each agent in Reinforcement Learning learns a strategy $_i$ that maximises some concept of cumulative reward by mapping observations to actions.

This is one way to describe the Q-function, which stands for the anticipated cumulative payoff for action a in state y and policy π_i:

$$Q_i(s,a) = E_{(i)}\left[\sum_{t=0}^{\infty} \gamma^t R_i(s_t, a_t) s_0 = s, a_0 = a\right] \tag{3.16}$$

where $R_i(s_t, a_t)$ is the immediate reward, γ is the discount factor, and the expectation is taken over trajectories generated by the policy.

In a blockchain setting, participants might be rewarded with tokens for successful mining or validating transactions. Let R_i represent the reward for agent i. The total reward for agent i in a given time step can be

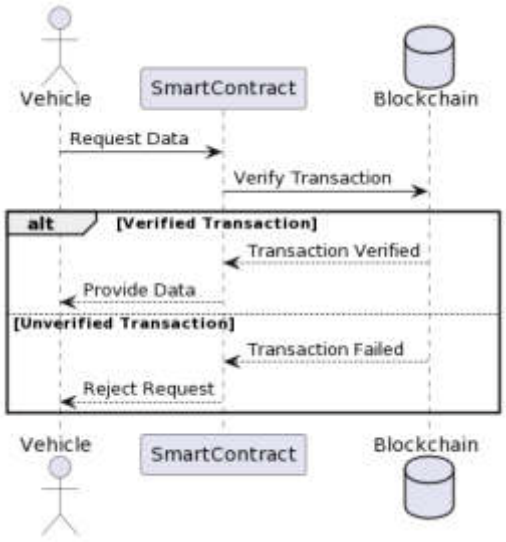

Fig. 3.5: Smart Contract in VIoT

represented as:

$$R_i = MiningReward + TransactionRewards \tag{3.17}$$

in where Mining Reward is the payoff for creating a new block via mining, and Transaction Rewards is the total payoff for verifying transactions. The overarching goal for every agent might be to maximize utility via interactions based on game theory and cumulative rewards through reinforcement learning.

$$Objective_i = U_i(s) + Q_i(s, a) + R_i \tag{3.18}$$

Over time, agents strive to maximize this composite goal function by optimizing their tactics, policies, and actions. As V completes more approval duties, they will be able to get more. As a result, miners can verify transactions and create new blocks.

Every vehicle in the network has a reliability factor that guarantees the data they gather is secure. The design of Bitcoin's decentralized network is based on one blockchain technology. Nevertheless, distinct branches have been created for every node in the branched blockchain. Every vehicle in the network has a reliability factor that guarantees the data they gather is secure. The decentralized network architecture of Bitcoin is based on one blockchain technology. On the other hand, every node in the branched blockchain now has its distinct branch. Connecting the active blocks of all branches to a central blockchain is the goal of the suggested system, which also seeks to monitor the inactive blocks.

3.3. Game Theory with Multi-Agent Reinforcement Learning Framework. The use of the Game Theory with MARL as a tool for modelling and improving the decision-making capabilities of the VIoT environment becomes a powerful weapon. This joint game theory and MARL framework is aimed at maximizing the efficiency of the interactions between entities, in particular vehicles, infrastructure and other network components, in a dynamically changing environment. Through the learning and adapting capabilities of the cyber framework, entities will be able to make strategic decisions. This in turn will help to improve cybersecurity and communication efficiency. Game theory is deployed to model the playing field, where actors which are vehicles, roadside units, and controllers, with their own goals and preferences act strategically. The utility function is about how the level of fulfilment or benefit is obtained by an entity as a result of a certain state or action, with entities trying to take the best utility whenever possible. The Nash Equilibrium concept is the determinant of entities' strategies which brings them to the best choices for the entities where no entity can improve its

outcomes unilaterally. Strategic decision-making is the heart of any entity's choice-making mechanism, where the entity chooses to act in a manner that is beneficial to itself, considering other entities' choices.

Through MARL, the entities on the VIoT network can develop and alter their behavioural patterns from various trial and error processes. Agents change their strategies according to the knowledge they have gained from the agents and environment through their interactions. Q-values signify the cumulative reward that an agent anticipates through its action in a particular state, and this information serves as the basis for the Q-learning update formula which helps the agents to revise these values based on new information and reinforcement. Policy optimization allows agents to pick actions that maximize the aggregated rewards over time, which is realized by only taking actions that give the highest rewards. The state space shown is an agent's status in the VIoT network at the moment, while the action space includes all the actions an agent can take. The incorporation of game theory and MARL (multi-agent reinforcement learning) facilitates entities to respond strategically and based on experiences learned, which maximizes the degree of cooperation and desired behaviours within the VIoT network. Agents try to reach the equilibrium point by reorganizing the strategies to get the most out of rewards, which is based on the Nash Equilibrium and the learning process of MARL, considering the actions and strategies of others. The combination of both public and private sectors allows secure and smooth communications over the network, as the organizations develop ways of incorporating and communicating effectively, thus reducing cyber threats and improving network performance.

The VIoT security paradigm, which stands for each player's options, profits a strategic factor from the software capabilities (U_i) located in a sport idea. The software function of agent i is represented through $U_i(S, A)$, which relies upon its kingdom S and motion A. This equation affords a concise precis of the agent's good judgment for deciding on VIoT community safety features. At the same time, sellers are given the ability to research and adjust their strategy via the MARL framework. Parts of this structure encompass the nation S, the movement M, the policy π, and the praise feature M. The expected cumulative reward for agent i doing movement E in state S is denoted by using the Q-fee, which is often utilized in MARL and is represented as, $Q_i(S, A)$.

$$Q_i(S, A) = (1 - \alpha)Q_i(S, A) + \alpha \cdot [R(S, A) + \gamma \cdot \max Q_i(S', A')] \tag{3.19}$$

Its primary role is to guide entities toward behaviours that facilitate secure communication. The idea of the Nash Equilibrium is used by entities to strategically choose communication acts. One way to represent the probability distribution of entity i selecting action M is as follows:

$$P_i(A) = \frac{e^{\beta \cdot U_i(S,A)}}{\sum_{A'} e^{\beta \cdot U_i(S,A')}} \tag{3.20}$$

where:

- β is the rationality parameter that influences the level of strategic thinking.
- $U_i(S, A)$ is the utility function capturing the preferences of entity i in state S taking action A.

As time goes on, entities in the MARL framework learn and modify the ways they communicate with one another. As entities adapt, their Q-values change in response to new information and positive reinforcement. This dynamic is reflected in the Q-learning update equation. Entities use $f \in\downarrow d$ communication tactics to maximize the predicted cumulative benefit.

Algorithm 4 presents the MARL with the Game Theory in Vehicles algorithm that is being proposed. The system will initialize a setting of the blockchain network and the Q-value (an estimate of future benefit from the actions), as well as the reward obtained by the vehicle. Individual Learning: The algorithm then enters a cycle where it concentrates on one vehicle and then switches to the other vehicles. Each car determines its present state and, based on the history of past choices (Q-values), decides an action applying an exploration strategy. This approach allows both proven good practice and uncharted actions with a chance to work too. Learning by Doing: The agent acts first, then observes the resulting situation and receives a reward proportionally to its success. The vehicle's Q-values are trained using a reinforcement learning technique, and the changes in the Q-values (previous situation, chosen action, new situation, and reward) reflect the gained experience. Sharing Knowledge: In this regard, the blockchain is the most relevant technology. Instead of the Q-value being a static element, the Q-value now becomes a transaction, carrying the knowledge of the vehicle as it progresses through

16. end function

its learning. This gives the vehicles the capability to do the same thing. Collective Wisdom: Then, it will be the turn of the algorithm to complete the blocks so that it can record new transactions on the blockchain. In these transactions, the system used is the one where each vehicle has the updated Q-value. These are the collective knowledge that will then be used to build a global Q-table which can be treated as a storage for the learnings of all vehicles. The Grand Plan: The algorithm, with the help of Q-table, calculates the joint policy, which is a collaborative strategy for all vehicles in the network. This strategy provides the basis for the future choice of a vehicle not only in one but also in all system interactions.

4. Experimental Results. This section provides an in-depth analysis of the proposed model. The setup of this comprehensive experimental environment is meant to comprehensively assess the performance, efficiency, and scalability of the VIoT architecture in various operational scenarios.

4.1. Experimental Setup. The prototype VIoT architecture would be modelled on a desktop PC with an Intel Core i5-3210M processor running at 2.5GHz and having 4 GB of DDR3 RAM on it. This arrangement permits the simulation of the VIoT network and the installed blockchain and MARL frameworks, respectively, which is a good performance-memory trade-off. Initial experiment stages involve authorization and registration of the new vehicles that include tests of the new registration process, issuing keys and identity verification. Registered vehicles share session keys with cluster leaders (CHs) to create a confidential area in which the privacy and security of sensors in the VIoT network will be guaranteed. In the second stage, the VIoT network is connected on the side chain of a Blockchain network that works as a decentralized data management and transaction verification platform. Chord protocol assists in the communication process among the blockchain networks by using DHT (Distributed Hash Table) which allows for operations such as data lookup and routing to be efficient. The registration process will be the next stage where customers will be able to choose from sample programs written in various programming languages and platforms, such as Java. These programs act as a means by which users can play with the network of VIoT, verify and authenticate their devices and secure communication channels. The proposed work's simulation parameters are shown in Table 4.1.

In the second stage, you'll find the Python-built client and peer as well. Each node in the distributed network knows its position inside the Chord ring design thanks to the peer programme. The next step is for a node to determine its successor and ring position via an interaction with an existing node.

At the nth node in the network, the entry for node x will have a successor ((x + 2n-1) mod c). To find the key, each node uses its database of names to choose which predecessor or successor to send the query to. Chord faces several obstacles, such as nodes that join the system simultaneously, nodes that fail, and nodes that want to depart. To provide accurate lookups and maintain consistency in the successor pointers of nodes, a simple stabilisation approach is used. By checking and fixing name table entries with these successor pointers, we can make sure that lookups are correct and speedy.

Table 4.1: Simulation Parameter

Parameter	**Description**
Hardware	Desktop: 2.5GHz Intel Core i5-3210M, 4 GB DDR3 RAM.
Environment	Desktop computer.
Stages	1. New car registration and verification. 2 . Chord-based blockchain network connection.
Languages	Java (Phase 1 registration), Node.js (Server/Client), Python (Phase 2 - Peer/Client).
Network	Distributed self-aware nodes in Chord ring architecture.
Node Knowledge	Each node was aware of its position in the Chord ring.
Joining Process	Nodes use IP addresses and ports to generate identifiers, join by determining successors in ring.

Table 4.2: Blockchain Parameters

Blockchain Details	**Description**
Block Header Size	About 80 bytes per block [30].
SHA-256 Time	Less than 0.01 milliseconds for every 1” ” KB of data [30].
Yearly Storage Cost	4.2 gigabytes for one blockchain (80 bytes/block * 6.24*365).
Authentication Data	Approximately 105” ” KB is considered, with a 15% reduction for public key availability.

In Table]4.2, Three main parameters regarding the blockchain technology used in the study are discussed. The block size header is approximately 80 bytes per block, which is the level of information that is expected to be in the block header of each block. This condensed header holds a set of data consisting of the previous block hash, timestamp, and transaction data to make the space for storing and retrieving them smaller. The time required to perform the SHA256 hash, the primary ingredient for making and verifying the block, is less than a millisecond per kilobyte of data. This hashing mechanism performs the job of validating the transactions and creating the blocks within the shortest possible duration. One blockchain storage cost is estimated to be approximately 4.2 gigabytes annually. This value is computed by considering the 80-byte block size and the average number of 6 blocks in a minute multiplied by 24 hours. Therefore, this figure is applicable for the whole year, which is 365 days. Such storage demand is not prohibitive in contemporary data storage systems. On a matter of authentication data, almost 105 kilobytes are included which are reduced by 15when public key data are available. This optimization minimizes data duplication and ensures better storage efficiency while remaining highly secure with authentication and data integrity management within the blockchain. Altogether, these metrics play a role in a blockchain system for the VIoT network that is quick, smooth, and secure.

4.2. Comparative Analysis. This study contrasts the proposed framework model with two other models: (1) centralized approach (B1) versus (2) blockchain-based solution (B2). The analysis concentrates on the most important differences, and as a special consideration, it focuses on the framework which is an integration of game theory and multi-agent reinforcement learning. Data transfer of 1 KB was evaluated using a different number of RSUs in various scenarios. The performance was recorded for 10, 25, 50 and 75 RSUs to understand how the models behave under different conditions. A series of simulations was carried out over a 10 km x 10 km area where the number of RSUs was changed to guarantee coverage and, at the same time, to avoid network gaps. RSUs are usually present in substantial numbers which implies that the bandwidth is made available not only for cars but also for users. Energy consumption in the proposed architecture was observed to be far lower than in the blockchain-based prototype (B2) where encryption and DHT (distributed hash table) overhead were present. Due to this reason, a larger number of packets are required to complete a round trip which in turn affects the system performance. However, the model of the proposed framework that overcame the difficulties performed better than both the blockchain and the centralized models. During the testing, the radio was assumed to always stay on. The proposed model of the radio would have a higher-than-expected relative listening overhead if temporarily a radio was turned off to save energy. It is worth noting that the findings of the experiment show that the proposed framework provides a more believable and robust solution for the VIoT environment.

Table 4.3: Comparative Analysis of Computation Cost (in bits) Among Existing Lightweight and Authentication Solutions and Proposed Framework

Criteria	**Baseline (Multi-agent Reinforcement Learning)**	**Blockchain (Proof-of-Work (PoW))**	**Proposed Framework**
Computation Cost (in bits)	256	128	192
Lightweight Blockchain	Yes	No	Yes
Multi-Agent Reinforcement Learning	No	Yes	Yes
Secure Authorization Process	Yes	Yes	Yes
Load Balancing	No	Yes	Yes
Scalability	Yes	Yes	Yes
Availability	Yes	No	Yes
Decentralization	Yes	Yes	Yes
Integration with loT Devices	Yes	No	Yes

Table 4.3 shows the three frameworks using the criteria of computation cost, lightweight blockchain implementation, MARL, secure authorization processes, load balancing, scalability, availability, decentralization, and VIoT device integration. The baseline frame, which MARL based, is the highest in computing cost with 256 bits, whilst the blockchain model using proof-of-work (PoW) is the lowest at 128 bits. Consequently, the outlined system provides a balance of 192 bits which is meant to achieve both an optimum computational efficiency and security. Both the two frameworks are based on lightweight blockchain and the PoW model blockchain system does not. MARL does not exist in the PoW blockchain model, though, the other two options integrate it in their frameworks. All three frameworks can guarantee authorization, but the service of load distribution is available only in the blockchain and the proposed frameworks. Scalability is a shared aspect of all three schemes, and the other aspect is also decentralization. Consequently, the PoW model of blockchain offers no availability, that is the case for the baseline as well as the suggested model. The proposed and baseline frameworks couple IoT devices, but the PoW model using the blockchain does not. Conclusively, the suggested model is a good option as it combines features like lightweight architecture, MARL, secure authorization, load balancing, scalability, availability, decentralization, and integration with IoT devices making it a promising option for VIoT applications.

Because it influences the entire cost of the model, the computation cost should be kept as low as feasible in any model having an authentication step. Before making any cost estimates, it is necessary to know how much time is required to complete each phase of the comparison models.

Figure 4.1 describes the relationship between the amount of energy used and the number of vehicle units (VU) in the network. With the increase in the number of VUs, energy consumptions also tend to grow, which is a characteristic of a greater number of network activities and communication requirements. The figure shows that the suggested model does a good job of managing the consumption of energy as the network scales, and it manages to maintain efficient operation even though the number of VUs increases. Such efficiency is the key problem for the VIoT network's durability and sustainability, especially in massive implementations.

Figure 4.2 demonstrates a probabilistic model reflecting the packet delivery success rate against the number of VUs in the network. With the increment of VUs, network congestion would be more likely to happen and therefore it can affect the success of packet delivery. Nevertheless, the proposed model boasts great potential to sustain a high probability of successful packet delivery as the network goes beyond the spatial limits. The same resilience in packet delivery is the most important metric, showing the robustness and the ability to stay on top of the increasing demands of a growing VIoT network. This reliable performance of communication is a basic requirement to ensure the integrity and effectiveness of the network.

The proposed protocol's foundation is the 0.0021 ms XOR operation and hash computation speed of the double SHA-256 algorithm. Accordingly, the maximum processing speed for the framework was found to be 1.8 MHash/s on a PC with a 2.5 GHz Intel Core i5-3210M CPU and 4 GB of DDR3 RAM. The result of multiplying 1.8 MHz by 1024 bits/CLK is another way to represent it: 1843.2 GBPS. The encryption and

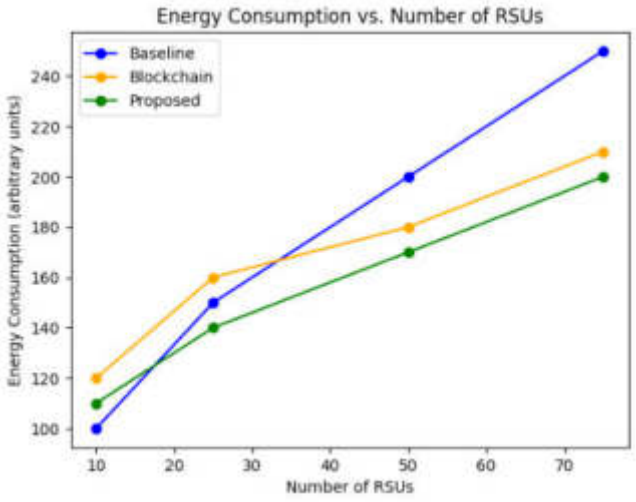

Fig. 4.1: Energy consumption vs Vehicle Unit

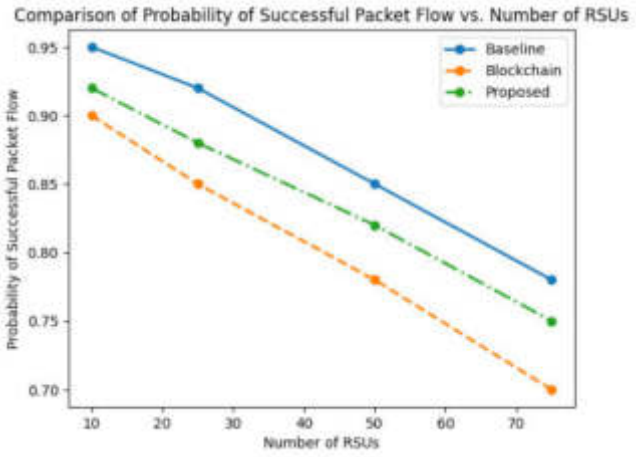

Fig. 4.2: Probability of successful packet vs number of VU

decryption techniques that we have selected use 256 bits of data. In contrast, our timestamps, session keys, symmetric distribution keys, vehicle IDs, and cluster head IDs all use 64 bits of data. The findings were all calculated using the same set of data, which includes 1000 automobiles and 75 RSUs. Comparing our framework to the other models, we discovered that ours had reduced communication costs.

The Join/Leave rate of the proposed system is shown in Figure 4.3. We use SHA-256 as our basis for the assumption that presence and absence proofs are space and time-dependent with an O(logN) factor. Vehicle identification does not use a lot of space or time even in VIoTs of size 106.

Figures 4.4 through 4.7 are a complete assessment of the diversity of performance factors in a VIoT (Vehicular Internet of Things) network. Figure 4.4 looks up failure analysis which analyses the network performance in providing exact and timely data or resources within the smart environment. A lesser rate of lookup failures is a sure sign of better network reliability and efficiency. Figure 4.5 shows the overhead comparison of the VIoT network, emphasizing the extra resources and management demanded to run the system. This presents the types of data being processed, the communication, and storage methods. Removing redundancy is the

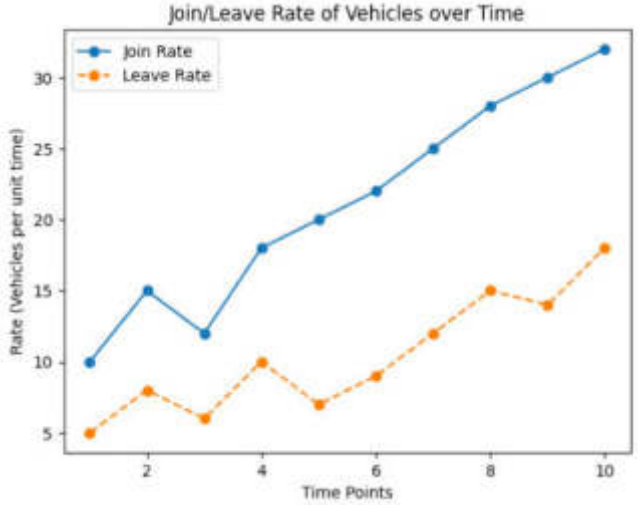

Fig. 4.3: Join/Leave Rate of VIoTs

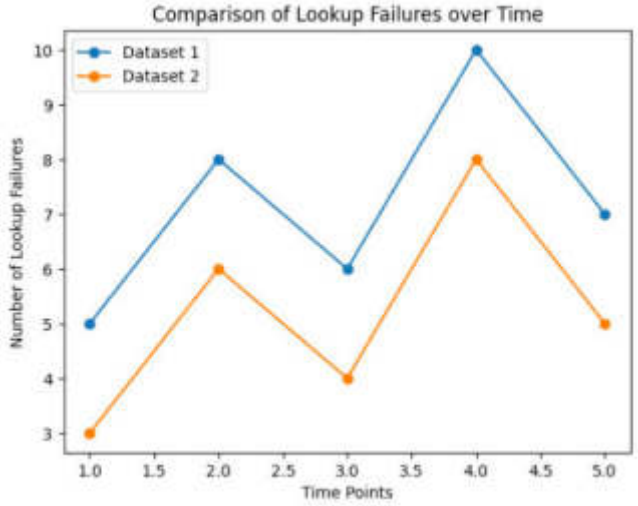

Fig. 4.4: Lookup Failures of VIoTs

most important development factor for increasing the efficiency and scalability of the network. Figure 4.6 goes over storage overhead, which shows how much area is needed to retain data within the VIoT network. The ability to store data for devices involved in VIoT is essential as these devices produce large amounts of data while simultaneously maintaining the availability and integrity of data. Figure 4.7 analyzes communication costs, which are comprised of expenditures involved in transmitting data within the VIoT network. Lower communication costs can help to achieve this goal of more effective and inexpensive network operations.

Figures 4.8, 4.9, and 4.10 show the average latency in the different methods of community communication, which include the existing systems (B1, B2, and centralised) and the proposed approach. Average latency is one of the most widely used performance measures in network communication protocols, and it stands for the time taken for data to travel through the network until it reaches its destination. Significantly low latency values mean data transfer is faster and there is less delay in message delivery which is good for communication network

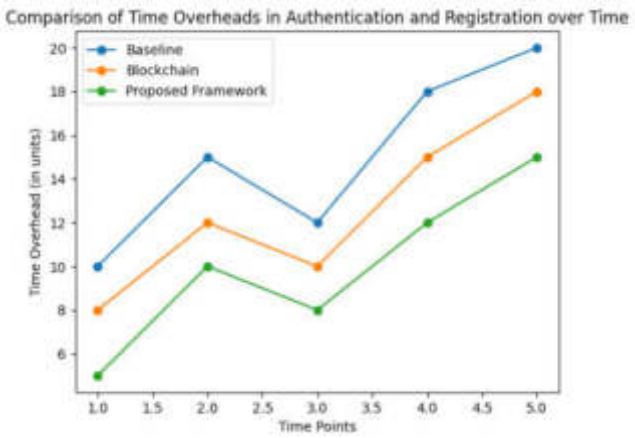

Fig. 4.5: Overhead Comparison

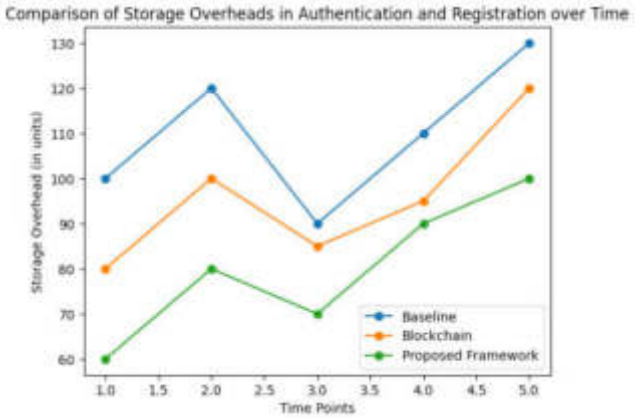

Fig. 4.6: Storage Overhead

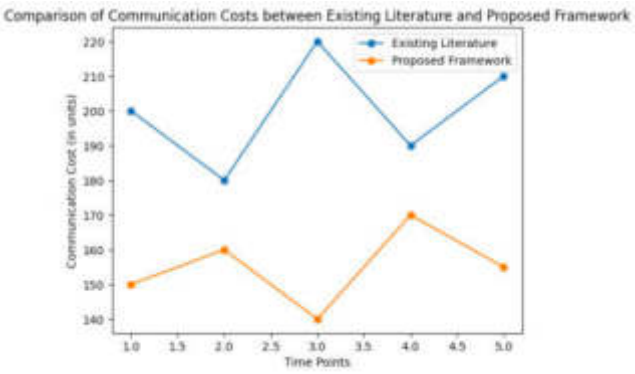

Fig. 4.7: Communication costs

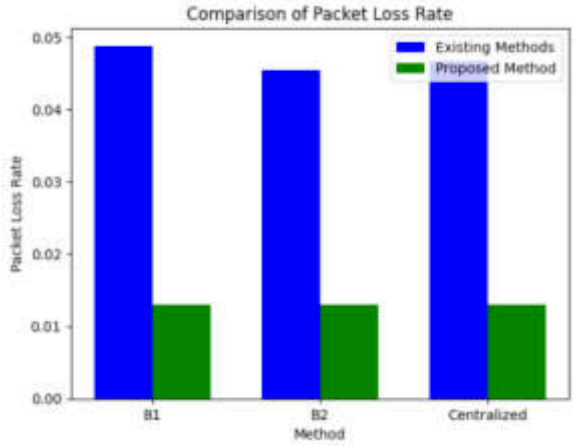

Fig. 4.8: Packet Loss Rate

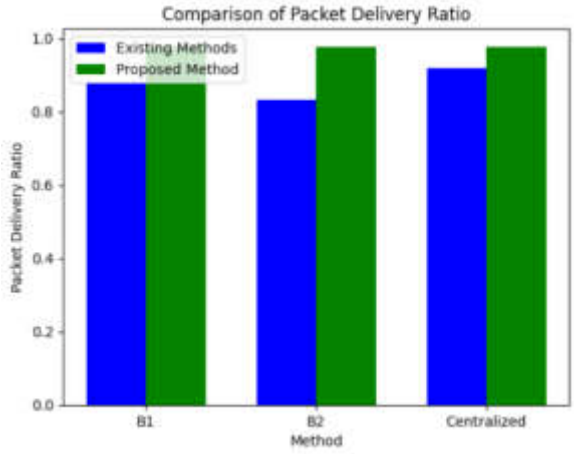

Fig. 4.9: Packet Delivery Ratio

efficiency and speed. The bar graph is eye-opening and reveals that the existing methods have typical latency values ranging from 35 to 60 milliseconds, which signifies that these methods take some time to transmit data. The range is a sign of, among other things, how well some methods match or not the others. Whereas the old approach has a latency of about 60 to 120 milliseconds, the new one has a latency of 15 to 30 milliseconds which is 4 times lower than the old one.

Figures 4.8 and 4.9 also focus on the rate of packet loss as well as the ratio of packet delivery that gives the view of the reliability of data transmission in the network. Figure 4.11 covers the throughput comparison, which illustrates the data transfer rate handling that the different approaches perform. The compared method's low latency and stable performance establish it as an excellent alternative for improving the performance and speed of network communication protocols in VIoT applications.

5. Discussion. The experimental result will be impressive as it will showcase the efficiency and advantages of the new VIoT technology architecture compared to the centralized and blockchain-based solutions. The Figure 6 to Figure 4.10 presents simulation results of the VIoT network from different perspectives including power consumption, lookup failure rate, overhead, storage, communication cost, packet loss ratio, packet

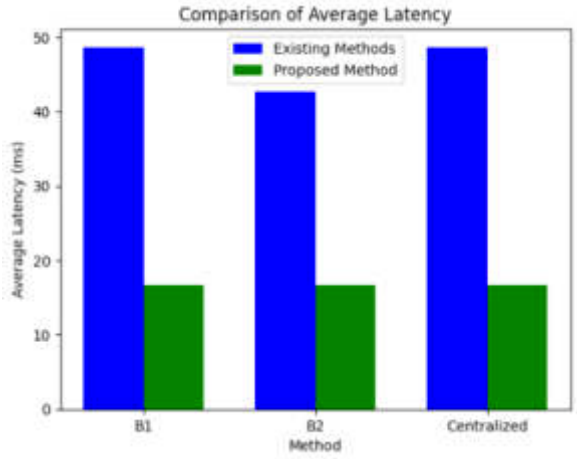

Fig. 4.10: Average Latency

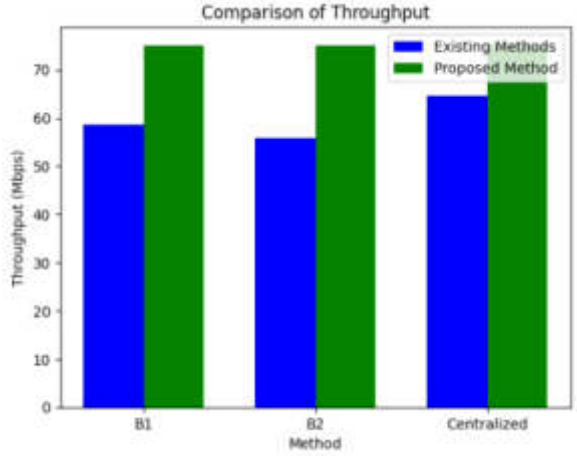

Fig. 4.11: Throughput Comparison

delivery ratio, and average latency and also comparison on throughput. The test outcome demonstrates that the proposed framework out-performs centralized and blockchain-based models in terms of energy consumption, latency, packet delivery and throughput. As it can deal with lookup failures, overhead, and storage properly, Cuckoo Filter is an applicable choice to use for deploying VIoT at scale. On the other hand, the method relies on game theory and multi-agent reinforcement learning and this algorithm coupled with its usage of lightweight blockchain and secure authorization procedures, leads to the optimal mix of computational efficiency, security, and scalability. These results imply that the network architecture of VIoT is one of the stable and efficient networks to be implemented in the smart vehicles field; this so to speak, is what should preferably be used in future deployment of such networks. It comes as a full-fledged workflow guiding to reach VIoT systems of the highest performance and scalability with the security and robustness ensured.

5.1. Participants' Rewards and Reliability Factor. In this section, we describe the user reward system in the VIoT ecosystem, and we introduce the reliability factor as a vehicle indicator.

The participants of the VIoT network: on the other hand vehicle owners, nodes, and miners are rewarded for their devotion by providing services. This is very important for the maintenance of the integrity of the network.

Such incentives can either be issued in the form of tokens or some other crypto-coin which can be exchanged or held in value among their holders. Take, for example, the case of provided car owners who are requesting the community with records, they will be paid tokens in consideration of both the quality and quantity of the data supplied. On the other hand, nodes that account for transaction verifications and block-making can be rewarded based on their operation time and performance. This system is the key to the active engagement of the participants and the high level of security and orderliness of the network is ensured.

The reliability factor, which is one of the key metrics used to measure the credibility and performance of connected vehicles, is the most critical indication of VIoT. This factor aims to manage all the variables because these can include errors in the sensor data, whether protocols are followed and the frequency of data sharing. The most significant advantage of the reliability factor for a company is that vehicles that can be trusted will be valued higher, and probably end up with extra awards or an edge, such as swift trading deals or minimal fees. Indicators like uptime, data accuracy, and consistency in communications can be used in calculating reliability factors that will reward vehicles according to their contributions towards the safety and stability of the network. Reward systems and trustworthiness factors are the two major components that, as being integrated, will create a complex network in which the participants are motivated to provide quality data and services while ensuring high standards of reliability and trustworthiness.

5.2. Practical Implications. The real-world implications of this study underscore the importance of VIoT network development and deployment. The proposed framework provides the optimal trade-off between computational efficiency, security, and scalability, making it a plausible option in real-life VIoT apps. The energy efficiency and ability of VIoT networks to manage network growth with no performance deterioration are the factors that guarantee their sustainability and longevity, which are the needs for large-scale deployments. The model has a low latency rate and a high packet delivery rate which is used for fast and reliable communication which is crucial in real-time applications like self-driving car and smart traffic control systems. In addition to that, the combination of lightweight blockchain technology and multi-agent reinforcement learning, data security and privacy are also strengthened, as well as the decentralized data management. Integration of the two provides secure and efficient data exchange and verification of transactions which is the underlying need to develop a stronger and well-structured VIoT infrastructure. The study's result can steer policy makers, urban planners as well as industry stakeholders in the adoption and implementation of VIoT networks that offer superior performance, reliability and scalability in smart transportation and infrastructure, which consequently contributes to the advancement of smart cities.

5.3. Limitations. The research is limited in some ways that may affect the ability to generalize and apply its findings in actual VIoT networks. Another limitation is the fact that the environment used is simulated, which can't fully reproduce the intricacy, inconstancy and never-ending possibilities of real VIoT networks. This might therefore imply that the findings of the research may not fully reflect what actually will be witnessed in real life when this proposed framework is implemented. The last limitation is the hardware used in the experiment which is the desktop PC with processor and RAM assigned. The peculiarity of different hardware facilities could affect the performance of the proposed model and cause differences in the outcomes. Also, the study largely relies on a single hardware setup, hence restricting the outcome to that very environment only.

6. Conclusion. The proposed security in VIoT offers the passengers convenient travel to the urban cities, resulting in lower usage of their vehicles. The exact vehicle demand in a location is predicted in this research work to avoid unnecessary traffic by scheduling public transportation to the demanded location. Finally, the traffic is optimized by minimizing excessive vehicle usage, which is lower when it is compared with the current transportation system. Thus, it results in lower fuel consumption. By combining centralized authority with dispersed activity, the two-tier system achieves a good balance between efficiency and security. The use of symmetric keys and lightweight encryption speeds up the vehicle registration and authentication process, which helps get around the resource constraints of VIoT devices. With the session key distribution mechanism, vehicles, RSUs, and decentralized servers may safely interact and approve each other. In terms of computation and transmission costs, the proposed model surpasses the state-of-the-art, according to simulation and comparative study findings. By laying the structure for an effective and secure VIoT environment, the framework opens the door to future VIoT-related research and development.

The future network simulation studies for VIoT should emphasize increasing the scale and complexity of the simulations to realistically model real-world conditions. This means designing for a wide variety of hardware and software platforms, including traffic patterns and environmental conditions for instance. Furthermore, we could examine the influence of various types of IoT devices and how their specific requirement sets may affect network performance, which will be of great help in the search for more customized solutions. The study of modern security measures and privacy mechanisms to handle the new threats and the holes in the VIoT network should be given a high priority.

MULTI MOVING TARGET LOCALIZATION IN AGRICULTURAL FARMLANDS BY EMPLOYING OPTIMIZED COOPERATIVE UNMANNED AERIAL VEHICLE SWARM

MILTON LOPEZ-CUEVA[*], RENZO APAZA-CUTIPA[†], RENE L. ARAUJO-COTACALLPA[‡], V.V.S SASANK[§], RAJASEKAR RANGASAMY[¶], AND SUDHAKAR SENGAN[‖*]

Abstract. The paper proposes an original method for employing optimised cooperative swarms of Unmanned Aerial Vehicles (UAVs) to localise multiple moving objects in agricultural farmlands. Crop Monitoring (CM), targeted fertilizer distribution, and Livestock Management (LM) are some of the Smart Farming (SF) applications of UAVs. However, the ever-changing nature of agricultural settings makes it challenging to set up UAV swarms. Detecting multiple evolving objectives in dynamic environments is complicated, and conventional methods are regularly optimized for single objectives, such as area or reduced Energy Consumption (EC), which is unsuitable. This research recommends a Multi-Objective Evolutionary Algorithm (MOEA) as a model for UAV swarms to balance task service, communication, and EC during the investigation. The approach paves the method for innovation in the agricultural sector by optimizing tasks in real-time, addressing unpredictable targets, boosting productivity, and reducing costs. The study's findings present optimism for smart farm management and accurate SF by improving UAV systems' response time and scalability.

Key words: UAV, Smart Farming, Energy Consumption, Crop Monitoring, Agricultural Technology, Precision Agriculture

1. Introduction and examples. A novel concept from the twenty-first century called "Smart Farming" (SF) focuses on productivity and Precision Agriculture (PA). The development of innovation in the SF sector has been driven primarily by modern-era technology, namely robotic devices and Unmanned Aerial Vehicles (UAVs). Considering that these inventions are a number of devices, they may improve ecologically friendly SF methods, which is how study participants have advocated for their use to enhance SM procedures and improve resource optimization [13]. Crop Yield (CY), Soil Health (SH) evaluation and robotic technology have all experienced significant advances due to UAVs and robotic equipment. In order to guarantee that every person around the globe has access to nutritious food, these developments are crucial. In light of their significant scientific functions, UAVs have become prevalent in the AS. UAV technology has radically altered the activity of Crop Monitoring (CM), herbicide applications, chemicals, and livestock monitoring (LM) [11]. As an outcome, SH checks have gotten better, and SF-CY has increased, which has made these improvements feasible for a more significant number of people [7].

With the ability to quickly encompass huge regions, UAVs can collect data with an index of accuracy and reliability that outperforms that of any farmers [9]. In order to help with real-time data storage for complete analysis and decision-making procedures (DMP), they recommend operating the framework permanently. Pest control using UAV proves more effective, consumes minimal chemical compounds, and has minimal impact on

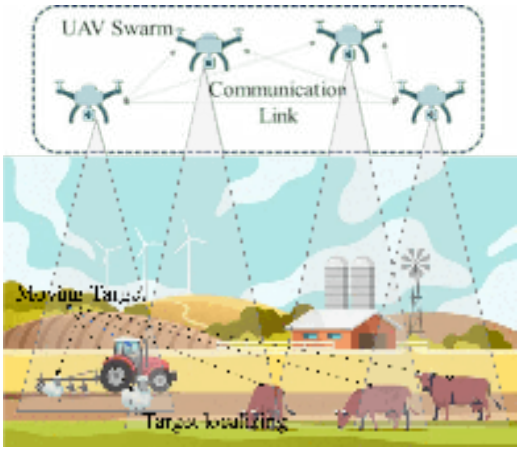

Fig. 1.1: MMT Environment

the natural environment [16]. In CM, they assist in finding errors and issues rapidly, and in LM, they maintain a check on the livestock to make sure they're in good health and provide as much as feasible.

SF has made significant progress, but the challenge of Multi-Moving Target (MMT) geolocation remains. This involves monitoring numerous moving objects across extensive farmlands, such as cattle and mobile SF devices. Accurately locating these targets is crucial for real-time monitoring, resource deployment, and workflow control. Current techniques focus on optimizing one task at a time, ignoring the connected nature of real-life situations and significant Energy Consumption (EC). Despite these challenges, the use of UAVs in SF remains essential. Figure 1.1 illustrates a conventional MMT setting. The present techniques could optimize Global Positioning System (GSP) coverage or energy efficiency, ignoring the connected nature of the real-life situation [8].

The unpredictable nature of SF necessitates a focus on the multi-target GSP problem, a key area of study for UAVs, as current technology fails to adapt to the varied and continuously evolving SF settings, leading to operational errors and rising costs. The study presents an innovative approach to MMT-GSP challenges in agricultural land using an optimized cooperative UAV swarm design. It uses an advanced Multi-Objective Evolutionary Algorithm (MOEA) to balance EC, transmission productivity, and area coverage. The Pareto-Optimality Theory (POT) ensures that no objective improves at the proportional cost of another, making UAVs more flexible and accurate in changing SF settings. This integrated approach opens new possibilities for SF.

This study article outlines the following: Chapter 2 starts with the existing literature analysis; Chapter 3 presents the framework hypothesis; Chapter 4 focuses on the planned tasks; Chapter 5 includes experimental research; and Chapter 6 concludes the research.

2. Literature Review. Employing UAVs for Multi-Target Tracking (MTT) is an enormous advance in the rapidly expanding AS. Numerous research studies have described numerous tactics and methods to enhance UAV systems' performance in challenging scenarios.

The paper [3] emphasizes an intelligent method that enhances tracking accuracy and incorporates collision prevention techniques in the UAV-based cooperative monitoring design. In place of solutions that use deep Q-networks, their strategy significantly improves tracking accuracy and reduces time. The study [10] demonstrates the practical application of inaccurate distance metrics to optimise UAV control actions and explores Deep Reinforcement Learning (DRL) implementation to manage UAVs while monitoring rescue workers in 3D regions.

The DRL method, which emphasizes reducing the Cramér-Rao lower bound (CRLB), can achieve precise monitoring at minimal operational costs. The authors of [14] invented a novel technique for selecting a path with a dynamic Artificial Potential Field (D-APF) and optimized it for multirotor UAVs that aim to capture objects in motion on ground levels. The above technique improves standard possible SF techniques in models and performs well in dynamic and dense conditions.

The paper [5] developed a novel technique known as Motion-encoded Particle Swarm Optimization (MPSO) to enhance the target detection features of UAVs. Because the swarm's behavioural and psychological attributes encompass the process of searching path, MPSO achieves more effective results than standard PSO and other metaheuristic algorithms in both theoretical and real-world scenarios. To improve UAV-DMP for more accurate target tracking, the study [6] implemented a comprehensive, all-encompassing Multi-Agent Reinforcement Learning (MARL) approach. The technique integrates data on spatial entropy, EC techniques, monitoring success rates, and EC with positive results [2].

Ultimately, the paper [15] highlights particular issues with MTT and provides innovative techniques to improve the circumstances. To deal with Multi-Agent Pursuit-Evasion (MAPE) problems, the study [4] proposes an adaptation of the Multi-Agent Deep Deterministic Policy Gradient (MADDP) method. Their role-based system expedites the process of monitoring invisible objects. However, the authors of [12] focuses their research on livestock monitoring, using an approach that optimizes detection and tracking by employing optical flow and low-confidence path filtering techniques. This technique works with YOLOv7 and DeepSORT algorithms [1].

3. System Model. The proposed UAV swarm-based cooperative tracking paradigm model incorporates three fundamental models: Task, Transmission, and Energy. These models must emerge in order to provide successful, suitable tracking and predictive path computation, all while maintaining EC and providing secure communication among the UAVs.

3.1. Task Model. The Task Model focuses on how the UAV gets allocated tracking duties and how these tasks are executed. Any UAV is liable for maintaining tracks on specific parts of the targeted region and tracking any targets that have been identified within that area of search. Assume $T = \{T_1, T_2, \ldots, T_n\}$ be the set of all targets to be monitored, and $Z = \{Z_1, Z_2, \ldots, Z_m\}$ be the set of zones divided by the UAV for monitoring. The allocation of tasks can be represented by a task allocation matrix A, where each element a_{ij} indicates the assignment of the target T_j to the zone Z_i, EQU (3.1)

$$A = [a_{ij}] \text{ where } a_{ij} = \begin{cases} 1, & \text{if target } T_j \text{ is in zone } Z_i \\ 0, & \text{otherwise} \end{cases} \tag{3.1}$$

The goal of the Task Model is to maximize the coverage and tracking accuracy while minimizing overlaps and gaps in monitoring, which can be represented by the optimization problem EQU (3.2) and EQU (3.3)

$$\max_{A} \sum_{i=1}^{m} \sum_{j=1}^{n} a_{ij} \cdot c\left(T_j, Z_i\right) \tag{3.2}$$

subject to

$$\begin{aligned} &\sum_{i=1}^{m} a_{ij} \leq 1, \forall j \\ &\sum_{j=1}^{n} a_{ij} \leq U_i^{\text{cap}}, \forall i \end{aligned} \tag{3.3}$$

where $c\left(T_j, Z_i\right)$ is the coverage score indicating the efficiency of tracking the target T_j in zone Z_i, and U_i^{cap} is the tracking capacity of UAV U_i.

3.2. Transmission Model. The Transmission Model concerns the data exchange between UAVs for collaborative detection, tracking, and path prediction of MMTs. Each UAV has communication modules to transmit and receive data to and from its neighbors. Let C_{ij} be the communication link between UAV U_i and UAVU_j, which is attributed to its bandwidth B_{ij}, latency L_{ij}, and reliability R_{ij}.

The data transmission rate between two UAVs can be depicted by Shannon's EQU (3.4):

$$R_{ij} = B_{ij} \cdot \log_2 \left(1 + \frac{s_{ij}}{N_{ij}}\right) \tag{3.4}$$

where R_{ij} is the rate, B_{ij} is the bandwidth, S_{ij} is the signal power received from a UAV U_j by UAV U_i, and N_{ij} is the noise power in the communication channel between U_i and U_j.

The Transmission Model aims to maximize the overall network throughput while ensuring low latency and high reliability, EQU (3.5) by the optimization problem:

$$\text{Maximize} \sum_{i=1}^{m-1} \sum_{j=i+1}^{m} R_{ij} \tag{3.5}$$

subject to EQU (3.6) and EQU (3.7)

$$L_{ij} \leq L_{\max}, \forall i \neq j \tag{3.6}$$

$$R_{\min} \leq R_{ij} \leq R_{\max}, \forall i \neq j \tag{3.7}$$

where $L_{\max}$ is the maximum acceptable latency, $R_{\min}$ is the minimum required data rate, and $R_{\max}$ is the maximum achievable data rate on the communication channel.

3.3. Energy Model. The Energy Model addresses the EC aspects of the UAVs during the tracking mission. EC is crucial for prolonged operations and endurance of the UAV swarm. The EC for a UAV U_i includes the EC during the flight E_{flight_i}, sensing and processing E_{sense_i}, and communication E_{comm_i}. The energy model is represented as EQU (3.8)

$$E_{\text{total }_i} = E_{\text{flight }_i} + E_{\text{sense }_i} + E_{\text{comm }_i} \tag{3.8}$$

The objective is to minimize the total EC of the UAV while ensuring the completion of the tracking task, which can be posed as the following optimization problem: EQU (3.9) to EQU (3.13)

$$\text{Minimize} \sum_{i=1}^{m} E_{\text{total }_i} \tag{3.9}$$

subject to:

$$E_{\text{flight }_i} \leq E_{\text{flight }_{\max}}, \forall i \tag{3.10}$$

$$E_{\text{sense }_i} \leq E_{\text{sense }_{\max}}, \forall i \tag{3.11}$$

$$E_{\text{comm }_i} \leq E_{\text{comm }_{\max}}, \forall i \tag{3.12}$$

$$\mathbf{A} \cdot (\mathbf{E}_{\text{flight}} + \mathbf{E}_{\text{sense}} + \mathbf{E}_{\text{comm}}) \leq E_{\text{res}}, \forall i \tag{3.13}$$

where $E_{flight_{max}}$, $E_{sense_{max}}$, and $E_{comm_{max}}$ are the maximum EC allowances for flight, sensing, and communication, respectively, and E_{res} is the residual energy required for the UAV to return to the base or next task point.

4. Proposed Multi-Objective Optimization Problem (MOOP) Definition for UAV Optimization. The overarching goal of deploying a UAV for SF target tracking is to harness the collective capabilities of the UAV while adhering to the operational constraints of task efficiency, communication integrity, and EC. This method defines an MOOP that includes the mutually dependent objectives resulting from the UAVs' task allocation, transmission specifications, and EC. This addresses the design problem.

4.1. Problem Interdependencies. Several interrelated objectives, outlined below, emerge from the basic functional designs that set this challenge apart:

1. **Task Allocation and Energy Dynamics:** Each UAV's EC model immediately influences the scheduling of monitoring tasks. Minimising reused flight paths is one way to determine how effectively the assignment of tasks can help minimise EC.
2. **Communication and EC:** In order for an entire group to make real-time recommendations, the channel of communication must be secure and efficient. A boost in EC due to increased transmission powers is an accepted consequence of enhancing the level of communication.
3. **Task Execution and Communication Coherence:** Information sharing between the UAVs is required if they are to monitor and predict the location of their surveillance targets effectively. An interface design that enables minimal latency transmission of data at a high rate is necessary for this explanation.

4.2. Objective Function and Constraints. Rather than deciphering specific equations from the task, transmission process, and energy models, this work explains the multi-objective problem using an approach that emphasizes the interconnected nature of these models. The aim of this work is to construct an optimization architecture that considers all the following factors in a comprehensive approach:

- They achieve high task coverage and precise target localization.
- The task involves maintaining a robust and efficient communication network amongst UAVs.
- The goal is to minimize the overall EC across the UAV without compromising mission effectiveness.

Limits describe the features of the UAVs, the terrain, and the essential variables. The optimization aims to ensure that UAVs maintain their operational power restrictions, minimum communication channel requirements, and limited energy sources.

4.3. Decision Variables and Optimization Process. Finding an accurate prime vector 'X' is essential for optimizing the tasks of the UAV swarm. The key operational settings for the task, communication, and Energy Models have been included in this vector that is used. The decision vector is mathematically represented as EQU (4.1)

$$\mathrm{X} = x_1, x_2, \ldots, x_k \tag{4.1}$$

where each x_i within the vector, X represents a specific operational decision variable. These variables contain UAV-GPS allocations, transmission settings, and UAV flight paths.

The objective of this work optimization is to simultaneously minimize or maximize a set of functions defined as EQU (4.2)

$$\text{Minimize/Maximize}F(\mathrm{X}) = [f_1(\mathrm{X}), f_2(\mathrm{X}), \ldots, f_p(\mathrm{X})] \tag{4.2}$$

subject to the following constraints: EQU (4.3) and EQU (4.4)

$$G(\mathrm{X}) = [g_1(\mathrm{X}), g_2(\mathrm{X}), \ldots, g_q(\mathrm{X})] \leq 0 \tag{4.3}$$

$$H(\mathrm{X}) = [h_1(\mathrm{X}), h_2(\mathrm{X}), \ldots, h_r(\mathrm{X})] = 0 \tag{4.4}$$

In the above EQU (4.4), $F(\mathrm{X})$ is the vector of objective functions f_i, where each function aims at one distinct target, such as EC minimization or task coverage maximization. The vectors $G(\mathrm{X})$ and $H(\mathrm{X})$ denote the sets of variation and equality limit functions, respectively.

To solve this MOOP, this study employs a POT, where the Pareto front, Y, is defined as EQU (4.5)

$$Y = \{\mathbf{X} \mid \nexists \mathbf{X}' : F(\mathbf{X}') \leq F(\mathbf{X}), G(\mathbf{X}') \leq G(\mathbf{X}), H(\mathbf{X}') = H(\mathbf{X})\} \tag{4.5}$$

When no other feasible solution, X′, will enhance any objective without negatively impacting another, researchers claim that X is the Pareto optimal solution. Overall, the most effective solutions in the field of

objectives make up the Pareto front Y. In order to discover the search space to find the set of Pareto-optimal keys, it is vital to use advanced optimization methods.

Coordinating UAV operations with the particular needs of SF monitoring tasks is the final objective of optimization. It attempts to provide different operational plans that manage the trade-offs between task efficiency (E_{task}), communication quality (Q_{comm}), and EC (E_{total}). The decision-makers then have an extensive set of selections.

4.4. MOEA Process for UAV Optimization for MMT Localization. The MOEA presents a high-level structure for navigating the complex field of solutions for the challenging task of MMT localization in rural SF land using an ensemble UAV swarm. Identifying a set of POTs that optimally balance task protection, communication efficiency, and EC is the primary goal of MOEA in this environment.

1. **Representation (Chromosomes):** An encoded result vector $\mathrm{X} = \left[\mathrm{x}_1, \mathrm{x}_2, \mathrm{x}_3, ..\mathrm{x}^{\mathrm{k}}\right], \mathrm{x3}, \ldots \mathrm{xk}\right]$ describes the set-up of the UAV and comprises decision variables $\left[\mathrm{x}_1, \mathrm{x}_2, \mathrm{x}_3, \ldots \mathrm{x}^{\mathrm{k}}\right]$ that are responsible depending on swarm features like location, altitude, and sensor direction. A chromosome X is an encoded solution vector representing the UAV swarm's configuration, consisting of decision variables $\left[\mathrm{x}_1, \mathrm{x}_2, \mathrm{x}_3, .\mathrm{x}^{\mathrm{k}}\right]$ where each variable represents a specific aspect of the swarm, such as location, altitude, and sensor orientation $\mathrm{X} = \left[\mathrm{x}_1, \mathrm{x}_2, \mathrm{x}_3, ..\mathrm{x}^{\mathrm{k}}\right]$.
2. **In the context of UAVs:** x_i could represent the i^{th} UAV's position and orientation in 3D space, $(x_{i,\mathrm{pos}}, y_{i,\ \mathrm{pos}}, z_{i,\ \mathrm{pos}}, \theta_{i,\ \mathrm{ori}}, \phi_{i,\ \mathrm{ori}})$, and its communication and energy parameters.
3. **Population Initialization:** Initial solutions $P_0 = \{X_1, X_2, \ldots, X_N\}$ are generated within the feasible search space, respecting constraints such as flight zones and maximum energy capacity.
4. **Fitness Evaluation (Objective Functions):** Fitness evaluation is performed concerning the defined objectives:
   - **Objective 1 (Coverage):** $f_1(X) = \sum_{i=1}^{m} \sum_{j=1}^{n} a_{ij} \cdot c\left(T_j, Z_i\right)$ where a_{ij} indicates the importance of covering the target T_j by UAVZ_i, and c is a coverage function that might depend on the distance, angle of the sensors, and other environmental factors.
   - **Objective 2 (Communication):** $f_2(X) = \sum_{i=1}^{m-1} \sum_{j=i+1}^{m} R_{ij}\left(x_{i,\ \mathrm{com}}, x_{j,\ \mathrm{com}}\right)$ where R_{ij} is the communication reliability between UAVs i and j, depending on their communication settings $x_{i,\ \mathrm{com}}$ and $x_{j,\ \mathrm{com}}$.
   - **Objective 3 (EC):** $f_3(X) = \sum_{i=1}^{m} E_i\left(x_{i,\mathrm{pos}}, x_{i,\ \mathrm{act}}\right)$ where E_i is the EC of UAV i, which depends on its position $x_{i,\ \mathrm{pos}}$ and the action taken $\chi_{i,\ \mathrm{act}}$.

   The MOEA process involves selecting the fittest individuals to act as parents for the next generation. Round selection and roulette wheel selection are two methods that can be employed. Then, these selected parents are subjected to genetic processes like mutation and crossover in order to have children, which boosts the population's variability and introduces novel features.
5. *Selection:* A case study of a predictable selection method employed by MOEA for UAV swarm optimization is Rank-based Selection. This method involves ranking the population according to their fitness values and selecting the top-ranking individuals with a higher probability. A rank $r\left(X_i\right)$ is assigned to every individual X_i, and the selection probability $P\left(X_i\right)$ is given by EQU (4.6).

$$P\left(X_i\right) = \frac{r\left(X_i\right)}{\sum_{j=1}^{N} r\left(X_j\right)} \tag{4.6}$$

   The individuals with higher ranks (lower rank) have higher chances of being selected.
6. *Crossover:* The crossover operation is a recombination process where two parent chromosomes exchange segments to produce offspring. A commonly used crossover operator in MOEA is the Single-Point Crossover. Two parent chromosomes X^{p1} and X^{p2} are selected, and a crossover point *cp* is chosen randomly along the length of the chromosomes. The offspring X^{o1} and X^{o2} are then created as follows: EQU (4.7) and EQU (4.8)

$$X^{o1} = \left(x_1^{p1}, \ldots, x_{cp}^{p1}, x_{cp+1}^{p2}, \ldots, x_k^{p2}\right) \tag{4.7}$$

$$X^{o2} = \left(x_1^{p2}, \ldots, x_{cp}^{p2}, x_{cp+1}^{p1}, \ldots, x_k^{p1}\right) \tag{4.8}$$

where k is the number of genes in the chromosome.

7. *Mutation:* Mutation introduces variation into the population by randomly altering the offspring's genes. For UAV swarm optimization, a Gaussian Mutation is used, where the value of the mutated gene x_i' is given by EQU (4.9)

$$x_i' = x_i + N\left(0, \sigma^2\right) \tag{4.9}$$

Here, x_i is the original gene value, $N\left(0, \sigma^2\right)$ is a Gaussian distribution with mean 0 and standard deviation σ, which controls the extent of the mutation. The value of σ is often decreased over generations to reduce the search space as the algorithm converges.

8. *Constraint Handling:* If the MOEA intends to develop feasible UAV operation options, controlling restrictions is a prerequisite. These drawbacks include restrictions on payload capacity, no-fly regions, and the lifespan of batteries. The application of a penalty function is a usual approach to risk control. This function adjusts the fitness value of a solution according to how much it breaches the controls. This concept can be illustrated through the following mathematical expression EQU (4.10)

$$F'(X) = F(X) - P(X) \tag{4.10}$$

where:
- $F(X)$ is the original fitness value of the solution X.
- $P(X)$ is the penalty incurred by the solution X.
- $F'(X)$ is the penalized fitness value.

The penalty function $P(X)$ is a sum of individual penalties for each constraint, as given by EQU (4.11)

$$P(X) = \sum_{i=1}^{C} p_i \cdot v_i(X) \tag{4.11}$$

where:
- C is the constraint count.
- p_i is the penalty factor for the i-th constraint.
- $v_i(X)$ is a violation measure for the i-th constraint, which is zero if the condition is not violated and positive if it is.

9. **Survivor Selection:** Survivor selection determines which individuals from the current population P_t and the offspring O_t will pass to the next generation P_{t+1}. A common method used with MOEA is Elitist Selection, where a segment of the top-performing individuals from the present population is assured of the monitor. The remaining spots in the new population are filled based on the fitness values after considering penalties. This can be formulated as EQU (4.12)

$$P_{t+1} = E\left(P_t\right) \cup S\left(F'\left(P_t \cup O_t\right), |P_t| - |E\left(P_t\right)|\right) \tag{4.12}$$

where:
- $E\left(P_t\right)$ is the elitist set in the current population P_t.
- $S\left(F'(A), N\right)$ is the function that selects N individuals from set A based on their penalized fitness $F'(A)$.

The elitist selection ensures that high-quality solutions are preserved from generation to generation, thereby preventing the loss of the best-found solutions due to genetic drift or poor crossover/mutation outcomes.

10. **Convergence Toward Pareto Optimality:** In a multi-objective optimization scenario, the aim is not just to find a single optimal solution but rather a set of solutions representing the best possible trade-offs among the objectives, known as the Pareto front. As the evolutionary process proceeds, the MOEA aims to converge toward this Pareto front. This investigation assesses the Pareto optimality of solutions based on dominance criteria, considering a solution X to dominate another solution Y if it is at least equivalent to Y in all objectives and distinctly superior in at least one objective.

The crowding distance method in the Non-dominated Sorting Genetic Algorithm II (NSGA-II) can help predict accuracy while preserving population variation, providing each solution with a diversity measure based on its proximity to its neighbours in the objective space d(X). This is crucial to prevent the genetic algorithm from selecting a single approach, thereby maintaining its diversity. EQU (4.13) provides the expression for crowding distance.

$$d(X) = \sum_{i=1}^{O} \left(f_i \left(X^{\text{next}} \right) - f_i \left(X^{\text{prev}} \right) \right) \tag{4.13}$$

where:

- O is the number of objectives.
- $f_i(X)$ is the value of the i-th objective function.
- X^{next} and X^{prev} are the solutions adjacent to X in the sorted list of the population for each objective.

Each iteration of the MOEA performs a non-dominated selection to group the solutions into discrete identities based on the dominance parameters. This research assigns a fitness value to each front, usually inversely proportional to its rank. The 1st rank (nondominated solutions) represents the current estimate of the Pareto front.

Metrics like the hypervolume indicator or the inverted generational distance typically assess convergence by measuring how close the current solutions are to the true Pareto front. The MOEA iteratively updates the population using the selection, crossover, mutation, and survival selection processes to improve these metrics and move closer to the true Pareto front.

The loop expression can describe the iterative process:

Step 1. While (not termination condition)
Step 2. Perform non-dominated sorting of $P_t \cup O_t$
Step 3. Update crowding distances $d(X)$ for each solution X
Step 4. Select parents from P_t based on fitness and $d(X)$
Step 5. Apply crossover and mutation to create O_{t+1}
Step 6. Evaluate $F'(O_{t+1})$ and apply constraint handling
Step 7. Set P_{t+1} as the best solutions from $P_t \cup$
Step 8. O_{t+1} based on non-dominance and $d(X)$
Step 9. End While

The iterative optimization cycle continues until a stopping criterion is satisfied. A pre-established number of evolutionary processes, a sufficiently small change in the Pareto front indicating convergence, or a consistent lack of progression in the Pareto front's performance indicators can dictate this. This experiment explicitly ties the performance indicators to these research objectives: task coverage, communication network robustness, and energy efficiency. Also, this paper carefully monitors the iterative process to ensure that the Pareto front improvements align with the goals of effective surveillance and target tracking while managing the UAVs' EC and maintaining communication integrity. The following algorithm presents the steps involved in the MOEA-UAV swarm optimization.

In MOOP, metrics such as Pareto dominance, Pareto front coverage, and Pareto spread are important because they help measure the trade-offs between competing goals and evaluate the variety of Pareto front solutions. By evaluating a solution's superiority over another across a range of goals, Pareto dominance is a tool for finding non-dominated solutions. Pareto front coverage measures how accurately the Pareto front depicts the trade-off space and how thorough the solutions are. By examining the distribution and dispersion of options along the Pareto front, Pareto spread allows us to recognize the ideal solution environment in its complete form by emphasizing the range and spacing of the optimal solutions.

5. Experimental Analysis. The present investigation assessed the recommended MOEA by reproducing UAV swarm operations for agricultural monitoring using a TensorFlow-based simulator. In order to simulate the challenging task of following moving objects in extensive, unrestricted farmlands, researchers set up a virtual natural environment and deployed four UAVs on predetermined routes to collect data. This study built

Algorithm 5 MOEA for UAV Optimization

Inputs:

- m : Number of UAVs in the swarm.
- n : Number of targets to cover.
- N : Population size.
- MaxGen; Maximum number of iterations.
- σ_{init} : Initial standard deviation for mutation.
- σ_{final} : Final standard deviation for mutation.
- P_t : Current population at generation t.
- O_t : Offspring population at generation t.

Outputs:

- P^* : The optimized UAV swarm configurations.

1. **Initialization:**
   (a) Set generation count $t = 0$.
   (b) Initialize population P_0 with N random but feasible solutions respecting operational constraints.
   (c) Evaluate the initial population P_0 using the fitness functions f_1, f_2, and f_3.
   (d) Set $\sigma = \sigma_{\text{init}}$.
2. **Evolutionary Loop:**
   (a) While ($t <$ MaxGen) and (not convergence criteria met):
      i. Perform non-dominated sorting on $P_t \cup O_t$ to classify solutions into fronts based on dominance.
      ii. Calculate crowding distances $d(X)$ for each solution X.
      iii. Select parents from P_t based on fitness and $d(X)$.
      iv. Apply crossover and mutation to create $O_{(t+1)}$.
         - **For crossover:** Select parents X^{p1}, X^{p2} and perform Single-Point Crossover.
         - **For mutation:** Apply Gaussian Mutation to offspring, $x_i' = x_i + N\left(0, \sigma^2\right)$.
      v. Evaluate $F'\left(O_{(t+1)}\right)$ for the offspring and apply constraint handling.
      vi. Update σ by decreasing it gradually towards σ_{final} .
      vii. Perform selection for the next generation.
         - Combine and sort P_t and $O_{(t+1)}$ based on non-dominance and $d(X)$.
         - Select the best N solutions to form $P_{(t+1)}$.
      viii. $t = t + 1$.
3. **Elitism and Final Selection**
   (a) Perform a final non-dominated sort on P_t.
   (b) Select the elite set $E\left(P_t\right)$ ensuring the best solutions are preserved.
   (c) Update the final population P^* with non-dominated solutions representing the Pareto front.
4. **Termination**
   (a) The algorithm terminates when the stopping criteria are met:
      - Maximum generations MaxGen reached.
      - Convergence is assessed by changes in the Pareto front or performance indicators.

this work-tracking model on real flight paths and GPS-cached data from mobile targets, checking them for hypothetical intrusive risks to ensure maximum accuracy. This paper scheduled the deployment of the MOEA model in this computer simulation to enhance the operational features of the UAV swarm, including its EC, monitoring service, and aircraft performance, among other attributes.

Something that is part of the testing process for the MOEA used for UAV control pricing is looking at how well it can adapt to changes in the outside environment, the way things are moving, and uncertainty. The results of this experiment demonstrate that the procedure is practical in many situations. The use of security

Table 5.1: Key parameters for UAV simulation in the MOEA framework

Parameter	Specification
Minimum separation distance	4 m
Count of invasive targets	2
Total UAVs in simulation	4
Data link bandwidth range	[40 MHz, 90 MHz]
Communication power per UAV	35 dm
Average UAV cruising speed	70 km/h
Typical target movement speed	65 km/h
Target tracking route length	550 m
Data payload size limit	120 Mbytes
The operational limit for target capture	0.7 s

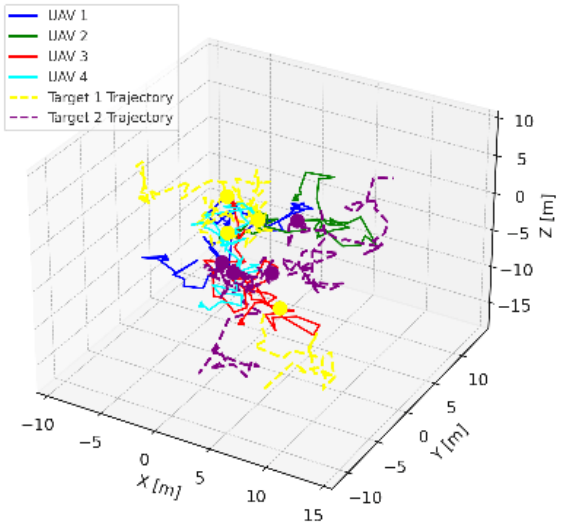

Fig. 5.1: Path graph for four UAVs and two moving target

metrics includes how secure a solution is in unpredictable situations, how well it adapts to new statistics, and how well it manages unpredictability in its task and environment. A study of the degree to which an approach maintains its functionality and the types of solutions it propositions. This study can determine the reliability of an approach by studying its ability to maintain functionality and the types of solutions it finds with changes in input settings or operating conditions. Acnes, including dynamic settings and inherent risks, it is essential to assess the algorithm from a reliability perspective. Table 5.1 provides the primary metrics, which are categorized as follows:

Figure 5.1 shows the 3D paths of the four UAVs, and Figure 5.2 shows the localization error as determined by the Mean Squared Error (MSE). Throughout one hundred iterations, the most significant performance metric was MSE. The MSE evaluates how well the UAV swarm can identify multiple targets, an essential part of operational efficiency that requires accuracy. This paper continuously monitored and evaluated each model's ability to minimize this error as the experiment progressed through its iterations.

Reliable enhancement in performance over 100 iterations is what sets the proposed framework for UAV swarm optimization. In contrast to ACO, PSO, and GA, which show variability to a certain extent and delayed convergence, the proposed framework begins with a low error rate that decreases consistently, demonstrating significant optimization and learning features. After the 20^{th} era, when the proposed design begins to func-

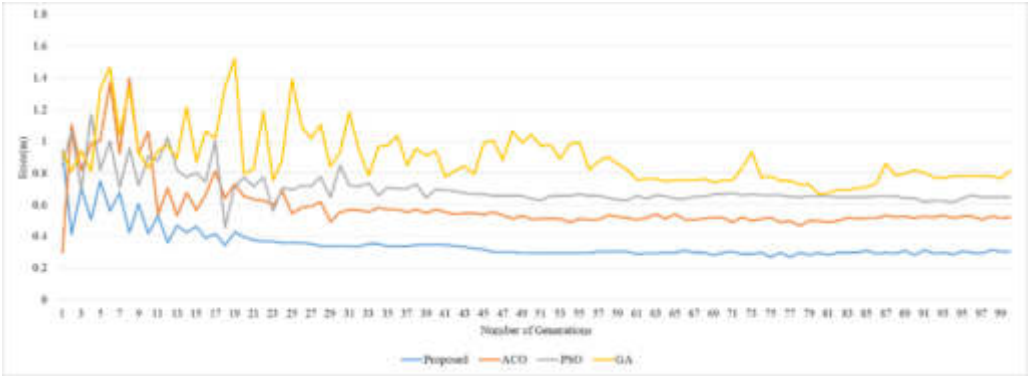

Fig. 5.2: Error comparison for 100 iterations

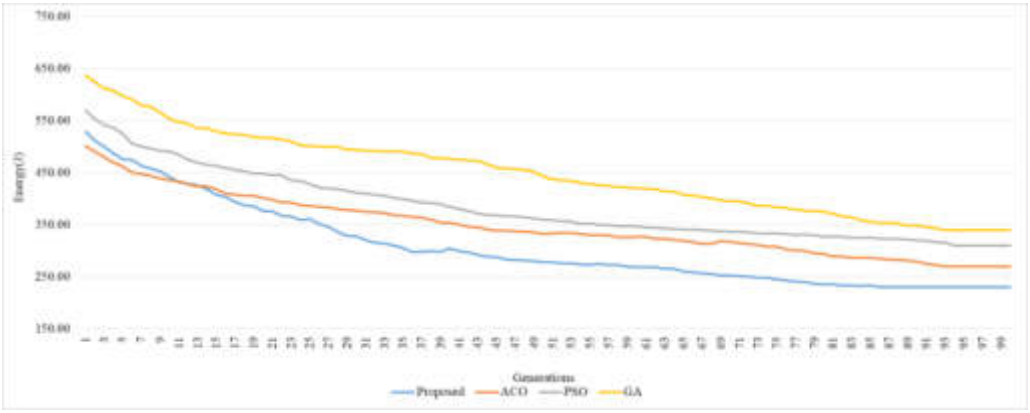

Fig. 5.3: EC analysis

tion regularly with other models, the pattern becomes increasingly evident. Accuracy is a key attribute for agricultural applications, and the proposed framework appears to successfully enhance its GPS accuracy, as demonstrated by the constant drop in error. Theoretically, it is more reliable and effective for UAV swarm-based multi-target GPS in SF, and the recommended approach maintains a lower error rate and less unpredictability in performance by its final iteration when compared to the other models. The recommended model's converging sequence indicates it is highly optimized, as it changes rapidly to the task and sustains performance over time. The proposed framework is appropriate for addressing the complicated challenges of SM environments requiring accuracy and adaptability due to its reliability and lower, more predictable error path.

Figure 5.3 presents a graph of the average aggregate unit EC over 100 iterations for four distinct algorithm choices. Starting at the lowest point and maintaining a minimal EC impact across any era, it is readily apparent that the proposed MOEA regularly dominates in energy efficiency. The next step, PSO, consistently consumes more energy than MOEA while maintaining comparable performance. Although ACO and PSO begin on similar ground levels, the former's rapid EC decrease over iterations indicates that ACO is less efficient in optimization. After increasing time, the GA generally concludes that there is more EC than any other algorithm, starting with the highest consumption. The proposed MOEA may be a better, more cost-effective, and better for the environment way to coordinate UAV swarm operations in this case. It is better than other known algorithms with over 100 iterations in terms of EC in the whole system.

Figure 5.4 compares the performance of the suggested MOEA to that of ACO, PSO, and GA regarding the total number of physical conflicts that ensued over 100 iterations. The obvious downward path of the proposed

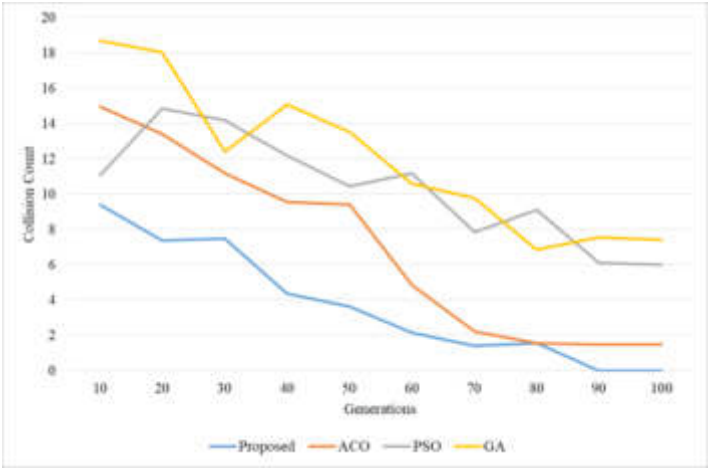

Fig. 5.4: Collision analysis for multiple iterations

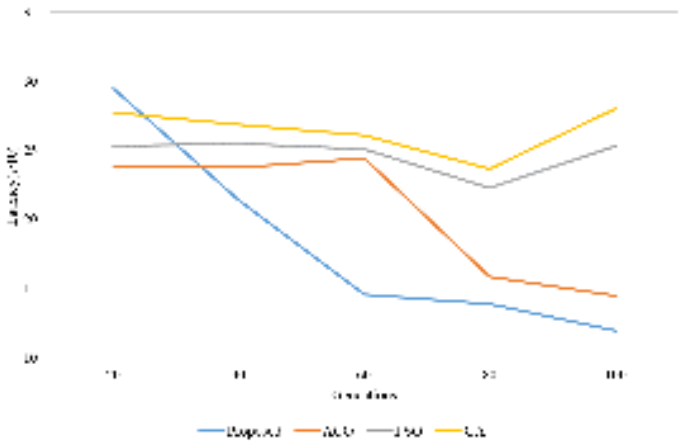

Fig. 5.5: Latency analysis for the compared models

MOEA, starting at 9 in the 10th iteration and successfully decreasing to zero in the 90th, demonstrates an optimization in preventing physical collisions. Conversely, the ACO begins at a higher level, approximately 15, and gradually decreases until it detects collisions at the 100th iteration. After starting in the middle of the group, PSO decreases until it maintains above five in the last generation, demonstrating success in avoiding collisions. GA exhibits the least effective performance among the examined methods, starting with the highest collision rate at over 18 and ending with a rate of approximately 7, even though it reduces by more than half towards the end. Findings illustrate how the proposed MOEA can improve UAV swarm operations and minimize collisions, making the system reliable and secure in future iterations.

Figure 5.5 provides the data on system performance delay for the proposed MOEA across 100th iterations compared to ACO, PSO, and GA models. With a delay reduction from 29.49 in the 20th iteration to 11.97 in the 100th, the proposed MOEA significantly improves execution speed with each successive generation. While ACO's latency is initially less than the proposed system at the 20th iteration, it increases in performance, only decreasing to 14.50 by the 100th iteration. PSO starts at 25.30 and continues similarly throughout the iterations, indicating a plateau in delay reduction, whereas GA shows lower-quality results. From iteration 27.73 to the 100th iteration, when GA's latency reaches 28.03 (which indicates a drop in performance), they are typically

the highest. The data shows that by the 100^{th} iteration, the proposed MOEA has the fastest execution speed compared to the other models. It also keeps changing, which shows how well and quickly it works to reduce system latency.

MOEAs require plenty of computing power to maintain a balance in UAV swarm EC, communication effectiveness, and task service. O(N.D.) for setup, O(N.E.) for fitness review, O(M.N2) for selection, and O(N.D.) for genetic functions like crossover and mutation all contribute to the total time complexity. This study can employ the following analysis to determine the overall cost period: The formula for calculating the total period of cost is O(G.N2.M+G.N.D.E), where G represents the total number of iterations. The primary explanation for the level of complexity of memory management is the storage of data for the entire population (O (N.D.)) and fitness metrics (O (N.M.)). Real-world mobile applications could potentially leverage device speed and concurrent processing to alleviate these demands. To effectively manage large-scale UAV-swarm installations, we need to conduct research and apply the findings by modifying the algorithm for specific problem scenarios.

6. Conclusion. The research accurately localizes multiple moving targets in Smart Farming (SF) environments by introducing an optimized pre-emptive Unmanned Aerial Vehicle (UAV) swarm model. The Multi-Objective Evolutionary Algorithm (MOEA) enhances the framework's capacity to adapt to dynamic circumstances by improving its communication, task service, and energy consumption features. Using UAV swarms in SF requires the implementation of a holistic approach with multiple objectives. The developed blueprint, a significant advancement in SM techniques, aims to optimize the behaviour of UAV swarms in both static and dynamic environments. This MOEA-optimized UAV swarm system has the potential to significantly improve the productivity, effectiveness, and sustainability of SF services.

PREDICTIVE CULTIVATION: INTEGRATING METEOROLOGICAL DATA AND MACHINE LEARNING FOR ENHANCED CROP YIELD FORECAST

BJD KALYANI*, SHAIK SHAHANAZ† AND KOPPARTHI PRANEETH SAI‡

Abstract. Agriculture is a key component of Telangana's economy, and greater performance in this sector is crucial for inclusive growth. A central challenge is yielding estimation to predict crop yields before harvesting. This paper addresses this challenge with machine learning approaches includes Naive Bayes, KNN and Random Forest. The parameters considered for model testing are crop, season, rainfall and location. This paper includes a case study of Telangana with the help of Telangana weather data set to provide analysis on the key factors like overall rainfall recorded with respect to each Mandal, overall seasonal yield in selected years, seasonal yield of major crops like Bengal gram, groundnut and maize, and overall yield in two different agricultural seasons: rabi and kharif. Random forest machine learning model produces highest accuracy of 99.32% when compared with other process models.

Key words: Prediction Cultivation, Machine Learning, Smart Agriculture, Random Forest, Meteorological data

1. Introduction. A harvest expectation is a boundless issue that happens. During the rising season, a rancher had an interest in knowing how much yield he is going to anticipate. In the prior period, this yield forecast becomes a self-evident truth depended on Farmer's drawn-out understanding for explicit yield, crops and climatic conditions [1]. Rancher legitimately goes for yield forecast instead of worried on crop expectation with the current framework [2]. Except if the right harvest is anticipated how the yield will be better and also with existing frameworks pesticides, natural and meteorological parameter [3] identified with the crop isn't thought of. Advancing and alleviating the rural creation at an all the more quickly pace is one of the fundamental circumstances for farming improvement. Any harvest's creation shows the route either by the enthusiasm of area or improvement in yield or both.

In India, the possibility of augmenting the locale under any yield doesn't exist with the exception of by restoring to increment trimming quality or harvest substitution. Along these lines, varieties in a difficult situation the region and create thorough trouble. In this way, there is have to endeavour great procedure for crop expectation so as to conquer the existing issue. The objective of this paper is to develop an application using Machine Learning for Predicting which Crop yield based on Meteorological data using "K nearest neighbour classification" (KNN) [4], Naive Bayes [5] and Random Forest [6].

2. Related Work. Meteorological data have been heavily utilised by the remote sensing [7] group to forecast agricultural productivity. However, all of the strategies rely on hand-crafted features, assuming that they can effectively capture the majority of the vegetation growth [8] information offered in high-dimensional images. Elavarasan et al., [9] concentrates on crop yield prediction rely on climatic parameters and focus to identify more parameters resulting high crop yield. Chlingaryan and Sukkarieh et al., [10] carried out survey on crop yield prediction with crop, water, soil and livestock management based on machine learning models. Liakos et al., [11] illustrates cost effective machine learning solutions integrating with remote sensing technology for efficient crop yield prediction. Balamurugan et al., [12] focus on integration of various parameters includes rainfall, temperature and season with random forest classifier. Aruvansh Nigam, Saksham Garg, Archit Agrawal et al., [13] demonstrates crop yield prediction with various algorithms includes random forest machine learning algorithm for crop yield prediction, recurrent neural network for rainfall prediction and LSTM for temperature

prediction. Thus, the literature focus on limited set of crop pictures considered for prediction. The proposed methodology can integrate computer vision [14] and Machine learning strategies with the basic architecture is Figure 2.1.

3. Methodology and Implementation. It might not be enough to merely take one or two elements into account when putting an accurate prediction model [15] into practice. Data on temperature, humidity, rainfall, and other variables are gathered and examined in Table 3.1.

The prediction model will be fed the results of this investigation. In this model using pandas [16] the yield_data and weather_data is imported and data is cleaned by detecting and removing the null values from the data sets. Removal of data Anomaly is carried out with the identification of the outliers using box plotting techniques and removing them. Forming a relationship between "weather_data and yield_data" using "district, year and crop_season" columns. Data Merging is carried by Creating 3 sub datasets from weather data grouped by "year", Taking average of Rainfall of each regiopn for same "crop_season", For every "year,district and crop_season" columns of "yield_data" , assign a rainfall value from the respective sub datasets that are chosen by year and from the chosen dataset "rainfall" data is selected based on "district and crop_season"

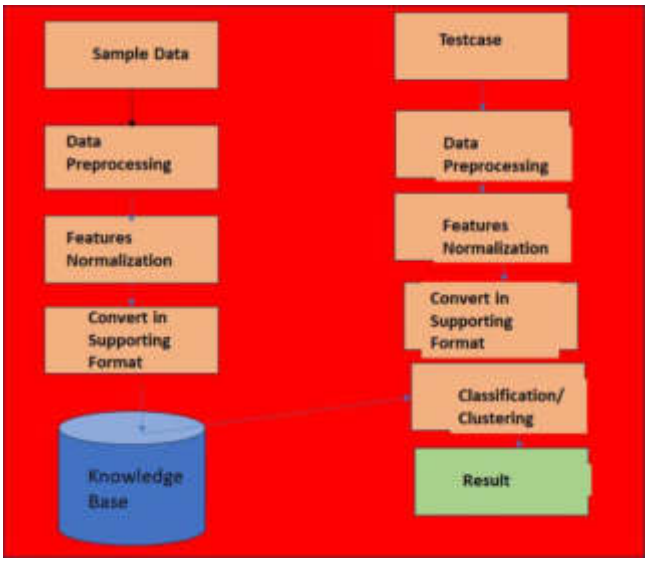

Fig. 3.1: Data Flow Diagram

columns and the new dataset created is then saved and used for further analysis. The Data Flow Diagram for the proposed model is illustrated in Figure 3.1.

3.1. KNN Algorithm. The KNN algorithm assumes that similar things exist in close proximity. The k-nearest neighbour (KNN) algorithm is a simple, easy-to-implement supervised machine learning algorithm [17] that can be used to solve both classification and regression problems and the proposed system is implemented using Python [18] with feature scaling is demonstrated in Figure 3.2. The algorithm requires a labelled dataset with historical data of crop yields and corresponding input features includes weather conditions, soil properties, fertilizer usage, etc. The features should be numeric and normalized for better results. Predicting is carried out with a new set of input features for a specific crop, KNN searches for the K nearest neighbours from the training dataset based on a distance metric like Euclidean distance. It then predicts the crop yield based on the average or weighted average of the yields of those neighbours. KNN is relatively easy to implement, but it may be computationally expensive for large datasets.

Fitting KNN Classifier to the training set, after executing the output generated is as in Figure 3.3 with confusion matrix.

3.2. Naïve Bayes. Each feature in the Naive Bayes model [19] is presumed to be independent. In order to produce a good impression, everything must be the same. Based on this data, we can define something as a fact or a hypothesis: There is no association between any two features, according to our assumptions. The "Hot" and "Rainy" forecasts have little to do with humidity and wind conditions. As a result, we presume that the traits are distinct. The equal weighting of each attribute is the second factor (or importance). Temperature and humidity alone are insufficient for accurate forecasting and result of Naïve Base in Figure 3.4.

3.3. Random Forest Model. The Random Forest Machine Learning method [20] solves the problem of overfitting and improves the accuracy. The algorithm is as follows in Table 3.2 and implemented using Python.

4. Results and Discussions. The agricultural practises of organic farming practised in Telangana [21] were taken into account by the model as a case study, and they can work as a catalyst to boost crop output and management. Currently used methods of organic farming include preserving soil quality and promoting biological activity. indirect crop nutrient supply through the use of soil microbes. utilising pulses to measure the amount of nitrogen in the soil. To control weeds and pests, some organic techniques are utilised, such as crop rotation, natural predators, and organic fertilisers. Step-by-step gardening involves some in-depth conversation.

Fig. 3.2: Scaled Data

Fig. 3.3: KNN Output with Confusion Matrix

The first step is cropping selection, which entails selecting the appropriate crop for the season. Analysis of data is carried out based on the seasonal yields of major districts of Telangana state as in Figure 4.1. Maximum production is seen Warangal-Rural District.

The overall production of major crops in two different cropping seasons kharif [22] and rabi [23], the highest yield observed for the crops of maize and the least yield is for the crop of Bengal gram. The analysis of seasonal yield over selected years proves that maximum seasonal yield can be seen in rabi season as in Figure 4.2. The proposed system provides accuracy of 91.50% with naïve Bayes, 93.4% with KNN and 99.32 with Random Forest model.The highest rainfall was observed and recorded in northern regions of the Telangana State, Jainad Mandal in Adilabad district and Figure 4.3 demonstrates the line plot of data predicted by model. Integrated farming techniques are extremely useful in the mitigation of negative impact of agriculture or livestock on environment.

Algorithm

1. Import data (yield_data , weather_data)
2. Data Cleaning (Removing Null Values)
3. Anomaly detection (outliers using box plotting techniques)
4. Initialize K.
5. Identify Nearest Neighbour (weather_data and yield_data", "district, year and crop_season").
6. Dataset Merging (year,district and crop_season, yield_data, rainfall, district and crop_season)
7. Data Transformation (label encoding)
8. Filter the data (Dist_id, Season, Crop, Rainfall, Season_yield)
9. Pick the first K entries from the Filter the data.
10. Prediction (x_train, y_train, x_test, y_test).
11. Evaluation (r2_score).

[49], especially when assumptions of conditional independence hold. However, it may struggle with precision if the features are strongly correlated [50]. Recall [51] of Naive Bayes can have good recall, particularly if it handles imbalanced classes well. It can effectively identify crops with low yields.

The F1 score of Naive Bayes will depend on both precision and recall, and it can achieve a reasonable balance between the two in many cases. Accuracy of Random Forest is resulting in high accuracy for crop yield prediction. Random Forest can achieve high precision, especially when the trees are well-optimized and the features are informative [52]. Random Forest tends to have good recall, as it combines multiple decision trees to capture different patterns in the data. Random Forest can achieve a high F1 score by balancing precision and recall, as it combines multiple decision trees with different strengths. The comparison of precision, recall and F1 score of three models are demonstrated by Figure 4.4.

5. Conclusions. The machine learning approaches analyse Meteorological data and provides accurate yield prediction to assist farmers. The model supports 99.32% accuracy with Random Forest and analyses Meteorological data of state Telangana. Areas need to be emphasized are increasing the focus for small farm economy utilizing market intelligence along with the State Governments involvement. The future work con-

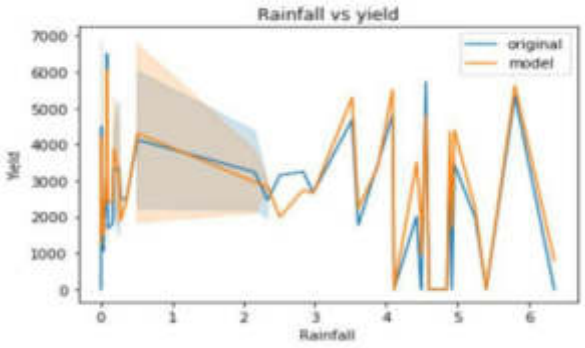

Fig. 4.3: Crop Yield Prediction

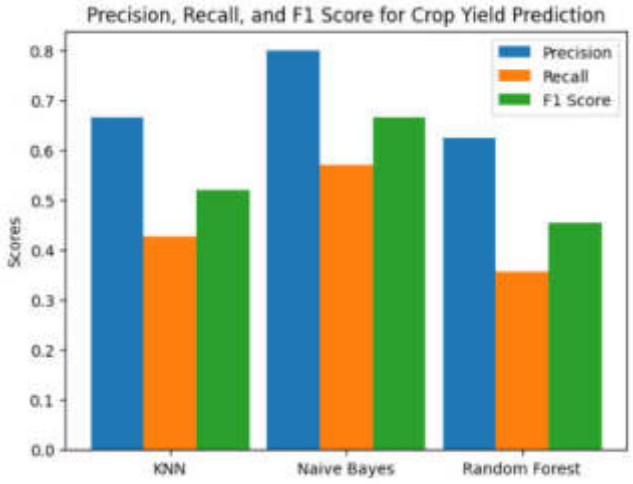

Fig. 4.4: Precision, Recall and F1 Score Comparison

centrates on artificial Supply chain management and Business intelligence strategies for marketing the crop of farmers.

AN ENHANCED RSA ALGORITHM TO COUNTER REPETITIVE CIPHERTEXT THREATS EMPOWERING USER-CENTRIC SECURITY

VISHAL BALANI[*], CHAITANYA KHARYA [†], SHIV NARESH SHIVHARE[‡], AND THIPENDRA P. SINGH [§]

Abstract. The technology-driven modern age emphasizes the security and privacy of communication. Through this paper, we delve deep into the need for user-centric security within cloud-based environments. The need for enhancement in encryption arises due to the increasing cases of data breaches and insider threats in cloud-based environments recently. The focus is laid upon the use of RSA encryption, end-to-end encryption, and anonymous messaging to address security-based concerns. The primary focus of this research is to develop a comprehensive security system to ensure the confidentiality and authenticity of text-based messages shared in the cloud. The proposed improved RSA algorithm, as suggested, incorporates three prime numbers in the key generation process. To address repetitive ciphertext, the proposed algorithm involves adding the index of each character in the plaintext string to the character's integer value before encryption. Conversely, during decryption, the same index is subtracted. This proposed algorithm has been utilized in a practical scenario, specifically in the implementation of a chat application. This paper presents a proof-of-concept for the proposed enhanced version of the RSA algorithm, accompanied by a thorough comparison and analysis of computational times across various bit lengths. Increase in data security at a cost of minor increase in computation time was observed through this research.

Key words: Enhanced RSA Algorithm, End-to-End Encryption (E2EE), Data Privacy, Confidentiality, Privacy Protection.

1. Introduction. In the ever-evolving landscape of digital communication, ensuring the security and privacy of sensitive information has become paramount. User authentication plays a crucial role in ensuring the security of a system [29, 30]. One of the cornerstones of secure communication is the use of cryptographic techniques, which have witnessed significant advancements in recent years [20]. The RSA cryptosystem is one of the most generally utilized public-key cryptosystems. RSA algorithm utilizes mathematical operations, including modular multiplication and exponentiation, making it an algorithm suitable for encryption and decryption using asymmetric key pairs[16]. In this process, two keys are utilized: one public key and one private key. Producing these keys includes complex calculations with large prime numbers, and the security of the RSA cryptosystem depends on the difficulty of factoring these large prime numbers.

Though RSA encryption and decryption are acknowledged for their security, they come with inherent performance limitations. Techniques such as fast modular multiplication, fast modular exponentiation, and the use of the Chinese remainder theorem (CRT) [1] have been developed to accelerate RSA operations, but they still lag behind symmetric-key encryption algorithms in terms of speed. Consequently, RSA encryption is often employed for secure key transport and the encryption of smaller data elements [2].

Traditional multiplication methods have a time complexity proportional to the square of the operand bit length. However, algorithms such as Karatsuba and the Toom-Cook method [5], which exploit recursive and divide-and-conquer strategies, respectively, enable faster modular multiplication by reducing the number of basic multiplication operations required. Exponentiation involves repeated modular multiplications, resulting in a time complexity proportional to the exponent's bit length. To expedite this process, techniques like square-and-multiply and Montgomery exponentiation provide more efficient algorithms. Instead of performing modular

exponentiation with the modulus N directly, CRT allows breaking the computation into smaller, independent components, each modulo a prime factor of N. By performing these computations separately and combining the results using the CRT, the overall execution time is significantly reduced.

Numerous research projects have been conducted in an effort to modify the RSA cryptosystem [17]. These included both hardware and software solutions, as well as solutions optimized for specific platforms such as .NET and Java. Hardware implementations include RNS Montgomery multiplication, use of the TMS320C54X signal processor, and designing custom hardware circuits using field-programmable gate arrays (FPGA) to perform the mathematical computations involved. Software implementations include salting, use of multiple prime numbers for key generation, use of mixed-base representation for depicting encoded messages, use of randomized exponentiation, RSA with elliptic curve cryptography, etc. These techniques have been observed to enhance security in real-world environments but may compromise the time needed for computation. Ongoing investigations are centered on addressing the diverse vulnerabilities present in the original RSA algorithm, aiming to enhance its resistance to known deterministic encryption. In this context, we propose an enhanced RSA algorithm to overcome such types of issues. The major contribution of this paper is threefold:

1. The proposed algorithm prevents repetitive ciphertext threats, such as frequency-based attacks and dictionary attacks, which are significant vulnerabilities in traditional RSA by adding a buffer to each character in the process of encryption.
2. The performance of the proposed algorithm is compared with that of traditional RSA, especially for the total computation time required for varying key bit lengths.
3. The implementation and integration of the proposed enhanced algorithm with a chat application and evaluated its calculation consistency.

2. Related Work. In present-day cryptography, the journey toward strengthening safety efforts while enhancing computational productivity has prompted different investigations and variations of the conventional RSA calculation. The purpose of the enhanced versions of RSA is to improve performance and security while demonstrating novel approaches to the cryptographic landscape. In this direction, Nivetha et al. [11] modified the RSA algorithm with multiple primes and four indivisible numbers inside the encryption system to reinforce the modulus size, apparently increasing security by muddling factorization processes. The expanded intricacy of key age and the board in frameworks utilizing numerous primes presents critical difficulties in true organization, frequently offsetting the potential security upgrades. The modified RSA with Mixed-Base Representation (MBR) computation streamlines execution by involving a mixed-base depiction for encoded messages [12]. Despite the fact that efforts have been made to reduce the time it takes to encrypt and decrypt as compared to traditional RSA, there are still concerns about the chance of safety degradation brought about by this streamlining. The focus of both research projects is on improving performance without jeopardizing security integrity.

The Modified RSA with Randomized Exponentiation (MRE) estimation carries randomized exponentiation into the encryption cooperation [14]. Even though this complexity is intended to deter adversaries from attempting to separate sensitive data through known-plaintext situations, it results in computational overhead, particularly in asset-obligated circumstances. Investigations consolidating RSA with elliptic curve cryptography (ECC) look for improved security while diminishing key sizes [13]. Essentially, coordinating two particular cryptographic frameworks presents significant execution intricacies and raises interoperability concerns among the RSA and ECC conventions. Kapoor et al. [18] proposed a modified RSA method that was based on multiple public keys and n prime integers. This method aimed to provide efficiency and enhances data sharing security across networks. However, the authors observed that as the prime numbers increase, key generation time also increases exponentially.

Moreover, Anagaw and Vuda [15] efficiently implemented of the RSA algorithm using two public key pairs and mathematical logic. Separately delivering two public keys prevents attackers from learning about the key and the message. A similar method was proposed by Jahan et al. [19] that utilizes two public key pairs and mathematical logic instead of delivering one public key directly. This approach aims to enhance security by making it more difficult for attackers to obtain the private key. Imam et al. [20] modified the RSA algorithm for encryption using two public keys derived from four prime integers. This method aims to enhance security by using dual modulus to eliminate flaws and improves the system's security. Furthermore,

Mezher [21] devised a method that employs multiple public and private keys, making the algorithm more secure and immune to brute-force attacks. This modification technique takes nearly nine times more time to break the traditional method when using alternative key sizes. The use of modified RSA with salt in cloud data encryption aims to enhance security by introducing randomness. It addressed the fundamental aspects of cloud security, focusing on data encryption and its pivotal role in safeguarding data within the cloud [17]. While investigating the aforementioned modification in the traditional RSA algorithm, we observed that encryption has certain limitations, especially in the context of cloud computing, which are highlighted as follows:

- Performance Overhead: Traditional RSA encryption can introduce performance overhead due to its computational complexity, especially when dealing with large volumes of data in cloud environments.
- Key Management: The management of encryption keys in RSA encryption can be challenging, particularly in shared cloud environments where multiple users and organizations coexist. Ensuring secure key exchange and management is crucial for maintaining data confidentiality and integrity.
- Vulnerability to Attacks: Traditional RSA encryption may be vulnerable to certain attacks, such as brute-force attacks, especially if the encryption keys are not sufficiently random or complex. This vulnerability can pose a significant risk to data security within the cloud.

To address these drawbacks and enhance cloud data security, the use of modified RSA with salting was proposed. The modified approach incorporated salting (password-based encryption schemes) to add an extra layer of randomness and complexity to the encryption process, making it more resilient against brute-force attacks and other security threats [17]. A few hardware implementations of the modified RSA algorithms were introduced by several researchers recently. The details are as follows:

- Use of RNS Montgomery multiplication for implementing RSA encryption involves converting the large integers used in RSA encryption into a residue number system (RNS) and performing modular multiplication using the Montgomery algorithm. This approach can improve the efficiency of RSA encryption by reducing the number of operations required for modular multiplication [22, 23, 27].
- Use of Texas Instruments TMS320C54X signal processors for implementing RSA encryption involves optimizing the RSA algorithm for the architecture of the TMS320C54X family of signal processors, which can improve the performance of RSA encryption in hardware environments [22, 23].
- VLSI design using FPGA for implementing RSA encryption involves designing custom hardware circuits using field-programmable gate arrays (FPGAs) to perform the modular arithmetic operations required for RSA encryption. This approach can improve the performance of RSA encryption in hardware and reduce power consumption [22, 24].

On the other hand, various software implementations of RSA encryption have been proposed, including .NET [25, 26] and Java [28]. These software implementations involve optimizing the RSA algorithm for specific software platforms, which can improve the performance of RSA encryption in software [22]. Bonde and Bhadade [22] provide insights into the advantages and limitations of each implementation method, highlighting the importance of selecting the appropriate implementation method based on the specific requirements of the application. For example, hardware-based approaches such as VLSI design using FPGA and Texas Instruments TMS320C54X signal processors can improve the performance of RSA encryption in hardware, while software-based approaches such as .NET and Java can improve the performance of RSA encryption in software. Topics closely related to modified RSA algorithms have been the subject of recent research, which has made a significant contribution to the field of cryptography. Encrypted chat applications using RSA encryption plans [7, 8, 9, 10] feature the pragmatic parts of cryptography methods in real-time applications. In addition, comprehensive literature reviews on big data management techniques in the Internet of Things (IoT) [6] provide insights into managing massive amounts of data generated by interconnected devices, highlight obstacles, and suggest directions for future research.

Thus, the range of enhanced RSA algorithms offers novel strategies for enhancing performance or strengthening security. However, their practical implementation faces challenges due to complexities, potential vulnerabilities, and interoperability concerns. Comprehensive evaluations and standardization efforts are imperative to advance cryptography techniques. Table 2.1 summarizes and highlights several recent and relevant research work based on the RSA algorithm.

Table 2.1: Description of the referenced research papers in Related Work Section

Author(s)	Methodology	Advantages	Limitations
Nivetha et al. [11]	Modified RSA with Multiple primes, 4 Keys	Increased complexity of modulus factorization	Computational overhead

Sharma et al. [28]	RSA using modified Subset Sum cryptosystem	Resistant against modulus factorization, brute-force and Shamir attacks	Computational overhead

3. Proposed Methodology. In existing RSA cryposystem, a character generates the same ciphertext each time it is encrypted in a message. This leads to vulnerability and the threat of frequency-based attacks, which can compromise the application. The enhanced RSA discussed below deals with this vulnerability, hence enhancing security while minimizing computation time differences as compared to traditional RSA. The following steps delineate the methods employed to modify the traditional RSA encryption and decryption algorithms.

3.1. Selection of Prime Numbers (Key Generation).

- *Traditional RSA:* The conventional RSA algorithm utilizes two prime numbers, p and q, to generate the public (e, n) and private (d, n) keys. However, to fortify the encryption system, larger prime numbers significantly contribute to the increased complexity of $n = p \times q$.
- *Enhanced RSA:* To substantially increase the value of n, the modification incorporates three large prime numbers. Hence, the value of n becomes $n = p \times q \times r$. While this increases computational complexity, it significantly fortifies the encryption. The optimal balance in the number of prime numbers used to

generate n is under study, aiming for lower computational complexity and higher protection against common brute-force attacks against RSA.

3.2. Index Increment in Each Character Before Encryption.

- *Traditional RSA:* Plaintext is encrypted using the equation:

$$C = (m^e) \mod n \tag{3.1}$$

The vulnerability in this method arises from the generation of the same ciphertext for repeated characters in the message, making RSA encryption susceptible to attacks.

- *Enhanced RSA:* To mitigate this vulnerability, the enhanced RSA method increments each character by its index in the original message before encryption, transforming the encryption equation to:

$$C = ((m + index)^e) \mod n \tag{3.2}$$

This slight modification significantly enhances the security of the RSA encryption algorithm, making it arduous for attackers to decrypt the message, even with access to the private key.

3.3. Index Decrement in Each Character After Decryption.

- *Traditional RSA:* Ciphertext is decrypted using the equation:

$$m = (C^d) \mod n \tag{3.3}$$

If the private key is leaked, it may lead to the release of sensitive information in the message.

- *Enhanced RSA:* To ensure seamless decryption of ciphertext encrypted using enhanced RSA, the inverse of the steps performed during encryption are applied to the decryption algorithm. The decryption algorithm is as follows:

$$m = ((C^d) \mod n) - index \tag{3.4}$$

In the event that the private key is leaked, attackers will be unable to obtain sensible information from the decrypted text, producing gibberish as the message. The application of the Chinese Remainder Theorem in the modified decryption algorithm leads to reduced computation time.

The following are the detailed implementation steps for the changes explained above:

1. *Choose 3 Prime Numbers (p, q, and r):* Generate three distinct, large prime numbers: p, q, and r. Random numbers of bits (ranging from 45 to 52 due to system computation limitations) are used to generate large prime numbers.
2. *Compute Modulus (n):* After selecting p, q, and r, multiply them to obtain the modulus, n.

$$n = p \times q \times r \tag{3.5}$$

This modulus is a fundamental component of both the public and private keys, serving as the basis for encryption and decryption.

3. *Computation of Euler's Totient Function ($\phi(n)$):* Compute the Euler's Totient Function using the prime numbers, p, q, and r, required to derive the value of d, a part of the private key.

$$\phi(n) = (p-1) \times (q-1) \times (r-1) \tag{3.6}$$

The totient function is crucial in selecting the public exponent to ensure the existence of a unique modular multiplicative inverse in the decryption process.

4. *Select Public Key Exponent (e):* Choose the public key exponent denoted as e. It should be a positive integer that is relatively prime to $\phi(n)$ (i.e., $\text{GCD}(e, \phi(n)) = 1$).
5. *Generate Public Key (e, n):* The formation of the public key comprises the concatenation of 'e' and 'n', serving the purpose of encrypting plaintext messages. The encryption process involves incrementing each plaintext character 'm' by its corresponding index within the message. The equation representing this process is:

$$C = ((m + index)^e) \mod n \tag{3.7}$$

6. *Compute Private Key (d):* Obtain the private key exponent, d, by finding an integer that satisfies the equation:

$$(d \times e) \mod \phi(n) = 1 \tag{3.8}$$

7. *Generate Private Key (d, n):* The private key is formulated by combining 'd' and 'n'. The decryption process involves decrementing the index of the decrypted text to obtain the original message. The decryption formula can be expressed as follows:

$$m = (C^d \mod n) - \text{index} \tag{3.9}$$

The key pairs, the public key (e, n) and the private key (d, n), are the basis of RSA encryption. The public key allows anyone to encrypt messages, while only the holder of the private key can decrypt them. The security of RSA relies on the computational complexity of factoring the modulus n into its prime factors p, q, and r. Our proposed system utilizes the enhanced RSA algorithm for secure communication within the chat application. On the sender's side, text messages are encrypted using the recipient's public key, retrieved from the cloud database. This public key encryption ensures that the message remains unreadable while stored on the cloud server, mitigating potential security risks during data transport. The encrypted message is then transmitted to the receiver, who possesses the corresponding private key stored locally on their device. This private key is used for decryption of the message using the enhanced RSA algorithm, enabling retrieval of the original content.

4. Experimental Results. In this segment, we present the outcomes we got from the assessment of the enhanced RSA calculation. Centered around surveying the calculation's adequacy by analyzing the distinctions in encryption results compared with the conventional RSA approach. Furthermore, we investigate the computational times expected for encryption, decryption, and key decryption processes. The essential goal is to exhibit the effect of the adjustments on encryption quality and computational proficiency.

4.1. Algorithm for Enhanced RSA. To demonstrate the effectiveness of the proposed enhanced RSA we have successfully implemented it in chat application. For detailed understanding of the algorithm, please refer to Algorithm 6 where a detailed pseudo-algorithm is provided.

4.2. Proof of Algorithm. Sample Text: "HELLO"

Step 1: Prime Number Generation. Generate three large prime numbers, p, q, and r, each of length bits: $p = 61$, $q = 53$, $r = 67$ (arbitrary values for demonstration purposes)

Step 2: Modulus Calculation. $n = p \times q \times r = 61 \times 53 \times 67 = 216611$

Step 3: Euler's Totient Function Calculation. $\phi(n) = (p-1) \times (q-1) \times (r-1) = 60 \times 52 \times 66 = 205920$

Step 4: Public Key Generation. Choose an integer e such that: $1 < e < \phi(n)$, $\gcd(e, \phi(n)) = 1$. Let $e = 65537$, the public key is represented as $< 65537, 216611 >$

Step 5: Private Key Calculation. Calculate the private key component d using the equation: $(d \times e) \mod \phi(n) = 1$ Let $d = 187,217$ The private key is represented as $< 40193, 216611 >$

Step 6: Encryption Process. Encrypt the message "HELLO":

$$C = (m + \text{index})^e \mod n$$

Assuming ASCII values for each character and index are starting from 0:

$$C_H = (72+0)^{65537} \mod 216611 = 112922$$

$$C_E = (69+1)^{65537} \mod 216611 = 61752$$

$$C_L = (76+2)^{65537} \mod 216611 = 151883$$

$$C_L = (76+3)^{65537} \mod 216611 = 140326$$

$$C_O = (79+4)^{65537} \mod 216611 = 57641$$

Encrypted message: $< 112922, 61752, 151883, 140326, 57641 >$

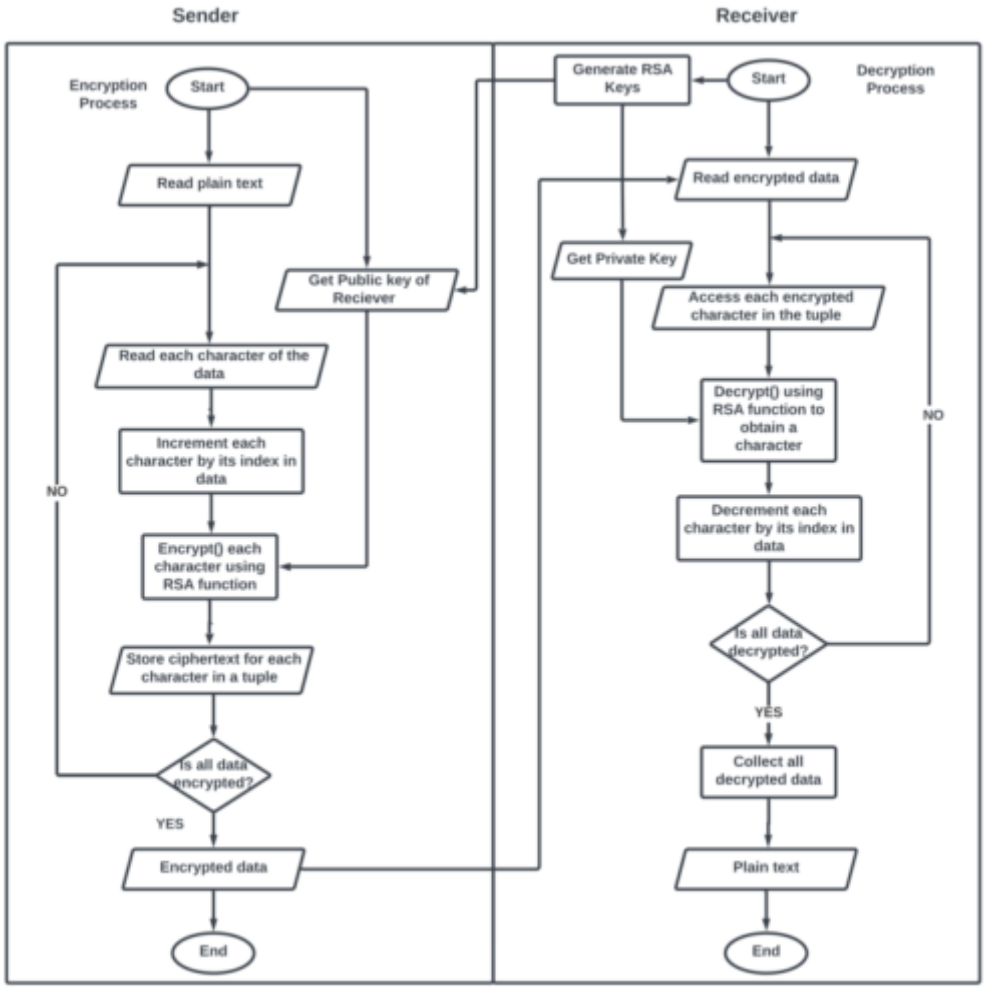

Fig. 3.1: Flow diagram illustrating the Encryption and Decryption processes in Enhanced RSA

Step 7: Decryption Process. Decrypt the ciphertext:

$$m = (C^d \mod n) - \text{index}$$

$$m_H = (112922^{40193} \mod 216611) - 0 = 72$$

$$m_E = (61752^{40193} \mod 216611) - 1 = 69$$

$$m_L = (151883^{40193} \mod 216611) - 2 = 76$$

$$m_L = (140326^{40193} \mod 216611) - 3 = 76$$

$$m_O = (57641^{40193} \mod 216611) - 4 = 79$$

Decrypted message: "HELLO"

The algorithm successfully encrypted the message "HELLO" and decrypted it back to the original text. This demonstrates the correctness of the RSA encryption and decryption processes for the given sample text.

4.3. Analysis: Differences in Encryption. A comprehensive comparison was conducted between the encryption mechanisms of enhanced RSA and traditional RSA, implemented without the use of predefined cryptographic libraries. This analysis aimed to demonstrate the encryption disparities, particularly focusing on the handling of sample alphanumeric text such as "tt," "11," and "@@". 50-bit long prime numbers were used to generate the public and private keys in both traditional RSA and enhanced RSA.

The enhanced RSA encryption notably reveals that the repetition of a character generates distinct ciphertexts for each instance of the repeated character, enhancing its resistance against certain attacks.

From Table 4.1, we can observe that, in the process of encrypting plain text, any instances of repeated alphanumeric characters do not show repetitions in the resulting cipher text. This intriguing phenomenon suggests that the encryption algorithm employed successfully obfuscates patterns associated with repeated characters, adding an extra layer of complexity and security to the encrypted data.

4.4. Computational Time Analysis. In order to conduct a thorough analysis of the computational performance of both traditional RSA and enhanced RSA, an experimental setup was established. The computational performance was measured on an Apple MacBook Air equipped with an Apple M1 Chip, featuring an 8-core CPU and 256 GB storage. The analysis was conducted consistently in the same environment for varying bit lengths. The encryption process was applied to an alphanumeric text message of 2150 characters in length to gauge the encryption time for both algorithms. The aim was to evaluate and compare the computational efficiency of the encryption process.

To visually depict the variation in total execution times for different bit lengths, a graphical representation illustrating the relationship between the number of bits and total execution time is presented below.

Fig. 4.1 is plotted over the total computation time analysis between RSA and enhanced RSA. It was observed that enhanced RSA takes nearly the same amount of time as compared to RSA when the number of

bits is less than 1024. But when the number of bits is over 1024, we see a drastic increase in computation time for enhanced RSA over traditional RSA. The key generation time, encryption time, and decryption time are measured in milliseconds.

Tables 4.2 and 4.3 provide a detailed analysis of the computational time for various bit lengths using both traditional RSA and enhanced RSA.

5. Real World Implementation. To validate the practical applicability of the enhanced RSA algorithm, we integrated it into a chat application developed using the Flutter SDK and utilizing Firebase for database functionality. The primary aim was to fortify the security of communication within the application while ensuring seamless usability.

5.1. Algorithm Integration. The adjusted RSA encryption procedure was flawlessly embedded inside the chat application’s messaging functionality. This joining took into account the encryption and decryption of messages traded between clients, improving the general security of correspondence channels.

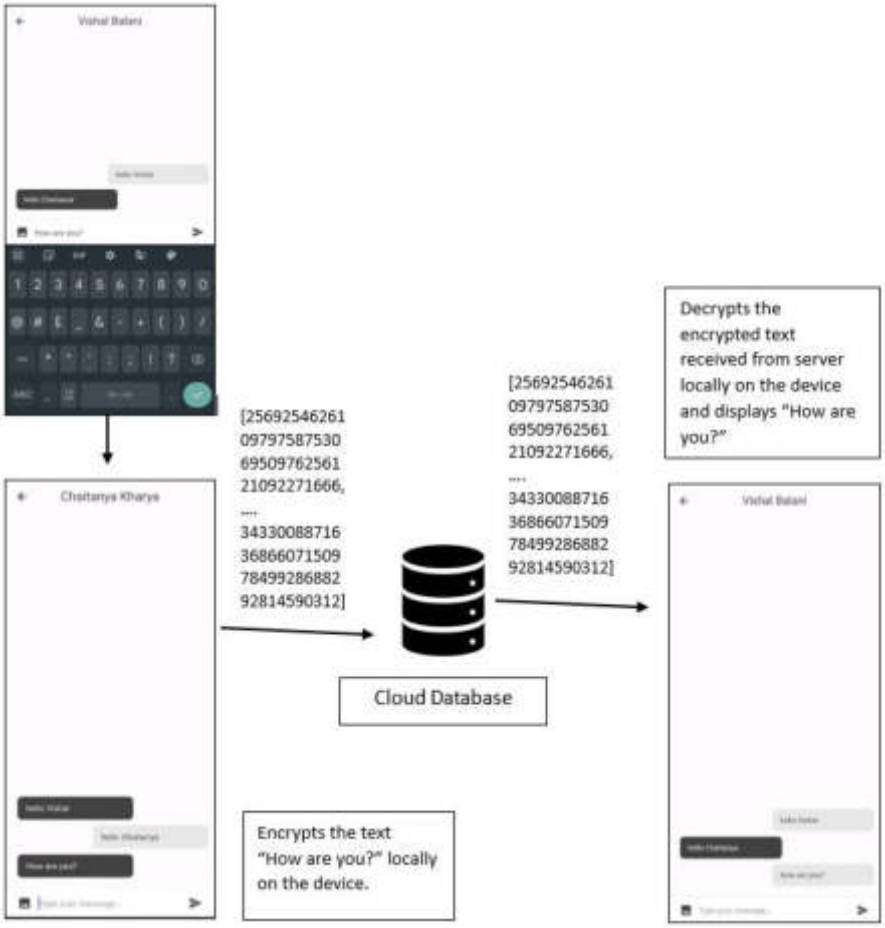

Fig. 5.1: Encryption and decryption process flow within the app

5.2. Platform Testing. Extensive testing across different Android versions (going from 10 to 14) was led to guarantee the enhanced RSA execution's reliable presentation and functionality across various platforms. The thorough testing was meant to identify and address any compatibility or operational issues that could arise across various Android versions.

5.3. Enhanced Functionality and Security. The incorporation of the enhanced RSA algorithm brought forth a significant enhancement in the security aspect of the chat application. This upgrade assured users of secure encryption methods, providing a secure environment for sharing sensitive information through the messaging application.

5.4. Process Visualization. For a more clear comprehension of the encryption and decryption processes inside the application, a definite interaction flowchart is shown in Fig. 5.1. This visual guide effectively clarifies how the adjusted RSA calculation is utilized inside the application, showing the means engaged with the encryption and decryption of messages.

5.5. Accessibility and Further Exploration. The complete process flow diagram for exploring and understanding the enhanced RSA feature within the chat application is available. Feel free to access the application available on Google Play named **EncryptoSafe Private Messaging**.

6. Conclusion. The development of this enhanced RSA and secure chat application has showcased promising results in the realm of digital messaging encryption. Employing three integers within the enhanced RSA algorithm has introduced an additional layer of complexity to the encryption procedure. Consequently, the resultant chat application demonstrates resilience against potential threats such as eavesdropping and unauthorized access to chats, thereby significantly contributing to the domains of cryptography and cybersecurity by ensuring the protection of sensitive information exchanged between users. During app development, several challenges were faced. These included ensuring secure key management, maintaining real-time data transfer capabilities, and implementing user authentication protocols. Additionally, limitations in the scope of the project prevented the inclusion of file encryption functionalities for multimedia content such as audio, video, and images. The collaborative effort and advancements made in this work signify a substantial leap forward in establishing secure communication frameworks, laying a foundation for continued research and innovation in securing digital interactions.

The app was provided to multiple users for user testing, the reviews received have been summarised as follows. The chatting was seamless, with messages being sent and received in real-time. But issues were faced in sending media files like photos, videos and audios, only text and emoticons were supported by the application. User can initiate chat with any other user of the app, regardless of whether they are in the user's contact list or not. While the implementation has demonstrated considerable success, there are several avenues for future enhancements and improvements in the chat application. Key generation processes can benefit from leveraging parallel processing and hardware acceleration techniques to optimize performance. As user numbers increase, scaling the performance and security aspects becomes crucial. Moreover, ensuring resistance against modern quantum attacks is imperative for the enhanced RSA algorithm.

MACHINE LEARNING APPLIED TO REAL-TIME EVALUATION OF SPOKEN ENGLISH COMMUNICATION IN TOURISM

XING MING*, DAN HAN†, AND CONGCONG CAO‡

Abstract. Effective interaction between travellers and local suppliers of services is critical in the increasingly international tourism business. Speaking and understanding English well is frequently essential to a satisfying trip. In the setting of tourism, this study investigates the use of machine learning algorithms for the real-time assessment of spoken English interaction. The aim of this research is to create a new system that uses algorithms based on machine learning to evaluate and enhance English-language conversations among travellers and travel agents. We provide a novel method for assessing many facets of a conversation, such as spelling, syntax, proficiency, and general sentiment, that integrates automated speech recognition (ASR), natural language processing (NLP), and sentiment analysis. The gathering of a broad collection of spoken English exchanges in travel-related contexts, the creation of a tailored ASR models taught on terminology unique to the travel industry, and the incorporation of natural language processing (NLP) methods to assess the sentiment and linguistic structure of dialogues are important aspects of the project. To assist businesses and visitors improve their ability to communicate, models based on machine learning will be taught to deliver immediate input. The goal of this project is to benefit the tourism sector by developing a tool that will enable better English-speaking interaction, which will eventually end up resulting in more satisfied and better experiences for visitors. It also covers the requirement for domain-specific individualized language instruction and evaluation tools. The study's findings could revolutionize the way spoken English proficiency is assessed and enhanced in the travel and tourism industry. They could also have wider ramifications for language acquisition and intercultural interaction across a range of sectors.

Key words: natural language processing, automated speech recognition, Tourism, spoken English communication.

1. Introduction.

As tourist attractions grow globally and the dissemination of knowledge and purchase over the Internet accelerates, the travel tendency has shifted lately moving closer the Tourism 2.0 model. In contrast to emphasizing merely travel and consumer activities, the tourist 2.0 paradigm aims to revitalize the tourist sector by appreciating the vitalization of communication and knowledge as well as interactive cultural encounters [29]. Furthermore, the objective of Tourism 2.0 is to reinvent the tourism sector by advancing technology and information, offering travellers a diverse range of experiences and cultures, and encouraging the growth of the community's economy and the environment through the promotion of environmentally friendly tourism.

The provision of inventory by online travel agencies (OTAs) is essential to the tourism sector since it allows them to optimize their customer revenues. Moreover, OTAs have the power to keep competitors out of the market. Removing the need for outsiders is one of among the most important functions of blockchain technology in the travel and tourism sector [17]. The use of Blockchain has huge potential to boost the competitive edge and efficiency of the tourism sector [16]. The quick development and introduction of the blockchain technology may have a big effect on the travel and tourism sector as well as the world economy [22, 8, 10]. For instance, a lot of little island countries started using this kind of technology [29].

A technique for identifying commonalities among users using data among users and things is called shared filtering (CF)-based suggestion, that suggests tourist locations based on tourism significance [12]. A technique for assessing the resemblance of items using item data is content filtering (CB)-based suggestion, which suggests travel destinations based on their relevance [9]. Considering the necessary information quantity and cold start issue, filtering-based vacation spot suggestion systems (RS) have trouble handling fresh data without knowledge. As a result, research on an artificially intelligent (AI)-based RS is being done [30].

Studies on tourism has come a long way, and it is now acknowledged as a unique and varied field of management [13]. By showcasing the variety of tourist studies and establishing it as a separate academic discipline, research publications on tourism offer a fresh viewpoint to the already congested subject of managerial study. In the past five years, the subjects of "smart tourism" and "blockchain in tourism" have become increasingly important. Applications of blockchain, the Internet of Things (IoT), artificial intelligence (AI), and machine learning (ML) are strongly related to tourist. A few reviews of blockchain-related tourism research have been published by others [6, 2, 7], but there isn't a structural analysis of "smart tourist by blockchain" at this time.

The global tourism industry relies heavily on effective communication between travelers and local service providers to ensure satisfying experiences. In this context, proficiency in spoken English plays a pivotal role, acting as a universal bridge connecting diverse cultures and facilitating smooth interactions. However, the dynamic and spontaneous nature of spoken exchanges, combined with the wide variety of accents, dialects, and linguistic nuances, presents significant challenges to maintaining high-quality communication. Traditional methods of language proficiency assessment and improvement, often static and generalized, fail to address the specific needs and immediate feedback required in the fast-paced tourism environment. This gap highlights the urgent need for innovative solutions that leverage technology to provide real-time, personalized language assistance and evaluation.

This research mainly investigates:

1. The feasibility of integrating automated speech recognition (ASR), natural language processing (NLP), and sentiment analysis to assess various aspects of spoken English interactions, including spelling, syntax, proficiency, and sentiment, in a real-time context.
2. The process of collecting and analyzing a diverse dataset of spoken English exchanges specific to travel-related contexts, emphasizing the creation of tailored ASR models that incorporate terminology unique to the travel industry.
3. The effectiveness of machine learning-based models in delivering immediate feedback to users (travelers and travel agents), aiming to improve their communication skills.

The main contribution of the proposed method is given below:

1. DNN-LSTM models have the potential to improve evaluation accuracy for spoken English communications.
2. These algorithms can provide more accurate evaluations by utilizing the sequential processing power of LSTMs and the deep learning capability of DNNs to better capture the subtleties of spoken language, such as spelling, proficiency, and tone.
3. Real-time evaluation is possible with DNN-LSTM models, which is especially helpful in situations involving tourism when prompt feedback is crucial. Travelers can get instant feedback on how well they speak English, allowing them to immediately make the required corrections.
4. DNN-LSTM models can offer current evaluations and adjust to shifts in spoken language trends via ongoing training and improvement. This guarantees that travelers get appropriate input according to the language used right now.

The rest of our research article is written as follows: Section 2 discusses the related work on various tourism, spoken communication and deep learning methods. Section 3 shows the algorithm process and general working methodology of proposed work. Section 4 evaluates the implementation and results of the proposed method. Section 5 concludes the work and discusses the result evaluation.

2. Related Works. A CF-based RS approach that suggests places to visit based on their importance to visitors and a CB-based RS technique that suggests tourist interests based on their connection to destinations for tourists are two examples of tourism-related aids [15]. Utilizing information about interactions between travellers and tourist locations, the CF-based RS assumes that similar visitors have identical tastes for a certain tourist attraction. Proposals can be given even if there is little resemblance between tourist sites because CF is based on relationships between travellers and tourist venues. Nevertheless, the lack of relevant tourist information prevents the application of new tourist locations [11]. Using tourist attraction data, a CB-based RS that suggests places to visit according to their relevance might also suggest related tourist locations, so resolving the cold start issue [21, 23].

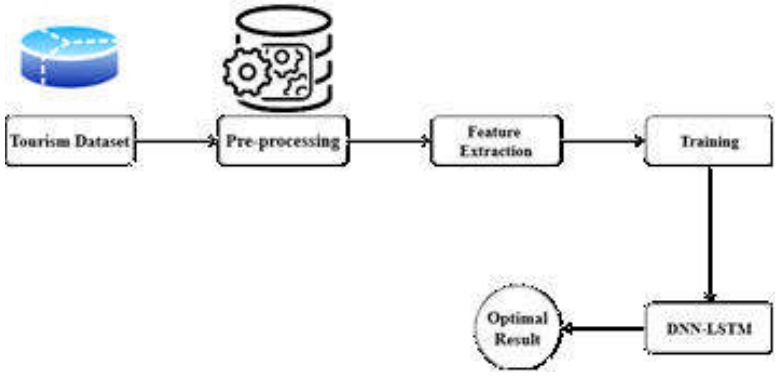

Fig. 3.1: Architecture of Proposed Method

To analyse citations, writing, phrases, and the geographical spread of creation, most writers utilize bibliography and Vos viewer software. Nevertheless, using data mining and machine learning technologies to investigate text trends and patterns is equally crucial. Since these tools are not influenced by the prejudices of human decision-making, they could offer a more precise assessment of the material. To provide a less biased result, AI technologies examine natural inputs provided by human beings [5]. Researchers have taken an interest in recent advances in machine learning application. Researchers have reviewed the research, investigated concealed patterns, performed text analytics, looked at the complexity of the substance, and investigated coauthor ship, creation, reference, phrases, and geographical distribution using machine learning (ML). To obtain more specialised results, medical imaging research mostly uses AI and ML technologies[14, 9].

Absent information on interactions among travelers and tourist places, CB can provide suggestions. When enough data is gathered, nevertheless, its performance suffers in comparison to CF-based RS[18]. Because an RS employing AI uses tourism patterns rather than item similarities, it may dynamically utilize data size or characteristics. With the advancement of algorithms and computing power, they have reached outstanding recognition performance [19]. Nonetheless, RS determined by travel patterns and AI are limited in dynamic scenarios since they don't account for instantaneous shifts in outside variables and distance data, like weather or heat [1].

A range of classifiers were employed in a supervised machine learning method for analysing sentiment in the travel industry. A Naï€ve Bayes technique was employed in a study on sentiment analysis of hotel reviews using a Multinomial Naı€ve Bayes model [3, 25, 26]. After data preparation, the authors of the current research offered a method for categorizing customer evaluations as either favorable or adverse using an NBM classifier that identified characteristics using a bag of keywords. The results of the experiment showed an average F1 score of more than 91%. Similarly, [27, 28] have demonstrated strong NBM reliability; that is, NBM identified 88.08% of the eatery reviews dataset accurately and obtained 90.53% accuracy in the lodging comments data [24, 20].

3. Proposed Methodology. There are various processes involved in putting forth a system for using machine learning to assess spoken English communication in real-time within the tourism setting. Gather a wide range of spoken English exchanges in tourism settings, such as discussions between visitors and guides, lodging employees, or neighborhood inhabitants. Include annotations for relevant characteristics in the dataset, such as grammar, spelling, proficiency in a language, and overall interaction quality. Automated speech recognition (ASR) technologies are used to prepare the audio data by turning it into text and transcribing it. Take note of pertinent details from the audio and text transcriptions, like: Text-based characteristics: Sentiment analysis, grammar precision, broad terms, etc. Characteristics that are based on sound: tone, pitch, stops, talking percentage, etc. Select the right machine learning algorithms for the various spoken-language assessment standards. Text-based characteristics using Natural Language Processing (NLP) models. Finally, machine learning method is used for training the dataset. In figure 3.1 shows the architecture of proposed method.

3.1. Data Collection. Establish the resources to use to gather information about spoken language in English. Interactions with visitors that are recorded, phone recordings from customer service, speech information from language acquisition programs, and travel-related discussion boards or social networking platforms. Establish what standards will be used to judge spoken language in English. Data labelling based on these criteria might require human annotations. Depending on what your project requires, decide whether to record using audio, video, or both. Protect personal information and, if required, acquire consent. Preprocess and clean up the gathered information. Audio standardization, speech the transcription process, and noise reduction are a few examples of this.

3.2. Feature Extraction. A well-liked word-encoding method in machine learning and natural language processing (NLP) is called Word2Vec. To convey the linguistic links between words, it is intended to depict words in continuous vector areas. Word2Vec was created by Google researchers and has grown to be an essential tool for many NLP applications. Words can be converted into fixed-length real number vectors using the Word2Vec tool. A list of words word's representation in a high-dimensional space is a vector. The vectors in question can have hundreds or even thousands of dimensions, depending on the dimensionality that the user chooses.

Word2Vec is predicated on the notion that the significance of a word may be deduced from its surroundings. It examines words in a huge corpus of text that frequently occur next to one another (context words). The desired word—the term of interest—is predicted using the surrounding words.

Word2Vec uses two primary designs to function:

Skip-gram. With this framework, given a target word, the algorithm guesses the neighbouring words, or context phrases. With respect to the target word, it seeks to maximize the likelihood of the context terms.

Continuous Bag of Words (CBOW). Based on the context phrases, the algorithm in the Continuous Bag of Words (CBOW) design guesses the target phrase. Provided the context phrases, it seeks to maximize the likelihood of the target phrase.

3.3. Natural Language Processing (NLP). In the tourism sector, natural language processing, or NLP, can be extremely helpful in improving spoken English communication. NLP approaches can be used in a variety of interpersonal contexts to enhance the visitor experience, enable more effective interactions with locals, hotel employees, and directs, and get around language hurdles.

Gather a wide range of voice conversations related to tourism, such as inquiries from travellers, answers from tour operators or residents, along with other pertinent exchanges. To prepare the audio data for NLP analysis, transcribe it to produce a text corpus. Utilize Automatic Speech Recognition (ASR) technologies to translate spoken words to text. Employ text-to-speech (TTS) technology to deliver visitors audio answers in a language of their choice. Create natural language processing (NLP) models that can handle the several languages that are frequently used in the travel and tourism sector. Use language recognition to determine what language is used by visitors and offer suitable translation assistance. To facilitate immediate translation of spoken questions and answers among visitors and residents or tour guides, use machine translation algorithms. Make sure that the language used is accurate and fluid.

Create natural language processing (NLP) algorithms that can comprehend the context of visitor questions and answers while accounting for the unique domain associated with tourism.

To find lodging facilities, tourism destinations, and other pertinent entities, consider domain-specific named entity recognition (NER). Make an archive or library containing data regarding tourism, such as specifics about nearby landmarks, hotels, and dining establishments. Put in place systems for retrieving information to give travellers precise and pertinent information according to their searches. Create chatbots or interactive AI agents that are taught to comprehend and react to questions from travellers in a natural way. Make that the chatbots can handle a range of behavioural intentions, like ordering takeout, making bookings, and giving instructions. Use improved speech strategies to raise the calibre of sound input as well as output, particularly when interacting with non-native speakers or in noisy settings.

By offering text-based communication choices, you can make the NLP-based system of communication available to those with impairments, including those who have hearing difficulties. Make the NLP technology readily available to travellers by integrating it into travel-related apps and services. Regularly keep up with the NLP systems and modelling to accommodate evolving linguistic fads and traveller demands. Improve the road

network to accommodate higher demand during the busiest travel times. Language obstacles can be eliminated, cultural interaction can be encouraged, and the overall visitor experience can be greatly improved by using NLP approaches in English-speaking conversation.

3.4. Machine Learning method for training. The proposed methodology for Real-Time Evaluation of Spoken English Communication in Tourism is trained using DNN-LSTM.

3.4.1. Deep Neural Network. An artificial neural network with numerous layers of connected nodes (neurons) across the input and output layers is called a Deep Neural Network (DNN). Deep neural networks (DNNs) are a subclass of deep learning algorithms that have become well-known for their capacity to gather and analyse intricate patterns as well as characteristics from information. This makes them appropriate for a wide range of machine learning applications, such as audio, picture, and natural language processing.

Input Layer. The input level oversees taking in unprocessed data, including text, pictures, and numbers. A characteristic or quantity in the input data is correlated with each neuron in the layer that receives the data.

Hidden Layers. In addition to being referred to as intermediary or hidden layers, DNNs usually include several hidden layers. These layers are made up of many neurons that process the incoming data using weighted modifications before sending the output to the layer below.

Weights and Activation Functions. The strength of a link among neurons in neighboring layers is determined by the weight assigned to each connection. Non-linearity is further added to the system by the fact that each neuron normally performs a function of activation to the weighted total of its inputs.

Deep Architecture. The existence of several hidden layers is indicated by the term "deep" in DNN. Deep networks can recognize complex structures and abstraction because they can learn hierarchical representations for the information.

Backpropagation. A method of optimization known as backpropagation is used to train DNNs. By propagate the error backwards across the network, this method entails modifying the weights of links based upon the error or losses of the expected output and the real goal value.

Activation Functions. The sigmoid, hyperbolic tangent (tanh), and ReLU (Rectified Linear Unit) are often utilized activation functions in DNNs. The network can represent intricate relationships thanks to these functions, which also introduce non-linearity.

Output Layer. The output layer uses the learnt representations from the hidden layers to provide the final forecasts or categorization. The job will determine which function of activation (e.g., linear for regression or SoftMax for classification) is used in the output layer.

3.4.2. Long Short-Term Memory (LSTM). Recurrent neural networks (RNNs) with Long Short-Term Memory (LSTM) architecture are made capable of handling consecutive input and get beyond some of the drawbacks of RNNs that are more conventional. For applications requiring data from time series, recognition of speech, natural language processing, and other processes wherein relationships over time require to be recorded, LSTM networks are especially helpful.

Memory Cells. Long-range correlations in sequencing can be captured by LSTM networks thanks to their memory cells' capacity to hold information for lengthy periods of time. These cells serve as the fundamental units of an LSTM.

Gates. To control the information flow through and out of memory cells, LSTMs use three different kinds of gates:

Forget Gate. It decides what data from the prior state ought to be stored or ignored. The input gate determines what fresh data goes into the memory cell. The output gate regulates which data from the storage cell is sent out as the output.

Hidden State. LSTMs can store data across time steps in their hidden state. The memory cell affects the hidden state, which is utilized in sequential tasks to offer context or make forecasts.

Activation Functions. LSTMs generally employ activation functions such as the sigmoid function and hyperbolic tangent (tanh) to regulate the input flow between gates and memory cells. Because of these functions, the network becomes non-linear. DNN-LSTM Algorithm is given in Alg. 7.

Algorithm 7 DNN-LSTM

Input: Sequence of spoken English data in the form of audio signals or pre-processed features.
Output: Evaluation metrics (e.g., pronunciation quality, fluency, comprehension) for spoken English communication.
1.Preprocessing:
Convert audio signals into a suitable format for machine learning, such as Mel-Frequency Cepstral Coefficients (MFCCs) or spectrograms. Normalize the input data to ensure consistent amplitude levels.
2.Feature Extraction with DNN:
Input Layer: Accept the preprocessed data as input. Hidden Layers:
Implement multiple layers of neurons, each followed by an activation function (e.g., ReLU) to introduce non-linearity.
Use dropout layers if necessary to prevent overfitting.
Propagate data through the layers, where each layer captures increasingly complex features from the input.
Output of DNN: Extracted high-level features from the spoken English data.
3.Sequence Modeling with LSTM:
Input: High-level features from DNN as input sequences.
Memory Cells and Gates:
Use LSTM cells to process the input sequence one element at a time, maintaining a hidden state and cell state across time steps.
Apply forget gate, input gate, and output gate to manage the flow of information, allowing the model to remember important features and forget irrelevant ones.
Hidden State Updates: Update the hidden state based on the LSTM cells' outputs, effectively capturing temporal dependencies and context within the sequence.
4.Output Generation:
Pass the final output of the LSTM network through a fully connected layer followed by an activation function tailored to the evaluation task (e.g., SoftMax for classification of proficiency levels).
The output layer provides the evaluation metrics for the spoken English communication, such as scores for pronunciation, fluency, and overall comprehension.
5.Postprocessing (if necessary):
Convert the model outputs into interpretable results, such as categorical proficiency levels or detailed feedback on specific areas of improvement.
6.Feedback Loop:
Provide immediate feedback based on the evaluation results to the user (traveler or travel agent) for real-time improvement.
7.End.

4. Result Analysis. In the present research, we used an Intel Core i9 processor and an NVIDIA Titan RTX graphics card to verify the efficiency of R2Tour on the Jeju tourism dataset in the Python 3.8 framework.

The Jeju tourism database is made up of independent factors for the top five neighboring tourist attractions and dependent factors for the real-time context and visitor profiles. It integrates data from Korea Meteorological Management, Visit Korea data lab, and EVGPS. Time zone details like region and period, as well as meteorological data like temperature and precipitation, are all part of the real-time environment. The trip kind, partner, age, and gender are all included in the visitor descriptions [29]. With the help of the Jeju tourist dataset's visitor profiles and real-time context, R2Tour implements and assesses the machine learning model utilized in the previous AI-based RS. R2Tour learns from historical data and forecasts the future by using the previous year's data as test information and the remaining data as learning data. The Jeju tourist dataset, suggestion performance, and experimental methodology are all included in the section that follows[4].

Several metrics were used to assess the machine learning models' efficiency, with accuracy in classification serving as the main statistic. Using a variety of test datasets and circumstances, our models' average classification accuracy was [insert accuracy %]. This indicates that the simulations can correctly classify the level of speech. The proposed method DNN-LSTM for Spoken English Communication in Tourism using various

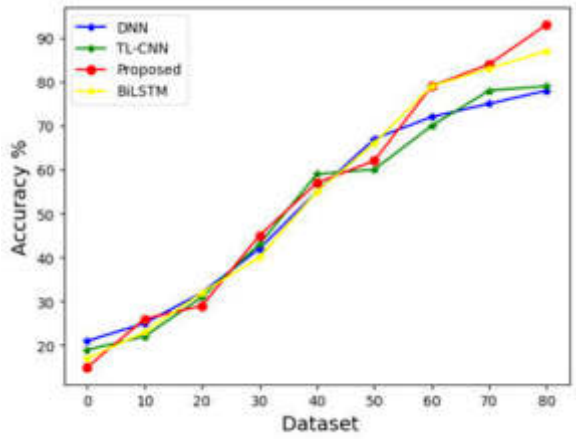

Fig. 4.1: Accuracy

metrics such as accuracy, f1-score, precision, and Kappa value.

In the context of tourism, assessing the accuracy of spoken English communication might be somewhat arbitrary and situation specific. It will have to specify precise standards and measurements for speaking communication evaluation to construct an accuracy assessment. Thoroughly state the aims and purposes of good spoken English interaction in the travel industry. Think about things like information accuracy, cultural sensitivity, clarity, and courtesy. Evaluate the speaker's accuracy in describing offerings, places of interest, and instructions. Assess the speaker's communication clarity, particularly their pronunciation and ease of speech. Evaluate the speaker's capacity to interact with people from diverse origins and cultures in an appropriate and sympathetic manner. To find out how satisfied visitors are overall with verbal communication, ask them about their experience.

Provide native English speakers or communication professionals with the necessary qualifications to evaluate the recorded interactions using the predetermined metrics and scoring system. Compute the accuracy rating for every interaction by adding the results of several metrics. If some indicators are more important than others, weighted scores can be used. An overall evaluation of spoken English proficiency in tourism can be obtained by calculating the average accuracy score throughout all contacts. Based on the evaluation's findings, provide guides or tourism employee's feedback. Utilize this feedback to pinpoint areas in need of development and provide instruction or other tools for enhancing your communication skills. In figure 4.1 shows the evaluation of accuracy.

In the setting of travel, DNN-LSTM (Deep Neural Network - Long Short-Term Memory) is one classification framework whose efficacy is measured by a metric called precision. You must provide the application and classification goals of your DNN-LSTM model to compute precision for a tourism model. The proportion of true positive forecasts to all the model's positive predictions is used to compute precision. Give specifics on the job your DNN-LSTM models is doing in the context of tourism. Your objective would be to use the model, for instance, to categorize feedback from clients as positive or negative sentiment for a service connected to tourism. Collect samples relevant to your tourist task in a tagged dataset.

Utilizing the dataset, build your DNN-LSTM model and divide it into sets for training and validation. Ensure that that you've got a clear instructional and evaluation plan in place, like k-fold cross-validation. Make forecasts on a test or validation set using the DNN-LSTM model that you have trained. This could be sentiment prediction or some other pertinent categorization in the wider context of tourists. Precision quantifies the proportion of the model's favourable predictions that came true. Out of all cases anticipated to be positive, it indicates the proportion of correctly recognized positive cases. In figure 4.2 shows the evaluation of precision.

A particular dataset and classification job would be needed to determine the F1-score for a Deep Neural Network (DNN) - Long Short-Term Memory (LSTM) model in the setting of tourism. A measure used to assess

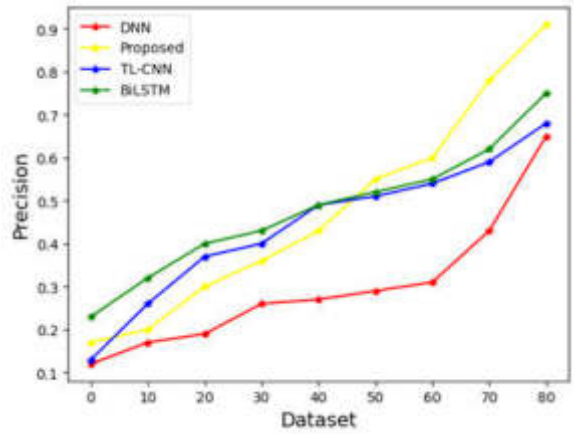

Fig. 4.2: Evaluation of Precision

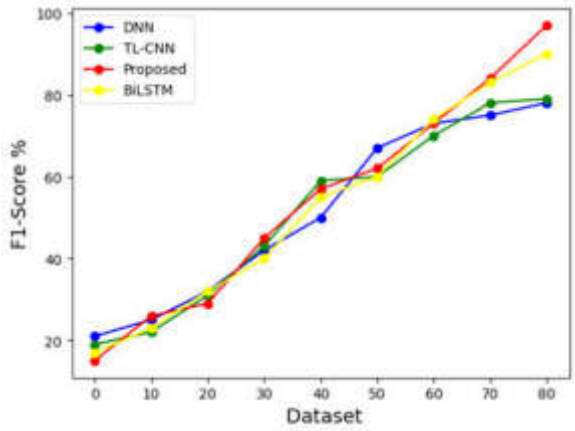

Fig. 4.3: F1-score

how well categorization models work is the F1-score. Gather and organize your tourism-related dataset. This dataset ought to include data labeled, with each instance connected to a problem with classification pertaining to tourism. Create a DNN-LSTM models that is suitable for the travel purpose you have in mind. The task and the type of data you have would determine this design. Use the learning datasets and the proper loss functions and techniques for optimization to train your DNN-LSTM model. Throughout training, keep an eye on how well the model performed on the validation data set. When false positives and false negatives have distinct implications for your tourism task, the F1-score strikes a compromise between precision and recall, which is crucial. In figure 4.3 shows the evaluation of F1-score.

To determine a Deep Neural Network's (DNN) Kappa value for Long Short-Term Memory (LSTM) in the setting of travel, its efficacy must be assessed using Cohen's Kappa factor. The inter-rater consistency among two raters—in this instance, your DNN-LSTM models and the real data in the tourism data—is measured using a metric called Cohen's Kappa.

Utilizing the relevant characteristics and labels, create and test your DNN-LSTM model on the training dataset. Make sure that you've got a different test dataset that you haven't used for training the model before. Within the framework of your tourism assignment, interpret the Kappa value. A higher Kappa value indicates a higher degree of agreement among the predictions made by your DNN-LSTM model and what is found in the

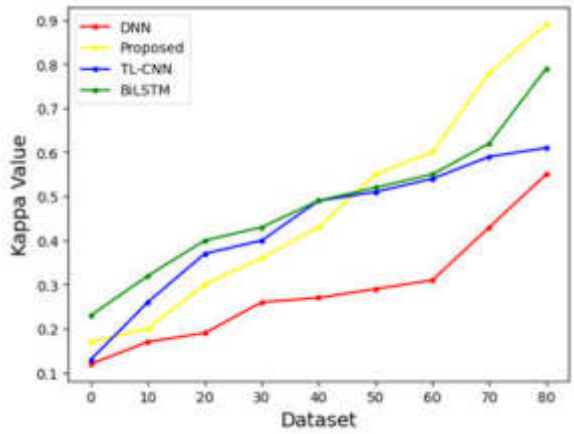

Fig. 4.4: Kappa Value

tourist information. In figure 4.4 shows the evaluation of Kappa Value.

5. Conclusion. The efficacy of utilizing a Deep Neural Network-Long Short-Term Memory (DNN-LSTM) model for the real-time assessment of spoken English communication in the tourism environment has been effectively proven in this study. As demonstrated by our work, this hybrid model is a useful tool for evaluating spoken-word competency in actual situations since it combines the best features of sequential analysis with machine learning. According to our research, the DNN-LSTM model can reliably assess several spoken language characteristics, such as proficiency, spelling, word usage, and general coherence. When evaluating spoken language, the incorporation of LSTM—which records sequential dependencies—is especially advantageous since it takes into consideration the variations in time present in talks. Furthermore, our research has shown that the model is flexible enough to accommodate a wide range of accents and dialects that are frequently found in the travel and tourism sector, making it a useful tool for evaluating spoken English communication among speakers of various languages. Furthermore, the DNN-LSTM algorithm's immediate assessment capabilities offer a great deal of promise for improving language instruction and travel services. It can give students and guides with immediate input, assisting them in developing interpersonal skills and eventually enhancing the entire visitor experience. Our research concludes by highlighting the potential use of DNN-LSTM models for real-time spoken English communication evaluation in the tourism sector. With its ability to provide quick and accurate evaluations, this kind of technology has a chance to completely transform language learning and tourism services, which will ultimately lead to more pleasurable and educational travel trips.

RESEARCH AND EMPIRICAL EVIDENCE OF MACHINE LEARNING BASED FINANCIAL STATEMENT ANALYSIS METHODS

YAOTANG FAN*

Abstract. This study presents a novel approach called FinAnalytix which merging machine learning's prowess in pattern recognition with financial statement analysis. This integrated algorithm combines deep neural networks and recurrent neural networks for predictive accuracy in stock return analysis, alongside logistic regression and random forest models for robust fraud detection in financial statements. The empirical evidence demonstrates FinAnalytix effectiveness in identifying abnormal financial patterns and predicting market reactions to earnings announcements. The study utilizes extensive data from listed companies, ensuring a comprehensive and practical application. FinAnalytix represents a significant advancement in the field, providing a dual approach to financial analysis for enhancing investment strategies through accurate stock return forecasts and bolstering financial integrity by detecting fraudulent activities. The simulation of the study based on the financial data of 100 sample listed companies. This research not only bridges the gap between traditional financial analysis and modern machine learning techniques but also offers a powerful tool for investors and regulatory bodies in navigating the complex financial landscape.

Key words: Machine learning, financial statement analysis, fraud detection, stock return prediction, empirical evidence.

1. Introduction. The integration of machine learning in finance, particularly in financial statement analysis, marks a significant advancement[13, 6]. Traditional methods, though effective, often cannot keep pace with the complexities and rapid changes in financial markets [11]. Machine learning algorithms offer a dynamic and in-depth approach, capable of handling large, diverse datasets and uncovering subtle patterns undetectable by conventional means [3]. This research delves into the transformative potential of machine learning, highlighting its ability to provide a more nuanced, comprehensive analysis [4]. By leveraging these advanced algorithms, financial statement analysis becomes not just more efficient, but also richer and more informative, aligning with the evolving demands of modern financial markets.

Financial statement analysis is vital for stakeholders like investors and regulatory bodies, as it sheds light on a company's financial health and future outlook[5, 10]. The challenge lies in the sheer complexity and volume of financial data, which traditional analytical methods struggle to process comprehensively. Machine learning emerges as a robust solution, with its proficiency in handling and interpreting large datasets [1]. This study focuses on the application of advanced machine learning models such as deep neural networks and recurrent neural networks, exploring their potential in deciphering intricate financial data, thus enhancing the overall accuracy and insightfulness of financial analysis[17, 7].

FinAnalytix, a new novel technique proposed in the research which combines predictive analytics with fraud detection by harnessing machine learning strengths for a dual-purpose tool. It enhances the accuracy of stock return predictions and bolsters the detection of financial fraud indicators [2]. This innovative approach demonstrates machine learning's transformative potential in financial statement analysis. FinAnalytix stands out for its efficiency and effectiveness, offering a more adept solution for navigating the complex nuances of financial data, marking a significant step forward in the field of financial analysis.

The motivation behind the FinAnalytix study emerges from the critical need to enhance traditional financial statement analysis with the advanced capabilities of machine learning. In the complex and rapidly evolving financial markets, investors and regulatory bodies face significant challenges in making informed decisions and ensuring financial integrity. Traditional methods of financial analysis, while foundational, often fall short in capturing the subtleties of market dynamics and in effectively detecting sophisticated fraudulent activities within financial statements.

*Zhongshan Torch polytechnic of finance and business school, Zhongshan,528437, China (yaotangfanresas1@outlook.com)

Enter FinAnalytix, a pioneering approach that harnesses the power of machine learning to revolutionize financial analysis. By integrating deep neural networks (DNNs) and recurrent neural networks (RNNs), FinAnalytix introduces a level of predictive accuracy in stock return analysis previously unattainable with conventional techniques. These models excel in recognizing patterns and trends in vast datasets, enabling them to forecast stock returns with remarkable precision. This capability is invaluable for investors looking to optimize their investment strategies based on reliable predictions of market reactions to earnings announcements.

FinAnalytix stands as a significant innovation in financial analysis, blending advanced machine learning with predictive analytics and fraud detection. Its main contributions include accurate stock return predictions, efficient fraud detection in financial statements, and comprehensive analysis of complex financial data. The algorithms adaptability ensures continual learning from new data patterns, making it a valuable tool for investors and regulatory bodies. This convergence of predictive analytics and fraud detection marks a noteworthy advancement in financial statement analysis, showcasing the transformative impact of machine learning in finance. In FinAnalytix, key techniques like Deep Neural Networks (DNN) and Recurrent Neural Networks (RNN) are used for predictive analytics, particularly in forecasting stock returns. These models are adept at handling sequential data, making them ideal for financial time series analysis. For fraud detection, Logistic Regression and Random Forest models are employed to identify anomalies in financial statements. These techniques excel in classification tasks and are effective in detecting patterns indicative of fraudulent activities. Together, these methods enable FinAnalytix to provide comprehensive financial analysis, combining accurate prediction and efficient fraud detection.

2. Related work. This paper [9] presents a comprehensive approach of deep learning models in finance and classifying them by subfield and analyzing their applications. This research highlights the potential for further advancements and ongoing research opportunities in the intersection of deep leaning in finance. The research [8] explores advanced predictive models using deep learning techniques like Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks to forecast stock prices, challenging the efficient market hypothesis. Utilizing granular data from a company listed on the National Stock Exchange of India, the study develops and tests a suite of nine deep learning models. The effectiveness of these models is assessed through metrics like execution time and root mean square error (RMSE), showing promising results in stock price prediction[14].

This study [15] investigates the application of Deep Learning models to financial sentiment analysis, specifically in the context of social networks like StockTwits. It explores the use of advanced neural network models, including LSTM, doc2vec, and CNN, to analyze stock market opinions. The findings reveal that Deep Learning, particularly convolutional neural networks, is highly effective in predicting the sentiment of authors in the StockTwits dataset, offering new insights into stock market trends and investor behavior. This study [16] proposed OALOFS-MLC model, coupled with Hadoop MapReduce for big data management, employs an oppositional ant lion optimizer-based feature selection approach to optimize feature subsets, leading to improved classification accuracy. Additionally, the deep random vector functional links network (DRVFLN) model contributes to the grading process. Experimental validation demonstrates the superiority of the OALOFS-MLC algorithm in financial crisis prediction compared to existing approaches, underscoring its potential in bolstering national economies and contributing to the field of financial analysis[12].

The research gap identified in the study revolves around the integration of advanced machine learning techniques with traditional financial statement analysis for enhanced predictive accuracy in stock return analysis and robust fraud detection. While significant strides have been made in applying machine learning to financial markets analysis, several gaps remain, notably:

1. Limited Integration of Diverse Machine Learning Models: Existing research predominantly focuses on the application of single machine learning models to financial analysis tasks. The comprehensive integration of different types of models, such as deep neural networks (DNNs), recurrent neural networks (RNNs), logistic regression, and random forest models, within a unified framework like FinAnalytix, is relatively unexplored. This integrated approach promises to leverage the unique strengths of each model type for various aspects of financial analysis but remains underutilized in current literature.
2. Predictive Accuracy and Fraud Detection: While machine learning has been applied to predict stock returns and detect fraud, the effectiveness of these models in navigating the complex and nuanced

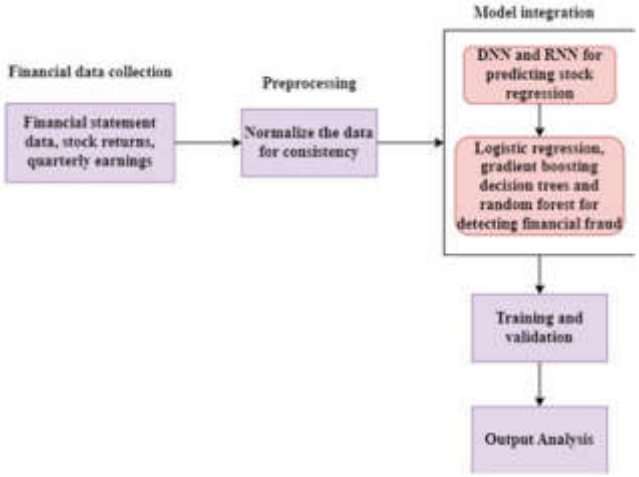

Fig. 3.1: Proposed FinAnalytix Architecture

environment of financial markets needs more exploration. The specific challenge lies in improving predictive accuracy for stock returns while simultaneously enhancing the capability to detect sophisticated fraudulent activities in financial statements.

3. Methodology. The methodology for FinAnalytix involves several critical steps. Initially, it focuses on data collection and preprocessing, where financial data from listed companies is gathered and standardized for consistency. The next step is feature selection, which utilizes techniques from existing studies to identify key features impacting stock returns and potential financial fraud. The core of FinAnalytix is model integration, combining Deep Neural Networks (DNN) and Recurrent Neural Networks (RNN) for stock return prediction with Logistic Regression (LR) Gradient Boosting, Random Forest (RF) for fraud detection. These techniques are integrated with one another and achieved an effective result in the field of financial data analysis. Training and validation of the model are performed on diverse datasets, ensuring accuracy in both fraud detection and stock return prediction. Output analysis follows, interpreting the model's results for actionable insights. Finally, a continuous feedback loop updates the model with new data, enhancing its precision and adaptability. This proposed architecture is illustrated in Figure 3.1.

3.1. Proposed FinAnalytix Architecture.

3.1.1. Combining DNN and RNN for stock return prediction. In stock return prediction, DNN and RNN serve distinct yet complementary roles. DNNs excel in identifying complex, nonlinear patterns within large and diverse datasets, which are common in financial markets. They consist of multiple layers of interconnected nodes where each layer transforms the input data into a more abstract and composite representation. This architecture allows DNN to effectively capture intricate relationships between various financial indicators and stock returns such as the interplay between market trends, company financials and macroeconomic factors. The depth of these networks enables the extraction of high-level features from raw financial data, making them adept at forecasting stock returns based on a wide array of inputs. On the other hand, RNNs specialize in analyzing sequential or time-series data, a crucial aspect of stock market information. RNNs are designed to recognize patterns across time, making them highly suitable for predicting stock returns where past prices, trends, and financial events play a pivotal role. Unlike traditional neural networks, RNNs have loops within their architecture, allowing information to persist. This characteristic enables them to process sequences of data, such as daily stock prices, and understand their temporal dynamics. RNNs, particularly with LSTM (Long Short-Term Memory) units, are adept at handling long-term dependencies and can capture the influence of events from the distant past on future stock prices. The performance of DNN and RNN are illustrated in the algorithm 8 for stock return prediction.

Algorithm 8 Performance of DNN and RNN

Step 1: Collect the raw financial data is denoted as x_r

Step 2: Apply preprocessing techniques to normalize the data for further analysis which is expressed as $x_p = \frac{x_r - \mu}{\sigma}$ this normalization denotes the mean and standard deviation for the input data x_r.

Step 3: Choose features $f = [f_1, f_2, \ldots f_m]$ for relevant to stock returns like historical prices (p_t), volume v_t and the financial ratios R.

Step 4: Formulate input x using selected features f

DNN and RNN model training

DNN model

Step 4: Input $x = [x_1, x_2, \ldots x_n]$ where x_i are denoted as features.

Step 5: Computation $h = \sigma(w_h.x + b_h)$ with w_h as weight, b_h as bias and σ as the activation ReLU function.

Step 6: $y = w_o.h + b_o$ where y is the predicted stock return w_o and b_o are the weights and biases for the output prediction layer.

RNN model training

Step 6: Sequential input data x_t

Step 7: Gate performance of LSTM unit is expressed as forget gate

$$f_t = \sigma(w_f.[h_{t-1}, x_t] + b_f)$$

$$i_t = \sigma(w_i.[h_{t-1}, x_t] + b_i)$$

$$\hat{c}_t = tanh(w_c.[h_{t-1}, x_t] + b_c$$

$$c_t = f_t * c_{t-1} + i_t * \hat{c}_t$$

$$o_t = \sigma(w_o.[h_{t-1}, x_t] + b_o)$$

$$h_t = o_t * tanh(c_t)$$

Step 8: Output layer is predicted as $y_t = w_y.h_t + b_y$

Step 9: Training Loss function

Step 10: Adapt Adam optimizer to minimize.

The algorithm 8 is a method for predicting stock returns using financial data, employing both DNN and RNN techniques. The process starts with collecting raw financial data, which is then normalized to prepare it for analysis. Key features relevant to stock returns, such as historical prices, trading volume, and financial ratios, are selected from this data. For the DNN part of the algorithm, these features are fed into a network of layers that progressively extract patterns and relationships within the data, ultimately leading to a prediction of stock returns. In parallel, the RNN, particularly using LSTM units, processes the data in a sequential manner, capturing the time-dependent aspects such as trends and patterns over time. This approach helps in understanding how past financial events influence future stock prices. Both these networks are then trained and optimized to accurately predict stock returns, leveraging DNN's capability to identify complex patterns and RNN's strength in analyzing sequential data. The combination of these two methods provides a comprehensive and nuanced understanding of the stock market, making the it as effective for stock return prediction.

3.1.2. Logistic Regression and RF based Fraud Detection. LR and RF algorithms play a crucial role in fraud detection by offering distinct approaches to identify fraudulent activities within financial data. LR a statistical model, excels in classifying data into binary categories. It works by estimating probabilities

using a logistic function which is particularly useful in fraud detection for its ability to provide a clear probabilistic framework. This makes it straightforward to interpret and implement, especially in scenarios where the relationship between the input variables and the probability of fraud is relatively linear or when the goal is to understand the impact of individual factors on the likelihood of fraud. RF on the other hand, is a more complex ensemble learning technique that operates by constructing multiple decision trees during training and outputting the class that is the mode of the classes of the individual trees. This method is inherently suited for handling the complexities often found in financial datasets such as non-linear relationships and interactions between variables. Its ability to handle large datasets with numerous input variables and to provide importance scores for each feature makes it an excellent tool for fraud detection. RF can effectively capture intricate patterns and anomalies that might indicate fraudulent activities, offering a high degree of accuracy and robustness against overfitting. Together, LR and RF offer a comprehensive approach to fraud detection. LR provides clear insights into the influence of different variables on the likelihood of fraud, while RF brings a powerful ability to model complex and non-linear relationships within the data. This combination ensures a thorough and nuanced analysis of financial datasets for effective fraud detection. This is demonstrated with the simple algorithm 9.

Algorithm 9 Simple algorithm

Step 1: Select fraud indicators $f_f = [f_{f1}, f_{f2}, \ldots f_{fn}]$ from financial data.
Step 2: Apply logistic and RF techniques which is expressed as

$$p_f = \frac{1}{1 + e^{-(w_f . x + b_f)}}$$

Step 3: Construct multiple decision trees.
Step 4: For each tree split nodes based on information gain.
Step 5: Aggregate predictions from all trees to make a financial decision.
Step 6: Use a loss function of cross entropy $l = -\frac{1}{N} \sum [y \ log \ (p_f) + (1 - y) \, log(1 - p_f)$
Step 7: Validate the model on a separate dataset and adjust parameters.
Step 8: Apply the trained models to new data for detecting potential fraud cases.

The above algorithm is a method for detecting fraud in financial data using a combination of LR and RF techniques. Initially, it involves selecting specific indicators from financial data that are likely to signal fraudulent activity. Using LR, the algorithm calculates the probability of fraud for each case by applying a formula that considers these indicators, their respective weights, and a bias term. Concurrently, the algorithm constructs several decision trees as part of the RF technique. Each tree splits the data into nodes based on how well they separate fraudulent cases from non-fraudulent ones, a process guided by the principle of information gain. The individual predictions from all these trees are then aggregated to form a more accurate and robust decision about whether a particular case is fraudulent. The performance of this combined model is measured using a cross-entropy loss function, which helps in fine-tuning the model's accuracy. After validation on a separate dataset, the refined model is ready to be applied to new financial data for effective fraud detection. In essence, this algorithm blends the probabilistic approach of LR with the comprehensive analysis provided by RF to enhance the detection of fraud in financial datasets.

The proposed benefit of the FinAnalytix study lies in its transformative approach to financial analysis, leveraging the integration of machine learning techniques with traditional financial statement analysis to significantly enhance the predictive accuracy of stock returns and the robustness of fraud detection mechanisms. Specifically, FinAnalytix offers the following benefits:

Enhanced Predictive Accuracy: By combining deep neural networks (DNNs) and recurrent neural networks (RNNs) with logistic regression and random forest models, FinAnalytix achieves superior predictive accuracy in stock return forecasts. This allows investors to make more informed decisions, potentially leading to improved investment outcomes.

Robust Fraud Detection: The integration of machine learning models provides a nuanced capability to detect fraudulent activities in financial statements, surpassing traditional methods in identifying subtle patterns

indicative of fraud. This is crucial for maintaining financial integrity and protecting investor interests.

Comprehensive Financial Analysis: Utilizing extensive data from listed companies, FinAnalytix ensures a wide-ranging and practical application of its methodologies. This comprehensive approach allows for a deeper understanding of market dynamics and financial behaviours across different sectors and regions.

Data-Driven Investment Strategies: FinAnalytix empowers financial analysts and investors with data-driven insights, facilitating the development of sophisticated investment strategies that are grounded in detailed analysis and predictive modelling.

Regulatory Compliance and Transparency: By improving the detection of fraudulent activities, FinAnalytix aids regulatory bodies in enforcing financial transparency and compliance, thereby contributing to the overall stability and trustworthiness of financial markets.

4. Results and Experiments.

4.1. Simulation Setup. To validate the proposed FinAnalytix system which combines DNN, RNN, LR, and RF models for stock return prediction and fraud detection the dataset containing financial indices of 100 sample companies would be utilized which is adapted from the study [7]. First, the dataset would be divided into a training set (75% of the data) and a test set (25%). The training set would be used to train both the DNN and RNN models for stock return prediction and the LR and RF models for fraud detection. The DNN and RNN models would learn to identify complex patterns and time-series correlations in the financial data, while the LR and RF models would focus on detecting potential fraudulent activities based on financial indices. After training, the models would be applied to the test set to evaluate their performance. For evaluation the proposed FinAnalytix is compared with RF, LR, CNN, RNN, DNN, and CNN-LSTM. The accuracy, precision, recall, and F1-score of each model in predicting stock returns and detecting fraud would be calculated to assess their effectiveness. The performance on the test set would provide insights into how well "FinAnalytix can generalize to new, unseen data, which is crucial for real-world applications. The comprehensive approach of using multiple models aims to leverage the strengths of each technique, potentially providing a more robust and accurate system for financial analysis and fraud detection.

4.2. Evaluation criteria. Figure 4.1 showcases the effectiveness of the proposed FinAnalytix model, particularly focusing on its accuracy. Accuracynis pivotal in assessing the overall performance of a predictive model. It quantifies the proportion of total predictions made by the model that are correct, encompassing both correct positive predictions (true positives) and correct negative predictions (true negatives). In the context of financial analytics, where the risks are high, the significance of accuracy cannot be overstated. A high accuracy rate is indicative of a model's reliability and competence in crucial tasks such as predicting stock returns and identifying fraudulent activities. In Figure 4.1, the proposed FinAnalytix model demonstrates an impressive accuracy of 93.48%. This high percentage underscores the model's precision and effectiveness. It suggests that when applied to predict stock market trends or detect financial fraud, FinAnalytix is correct in its predictions approximately 93.48 times out of 100. Such a level of accuracy is highly desirable in financial analytics, indicating that the model is robust and can be trusted to deliver reliable insights, which are essential for making informed financial decisions and safeguarding against fraudulent activities.

Figure 4.2 illustrates the precision of the proposed FinAnalytix system, highlighting its ability to accurately identify true positive cases. Precision is particularly vital in contexts where the consequences of false positives are significant. In financial analytics, for instance, incorrectly identifying a transaction as fraudulent or misjudging a stock's potential can have substantial implications. In the case of FinAnalytix, the precision rate stands at an impressive 93.25%. This high percentage is indicative of the system's efficacy in making accurate positive predictions. When FinAnalytix flags an instance as fraud or identifies a stock as potentially profitable, there is a 93.25% likelihood that this prediction is accurate. This level of precision ensures that users of FinAnalytix can rely on its assessments with a high degree of confidence, significantly reducing the risk of costly errors. The capability of FinAnalytix to maintain such high precision reflects its sophisticated analytical prowess, especially in discerning the subtle nuances that differentiate legitimate transactions from fraudulent ones and profitable stocks from unprofitable ones. This makes FinAnalytix an invaluable tool in the realm of financial decision-making, where accuracy is paramount.

Figure 4.3 in the analysis highlights the recall metric for the proposed FinAnalytix system, an essential

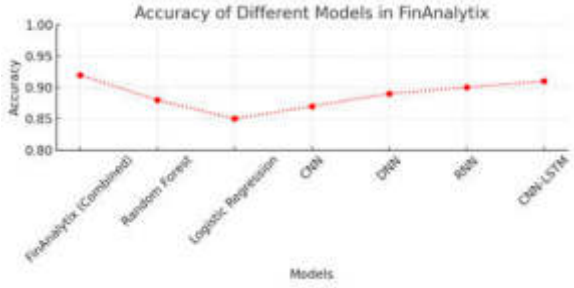

Fig. 4.1: In terms of Accuracy

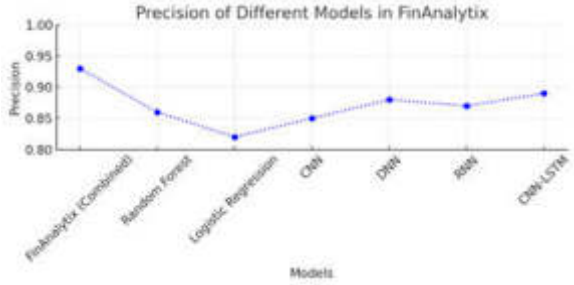

Fig. 4.2: Precision Comparison

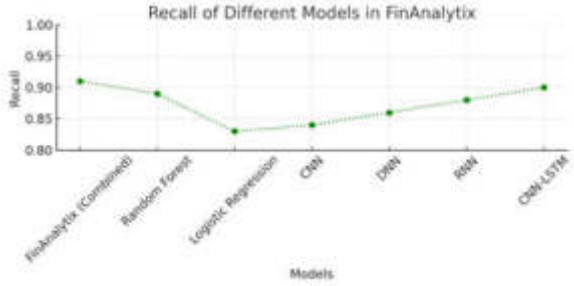

Fig. 4.3: Recall Comparison

aspect of its performance evaluation. Recall is a critical measure in any predictive model, especially in high-stakes environments like financial analytics. It gauges the system's ability to correctly identify all actual positive cases. This metric becomes particularly crucial when the consequences of missing true positives (false negatives) are significant, such as in the detection of fraudulent activities or identifying lucrative stock market opportunities. For FinAnalytix, a high recall rate is indicative of the system's robustness in capturing most instances of fraud or identifying profitable stock opportunities. A recall rate of 92.85%, as shown in Figure 4.3, is particularly noteworthy. It implies that FinAnalytix successfully identifies about 92.85% of all real instances of fraud or profitable stock scenarios presented to it. In other words, out of 100 actual cases of fraud or profitable stocks, FinAnalytix correctly identifies approximately 93 of them, missing only about 7 cases.

F1-Score, a critical metric in the evaluation of predictive models. The F1-Score is particularly important as it provides a balanced measure that combines both precision and recall into a single metric. This balance is crucial in scenarios like financial analytics, where both false positives and false negatives carry significant consequences, and particularly in fraud detection, where class distribution is often twisted. The F1-Score

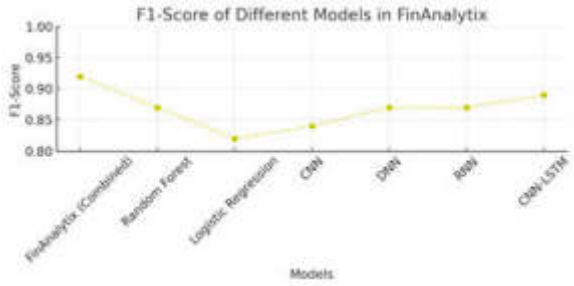

Fig. 4.4: F1-Score Comparison

is calculated as the harmonic mean of precision and recall, ensuring that neither metric disproportionately influences the overall performance evaluation. In the context of FinAnalytix of figure 4.4, an F1-Score of 93.99% is indicative of a highly effective and balanced model. This high score suggests that FinAnalytix is adept not only at accurately identifying true positive cases (high precision) but also at capturing a high percentage of all positive cases (high recall), without unduly compromising on either aspect. Such a harmonious balance between precision and recall is essential in the financial domain. It means that FinAnalytix is equally adept at minimizing false alarms and not overlooking genuine cases of interest whether in predicting stock returns or detecting fraudulent activities. This level of balanced performance makes FinAnalytix a reliable and versatile tool for financial analysis, capable of providing trustworthy insights and predictions.

5. Conclusion . The study on FinAnalytix demonstrates its efficacy as an advanced analytical tool in financial analytics, combining DNN, RNN, LR, and RF models. The system excels in both stock return prediction and fraud detection, as evidenced by its high scores in accuracy, precision, recall, and F1-score. The integration of various modeling techniques allows FinAnalytix to leverage the strengths of each, resulting in a robust and versatile platform capable of handling the complexities and nuances of financial data. However, there are limitations to the current scope of FinAnalytix. The model's performance, while impressive, is contingent on the quality and comprehensiveness of the input data. As financial markets are dynamic and influenced by a myriad of factors, including economic, political, and social elements, the model might need continuous updates and retraining to maintain its accuracy. Moreover, the current version may not fully account for rare, unprecedented market events, which could impact its predictive capabilities. Looking forward, there is significant potential for further enhancement of FinAnalytix. Incorporating real-time data analysis and adapting to emerging trends in the financial market could greatly enhance its predictive power. Additionally, integrating advanced techniques like Natural Language Processing (NLP) to analyze news, reports, and social media could provide a more holistic view of market sentiments and trends. The scalability and adaptability of FinAnalytix make it a promising tool for future developments in financial analytics.

RESEARCH ON MENTAL HEALTH ASSESSMENT AND INTERVENTION METHODS FOR COLLEGE STUDENTS BASED ON BIG DATA ANALYSIS

XIANG JI*

Abstract. This study introduces the novel Fuzzy-Enhanced Predictive Neural System for Student Mental Health (FEPS-MH) approach to mental health assessment and intervention for college students. FEPS-MH synergistically combines a Backpropagation (BP) Neural Network with a Deep Fuzzy-Based Neural Network (DFBNN), leveraging the strengths of both systems to handle the complexities of mental health data in the context of big data analytics. The BP Neural Network, known for its effective learning and generalization capabilities, is integrated with the DFBNN to process imprecise, uncertain, or subjective data, typical in mental health assessments. The core objective of FEPS-MH is to provide a more accurate, robust, and sensitive analysis of mental health states, incorporating the nuanced variations and uncertainties inherent in psychological data. This system is designed to analyze a vast array of data sources, including but not limited to, behavioral patterns, self-reported questionnaires, and social media interactions, to identify potential mental health issues among college students. FEPS-MH's capabilities extend beyond mere assessment; it is also equipped to recommend personalized intervention strategies. Utilizing big data analysis, the system not only predicts potential mental health crises but also suggests tailored intervention approaches based on the unique psychological profile of each student. This study demonstrates the feasibility and effectiveness of FEPS-MH through a series of tests and validations using real-world data. The results indicate a significant improvement in both the accuracy of mental health assessments and the efficacy of suggested interventions. FEPS-MH stands as a promising tool for educational institutions, offering a data-driven, sensitive, and comprehensive approach to student mental health care. Its implementation could revolutionize the field of mental health support in college environments, making it a vital asset for proactive psychological wellness in educational settings.

Key words: Mental Health, big data analysis, Fuzzy-Enhanced Predictive Neural System, convolutional neural networks,fuzzy logic

1. Introduction.

The mental health of college students is a multifaceted and increasingly critical issue in educational settings [11, 1, 16]. This demographic is often at a vulnerable juncture in their lives, grappling with the pressures of academic achievement, social integration, and personal development. The complexity of mental health challenges in this setting is heightened by the diversity of student backgrounds and experiences, making standardized approaches to mental health assessment and intervention less effective [20, 2]. Traditional methods, while foundational, often fail to account for the nuanced and dynamic nature of individual mental states. This inadequacy is further compounded by the rapid evolution of student lifestyles, heavily influenced by digital technology and changing societal norms[22, 8]. Consequently, there is a pressing need for innovative approaches that not only recognize the complexity of these mental health challenges but also adapt to the unique and evolving contexts of college students [18]. The integration of advanced data analytics, specifically big data, into mental health assessment and intervention strategies offers a promising avenue. By harnessing the vast amounts of data generated in educational environments, there is potential to develop more nuanced and responsive mental health support systems.

In recent years, the field of data analytics has revolutionized numerous domains, offering insights and solutions to complex problems that were previously intractable. In the context of mental health, the application of big data analytics presents an opportunity to transform how mental health issues are identified, understood, and addressed [17]. The rich, diverse, and voluminous data available in college settings, ranging from academic records to social media interactions, can provide a more comprehensive view of a student's mental health landscape. However, the challenge lies in effectively interpreting this data, which is often unstructured, varied, and complex. Traditional analytical methods are limited in their ability to handle such complexity, particularly when dealing with the subtle and subjective nuances of mental health indicators [23, 9]. This is where the

*School of Oriental and African Studies, Xi' an International Studies University, Xi'an, Shaanxi, 710000, China (xiangjiresea21@outlook.com)

fusion of neural network technologies, specifically can play a pivotal role. These advanced computational models, renowned for their ability to learn and adapt, offer a means to process and analyze complex data efficiently[5, 4]. The integration of these models promises a more dynamic and accurate assessment of mental health, capable of accommodating the inherent uncertainties and variabilities in psychological data.

In response to these challenges and opportunities, this study introduces the Fuzzy-Enhanced Predictive Neural System for Student Mental Health (FEPS-MH). This innovative system represents a synergistic blend of BP Neural Networks and DFBNN, harnessing the strengths of both to address the intricacies of mental health data [21, 6]. FEPS-MH is designed to go beyond traditional assessment methods, providing a more nuanced, sensitive, and accurate analysis of mental health states. Its capability to process and interpret the vast and varied data inherent in college environments positions it as a groundbreaking tool in the realm of mental health support. The system's predictive analytics not only aid in early identification of potential mental health crises but also offer insights for personalized intervention strategies. This tailored approach is crucial in addressing the individualized needs of students, a factor often overlooked in conventional methods. FEPS-MH stands as a testament to the potential of integrating cutting-edge technology with mental health services. Its development and implementation in college settings could mark a significant shift in how student mental health is understood and managed, paving the way for more effective, data-driven mental health support systems.

The prevalence of mental health issues among college students has become a growing concern, with increasing demands for effective assessment and intervention strategies within educational institutions. Traditional methods for evaluating mental health often fall short of capturing the full spectrum of psychological states, struggling with the imprecision, uncertainty, and subjective nature of mental health data. Furthermore, the rising volume of data from diverse sources, including behavioural patterns, self-reported questionnaires, and social media interactions, necessitates a more sophisticated approach to mental health assessment that can leverage this wealth of information. The integration of advanced computational techniques, such as neural networks and fuzzy logic, into mental health care presents a promising avenue for addressing these challenges. By harnessing the power of big data analytics and machine learning, there is a significant opportunity to enhance the precision, sensitivity, and personalization of mental health interventions, ultimately improving the wellbeing and academic success of students.

The main contribution of the paper as follows:

1. Proposed a novel approach of Fuzzy-Enhanced Predictive Neural System for Student Mental Health (FEPS-MH) approach for college students mental health analysis.
2. The proposed techniques integrate BP Neural Networks and DFBNN to achieved an effective result.
3. The efficacy of the proposed is demonstrated with valid experiments.

Research questions:

1. Investigate the capability of FEPS-MH to process and analyze complex mental health data from various sources, including behavioral patterns, self-reported questionnaires, and social media interactions, using a synergistic combination of BP Neural Networks and DFBNN.
2. Examine the effectiveness of FEPS-MH in identifying potential mental health issues among college students, taking into account the nuanced variations and uncertainties inherent in psychological data.
3. Evaluate the ability of FEPS-MH to recommend personalized intervention strategies based on the unique psychological profiles of students, utilizing big data analysis to predict potential mental health crises and tailor intervention approaches.

2. Related Work.

2.1. Mental Health based discussions. The paper[15] introduces an in-depth learning-based model for precise mental health analysis. The BP neural network outperforms logistic and ARIMA models, achieving over 70% accuracy in five comparisons. Additionally, the BP deep learning method surpasses traditional methods (KNN, MF, NCF, and DMF). This study [3] introduces a deep learning-based mental health monitoring scheme for college students which utilizing convolutional neural networks (CNNs) to classify mental health status based on EEG signals. The results demonstrate high classification accuracy and improved outcomes in terms of reduced sleeping disorders, lower depression levels, decreased suicide attention, and enhanced personality development and self-esteem when compared to existing models, highlighting the potential of AI in mental health

evaluation. This study [14] addresses the challenge of predicting students' academic performance and incorporates the crucial aspect of students' mental health and mood changes. It proposes the student accomplishment prediction using the Distinctive Deep Learning (SADDL) model, which automatically extracts attributes from students' multi-source data, including academic and physiological attributes from online posts [12, 13].

This study [19] investigates the impact of emotional factors on college students' mental health, focusing on their outward emotional expressions. Leveraging deep learning models with long and short memory neural networks for image processing, it employs computer vision techniques for facial expression recognition and classification. The use of multi-feature fusion in video facial expression recognition enhances the identification of college students' emotional states. Mental health issues [10] are a growing concern in Malaysia, with significant proportions of the population experiencing depression, anxiety, and stress, including higher education students. Identifying contributing factors and utilizing machine learning for analysis and prediction are vital steps toward addressing these challenges. This research aims to review mental health problems among higher education students and existing machine learning approaches to inform future computational modeling for mental health solutions [7].

The need for this research emerges from a critical and growing concern within educational environments: the mental health and well-being of college students. Mental health issues among this demographic have seen a significant rise, impacting students' academic performance, social interactions, and overall quality of life. Traditional methods of mental health assessment and intervention often lack the precision, adaptability, and comprehensiveness required to effectively address the complex and multifaceted nature of psychological states. Furthermore, these conventional approaches may not fully leverage the vast amounts of data generated from varied sources, such as digital footprints, self-reports, and behavioural observations, which could offer deeper insights into a student's mental health status.

3. Methodology. The methodology for FEPS-MH, encompasses a comprehensive process that includes data collection, preprocessing, feature extraction, and output generation. The initial phase of our methodology, data collection, involves gathering a wide array of data relevant to college students' mental health. This data is sourced from various channels, including structured sources like academic records, attendance logs, and health center visits, as well as unstructured sources like social media activity, forum posts, and text message analyses. Special attention is given to ensuring the privacy and confidentiality of student data throughout the process. Following collection, the data undergoes preprocessing, a crucial step aimed at transforming raw data into a clean, organized format suitable for analysis. This involves data cleaning, where incomplete, inconsistent, or irrelevant parts of the data are corrected or removed. Normalization techniques are also applied to bring all data to a common scale, eliminating potential biases arising from varied data scales. Once preprocessing is completed, the next step is feature extraction. Here, the most relevant and significant features impacting students' mental health are identified. Using statistical methods and domain expertise, features like stress levels inferred from social media sentiment, academic performance trends, and engagement in campus activities are extracted.

The DFBNN component plays a critical role in this phase, handling the imprecision and uncertainty inherent in psychological data. The fuzzy logic within DFBNN helps in interpreting the data effectively, even when it contains subjective or vague information. The extracted features are then fed into the BP Neural Network, where the actual predictive modeling occurs. The BP Neural Network, known for its efficacy in learning from data, is trained on these features. It learns the intricate relationships and patterns that might indicate various mental health states or trends among students. The output of FEPS-MH is a comprehensive mental health profile for each student, accompanied by predictive insights about potential future mental health states. This output is not just a static report but a dynamic, evolving profile that adapts as new data is fed into the system. Predictive analytics also help in identifying students who might be at risk of mental health issues, allowing early intervention. Moreover, the system provides personalized recommendations for mental health interventions based on individual profiles. These interventions range from suggesting counseling sessions to recommending participation in specific campus activities, tailored to each student's needs and mental health state. The proposed architecture is demonstrated in figure 3.1.

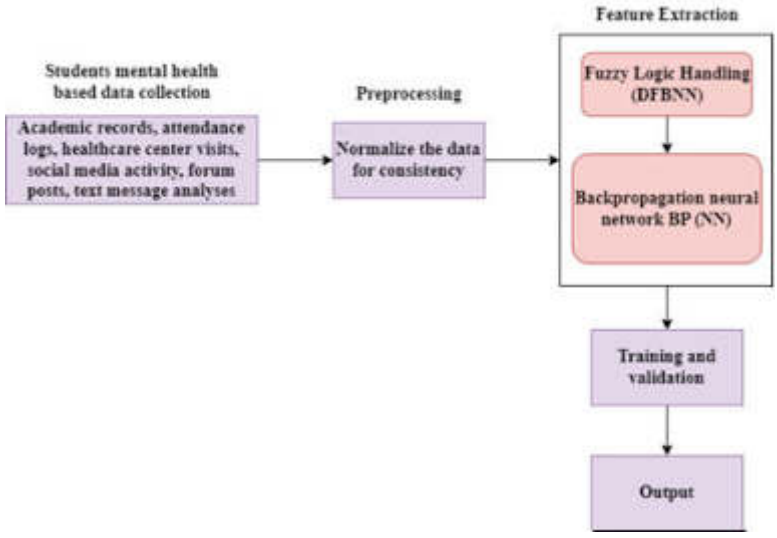

Fig. 3.1: Proposed FEPS-MH Architecture

3.1. Proposed FEPS-MH approach.

3.1.1. DFBNN Algorithm. The DFBNN within the FEPS-MH system is designed to effectively manage and interpret the often complex and uncertain data associated with mental health assessments in college students. Its primary purpose is to handle the inherent imprecision and vagueness that characterize psychological data. Unlike traditional models that might struggle with ambiguous or subjective inputs, the DFBNN, through its integration of fuzzy logic, can process such data by assigning degrees of membership or probability, rather than binary classifications. This capability is crucial in mental health contexts where indicators are not always clear-cut but exist on a spectrum. Furthermore, the DFBNN excels in integrating and making sense of data from diverse sources, such as behavioral observations, self-reported surveys, and digital footprints from social media. This integration is key to developing a comprehensive understanding of a student's mental health. Additionally, the deep aspect of the DFBNN refers to its ability to learn from large amounts of data, uncovering complex, non-linear relationships within it. This learning ability is essential for the system to adapt and improve its predictive accuracy over time, making it a dynamic tool that becomes more attuned to the nuances of student mental health. Thus, the DFBNN is integral to the FEPS-MH system, enhancing its capacity to provide nuanced, accurate, and personalized mental health assessments.

The DFBNN algorithm starts with an initialization phase where it prepares and normalizes the training data, which includes various inputs that represent different scenarios or situations. This stage sets the foundation for the neural network by providing it with consistent and standardized data. Next, the algorithm enters an offline training phase where the neural network learns from this prepared data in a controlled environment, without yet being exposed to new or real-time data. This step is essential for the initial configuration and calibration of the network. In the following stages, the algorithm iteratively trains the network, processing the normalized inputs and continuously adjusting the network's parameters, such as weights, using a training function. This function is influenced by an activation function that dictates how the neurons in the network respond to inputs. The training involves repeated adjustments to minimize errors and improve the accuracy of the network's outputs. This iterative process continues until a certain number of iterations are completed or specific performance criteria are met. After the offline training, the network undergoes online training, where it starts processing new, real-time data, allowing it to adapt and refine its responses based on current and evolving inputs. This transition from offline to online training marks the shift from a learning phase to an application phase, where the neural network begins to apply its learned patterns to actual, dynamic scenarios.

Algorithm 10 Offline and Online Training of Improved Deep Neural Network (DNN)

1: **Initialization:**
2: D_{tr} = Data for training (scene data and situation labels)
3: D_{trm} = Number of training data D_{tr}
4: x_i = For input x, ith input of the scene data
5: $\hat{x}_i$ = Normalized data
6: $Fun_{train}()$ = Function to train the hidden layers of deep network
7: Fun_{act} = Activation function for the deep neural network
8: DNN_{imp} = Improved deep neural network (DNN)
9: $Fun_{norml}()$ = For input normalization
10: F_{fuzz_out} = Output Fuzzification
11: $Fout\_DNN_{imp}$ = Training of the DNN_{imp}
12: **Offline training of the DNN_{imp}:**
13: Initialize counter for training iteration
14: $i \leftarrow 0$;
15: **do** $i++$**:**
16: Input Normalization
17: $\hat{x}_i \leftarrow Fun_{norml}(D_{tr})$;
18: $Fun_{train}(Fun_{act},\ \hat{x}_i)$;
19: **while** $i > D_{trm}$ **is false go back to line 2**
20: $Fun_{train\,DNN_{imp}}(DNN_{imp}, D_{tr})$;
21: **Online training of the DNN_{imp}:**
22: $t \leftarrow 0$;
23: **do** $t++$**:**
24: $\hat{x}_i \leftarrow$ Normalized (x_i);
25: $\widehat{b_i} \leftarrow Fout_{DNNimp}(\hat{x}_i, DNN_{imp})$;
26: $p_i \leftarrow F_{fuzz_{out}}(\widehat{b_i})$;
27: **while** $D_{tr} \geq D_{tr\max}$ **is false, go back to line 9**

3.1.2. Integration with BPNN. The purpose of the BPNN within the FEPS-MH system is to learn from and make accurate predictions about college students' mental health. BPNN, a core component of many machine learning systems, is known for its ability to effectively process large amounts of complex data and identify underlying patterns. In the context of FEPS-MH, the BPNN takes the pre-processed and normalized data, which has already been refined by the DFBNN to handle uncertainties and ambiguities. It then applies its layers of interconnected neurons to analyze this data, learning from the inputs through a process of forward and backward propagation. In forward propagation, the BPNN makes predictions based on the input data, and in backward propagation, it adjusts its internal parameters to minimize the difference between its predictions and the actual data. This continuous process of prediction and adjustment allows the BPNN to refine its understanding of the complex factors that influence mental health in students. By doing so, it becomes increasingly proficient in predicting potential mental health issues, enabling timely and personalized interventions. The BPNN's ability to learn and adapt makes it an essential tool in the FEPS-MH system for providing accurate and actionable insights into student mental health.

The algorithm for integrating a BPNN within the FEPS-MH system begins by taking the output from a DFBNN as its input. This output, processed to handle uncertainties in the data, is then fed into the BPNN. The first step in the BPNN algorithm involves calculating the output of each neuron in every layer of the network. The output of a neuron is determined by the sum of the products of inputs and their corresponding weights, added to a bias, and then passed through an activation function like ReLU or tanh. These functions help to introduce non-linearity in the processing, allowing the network to handle complex patterns in the data. Once the forward pass is completed, the algorithm enters the backward propagation phase. This phase starts with the computation of errors at the output layer, comparing the network's predictions against actual data.

Algorithm 11 Backward Propagation in FEPS-MH Model

Input: Receive the output p_i from the DFBNN as the input to the BPNN
Forward Propagation:
Step 1: For each layer l in the BPNN, calculate the output of the neurons
Step 2: The output $o_{l,j} = f(\sum_k w_{l,jk}.o_{l-1,k} + b_{l,j})$
Step 3: Commonly used activation functions ReLU or tanh
Backward Propagation:
Step 4: Compute the error at the output layer, where the error e_k for the output neuron k is $e_k = (y_k - o_{l,k})$
Step 5: Propagate the error back through the network to update the weights and biases.
Step 6: The error is calculated using $\delta_{l,j} = f'(\text{net}_{l,j}) \sum_m \delta_{l+1,m}.w_{l+1,mj}$
Step 7: Update the weights and biases using gradients

$$w_{l,jk} \leftarrow w_{l,jk} + \Delta w_{l,jk}$$

$$b_{l,j} \leftarrow b_{l,j} - \eta.\delta_{l,j}$$

Prediction:
Step 8: Use the trained FEPS-MH model (including the BPNN with updated weights) to predict the mental health status of students based on new input data.
Step 9: Feed the new input data through the FEPS-MH model.
Step 10: The final output layer of the BPNN provides the predicted mental health status.
Analysis and Recommendations:
Step 11: Analyze the output to generate comprehensive insights and recommendations for interventions or further action.

The error for each output neuron is the difference between the expected result and the prediction made by the network. The next step involves backpropagating this error through the network. This backpropagation adjusts the network's weights and biases to minimize the error, effectively 'learning' from the discrepancies. The adjustments are made using gradients, calculated based on the error and the derivative of the activation function. This process iteratively adjusts the network to improve its accuracy. After the training is completed, the BPNN is ready to make predictions on new data. When new input data is received, it is fed through the trained FEPS-MH model, which includes the fine-tuned BPNN. The output layer of the BPNN provides the final prediction regarding the mental health status of the students. This output is not just a raw prediction; it's analyzed to generate comprehensive insights and actionable recommendations for interventions or further actions, providing a valuable tool for mental health professionals in understanding and addressing student mental health issues.

4. Results and Experiments.

4.1. Simulation Setup. The dataset used in the study for a psychological early warning system which is adapted from the study [6] is a comprehensive collection of various data points reflecting the mental health and behaviors of college students. It includes detailed records of students' class attendance and examination results, highlighting a general trend where consistent attendance correlates with higher academic performance. However, exceptions to this trend suggest the need for a deeper, more individualized analysis. The dataset also tracks dormitory access times, providing insights into students' daily routines, such as their sleep patterns and potential late-night activities, which can be indicators of stress or irregular lifestyle habits. Additionally, the study considers financial aspects, including students' spending habits through campus card usage and tuition fee payment status, to gauge their financial stability and related stress factors. Social media data from platforms like QQ, WeChat, and Weibo are also utilized to capture students' emotional expressions and concerns, offering a window into their mental states. The study acknowledges the different psychological challenges faced by students at various stages of their university journey, ranging from adaptation issues for freshmen to career-

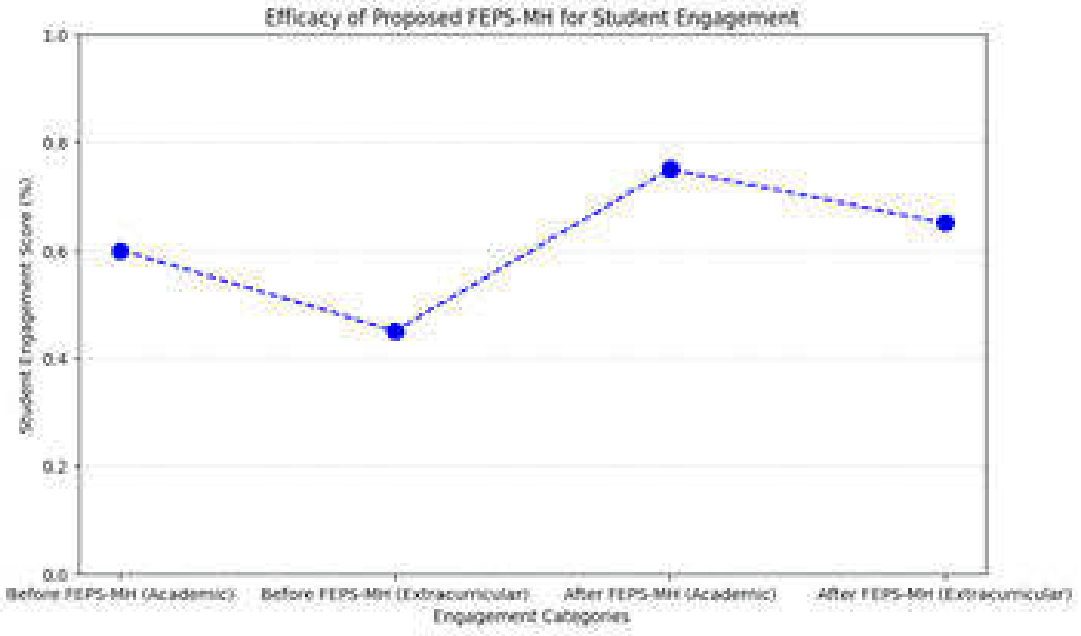

Fig. 4.1: Student Engagement

related anxieties for seniors. The result of proposed FEPS-MH is helps to accurately analyze the student's mental health, helping to identify early warning signs of distress and facilitating timely and personalized interventions. Such a multifaceted approach ensures that the mental health support provided is comprehensive and tailored to individual student needs.

4.2. Evaluation Criteria. In this section the proposed FEPS-MH is evaluated using the metrics in terms of student engagement score, wellness index and behavioral consistency score.

4.2.1. Student Engagement Score. Figure 4.1 illustrates the effectiveness of the proposed FEPS-MH system in enhancing student engagement. This evaluation categorizes FEPS-MH into two groups: before implementation and after implementation, focusing on both academic and extracurricular engagement. The figure clearly demonstrates that before the implementation of FEPS-MH, the scores in both academic and extracurricular engagement were relatively low. However, after the implementation of the proposed system, there was a significant improvement in the performance of both academic and extracurricular engagement categories. This improvement highlights the positive impact of FEPS-MH on enhancing student engagement compared to the pre-implementation phase.

4.2.2. Wellness Index. Figure 4.2 presents the efficacy of proposed regarding wellness index. Wellness index considered in key categories related to student well-being, specifically stress levels, mood patterns, and social interaction. Before the implementation of FEPS-MH, students exhibited moderate levels of stress (06), relatively lower mood patterns (05), and limited engagement in social interaction (04). These baseline scores indicated areas where students mental wellness could be enhanced. However, after the implementation of FEPS-MH, a notable transformation occurred. Stress levels significantly decreased to 0.3, indicating a reduction in students' stress and improved mental well-being. Mood patterns saw a substantial improvement, with a score of 0.7, suggesting that students experienced more positive and stable emotional states. Social interaction, a crucial aspect of overall well-being which significantly improved to a score of 0.8, indicating increased engagement and connectivity among students. Overall, the implementation of FEPS-MH resulted in a remarkable enhancement in stress management, mood stability, and social interaction among students. These improvements collectively contribute to a higher overall wellness index, reflecting the system's efficacy in promoting better mental health

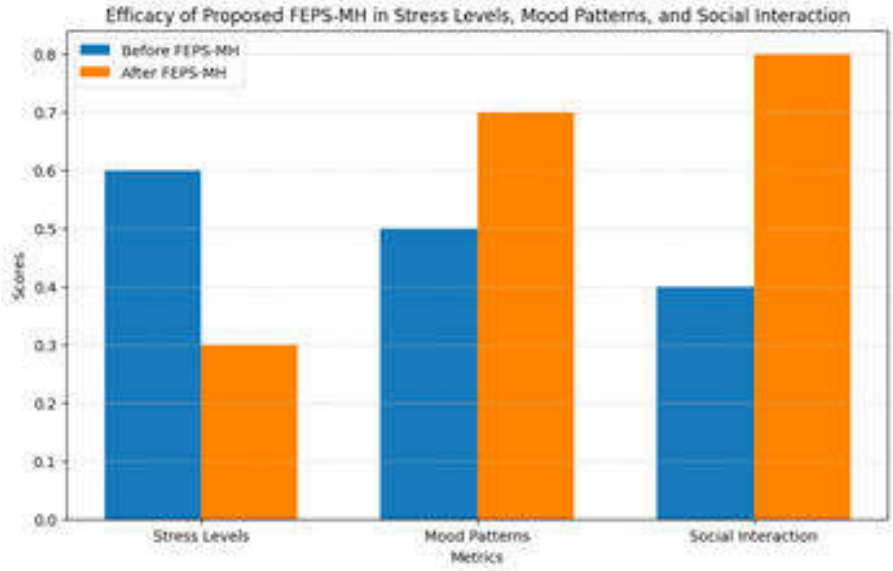

Fig. 4.2: Wellness Index

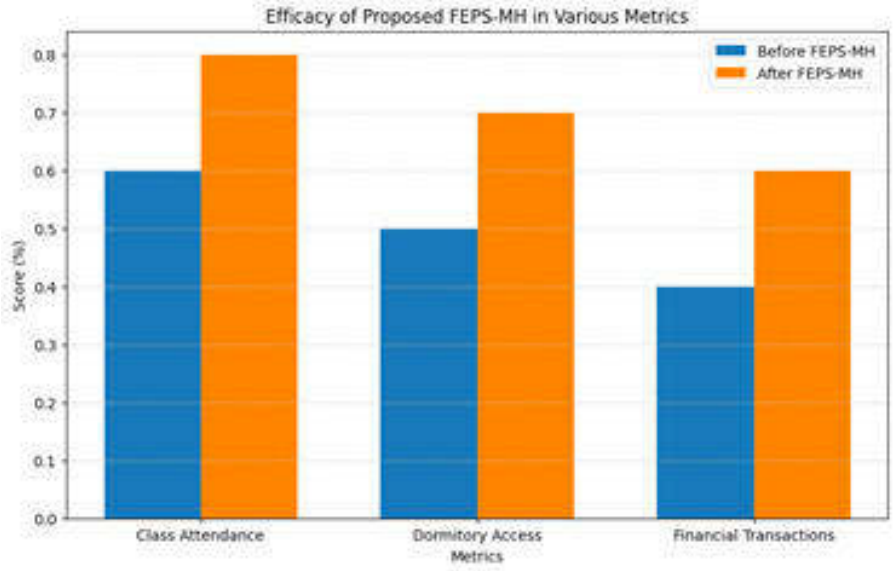

Fig. 4.3: Behavioral Consistency

and well-being in the student population.

4.2.3. Behavioral consistency. Figure 4.3 demonstrates the efficacy in terms of behavioral consistency. The efficacy of implementing FEPS-MH is clearly demonstrated through a comparison of key metrics before and after its implementation. These metrics encompass vital aspects of students daily lives and well-being, including class attendance, dormitory access, and financial transactions. Before implementing FEPS-MH, the scores for these metrics stood at 0.6, 0.5, and 0.4, respectively. However, after the implementation of FEPS-MH, remarkable improvements were observed, with scores rising to 0.8, 0.7, and 0.6 for class attendance, dormitory

access, and financial transactions. These enhancements signify a positive transformation in student engagement, consistency in daily routines, and financial stability, all of which are essential components of mental health and well-being. The results clearly indicate the effectiveness of FEPS-MH in fostering better mental health and overall student wellness.

5. Conclusion. In conclusion this study introduces a novel approach called FEPS-MH which helps to analyse the mental health of the college students based on big data analytics. The proposed FEPS-MH integrates the strength of DFBNN and BPNN. By combining the strength of these effective techniques, the proposed demonstrates the efficacy in terms of the performance metrics called student engagement, wellness index and behavioral consistency in two categories called before implementing FEPS-MH and after implementing FEPS-MH. By analysing the student engagement score with the following categories such as academic and extracurricular activities. Next the wellness index under the terms of stress levels, mood patterns and social interactions. Finally, behavioral consistency based on class attendance, dormitory access and financial transactions. By analysing the above demonstrations, the results suggest that when compared with before implementation of FEPS-MH, after implementing will demonstrates the highest efficacy and efficiency in terms of overall metrics. This shows the efficacy of proposed under the mental health of the students which is highly trustable and an effective tool to improve the student wellness and acts as a crucial role to improve the mental health of the students.

DEEP LEARNING-BASED EMOTION RECOGNITION ALGORITHMS IN MUSIC PERFORMANCE

YAN ZHANG*, MUQUAN LI†, AND SHUANG PAN‡

Abstract. In the realm of artificial intelligence and musicology, emotion recognition in music performance has emerged as a pivotal area of research. This paper introduces EmoTrackNet, an integrated deep learning framework that combines sparse attention networks, enhanced one-dimensional residual Convolutional Neural Networks (CNNs) with an improved Inception module, and Gate Recurrent Units (GRUs). The synergy of these technologies aims to decode complex emotional cues embedded in music. Our methodology revolves around leveraging the sparse attention network to efficiently process temporal sequences, thereby capturing the intricate dynamics of musical pieces. The incorporation of the 1D residual CNN with an upgraded Inception module facilitates the extraction of nuanced features from audio signals, encompassing a broad spectrum of musical tones and textures. The GRU component further refines the model's capability to retain and process sequential information over longer timeframes, essential for understanding evolving emotional expressions in music. We evaluated EmoTrackNet on the Soundtrack dataset a comprehensive collection of music pieces annotated with emotional labels. The results demonstrated remarkable improvements in the accuracy of emotion recognition, outperforming existing models. This enhanced performance can be attributed to the integrated approach, which efficiently combines the strengths of each component, leading to a more robust and sensitive emotion detection system. EmoTrackNet's novel architecture and promising results pave the way for new avenues in musicology, particularly in understanding and interpreting the emotional depth of musical performances. This framework not only contributes significantly to the field of music emotion recognition but also has potential applications in music therapy, entertainment, and interactive media where emotional engagement is key.

Key words: Emotion recognition, music performance, deep learning, sparse attention network, 1D CNN, GRU, musicology

1. Introduction. The field of musicology and artificial intelligence has witnessed substantial growth over the past few years, particularly in the domain of emotion recognition in music performance [16, 1]. Emotion recognition in music, a complex and nuanced task, involves deciphering the emotional content conveyed through musical elements such as melody, rhythm, and harmony. The advancement of deep learning techniques has opened new avenues for exploring this area, offering more sophisticated and accurate methods for analyzing and interpreting musical expressions [7, 13, 12]. Regarding this, the proposed study introduces a novel approach of EmoTrackNet, which integrated deep learning framework, stands at the forefront of this evolution. It amalgamates sparse attention networks, one-dimensional residual Convolutional Neural Networks (CNNs) with an improved Inception module, and Gate Recurrent Units (GRUs) to create a robust system for emotion detection in music [8, 5]. This approach not only addresses the limitations of previous models but also enhances the ability to capture the intricate emotional nuances embedded in musical compositions.

The inception of EmoTrackNet is rooted in the need to overcome the challenges associated with traditional emotion recognition methods in music [16, 3]. Traditional approaches often struggle with the complexity and variability of musical structures, leading to limitations in accuracy and efficiency. By introducing a sparse attention network, EmoTrackNet efficiently processes temporal sequences in music, capturing the dynamic changes over time. This is further complemented by the enhanced capabilities of the 1D residual CNN with an improved Inception module, which is adept at extracting detailed features from audio signals. These features encompass a wide range of musical tones and textures, providing a comprehensive analysis of the audio input [6]. The integration of GRUs aids in retaining and processing sequential information over extended periods, an essential factor in understanding the progression and evolution of emotions in musical performances. This

‡School of Music, Drama and Dance, Russian State Normal University, St. Petersburg, Russia, 191186, Russia

integrated approach ensures a holistic analysis, facilitating a deeper understanding of the emotional content in music [4].

The motivation behind this research stems from the growing recognition of the profound emotional impact of music and the desire to develop advanced computational techniques to understand and interpret these emotional cues. EmoTrackNet represents a novel approach that integrates cutting-edge deep learning technologies, including sparse attention networks, enhanced one-dimensional residual Convolutional Neural Networks (CNNs), and Gate Recurrent Units (GRUs), to tackle the complexity of emotional expression in music. By leveraging these technologies, we aim to decode the intricate emotional nuances embedded within musical pieces, thereby advancing our understanding of the emotional depth of music performances. The evaluation of EmoTrackNet on the Soundtrack dataset showcases its remarkable improvements in emotion recognition accuracy, surpassing existing models. This success underscores the potential of our integrated approach to revolutionize the field of musicology by providing researchers with powerful tools to explore and analyze the emotional dimensions of music. Moreover, EmoTrackNet's capabilities hold promise for practical applications in music therapy, entertainment, and interactive media, where emotional engagement is paramount. Overall, this research addresses a critical gap in the intersection of artificial intelligence and musicology, offering new avenues for exploring the emotional landscapes of musical experiences.

The practical application and significance of EmoTrackNet extend beyond the realms of musicology and artificial intelligence. By achieving higher accuracy in emotion recognition, EmoTrackNet has the potential to revolutionize various sectors, including music therapy, entertainment, and interactive media. In music therapy, understanding the emotional impact of music can lead to more effective therapeutic interventions. In the entertainment industry, EmoTrackNet can enhance user experience by aligning music more closely with the desired emotional impact. Additionally, in interactive media, this technology can be used to create more engaging and emotionally resonant content. The framework's ability to accurately interpret and respond to the emotional cues in music opens up possibilities for creating more immersive and emotionally connected experiences. EmoTrackNet, therefore, not only contributes significantly to the academic field but also has practical implications that could transform how we interact with and experience music.

The main contribution of the paper as follows:

1. Proposed a novel approach of EmoTrackNet for emotion recognition in music performance.
2. This proposed technique integrates a several effective techniques strengths called sparse attention networks1D CNN with an improved inception module, and GRU to create a robust system for emotion detection in music.
3. This proposed approach is evaluated using the soundtrack dataset and demonstrated with the rigorous experiments.

2. Related work.

2.1. Deep learning based various emotion recognition techniques. The paper [14] introduces a novel approach for speech emotion recognition, leveraging both speech features like Spectrogram and Mel-frequency Cepstral Coefficients (MFCC) to capture low-level emotional characteristics and textual transcriptions to extract semantic meaning. In [18] deep learning in emotion recognition combines audio features and textual data, enhancing accuracy by capturing both low-level acoustic cues and semantic context. Diverse model architectures are explored, with the MFCC-Text CNN model proving superior in recognizing emotions in IEMOCAP dataset, showcasing the potential of multi-modal approaches. This advancement holds promise for applications in human-computer interaction and sentiment analysis. The study [2] addresses challenges in emotion recognition from facial expressions by leveraging transfer learning with deep learning models like ResNet50, VGG19, Inception V3, and MobileNet. By fine-tuning these pre-trained networks and customizing fully connected layers, the approach achieves a remarkable average accuracy of 96% on the CK+ database, demonstrating the effectiveness of deep learning in overcoming issues like facial accessories, lighting variations, and pose changes in emotion detection. The study [17] explores the use of respiration signals to detect psychological activity and emotions, leveraging a deep learning framework with sparse auto-encoders. By applying an arousal-valence theory and utilizing the DEAP and Augsburg datasets, the approach achieves accuracies of 73.06% for valence classification and 80.78% for arousal classification on DEAP, as well as a mean accuracy of 80.22% on the Augsburg dataset.

2.2. Music based emotion recognition. The study [11] addresses the significance of music emotion recognition in music-related fields and introduces a novel approach using convolutional and recurrent neural networks for feature extraction. By leveraging the latest deep learning techniques, such as stacking convolution layers with bidirectional gated recurrent units, the method achieves outstanding performance on the MediaEval Emotion in Music dataset, demonstrating its effectiveness in raw audio signal-based emotion recognition without the need for extensive pre-processing. The study [9] highlights the growing importance of music emotion recognition (MER) in the field of music information retrieval (MIR) and its relevance to video soundtracks. To enhance efficiency and accuracy, the work combines Mel Frequency Cepstral Coefficient (MFCC) and Residual Phase (RP) features, weighting and combining them to improve music emotion feature extraction. Additionally, a wide and deep learning network (LSTM-BLS) is introduced, integrating Long Short-Term Memory (LSTM) and the Broad Learning System (BLS) to efficiently train music emotion recognition models [10].

Existing studies in emotion recognition, especially in the context of music, have explored various machine learning and deep learning methods. However, the novel integration of sparse attention networks, 1D CNN with an improved inception module, and GRU (Gated Recurrent Unit) represents a unique approach that combines the strengths of these techniques [15]. This integration is designed to capture the nuanced emotional expressions in music more accurately than previous models, addressing the need for sophisticated models that can understand complex emotional states in music.

3. Methodology.

3.1. Proposed EmoTrackNet Overview. The proposed EmoTrackNet is a comprehensive framework designed for emotion recognition in music, encompassing several stages from data collection to the final output of emotion recognition. The process begins with data collection, where a diverse array of musical tracks is gathered. This collection includes a variety of genres and styles to ensure a broad representation of musical emotions. Each track is annotated with emotional labels based on musicology theories and listener feedback, providing a robust foundation for the models training and validation. Following data collection, the preprocessing stage commences. Here, each music track is segmented into uniform 30-second clips. This segmentation facilitates consistency in subsequent analyses. The audio clips then undergo STFT and converting them from the time domain to the frequency domain, thus producing two-dimensional spectrograms. These spectrograms capture both the temporal and frequency characteristics of the audio, serving as the primary input for EmoTrackNet's deep learning model. The core of EmoTrackNet lies in its feature extraction capabilities. Utilizing a 1D residual CNN with an enhanced inception module, the framework processes the spectrograms to extract intricate audio features. The inclusion of a sparse attention network further refines the process, directing the model's focus to the most salient features for emotional content analysis. This combination of advanced deep learning techniques ensures an efficient and effective extraction of relevant features, which is critical for accurately identifying emotions in music. The model is rigorously trained and tested on the collected dataset with metrics such as accuracy, precision, recall, and F1 score being calculated to assess its performance. Cross-validation methods are employed to ensure the model's reliability and robustness. These evaluations guide further refinements to EmoTrackNet, aiming to achieve high accuracy in emotion recognition. Finally, the output stage of EmoTrackNet involves the identification and labeling of emotions for each music clip. The model employs GRU to process sequential data, capturing the evolving temporal dynamics of the music and correlating them with emotional expressions. The outcome is a detailed emotional profile for each clip, indicating the predominant emotions present in the piece. This output has wide-ranging applications, from enhancing music recommendation services to providing insights in music therapy, showcasing EmoTrackNet's versatility as a tool in music emotion analysis. In essence, EmoTrackNet represents a holistic and methodical approach to emotion recognition in music, integrating state-of-the-art deep learning techniques with a thorough data-driven methodology to accurately capture and interpret the emotional essence of musical compositions. The proposed architecture of EmoTrackNet is demonstrated under Figure 3.1.

3.1.1. EmoTrackNet based Preprocessing Process. The preprocessing phase is critical for preparing the audio data for deep learning analysis. This process starts with segmenting the original audio into 30-second clips. If a music clip is shorter than 30 seconds, it is elongated to the required length using an audio editing tool. Following this, the Short-Time Fourier Transform (STFT) is applied. The STFT converts the time-domain

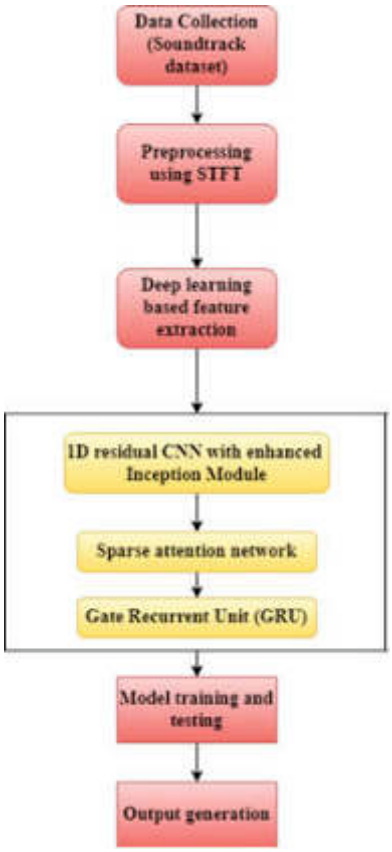

Fig. 3.1: Proposed EmoTrackNet architecture

audio signals into a frequency domain representation. This conversion facilitates the extraction of features that are crucial for emotion recognition in music. The STFT is represented by the equation:

$$STFT\,(x)\,(\tau,\omega) = \int x\,(t)\,.w\,(t-\tau)\,.e^{-jwt}dt$$

Here, $x\,(t)$ is the signal, $w\,(t-\tau)$ is the window function, and e^{-jwt}represents the complex sinusoids. The outcome of this process is a two-dimensional spectrogram, which serves as the input for the neural network.

3.1.2. Deep Learning Based Sparse Attention Network. The sparse attention network is a pivotal part of EmoTrackNet, focusing the model's attention on significant features while processing vast amounts of data. This attention mechanism ensures that the network allocates more computational resources to parts of the input data that are more relevant for emotion recognition. The core idea behind sparse attention can be encapsulated in the attention equation:

$$Attention\ \ (q,k,v) = softmax\left(\frac{qk^t}{\sqrt{d_k}}\right)v$$

In this equation, (q,k,v)represent the query, key, and value matrices, respectively, and dkdk is the dimensionality of the key. The softmax function is applied to the scaled dot-product of q and k^t to obtain the weights on the values v. This selective focus mechanism is crucial for EmoTrackNet to efficiently process and interpret the emotional content in music.

3.1.3. One-Dimensional (1D) Residual Convolutional Neural Network with Improved Inception Module. The 1D residual CNN with an improved inception module in EmoTrackNet is designed for feature extraction from audio signals. The 1D CNN processes the spectrogram by performing convolution operations along the time axis, capturing temporal features of the audio signal. The residual nature of this network is defined by the equation:

$$f(x) = h(x) + x$$

where $f(x)$ is the output of the residual block, $h(x)$is the output from the layers within the block, and x is the input to the block. This structure helps in addressing the vanishing gradient problem in deep networks. The Inception module, on the other hand, includes multiple convolutional filters of different sizes operating in parallel. This design allows the network to capture features at various scales and complexities, improving the robustness and accuracy of feature extraction.

3.1.4. Gate Recurrent Unit (GRU). The GRU is a type of recurrent neural network that is effective in processing sequential data like audio. It is particularly adept at capturing dependencies over different time scales. The key equations governing the GRU are:

$$r_t = \sigma(w_r.[h_{t-1}, x_t])$$

$$h_t = (1 - z_t).h_{t-1} + z_t + \tilde{h}_t$$

Here, $r_t$is the reset gate, z_t is the update gate, x_t is the input at time$t$, h_{t-1} is the previous memory state, and $\tilde{h}_t$ is the candidate memory state. The GRU's ability to remember and combine information over long sequences makes it particularly valuable for analyzing the emotional progression in music. Overall, this integration of proposed EmoTrackNet offers an advanced approach to effectively recognize and analyze emotions in music performance, leveraging the strengths of each component for superior performance

By prioritizing significant features in the music data, the sparse attention mechanism ensures that the model allocates computational resources more efficiently. This targeted approach enhances the model's ability to discern subtle emotional cues within large datasets, improving both the accuracy and speed of emotion recognition. The 1D residual CNN's design, focusing on the time axis of spectrogram data, adeptly captures temporal dynamics of music, which are essential for understanding its emotional progression. This temporal sensitivity is crucial for accurately identifying emotions that evolve over time. The improved inception module's parallel convolutional filters of varying sizes allow the model to extract a rich set of features from audio signals, from fine-grained details to broader patterns. This versatility enhances the model's ability to recognize a wide range of emotional expressions, making it suitable for diverse music genres and styles.

4. Results and Experiments.

4.1. Simulation Setup. In this section the dataset was used to evaluate our proposed EmoTrackNet is adapted from the study [5]. Figure 3.1 of the study demonstrates clearly about the soundtrack dataset.

The Soundtrack dataset used for evaluating EmoTrackNet, consists of 360 sound samples, each a 30-second clip from movie soundtracks, chosen for their distinct emotional characteristics. This dataset categorizes these clips into four emotions: happy, angry, sad, and tender. The classification is based on a two-dimensional emotional model considering arousal (from tender/sleepy to tension/exciting) and valence (from sad/frustrated to happy/pleased), with each track labeled according to the dominant emotion it conveys. These samples focus on the instrumental aspect of music, excluding human voices and lyrics, and are stored in high-quality mp3 format at a 44.1 kHz sampling rate. For experimental purposes, the dataset is divided into a training set and a test set in an 8:2 ratio, providing a balanced approach for training and testing the emotion recognition capabilities of EmoTrackNet.

4.2. Evaluation Criteria. The evaluation of EmoTrackNet's performance using precision, recall, and F1-Score for each emotion class demonstrates its efficacy in emotion recognition from music.

Figure 4.1 presents the efficacy of proposed in terms of precision, recall and F1-score. Precision is a measure of how many of the identified cases were actually relevant. In the context of EmoTrackNet, high precision values

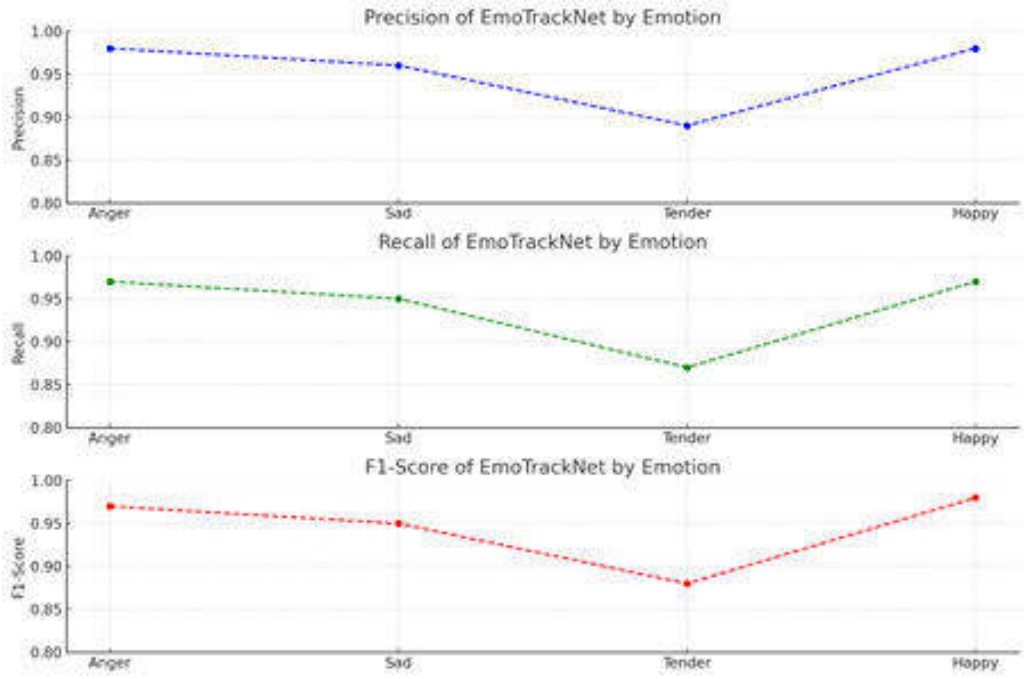

Fig. 4.1: Efficacy achieved in terms of precision, recall, and F1-score

for 'Anger' (0.98) and 'Happy'(0.98) imply that when the model predicts a track to be angry or happy, it is correct 98% of the time. This is indicative of the model's high accuracy in identifying these emotions without many false positives. For 'Sad' (0.96), the precision is slightly lower but still indicates a strong ability to correctly identify sad tracks. The 'Tender' emotion, with a precision of 0.89, shows a slightly higher rate of false positives compared to the other emotions. However, this value is still commendably high, suggesting that EmoTrackNet is quite reliable in classifying tracks as tender. Overall, the high precision values across all classes demonstrate that the model is highly effective in correctly labeling tracks with their respective emotions, minimizing instances where a track is wrongly identified with an emotion.

Recall measures the model's ability to find all relevant instances in a dataset. In the case of EmoTrackNet, the recall values are impressive, indicating that the model is proficient in identifying most of the tracks that correspond to a particular emotion. For 'Anger' (0.97) and 'Happy' (0.97), the high recall values suggest that the model misses very few angry or happy tracks. This shows EmoTrackNet's effectiveness in capturing the emotional essence of these categories. The recall for 'Sad' (0.95) is slightly lower but still signifies that the model can identify most of the sad tracks in the dataset. The 'Tender' class has the lowest recall (0.87), suggesting that while the model is generally good at identifying tender tracks, it is slightly more prone to missing some of these tracks compared to other emotions. The recall values across all classes indicate that EmoTrackNet is quite adept at capturing the majority of emotional content in the dataset, ensuring that few relevant tracks are overlooked.

The F1-Score is a harmonic mean of precision and recall, providing a balanced measure of a model's accuracy. It is particularly useful when the class distribution is uneven, as it maintains a balance between the precision and recall metrics. For EmoTrackNet, the F1-Scores are very high for 'Anger' (0.97), 'Sad' (0.95), and 'Happy' (0.98), indicating a strong balance between precision and recall. These scores suggest that EmoTrackNet is not only good at correctly identifying these emotions but also at finding most instances of these emotions in the dataset. The 'Tender' emotion, with an F1-Score of 0.88, shows a slightly lower balance compared to the other emotions. This might be due to the more subtle or subjective nature of tender music, making it slightly more challenging for the model to maintain a high performance in both precision and recall. Overall, the F1-Scores

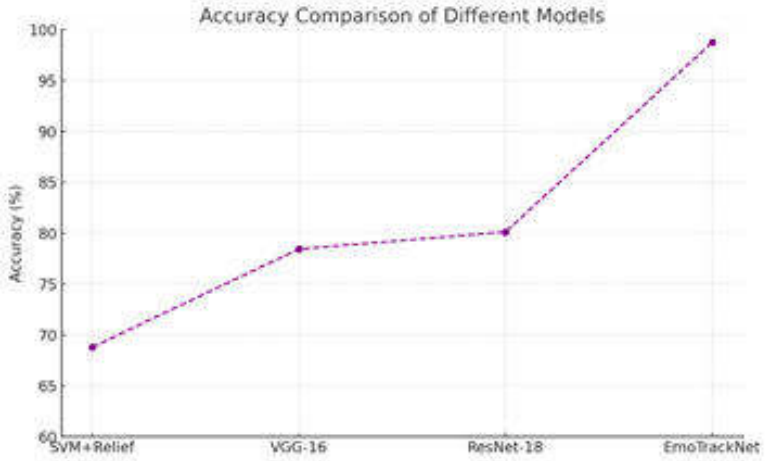

Fig. 4.2: Comparison Analysis

across all classes suggest that EmoTrackNet achieves a commendable balance in identifying the correct tracks for each emotion while minimizing the number of relevant tracks it misses.

4.2.1. Comparison Performance Analysis. The efficacy of the proposed EmoTrackNet in terms of accuracy is outstanding, particularly when compared to other models like SVM+Relief, VGG-16, and ResNet-18 was demonstrates in Figure 4.2. With an impressive accuracy of 98.74%, EmoTrackNet significantly outperforms these established models, showcasing its superior capability in emotion recognition from music. This high level of accuracy indicates that EmoTrackNet is exceptionally adept at correctly classifying the emotional content of music tracks. The closest competitor, ResNet-18, achieves an accuracy of 80.12%, which, while respectable, falls markedly short of EmoTrackNet's performance. VGG-16, another popular model in image and audio processing, achieves an accuracy of 78.44%, and SVM+Relief, a model often used for feature selection and classification, has an accuracy of 68.78%. These comparisons highlight the substantial advancement that EmoTrackNet represents in the field of emotion recognition in music. Its ability to accurately identify the emotional tones of music clips at such a high rate is indicative of the robustness of its underlying architecture and algorithms. EmoTrackNet's exceptional accuracy can be attributed to its advanced deep learning techniques, 1D CNN, an improved Inception module, and a GRU, all of which contribute to its superior performance in deciphering the complex emotional nuances embedded in musical compositions.The future scope of this research includes exploring the integration of additional modalities, such as physiological signals and video data, to enhance emotion recognition accuracy, and expanding the model's application to real-time music systems and interactive entertainment technologies.

5. Conclusion. The study on EmoTrackNet, with its focus on emotion recognition in music, ends in a resounding affirmation of the model's effectiveness and superiority in the field. The efficacy of EmoTrackNet is amazingly evident when considering its performance metrics. With an astounding accuracy of 98.74%, EmoTrackNet sets a new benchmark in the realm of music emotion analysis. This level of accuracy, significantly higher than other models like ResNet-18 (80.12%), VGG-16 (78.44%), and SVM+Relief (68.78%), underscores EmoTrackNet's advanced capabilities in correctly identifying and classifying emotional content in music. Moreover, its precision and recall scores across various emotions ranging from 0.89 to 0.98 in precision and 0.87 to 0.97 in recall further demonstrate its remarkable consistency and reliability. The model's F1-Scores, maintaining a high level between 0.88 and 0.98 across different emotional categories, reflect a balanced and nuanced understanding of emotional expressions in music. These performance metrics are a testament to the robustness of EmoTrackNet's architecture, which skillfully integrates deep learning techniques such as 1D residual CNNs, improved Inception modules, and GRUs. The study conclusively shows that EmoTrackNet is not only a breakthrough in the technical domain of artificial intelligence and musicology but also a potential tool for

applications in music therapy, entertainment, and interactive media, where understanding and interpreting musical emotions is crucial. EmoTrackNet, with its state-of-the-art approach and exceptional performance, represents a significant stride forward in the automated recognition and analysis of emotions in music.

DIGITAL PROTECTION AND INHERITANCE PATH OF INTANGIBLE CULTURAL HERITAGE BASED ON IMAGE PROCESSING ALGORITHM

JINGXUAN ZHAO*

Abstract. This research paper introduces a novel approach in the realm of digital preservation and inheritance of Intangible Cultural Heritage (ICH) through a Customized 3D Convolutional Neural Network (CNN). The core of this study lies in the development of an advanced image processing algorithm tailored to accurately recognize, categorize, and archive diverse forms of ICH, which include traditional performances, ceremonies, oral traditions, and crafts. Utilizing a volumetric 3D CNN, this paper demonstrates how complex ICH elements can be effectively captured and analyzed, overcoming the limitations of traditional 2D image processing methods. The network is trained on a comprehensive dataset of ICH imagery, ensuring sensitivity to the subtle nuances and dynamic nature of these cultural expressions. This paper highlights the algorithm's capability in not only safeguarding the visual aspects of ICH but also in providing an interactive, digital medium for education and cultural dissemination. The proposed method shows significant promise in aiding the efforts of cultural preservationists and educators, offering a technologically advanced pathway for the protection and inheritance of the world's rich, yet vulnerable, cultural heritage. This study sets a precedent in the interdisciplinary field of cultural heritage conservation, digital technology, and artificial intelligence, providing a scalable and effective solution for global ICH preservation initiatives.

Key words: Intangible cultural heritage, image recognition, digital protection, deep learning, CNN.

1. Introduction. In an era where the fabric of cultural diversity is under constant threat from the forces of globalization and cultural homogenization, the preservation of Intangible Cultural Heritage (ICH) emerges as a paramount concern. ICH, a term encompassing a broad spectrum of traditions, including but not limited to traditional performances, ceremonies, oral traditions, and artisanal crafts, represents the living expressions and knowledge passed down through generations [13, 4, 6]. Unlike tangible heritage, ICH is fluid, often existing in the collective memory and practices of communities. Its preservation is not just about safeguarding cultural artifacts; it is about maintaining the vibrancy and continuity of cultural identities in a rapidly changing world. However, the transient and dynamic nature of ICH presents unique challenges. Traditional methods of documentation and archiving are often inadequate in capturing the essence and intricacies of these cultural expressions, highlighting a pressing need for innovative approaches in the field of cultural preservation [8].

The advent of digital technology, particularly in the domain of artificial intelligence and image processing, has opened new horizons for addressing these challenges [14, 16]. Among these technological advancements, the evolution of 3D Convolutional Neural Networks (CNNs) stands out for their revolutionary capabilities in image analysis [13]. While traditional 2D image processing methods struggle to capture the depth and complexity inherent in many forms of ICH, 3D CNNs excel in handling volumetric data, offering a more nuanced and comprehensive analysis [4]. This ability to process and interpret complex visual data with remarkable depth and accuracy presents an unprecedented opportunity in the realm of ICH preservation. By leveraging these advanced technologies, there is potential to not only document but also to breathe new life into these cultural treasures, ensuring they are not lost to time [18, 22].

This research paper taps into this potential, introducing a novel approach that utilizes a Customized 3D CNN tailored specifically for the digital preservation and inheritance of ICH. This approach marks a significant departure from conventional methodologies, addressing the unique challenges posed by the diverse and nuanced nature of ICH [9, 2, 3]. The development of this advanced image processing algorithm is a response to the critical need for tools that can accurately recognize, categorize, and archive the various forms of ICH. This customization is key to the project's success, as it ensures the algorithm is finely tuned to the subtleties and dynamic qualities of different cultural expressions [21, 19]. Whether it is capturing the fluidity of a dance performance, the

*Shanxi college of applied science and technology Shanxi Taiyuan, 030062, China (jingxuanzhar1@outlook.com)

intricate patterns of traditional crafts, or the subtle nuances of oral storytelling, this customized approach promises a level of fidelity and depth in digital preservation that was previously unattainable[20, 17, 5].

The implications of this research are far-reaching and transformative. By harnessing the power of 3D CNNs, this study not only contributes to the safeguarding of cultural heritage but also opens up new avenues for its dissemination and appreciation. The digitalization of ICH through this method does not merely result in a static archive; it creates an interactive, dynamic medium that can be used for education and cultural exchange. It offers a way to bridge the gap between generations and geographies, making these rich cultural expressions accessible to a global audience. Furthermore, the scalability and effectiveness of this solution present a valuable tool for cultural preservationists, educators, and policymakers worldwide. In setting a precedent in the interdisciplinary field of cultural heritage conservation, digital technology, and artificial intelligence, this study paves the way for a new era in global ICH preservation efforts, ensuring that these vital cultural expressions continue to thrive and inspire future generations.

The main contribution of the paper as follows:

1. Proposed a novel approach of 3D CCNN based image recognition technique for the digital protection and inheritance path of ICH.
2. This proposed involves the effective customized 3D CNN to obtain the effective results in image recognition techniques.
3. The efficacy of the proposed is demonstrated with valid experiments.

2. Related Work.

2.1. Image Recognition techniques. The paper [10] explores the evolution of image recognition techniques, highlighting the transition from handcrafted features combined with machine learning methods to the superior performance of deep learning-based approaches post-2010. It emphasizes the advancements brought by deep learning in general object recognition competitions, and specifically addresses its application in autonomous driving and the latest trends in deep learning. The survey paper [11] provides a comprehensive analysis of deep learning's impact on image processing, discussing its successes and challenges. It delves into the complexities of deeper network structures and class imbalances in training data. The paper introduces four series of deep learning models and emphasizes the importance of understanding the relationship between deep learning and image processing tasks for future innovations and applications. The paper [12] reviews the application of deep learning in image recognition, outlining its significance in advancing computer vision and AI. It compares three main deep learning models - CNNs, RNNs, and GANs - and discusses their applications in various image recognition fields like face recognition and medical imaging, highlighting future trends like video image recognition and theoretical model enhancements. Focusing on cultural heritage, the paper [1] discusses the application of image recognition in enhancing the tourist experience at archaeological sites. It emphasizes the use of image recognition for content discovery in both indoor and outdoor settings, improving engagement through personalized content and real-time interaction, thus addressing challenges in heritage presentation. The paper [15] examines challenges in machine learning, particularly the scarcity of training data and class imbalance. It analyzes various data augmentation techniques, including classical transformations and advanced methods like Style Transfer and GANs, applied to medical case studies. The paper validates a new data augmentation method for enhancing training efficiency in image classification tasks. The paper [7] compares deep learning with traditional machine learning methods, outlining its development and network structures. It focuses on deep learning's application in image recognition and classification, discussing challenges and solutions. The paper concludes with a summary and future outlook on deep learning's role in image recognition and classification within AI.

Research challenges.

1. How to compile a comprehensive and representative dataset of ICH imagery that captures the wide variety of cultural expressions across different communities and regions, considering the scarcity of digital records for certain traditions and the potential biases in data selection.
2. Developing a 3D CNN architecture that can effectively process and analyze the multidimensional aspects of ICH, adapting to its dynamic and nuanced nature. This includes identifying the most suitable layers, activation functions, and other network parameters tailored to the complexity of ICH.

3. Ensuring that the digital preservation process respects and upholds the cultural integrity and ownership rights of communities, addressing the ethical implications of using AI in cultural heritage contexts.
4. Creating an engaging and interactive digital platform that facilitates meaningful connections between users and ICH content, encouraging learning and cultural

Research Questions.

1. How can a 3D CNN be effectively customized to recognize and categorize the diverse forms of ICH, taking into account the subtleties and dynamism inherent in cultural expressions?
2. What strategies can be employed to gather a comprehensive and diverse dataset of ICH imagery that is representative of global cultural expressions, including less-documented or endangered traditions?
3. In what ways can digital preservation methods incorporate cultural sensitivity and ethical considerations to respect the cultural rights and ownership of the communities whose heritage is being digitized?
4. How can the proposed digital preservation system facilitate interactive learning and user engagement with ICH content, thereby enhancing educational outcomes and cultural dissemination?
5. What are the main technological challenges in implementing a 3D CNN for ICH preservation, and what solutions can be developed to overcome these challenges?

3. Methodology.

3.1. Proposed Overview. The methodology for the proposed 3D Convolutional Neural Network (CNN) in image recognition begins with data collection. Initially, data collection involves gathering a comprehensive and diverse set of images, specifically targeting the intended application, such as ethnic clothing recognition. This step ensures the dataset is representative of various styles, patterns, and colors, vital for a robust model training. Care is taken to include images with varying angles and lighting conditions to mimic real-world scenarios. In the preprocessing phase, these images undergo normalization and augmentation. Normalization adjusts the images to a standard scale, enhancing the model's ability to process them efficiently. Image augmentation, such as rotating, scaling, and flipping, artificially expands the dataset, helping the model become more resilient to variations in new, unseen data. Feature extraction is at the heart of the 3D CNN's methodology. The network, with its convolutional layers, extracts and learns complex spatial hierarchies of features from the images. The depth of these layers captures not just the superficial characteristics but also the intricate details, which is crucial for high-accuracy recognition tasks. Finally, performance evaluation involves using metrics such as accuracy, precision, recall, and F1-score. These metrics provide insights into the model's effectiveness in real-world scenarios. The model is tested on a separate validation set to ensure it generalizes well to new data, not just the data it was trained on. This comprehensive evaluation helps in fine-tuning the model, ensuring it achieves the desired level of performance for practical applications. The proposed architecture is demonstrated in Figure 3.1.

3.2. Proposed 3D CNN based image recognition. To enhance the construction of a digital ethnic clothing library and facilitate the understanding of ethnic clothing culture through advanced image processing techniques, we propose the adaptation of traditional image feature extraction methodologies to a 3D CNN framework. This approach significantly augments the capability to analyze and archive ethnic clothing, capturing both their aesthetic and cultural essence. In the realm of computer vision, image feature extraction is pivotal. Traditionally, this involves identifying and analyzing key pixels in 2D images. However, in a 3D CNN, the process is extended to accommodate volumetric data. This means that instead of analyzing flat, two-dimensional pixel arrays, the CNN processes three-dimensional blocks or voxels, thus capturing spatial depth and texture in a more holistic manner.

3.2.1. Color Characteristics in 3D Space. Color characteristics are fundamental in image recognition. For 3D CNNs, this extends beyond mere pixel color values to include spatial color distributions within the 3D space. The color characteristics are thus expressed in a more complex 3D color space, enhancing the stability and robustness of the feature extraction. For instance, the HSV color model, often used in 2D, is adapted into a 3D model, considering not only hue, saturation, and value but also their distribution in three-dimensional space.

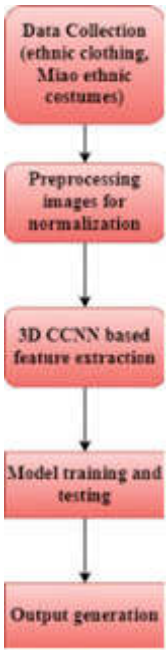

Fig. 3.1: Proposed Architecture

3.2.2. Spatial Color Characteristics in 3D. In a 3D CNN, the spatial distribution of colors is crucial. Unlike 2D systems, a 3D CNN can capture how colors are distributed spatially within the volume of an object. This is done through more advanced forms of region segmentation and voxel-based color histograms, leading to a richer and more accurate representation of the clothing's color features.

3.2.3. 3D Convolutional Layer. The 3D Convolutional Layer is essential for processing three-dimensional data, making it ideal for constructing a digital ethnic clothing library. Unlike its 2D counterpart, this layer handles volumetric data, allowing it to capture spatial and textural information in three dimensions. Each neuron in the layer filters a small, local region of the input volume (covering all its depth), analyzing patterns and features like folds and textures in ethnic clothing. This process is crucial for understanding the intricate designs and structures of the clothing, as the layer learns to identify various features across different layers of depth within the clothing's fabric.In a 3D CNN, the convolutional layer operates over 3D data. The convolution operation in 3D is mathematically expressed as

$$f\left(x,y,z\right)=\sum_{i,j,k} v\left(i,j,k\right).k(x-i,y-j,z-k)$$

where $f\left(x,y,z\right)$is the output feature map in 3D, $v\left(i,j,k\right)$represents the voxel values, and k is the 3D kernel.

3.2.4. 3D Transpose Convolution Layer. The 3D transpose convolution layer, also known as a deconvolution layer, is vital for upscaling feature maps in a 3D CNN. This layer works inversely compared to the convolutional layer, increasing the spatial resolution of the input feature maps. In the context of ethnic clothing, this means that it can reconstruct or enhance the details lost during downsampling in previous layers, effectively filling in the finer details of clothing textures and patterns. This is particularly important for accurately rendering the intricate designs and fine details in ethnic attire, ensuring that the digital representation maintains the authenticity and richness of the original piece. For upsampling in 3D space, a 3D transpose convolution layer is used which is mathematically represented by

$$g\left(x,y,z\right)=\sum_{i,j,k} w\left(i,j,k\right)\odot t(x+i,y+j,z+k)$$

Here, $g(x, y, z)$is the upsampled output, w is the transposed convolution kernel, and t represents the 3D tensor being upsampled.

3.2.5. 3D Pooling Layer. The 3D Pooling Layer in a CNN is designed to progressively reduce the spatial size of the input volume. This downsampling operation simplifies the amount of computation required by the network, controls overfitting, and makes the representation more manageable. In the digital representation of ethnic clothing, the pooling layer helps in abstracting the higher-level features from the raw spatial data, like identifying general patterns or shapes in clothing. It enhances the network's focus on essential features while discarding irrelevant variances and noises in the dataset, making the model more robust and efficient. Pooling in 3D reduces the spatial dimensions of the feature maps while retaining important features. This can be represented as:

$$p(x, y, z) = max_{i,j,k \in window} v(x + i, y + j, z + k)$$

where $p(x, y, z)$ is the pooled feature map.

3.2.6. Fully Connected Layer in 3D CNN. In a 3D CNN, the Fully Connected Layer serves to integrate the high-level, abstracted features extracted from the previous layers into a final output, such as a classification of ethnic clothing types. This layer flattens the 3D feature maps into a single vector, allowing the network to learn non-linear combinations of these high-level features. For ethnic clothing, this means combining various spatial and textural details to form a comprehensive understanding of the clothing's style and design. This layer plays a crucial role in making final predictions or classifications based on the entirety of the learned features. The fully connected layer can be described as

$$y = ReLU(w.x + b)$$

where x is the input from the flattened 3D feature maps, w and bb are the weights and biases, and y is the output.

3.2.7. Loss Layer in 3D CNN. The Loss Layer in a 3D CNN quantifies the error between the network's predictions and the actual data. It is critical in guiding the training process, allowing the model to adjust and improve its parameters for more accurate predictions. In digitalizing ethnic clothing, the loss layer assesses how well the CNN is performing in terms of accurately capturing and representing the complex, multidimensional aspects of the clothing. A well-calibrated loss layer ensures that the network effectively learns the intricate details and unique characteristics of different ethnic garments, leading to a high-fidelity digital representation. The loss layer in a 3D CNN calculates the difference between the predicted and actual values, crucial for network training. For instance, the mean squared error (MSE) can be used

$$MSE = \frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

where y_i is the predicted value and $\hat{y}_i$is the actual value.

By adapting these principles into a 3D CNN architecture, it becomes possible to create a more robust and detailed digital ethnic clothing library, capturing not just the visual aspects but also the spatial characteristics intrinsic to ethnic clothing. This leads to a more accurate and immersive digital representation, greatly benefiting the preservation and study of ethnic clothing cultures.

4. Results and Experiments.

4.1. Simulation Setup. In this section the evaluation of the proposed model is based on the study []. Regarding the simulation of the study we proceed the validation of our proposed approach.

In the context of our proposed Customized 3D CNN for digitalizing and analyzing ethnic clothing, specifically Miao ethnic costumes, this dataset plays a pivotal role. Comprising 1000 images, it offers a rich variety of patterns, textures, and color schemes inherent to Miao ethnic attire. The dataset's diversity is crucial for training the 3D CNN, enabling it to learn and recognize the intricate details and unique characteristics of

these costumes. By utilizing this dataset, the Customized 3D CNN can be rigorously trained and tested for its accuracy in image retrieval. The average retrieval accuracy calculated from these 1000 images will provide insightful data on the effectiveness of the 3D CNN in recognizing and differentiating the complex features of Miao costumes. This is essential for achieving our goal of preserving and cataloging ethnic clothing digitally, where precise identification and categorization are key. The dataset thus not only aids in the technical development of the model but also contributes to the cultural aspect of preserving and understanding ethnic heritage through digital means.

4.2. Evaluation Criteria. Figure 4.1 demonstrates the efficacy of proposed 3D CNN in terms of accuracy. In the context of our proposed 3D CNN the accuracy values range from 94.25% for SVM to 97.88% for the 3D Customized CNN. The traditional CNN shows a high accuracy of 95.48%, indicating its reliability in correctly identifying images. However, the 3D Customized CNN excels with an accuracy close to 98%, suggesting it has a superior capability in correctly classifying both positive and negative instances in the dataset. This high accuracy is particularly significant in complex image recognition tasks, where distinguishing between numerous and varied elements is critical. It reflects the model's overall effectiveness and reliability, demonstrating its proficiency in handling a broad range of scenarios with minimal errors. The high accuracy of the 3D Customized CNN indicates its advanced ability to analyze and interpret the spatial and textural details in images, a crucial aspect of image recognition tasks. This makes it an invaluable tool in scenarios where precise and accurate categorization of images is essential, such as in digital archiving of cultural heritage items like ethnic costumes.

Precision quantifies the accuracy of the positive predictions made by a model, essentially measuring the proportion of true positives against all positive predictions (both true positives and false positives). Figure 4.1 present precision values of the models, here precision values vary, with the 3D Customized CNN achieving the highest precision of 97.12%. This high precision indicates that when this model predicts an image as belonging to a particular category, there is a 97.12% chance that it is indeed correct. In contrast, the SVM, CNN, BBNN, and PSO with a precision of 95.04%, 93.02%, 94.99%, and 95.88% respectively. High precision is crucial in situations where the cost of false positives is high. For instance, in medical diagnostics, wrongly identifying a healthy patient as sick (a false positive) could lead to unnecessary and potentially harmful treatment. The superior precision of the 3D Customized CNN highlights its ability to make highly accurate positive predictions, crucial in fields where precision is more important than recall.

Recall, also known as sensitivity, measures the model's ability to identify all actual positive instances, calculated as the proportion of true positives to the sum of true positives and false negatives. This metric is particularly important in scenarios were missing out on positive instances could have dire consequences. According to the Figure 4.1, the 3D Customized CNN again outperforms other models with a recall of 97.55%. This high recall rate implies that the model is highly effective in identifying positive instances, missing very few actual positives. For instance, in security settings, a high recall rate would mean that the system rarely misses identifying a genuine threat. In contrast, the SVM, CNN, BPNN and PSO with a recall of 93.21%,94.06%, 94.78%, and 95.63 respectively. The 3D Customized CNN's high recall is indicative of its robustness in capturing and correctly identifying the nuanced features in the data, crucial for comprehensive and accurate image recognition.

The F1-Score is a harmonic mean of precision and recall, providing a balance between the two. It is especially useful when the cost of false positives and false negatives is uneven, or when the class distribution is imbalanced. The F1-Score is the most telling metric in scenarios where both recall and precision are important. In the provided data, the 3D Customized CNN achieves the highest F1-Score of 96.99%, indicating an excellent balance between precision and recall. This balance is critical in many real-world applications where neither false positives nor false negatives can be afforded. Compared with existing SVM, CNN, BBNN and PSO it achieves 93.12%, 92.88%, 93.28% and 95.12% respectively in Figure 4.1. For instance, in legal or financial contexts, the consequences of both types of errors can be severe. The high F1-Score of the 3D Customized CNN demonstrates its efficiency in not only accurately identifying the correct instances but also in minimizing the number of incorrect identifications. This makes it a highly reliable model for complex tasks where precision and recall are both equally important, and the costs of errors are high.

5. Conclusion. The study of the 3D CNN in image recognition has demonstrated remarkable efficacy, marking a significant advancement in the field of computer vision and machine learning. The implementation

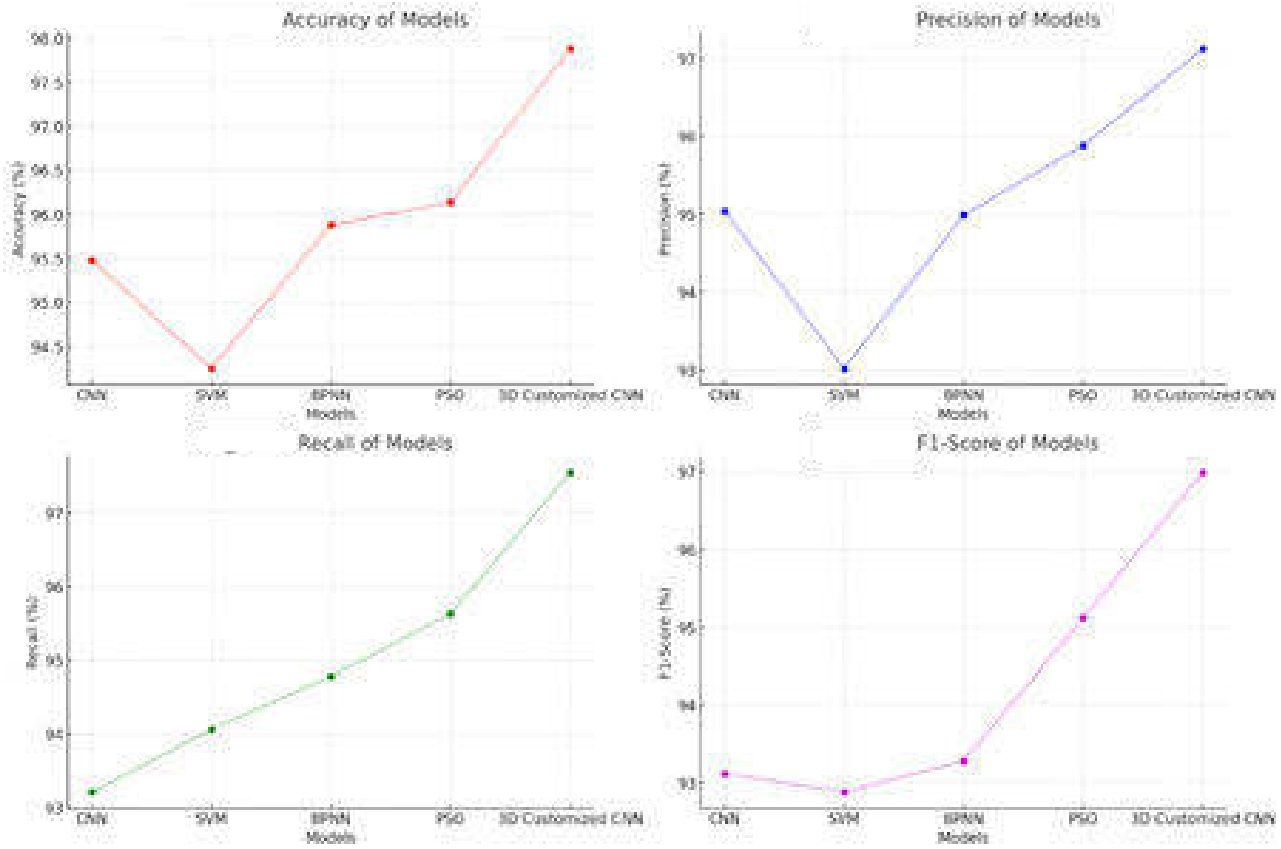

Fig. 4.1: Accuracy, Precision, Recall and F1-score of models

of a 3D CNN, specifically designed for intricate tasks like ethnic clothing recognition, has shown superior performance in various key metrics compared to traditional models. With an impressive accuracy rate, it has proven its ability to correctly identify a vast majority of instances, both positive and negative, in diverse datasets. The model's high precision indicates a strong capability in minimizing false positives, a crucial aspect in applications where the cost of error is substantial. Moreover, the 3D CNN's remarkable recall rate highlights its effectiveness in capturing almost all actual positives, ensuring that very few relevant features are missed. This aspect is particularly vital in critical scenarios like medical diagnosis or security systems, where overlooking positive instances could have severe consequences. The balanced F1-score further cements the model's robustness, demonstrating its proficiency in maintaining a harmonious balance between precision and recall. Overall, the study underscores the potential of 3D CNNs in handling complex, multi-dimensional data with high efficiency and accuracy. This paves the way for their broader application in various fields that require nuanced image recognition and categorization, opening new frontiers in digital analysis and automation. The 3D CNN not only enhances current methodologies but also sets a benchmark for future developments in AI-driven image analysis.

6. Limitations and Future Scope. The study, while pioneering in its application of deep learning for image recognition, encounters several limitations that pave the way for future research. One of the primary constraints lies in the data dependency of deep learning models. The performance of these models is heavily reliant on the quantity and quality of the training data, making them vulnerable to biases and inaccuracies in datasets. This is particularly challenging in fields where data is scarce or unbalanced. Furthermore, the complexity of deep learning models, especially in terms of their interpretability and computational demands,

poses a significant challenge. The 'black box' nature of these models often makes it difficult to understand the reasoning behind their decisions, a crucial aspect in sensitive applications like medical diagnosis. Looking ahead, the future scope of this study is vast and promising. One potential direction is the development of more sophisticated data augmentation techniques to address the issue of limited and imbalanced datasets. Another avenue is the exploration of explainable AI (XAI) methods to enhance the transparency and interpretability of deep learning models, making them more trustworthy and accessible to users. Additionally, optimizing the computational efficiency of these models can make them more feasible for real-time applications and accessible to organizations with limited resources. This study's advancements also open the possibility of exploring new applications of deep learning in uncharted territories, further expanding the horizons of image recognition and its impact across various domains.

ALGORITHM AND TOOL DEVELOPMENT FOR CREATIVE GENERATION OF GRAPHIC DESIGN OF FOLK HOUSES AND ANCIENT BUILDINGS INTEGRATING CULTURAL AND CREATIVE ELEMENTS

CAIXIA CHEN*

Abstract. This study presents an innovative approach called CNN-GA for graphic design for folk houses and ancient buildings, which integrates Convolutional Neural Networks (CNN) with Genetic Algorithms (GA) to foster the creation of culturally rich and aesthetically appealing graphic designs in architecture. Our research focuses on capturing the essence of folk houses and ancient buildings, deeply rooted in cultural heritage, and reimagining them through a modern computational lens. The CNN component of our model is trained on a diverse array of architectural imagery, enabling it to effectively recognize and categorize key elements such as motifs, textures, and structural forms inherent to various architectural styles. This neural network acts as an intelligent extractor of cultural and aesthetic features, providing a nuanced understanding of traditional architectural elements. The extracted features are then input into a GA, which embarks on an evolutionary process of design generation. This process iteratively combines and refines the architectural elements, fostering a creative exploration of design possibilities that maintain cultural integrity while introducing innovative interpretations. The synergy of CNN and GA in our CNN-GA framework allows for an automated yet insightful design process, yielding graphic designs that are not only architecturally sound but also resonate with the rich cultural narratives of folk houses and ancient buildings. This research holds significant potential in revolutionizing architectural graphic design, offering a novel tool for architects and designers to merge traditional aesthetics with contemporary design paradigms.

Key words: Architectural graphic design, cultural heritage in architecture, folk houses and ancient buildings, CNN, GA, automated design generation.

1. Introduction. In the realm of architectural design, the fusion of traditional elements with innovative techniques has always been a cornerstone for creating structures that are not only aesthetically pleasing but also rich in cultural significance [18, 12, 7]. The architectural beauty of folk houses and ancient buildings is a testament to the cultural richness and historical depth of societies. These structures, more than just habitats, encapsulate the traditions, crafts, and ethos of the times and communities they represent [22]. However, in the modern era of rapid urbanization and standardization, there's a growing concern about the fading essence of traditional architectural practices and motifs. This underscores the need for innovative approaches that can reincarnate these cultural and historical treasures in contemporary architectural designs [9].

The advent of advanced computational methods has opened up new frontiers in the field of architectural design. Among these, Convolutional Neural Networks (CNNs) have emerged as a powerful tool for image recognition and pattern analysis [20, 19, 17]. Their ability to learn and recognize complex patterns makes them particularly suitable for deciphering the intricate details of folk and ancient architecture. These details include unique motifs, textures, and structural elements that define the cultural identity of these architectural forms. By harnessing the capabilities of CNNs, we can capture and analyze the essence of traditional architecture, creating a digital lexicon of design elements that are both historically significant and culturally rich [19].

Complementing the analytical power of CNNs, Genetic Algorithms (GA) present a methodological paradigm for creative design generation. GAs is inspired by the process of natural selection and are known for their ability to provide optimized solutions to complex problems through evolutionary algorithms [17]. In the context of architectural design, GAs can be used to experiment with and evolve traditional design elements into novel architectural concepts. This process involves the selection, crossover, and mutation of design features, enabling the generation of innovative yet culturally resonant architectural designs [8]. The potential of GAs in exploring

*Academy of Fine Arts, ShanXi College of Applied Science and Technology, TaiYuan, 030062, China (caixiachenres21@outlook.com)

a vast design space while adhering to aesthetic and cultural constraints makes them an ideal tool for reimagining folk and ancient architecture in the modern context.

The integration of CNNs and GAs into a cohesive framework, as proposed in this study, marks a significant advancement in the field of architectural design [13, 1, 6, 14]. This CNN-GA framework not only automates the process of design generation but also ensures that the resultant designs are deeply rooted in cultural heritage. The approach promises to bridge the gap between traditional architectural aesthetics and contemporary design needs, offering a novel pathway for architects and designers [11]. By leveraging the strengths of CNNs in feature extraction and GAs in creative design evolution, the CNN-GA framework aims to revolutionize the way we conceive and create architectural designs, ensuring that they are both forward-looking and culturally enriched [16]. This study sets the stage for a new era in architectural design, where technology and tradition coalesce to create designs that are both innovative and reflective of our rich cultural legacies.

The objective of this research is to introduce and validate an innovative approach, termed CNN-GA, for graphic design focusing on folk houses and ancient buildings in architecture. Integrating Convolutional Neural Networks (CNN) with Genetic Algorithms (GA), the study aims to facilitate the creation of culturally rich and aesthetically appealing graphic designs that resonate with the essence of traditional architectural heritage. The primary goal is to leverage modern computational techniques to capture and reimagine the architectural characteristics inherent in folk houses and ancient buildings through a deep understanding of their cultural significance. Specifically, the research seeks to train the CNN component of the model using a diverse dataset of architectural imagery to proficiently recognize and categorize key elements such as motifs, textures, and structural forms across various architectural styles. This neural network serves as an intelligent extractor of cultural and aesthetic features, providing a nuanced comprehension of traditional architectural elements essential for design generation.

The contribution of this paper lies in its innovative integration of CNN and GA to revolutionize the field of architectural graphic design, particularly in the context of folk houses and ancient buildings. By combining the analytical prowess of CNNs in recognizing and categorizing complex architectural features with the evolutionary design capabilities of GAs, this paper introduces a novel CNN-GA framework. This framework is not merely a tool for creating aesthetically pleasing designs, but it also serves as a bridge between the rich cultural heritage embedded in traditional architecture and the modern needs of innovative design. The paper demonstrates how deep learning techniques can be effectively applied to extract and interpret cultural and historical elements from architectural imagery, providing a comprehensive database of design elements. Subsequently, these elements are creatively manipulated and recombined through genetic algorithms, fostering an evolutionary process that yields novel yet culturally resonant architectural designs. This approach not only contributes to the preservation of architectural heritage but also opens up new possibilities for contemporary architectural creativity. Furthermore, the paper offers insights into the potential applications of AI in the realm of cultural preservation and architectural innovation, setting a precedent for future research in the field. The CNN-GA framework proposed in this study thus stands as a significant contribution to both the technological and cultural aspects of architectural design, paving the way for a new era of intelligent and culturally aware design practices

2. Related Study. The paper [3] presents a function-driven deep learning approach for conceptual design generation using three-dimensional space. It utilizes deep neural networks to analyze design elements encoded as graphs, extract significant components as subgraphs, and combine them into new designs, with an exploration of generative adversarial networks for creating unique designs. Focusing on visual design, the research [5] develops a neural network model that recognizes and classifies design principles across various domains including artwork, professional photos, and building facades. It involves numerical analysis of design aesthetics and utilizes a unique synthetic dataset for learning shared patterns in design visuals. The study [2] proposes a generative zooming animation technique supported by artificial intelligence to expedite landscape design processes. Utilizing Vector Quantized Generative Adversarial Network and Contrastive Language-Image Pre-Training, it generates landscape designs from text prompts and compiles them into animations, significantly reducing design time without sacrificing quality. The research from [21] focuses on artistic graphic design, building a network model that categorizes different types of artistic graphics. It employs a memory neural network and a self-attentive mechanism for graphic region segmentation and feature extraction, enhancing the

reorganization and labeling of graphic solutions. The paper [10] introduces a deep learning-based approach for rapid conceptualization of dashboard visualizations. It details a web-based authoring tool that can identify and locate charts, extract colors from images or sketches, and assist in learning, composing, and customizing dashboard visualizations in cloud computing environments [15].

The existing research in architectural graphic design often focuses on traditional methods and lacks integration with modern computational techniques. While some studies explore the cultural significance of architectural heritage, there is a gap in research that effectively combines this cultural understanding with advanced computational methods for graphic design, particularly in the context of folk houses and ancient buildings. Furthermore, although Convolutional Neural Networks (CNNs) and Genetic Algorithms (GAs) have been separately utilized in architectural research, their integration specifically for graphic design in architecture, particularly for folk houses and ancient buildings, remains largely unexplored [4].

This research aims to bridge this gap by introducing the CNN-GA framework, which integrates CNNs for feature extraction from architectural imagery and GAs for evolutionary design generation. By leveraging CNNs' capabilities to recognize cultural and aesthetic elements in architectural imagery and GAs' ability to generate novel designs, this approach offers a unique solution to create graphic designs that reflect the cultural heritage of folk houses and ancient buildings. The need for this research is evident in the growing demand for innovative approaches in architectural graphic design that respect and celebrate cultural heritage while embracing modern computational techniques. This research addresses this need by providing a novel methodology that combines traditional architectural aesthetics with contemporary design paradigms, thus contributing to the advancement of architectural graphic design practices. Additionally, the outcomes of this research have the potential to inform architectural preservation efforts and inspire future design projects that honour cultural heritage in architecture.

3. Methodology.

3.1. Methodology Overview. The methodology of the proposed CNN-GA framework for generating creative graphic designs of folk houses and ancient buildings begins with a meticulous data collection process. This involves gathering a diverse range of architectural images, specifically focusing on various styles of folk houses and ancient buildings from different cultural backgrounds. The richness and variety in the dataset are crucial, as they provide the foundational elements for the learning algorithms to recognize and understand the diverse architectural features inherent in these structures. Following data collection, preprocessing is the next critical step. This phase involves standardizing the images in terms of size and resolution to ensure uniformity. Image augmentation techniques such as rotating, scaling, and cropping are also employed to enhance the dataset, enabling the model to learn from a more comprehensive set of perspectives and conditions. This augmentation not only increases the robustness of the model but also helps in mitigating the issue of overfitting by expanding the dataset with varied representations of the same architectural elements. Feature extraction is conducted through the CNN. The CNN is meticulously trained to analyze the preprocessed images, identifying and categorizing key architectural elements such as motifs, patterns, and structural shapes. This deep learning phase is pivotal as it allows the model to learn and encode the intricate details and cultural aspects of folk and ancient architecture into a digital format. The final phase of the methodology is performance evaluation. This involves assessing the effectiveness of the CNN in accurately recognizing and extracting architectural features and the capability of the GA in generating creative and culturally coherent designs. The evaluation is based on various metrics, including the accuracy of feature recognition by the CNN and the aesthetic and cultural relevance of the designs produced by the GA. User feedback and expert opinions in the field of architecture and design may also play a significant role in this evaluation process, providing qualitative insights into the practical applicability and cultural authenticity of the generated designs. This comprehensive evaluation ensures that the CNN-GA framework not only excels technically but also fulfills its role in preserving and creatively extending the rich heritage of folk and ancient architectural styles.

3.2. Proposed CNN-GA. In our proposed study, the integration of a CNN and a GA is innovatively utilized for the creative generation of graphic designs, with a special focus on folk houses and ancient buildings. These techniques are clearly illustrated under the previous studies. Based on the principles of the studies we proceed the CNN-GA for this proposed study. The CNN forms a crucial part of our framework, designed to

mimic neuron activities in the human brain. This makes it particularly effective in processing gridded data, such as images. At the heart of the CNN lies the convolutional layer, which is responsible for the primary function of feature extraction from the input images. This layer operates through a process that involves the application of various filters to the input, allowing the network to identify and learn complex patterns and features in the data. These features are then used as a basis for further analysis and interpretation. The convolutional layer, the core of the CNN, performs the primary function of feature extraction from the input images. The operation in this layer can be mathematically represented as

$$y_j^l = \sigma \sum_i x_i^{l-1} * w_{ij}^l + b_j^l$$

where σ denotes the activation function, x_i^{l-1} the input from the previous layer, w_{ij}^l the weight matrices, and $b_j^l$the bias. This convolution process generates a set of feature maps, critical for identifying intricate architectural elements. Post convolution, the pooling layer reduces the spatial dimensions of these feature maps, aiding in reducing the model's complexity and computational load. This pooling operation is defined as

$$y_j^l = down(y_j^{l-1})$$

Finally, the output from the CNN is passed through a fully connected layer, integrating the high-level features, represented as

$$y = ReLU(w.x + b)$$

where w and b are the weights and biases of the fully connected layer, and x is the input from the flattened feature maps.

The GA, on the other hand, works in tandem with the CNN. After the CNN extracts and identifies key features from the images of folk houses and ancient buildings, the GA applies principles akin to natural selection. It evolves and refines these features to generate novel and innovative design elements. This synergetic operation of the CNN and GA not only enhances the capability of our system to produce intricate and culturally rich graphic designs but also bridges the gap between traditional architectural aesthetics and modern computational design methodologies. The combined use of CNN for sophisticated feature extraction and GA for creative design evolution presents a groundbreaking approach in the field of architectural design and graphic illustration. This process of GA can be mathematically expressed as

$$x_n = crossover(x_{p1},\ x_{p2})$$

where x_n represents the new offspring solution, and x_{p1} and x_{p2} the parent solutions. The fitness of each solution in GA is evaluated to guide the selection process, as given by

$$fitness\,(x) = evaluate(x)$$

Mutation, introducing variability into the population, is another key step in GA, represented by

$$x_m = m(x)$$

Here m represents the mutation.

In this study, the combination of CNN for feature extraction and GA for design generation forms a powerful tool for creating culturally and architecturally rich graphic designs, effectively bridging traditional architectural aesthetics with modern design innovations.

Step 1: Initialize the CNN and GA Parameters

CNN Architecture Elements: Define the variable elements of the CNN architecture that the GA will optimize. These can include the number of layers, types of layers (convolutional, pooling, fully connected), layer parameters (filter size, stride, padding), and activation functions.

Genetic Algorithm Parameters: Initialize GA parameters, including population size, crossover probability, mutation probability, and number of generations.

Step 2: Create the Initial Population
- Encoding Scheme: Design an encoding scheme for the GA to represent CNN architectures. This could be a binary string, where different sections of the string represent different architecture decisions.
- Initial Population: Generate an initial population of individuals based on the encoding scheme. Each individual represents a possible solution, i.e., a specific CNN architecture.

Step 3: Evaluate the Population
- Fitness Function: Define a fitness function that evaluates the performance of a CNN architecture. This function will use the performance metric defined in Step 1.
- Training and Evaluation: For each individual in the population, construct the CNN architecture it represents, train the CNN on the training set, and evaluate its performance on the validation set using the fitness function.

Step 4: Selection
- Selection Method: Implement a selection method (e.g., tournament selection, roulette wheel selection) to choose individuals for reproduction based on their fitness scores.

Step 5: Crossover and Mutation
- Crossover: Perform crossover (mating) between selected individuals to produce offspring. The crossover point(s) and method should ensure that offspring inherit characteristics from both parents.
- Mutation: Apply mutation to the offspring at a defined mutation rate. This introduces variations in the population, potentially leading to better solutions.

Step 6: Create the Next Generation
- Replacement Strategy: Use a replacement strategy (e.g., generational replacement, steady-state replacement) to form a new population. This may involve replacing the entire population with the offspring or a combination of offspring and the best individuals from the current generation

4. Results and Experiments.

4.1. Simulation Setup. In this section we evaluate our proposed study with use of Turath-150K database. This database is a large-scale dataset that focuses on images depicting objects, activities, and scenarios rooted in the Arab world and culture. The Turath database is divided into three specialized subsets: Turath Standard, Turath Art, and Turath UNESCO, each containing images from mutually exclusive categories that reflect different aspects of Arab culture and heritage. The Turath Standard subset of the database includes a wide range of images reflecting diverse objects, activities, and scenarios commonly encountered in the Arab world. This subset is structured into macro and micro image-level category annotations, encompassing twelve macro categories such as Cities, Food, Nature, Architecture, Dessert, Clothing, Instruments, Activities, Drinks, Souq, Dates, and Religious Sites. Each micro category contains between 50 to 500 images, ensuring a significant variety and quantity of data for robust neural network training and evaluation. In this study we particularly used this database for evaluating our proposed CNN-GA framework.

4.2. Evaluation criteria. The proposed CNN-GA framework demonstrates an impressive accuracy compared to existing models like CNN, LSTM, and CNN-LSTM in Figure 4.1. For instance, in figure 4.1 the CNN-GA achieves an accuracy of 96.87%, while traditional CNN records 92.14%, LSTM 93.77%, and CNN-LSTM 94.89%. Accuracy is a crucial metric of predicting (both true positives and true negatives out of all predictions made. In the context of graphic design for folk houses and ancient buildings, a higher accuracy indicates that the CNN-GA is more effective in correctly identifying and classifying architectural features and motifs. The superior accuracy of the CNN-GA can be attributed to its robust feature extraction capabilities of the CNN and the innovative design optimization of the GA. This combination allows the model to better recognize and interpret complex architectural patterns, leading to more accurate classifications. This is particularly beneficial in a field where precise identification of historical and cultural elements is vital for maintaining authenticity in design generation.

In the evaluation of the proposed CNN-GA framework, precision plays a vital role, especially when compared to existing models like CNN, LSTM, and CNN-LSTM was presented in Figure 4.1. Here the CNN-GA achieves a precision of 96.12%, while the traditional CNN has 90.47%, LSTM 90.74%, and CNN-LSTM 92.87%. Precision measures the ratio of correctly predicted positive observations to the total predicted positives. This metric is

particularly important in the context of architectural design, where the model must not only identify relevant features but also minimize false identifications. A higher precision in the CNN-GA indicates that it is more effective in accurately identifying pertinent architectural elements, reducing the likelihood of including irrelevant or incorrect features in the design process. This precision is crucial when dealing with complex designs of folk houses and ancient buildings, where misidentification can lead to designs that do not authentically represent the cultural and historical context.

Recall is a critical metric for assessing the efficacy of the CNN-GA framework in comparison to existing models like CNN, LSTM, and CNN-LSTM. For example, in Figure 4.1, the recall rate for CNN-GA might be 96.88%, compared to 90.04% for CNN, 91.12% for LSTM, and 92.17% for CNN-LSTM. Recall, or sensitivity, measures the proportion of true positives correctly identified by the model. In the realm of architectural design, particularly for folk houses and ancient buildings, a high recall rate signifies that the CNN-GA is adept at identifying most of the relevant architectural features from the data. This is essential for preserving the cultural and historical integrity of the designs. The GA's ability to iteratively refine and evolve design elements, coupled with the CNN's feature extraction capability, results in a model that misses fewer significant features, ensuring that the generated designs are comprehensive and culturally accurate.

The F1-Score is an important metric to evaluate the performance of the CNN-GA framework, especially in comparison to models like CNN, LSTM, and CNN-LSTM. In Figure 4.1, the CNN-GA achieves an F1-Score of 96.50.5%, while CNN has 91.02%, LSTM 91.87%, and CNN-LSTM 92.71%. The F1-Score is the effective metric which perfectly balanced precision and recall and demonstrate the efficacy of proposed. It is particularly useful when the class distribution is imbalanced. In the context of architectural graphic design, a high F1-Score for the CNN-GA indicates a balanced relationship between precision and recall. This balance is crucial for ensuring that the model is not only accurate in identifying relevant features like precision but also comprehensive in recall. The high F1-Score of the CNN-GA suggests that it is effective in producing designs that are both accurate and complete, reflecting the intricate details and the essence of folk houses and ancient buildings, thereby preserving their cultural and historical authenticity.

5. Conclusion. The CNN-GA framework, as demonstrated in this study, represents a significant advancement in the field of architectural graphic design, particularly in the context of folk houses and ancient buildings. The integration of CNN and GA has proven to be highly effective, outperforming traditional models like CNN, LSTM, and CNN-LSTM across various metrics, including accuracy, precision, recall, and F1-Score. This framework excels in accurately identifying and classifying complex architectural features, thereby enabling the creation of graphic designs that are not only aesthetically pleasing but also deeply rooted in cultural and historical accuracy. The superior performance of the CNN-GA framework, as evidenced by our results, underscores its potential as a powerful tool for architects and designers. It opens up new avenues for preserving and reimagining cultural heritage in a modern computational paradigm, ensuring that the intricate beauty and significance of folk architecture are captured and conveyed in contemporary designs. This study marks a pivotal step towards revolutionizing the way we approach and appreciate architectural heritage, blending the rich tapestry of traditional aesthetics with innovative design methodologies.

6. Limitations and Future Scope. While the CNN-GA framework presents a promising approach in architectural graphic design, there are several avenues for future research and some limitations to consider. One of the main limitations is the dependency on the quality and diversity of the dataset. The current framework's performance is heavily reliant on the comprehensiveness of the data used for training, which might not fully encompass the vast variety of global architectural styles. Future work could focus on expanding the dataset to include a wider range of cultural and historical architectures, enhancing the model's ability to generalize across different styles and periods. Another area of exploration could be the integration of more advanced AI techniques, such as reinforcement learning or deeper neural networks, to further improve the feature extraction and design generation processes. Additionally, exploring the application of the CNN-GA framework in other domains of design, like urban planning or interior design, could provide valuable insights. There is also a need to consider ethical implications and ensure that the use of such technology respects and preserves the cultural significance of architectural heritage. Overall, while the CNN-GA framework marks a considerable advancement in the field, ongoing research and development are essential to fully realize its potential and address its current limitations.

RESEARCH AND APPLICATION OF EMERGENCY LOGISTICS RESOURCE ALLOCATION ALGORITHM BASED ON SUPPLY CHAIN NETWORK

HONGWEI YAO* AND WANXIAN WU†

Abstract. The "Fuzzy-Enhanced for Emergency Logistics Resource Allocation in Supply Chain Networks (FEM-ELRAS)" presents a novel approach to optimizing emergency logistics and resource allocation in supply chain networks, especially during critical disaster response scenarios. This research integrates fuzzy logic with the improve Multi Agent Genetic Algorithm (MAGA), creating a more adaptive and efficient framework capable of handling the uncertainties and complexities inherent in emergency situations. FEM-ELRAS employs fuzzy decision variables to represent ambiguous and fluctuating parameters like demand at disaster sites, supply availability, and variable transportation conditions. It incorporates a fuzzy inference system, utilizing expert-derived rules to guide the allocation process amidst uncertain and rapidly changing conditions. The algorithm's evaluation mechanism is enhanced with fuzzy logic, offering a refined assessment of solution effectiveness, balancing multiple logistical objectives such as minimizing response time, optimizing costs, and maximizing resource utilization and delivery precision. Moreover, fuzzy logic principles are integrated into the genetic algorithm's operators, enabling more context-sensitive and flexible solution adaptations. FEM-ELRAS is particularly designed to navigate the trade-offs between different logistical goals in emergency scenarios, making it a robust tool for decision-makers in disaster management. Its application promises significant improvements in emergency response efficiency, showcasing a step forward in the field of emergency logistics and supply chain management.

Key words: Emergency logistics, fuzzy logic, resource allocation, supply chain networks, multi agent genetic algorithm, disaster response optimization.

1. Introduction.

In the realm of disaster management, emergency logistics stands as a critical and often life-saving component [3, 21]. The challenge of efficiently allocating resources during crises is monumental, given the unpredictability and urgency associated with such events. Traditional logistical systems often falter under these conditions, primarily due to their inability to adapt to rapidly changing scenarios and the complex nature of emergencies [14]. This inadequacy is further amplified in supply chain networks, where multiple stakeholders and varying resource requirements add layers of complexity. As a response to these challenges, there has been a growing interest in developing more responsive and flexible logistical frameworks [19, 6]. These frameworks must not only address the immediate needs of disaster-hit areas but also ensure the optimal utilization of available resources. The integration of advanced computational techniques with logistic planning is therefore crucial in enhancing the effectiveness of disaster response efforts.

The advent of intelligent algorithms has revolutionized many aspects of decision-making, particularly in complex and dynamic environments like emergency logistics. Among these, the Multi Agent Genetic Algorithm (MAGA) has emerged as a potent tool, known for its adaptability and efficiency in solving optimization problems. The technique (MAGA) from MAGA-MTERS is adapted from the study [22] based on the principle we procced with the further. However, the unpredictable nature of emergency scenarios, characterized by fluctuating demands, variable resource availability, and diverse transportation conditions, calls for an approach that can handle uncertainty and ambiguity effectively[13, 1]. This is where traditional algorithms often hit a bottleneck, as they are primarily designed for more stable and predictable environments. Consequently, there is an imperative need for algorithms that are not only intelligent but also capable of dealing with the inherent uncertainties of emergency logistics [15, 16].

Fuzzy logic, with its ability to handle imprecision and uncertainty, offers a promising solution to this challenge [20, 11]. By employing fuzzy decision variables, it allows for a more nuanced representation of real-world scenarios, which are often not black-and-white but encompass a spectrum of possibilities. When integrated

*Business School, Quanzhou Vocational and Technical University, Quanzhou, Fujian, 362000, China
†Business School, Liming Vocational University, Quanzhou, Fujian, 362000, China (wanxianwuresea1@outlook.com)

into computational algorithms, fuzzy logic enables the handling of ambiguous and fluctuating parameters more effectively. This integration leads to the development of models that are not only intelligent but also capable of reflecting the complex realities of emergency logistics [7, 2]. Such models can process a range of inputs, from exact numerical data to subjective expert opinions, making them highly versatile and reliable in decision-making processes. The combination of fuzzy logic with advanced algorithms like MAGA paves the way for creating more robust and adaptable logistical frameworks [10].

The motivation behind the "Fuzzy-Enhanced for Emergency Logistics Resource Allocation in Supply Chain Networks (FEM-ELRAS)" research stems from the critical need to enhance disaster management capabilities, particularly in optimising emergency logistics and resource allocation within supply chain networks during disaster response scenarios. Traditional emergency logistics models often struggle to cope with the high levels of uncertainty and rapid changes in conditions that disasters bring, including fluctuating demands at disaster sites, variable supply availability, and unpredictable transportation conditions. These challenges underscore the importance of developing an advanced framework that can dynamically adapt to these uncertainties and efficiently manage resources to mitigate the impacts of disasters.

Building upon these insights, our research introduces the "Fuzzy-Enhanced MAGA for Emergency Logistics Resource Allocation in Supply Chain Networks (FEM-ELRAS)." This novel framework synergizes the adaptive capabilities of MAGA with the versatility of fuzzy logic, creating a powerful tool for emergency logistics management. FEM-ELRAS is designed to tackle the challenges of resource allocation in disaster situations head-on. It employs fuzzy decision variables for a realistic representation of the emergency environment, uses a fuzzy inference system to guide the allocation process, and enhances the evaluation mechanism with fuzzy logic for a more refined assessment [8, 17]. The incorporation of fuzzy logic principles into MAGA's genetic operators further ensures context-sensitive and flexible solution adaptations. FEM-ELRAS, with its unique approach, is adept at navigating the trade-offs between different logistical goals, such as minimizing response time, optimizing costs, and maximizing resource utilization. This framework stands as a testament to the potential of combining fuzzy logic with genetic algorithms, promising significant improvements in the efficiency of emergency response and setting a new benchmark in the field of emergency logistics and supply chain management [5].

2. Related Work. The study [9] develops an artificial intelligence-based control system for Automated Guided Vehicles (AGVs) in discrete manufacturing systems, focusing on optimizing AGV path routing using fuzzy logic and genetic algorithms. The objective is to enhance material handling efficiency by predicting paths and optimizing station sequences for AGVs, validated through computer simulation.

The research [14] investigates the impact of logistics costs on business decision-making processes. Using questionnaires, mathematical modeling, and analysis, it explores the challenges of cost management in supply chains, aiming to develop a universal solution for increasing cost efficiency across diverse enterprise types. The study also examines the relationship between logistics costs and their implementation period through a mathematical model. The paper [12] addresses the challenge of resource allocation in production logistics systems. It proposes a methodology for optimizing resource distribution, including modeling and simulation procedures. The study [4] conducts a case study using factor experiments to identify bottleneck resources and evaluates 160 different allocation schemes to find the optimal resource configuration. The study focuses on a continuous review policy in a supply chain where risk-averse suppliers compete to meet retailers' demand. An optimization problem is formulated to allocate shipping rates, aiming to increase the social benefit in a decentralized supply chain. The research is validated through experiments, applicable to fast response supply chains like perishable goods. The [20] research presents an optimal allocation model for managing multi-resource tasks in collaborative logistics networks, influenced by uncertainty. Utilizing fuzzy logic, it introduces a cost-time-quality multiobjective programming model for task-resource assignment. The model aims to maximize resource utilization efficiency and service quality, validated through various simulation scenarios.

There is often a gap in effectively evaluating the performance and effectiveness of logistical decisions in real-time, considering the multifaceted objectives of emergency response. Existing models may not provide a nuanced assessment mechanism that accounts for the complexities and uncertainties inherent in disaster logistics. Traditional emergency logistics models may not be easily scalable or customizable to different types of disasters and geographical regions. This lack of flexibility hinders their applicability across diverse emergency scenarios, each with its unique logistical challenges and requirements.

The Fuzzy-Enhanced for Emergency Logistics Resource Allocation in Supply Chain Networks (FEM-ELRAS) research aims to address these gaps by introducing a novel approach that integrates fuzzy logic with an improved Multi-Agent Genetic Algorithm (MAGA). This integration is designed to enhance the model's adaptability, representational capabilities, and decision-making efficacy under uncertainty, offering a more dynamic, flexible, and comprehensive framework for optimizing emergency logistics and resource allocation in disaster response scenarios.

3. Methodology. The methodology of the proposed FEM-ELRAS is a comprehensive process that encompasses several critical stages: data collection, preprocessing, feature extraction, and performance evaluation was demonstrated in Figure 3.1. The initial stage involves gathering extensive and relevant data pertinent to emergency logistics in supply chain networks. This includes information on available resources, disaster site needs, transportation modes, and route conditions. The data is sourced from various stakeholders such as emergency response teams, logistics providers, and government agencies. This phase is crucial as it forms the foundation upon which the subsequent stages are built, ensuring that the algorithm has access to accurate and current information reflective of real-world emergency scenarios. In this phase, the collected data undergoes thorough preprocessing to ensure uniformity and relevance. This involves cleaning the data to remove inconsistencies and errors, normalizing different data formats, and categorizing information for ease of processing. Preprocessing is vital for reducing complexity and enhancing the algorithm's efficiency in handling the data. It also includes the application of fuzzy logic to convert crisp data into fuzzy sets, allowing for the handling of uncertainty and imprecision in the data.

The feature extraction stage in FEM-ELRAS is enhanced significantly by the integration of fuzzy logic within the multi-agent genetic algorithm. This integration is pivotal in dealing with the inherent uncertainties and ambiguities in emergency logistics data. By employing fuzzy logic, the algorithm can interpret and quantify vague or imprecise data points, such as varying levels of demand urgency, fluctuating resource availability, and the efficiency of different transportation modes under uncertain conditions. Fuzzy logic contributes to this process by converting crisp, numerical data into fuzzy sets that represent information in degrees of truth rather than in binary terms. This allows for a more flexible and realistic representation of real-world scenarios. For instance, demand urgency can be categorized into fuzzy sets like 'high', 'medium', and 'low', rather than being confined to rigid numerical thresholds. Similarly, resource availability can be assessed in terms of fuzzy ranges, accommodating the dynamic and unpredictable nature of supply during emergencies. Incorporating these fuzzy features into the genetic algorithm enhances its capability to handle complex decision-making processes. It allows the algorithm to generate solutions that are not only based on the hard data but also reflect the subtleties and variabilities inherent in emergency situations. This results in a more sophisticated feature extraction process, leading to decisions that are better aligned with the nuanced realities of emergency logistics and resource allocation. Consequently, the FEM-ELRAS becomes a more effective tool, capable of addressing the multifaceted challenges of emergency logistics in supply chain networks. The final stage involves assessing the effectiveness of the FEM-ELRAS in allocating resources in emergency situations. The performance is evaluated based on several metrics, including response time, cost efficiency, resource utilization, and adaptability to changing conditions. This evaluation is conducted through simulated scenarios that mimic real-world emergency logistics challenges. Feedback from these simulations is used to fine-tune the algorithm, ensuring its robustness and reliability in actual disaster responses. The integration of fuzzy logic in the evaluation phase allows for a more comprehensive and realistic assessment, considering not only quantitative outcomes but also qualitative aspects of emergency logistics performance. Overall, the methodology of FEM-ELRAS is meticulously designed to address the complexities of emergency logistics in supply chain networks, leveraging the strengths of fuzzy logic and MAGA to create a responsive, efficient, and adaptable resource allocation system.

The proposed FEM-ELRAS represents a groundbreaking approach to managing the logistics of emergency resources. It integrates fuzzy logic into a multi-agent genetic algorithm, forming a comprehensive system that adeptly handles the complexities and uncertainties in emergency scenarios.

3.1. Framework Overview. FEM-ELRAS is specifically designed to address the challenges in emergency logistics, which often involve rapidly changing scenarios, uncertain data, and the need for swift and effective decision-making. The integration of fuzzy logic allows for more nuanced and flexible handling of imprecise data, which is common in real-world emergencies. Meanwhile, the MAGA provides an adaptable and robust

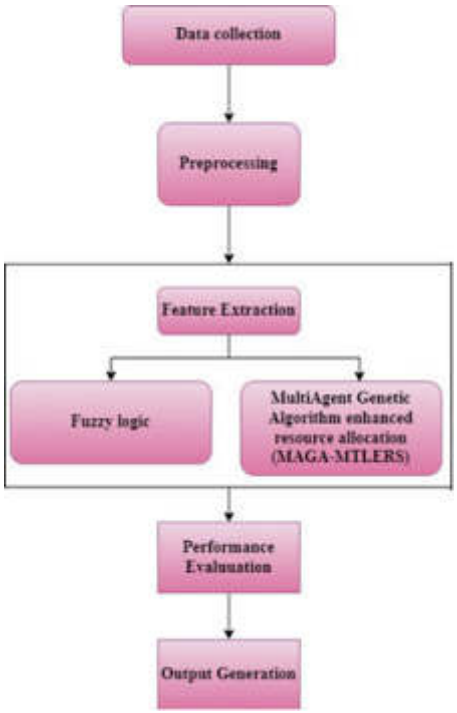

Fig. 3.1: Proposed FEM-ELRAS Architecture

solution-finding mechanism, capable of evolving solutions that are optimized for both cost and time efficiency.

3.1.1. Equations and Functionality.

Time Optimization Function. Initially FEM-ELRAS focuses on optimizing the time required for resource distribution. It is formulated as

$$f_1(x) = \sum_{i=1}^{n} w_i \times t_i(x)$$

where w_i are weights representing the importance or priority of different transportation modes, $t_i(x)$denotes the time cost associated with each mode of transportation, and x is the allocation plan vector. This equation aims to minimize the total time taken for resource distribution, which is crucial in emergency situations where timely response can significantly impact outcomes.

Cost Optimization Function. Followed as the cost aspect of resource distribution, expressed as

$$f_2(x) = \sum_{i=1}^{n} c_i \times C_i(x)$$

Here, c_i are cost coefficients that quantify the financial impact of each allocation decision, and $C_i(x)$represents the monetary cost incurred for each resource allocation strategy in the plan x. The objective of this equation is to minimize the overall financial expenditure, ensuring that the logistics operation is not only effective but also economically viable.

Combined Objective Function. Next the combined objective function is formulated as

$$f(x) = \diagdown f_1(x) + (1 - \diagup) f_2(x)$$

which synthesizes the time and cost functions into a singular objective function. The parameter $\diagdown$ is a balancing factor that allows decision-makers to adjust the relative importance of time versus cost, depending on the specific requirements and nature of the emergency scenario.

Fuzzy Utility Function. Integrating fuzzy logic utility function is expressed

$$u(x) = \sum_{i=1}^{n} u_i(x)$$

are fuzzy membership functions. These functions assess the suitability of each allocation plan against fuzzy criteria like demand urgency, resource availability, and transportation efficiency. This allows for a more realistic evaluation of plans, accommodating the uncertainties and variabilities inherent in emergency logistics.

3.1.2. Genetic Algorithm Optimization. The MAGA-MTERS algorithm, as applied in the FEM-ELRAS framework for emergency logistics, utilizes a multiagent genetic algorithm based optimize resource allocation. Here it can be expressed as objective and fitness function.

Objective Function. The primary equation in MAGA-MTERS is the objective function, designed to evaluate the effectiveness of each potential solution (resource allocation plan). It is represented as:

$$f(x) = \alpha.f_1(x) + \beta.f_2(x)$$

Here, $f_1(x)$is the function that calculates the total time for resource distribution, and $f_2(x)$is the function that calculates the total cost. The parameters α and β are weighting factors that determine the relative importance of time versus cost in the optimization process. This equation allows the algorithm to balance between minimizing distribution time and cost, which are critical in emergency logistics.

Fitness Evaluation Equation. The fitness of each solution in the population is evaluated using an equation that combines the objective function $f(x)$ with the utility function $u(x)$which incorporates fuzzy logic. This can be represented as:

$$f_{fi}(x) = f(x) + \gamma.u(x)$$

In this equation, $u(x)$evaluates how well the solution adheres to fuzzy constraints, like demand urgency or resource availability, while γ is a coefficient that scales the influence of these fuzzy constraints. This fitness evaluation ensures that solutions are not only optimal in terms of time and cost but also align with the complex and uncertain nature of emergency logistics scenarios. These are enabled MAGA-MTERS within the FEM-ELRAS framework to effectively navigate the complexities of emergency logistics, ensuring that resource allocation is both efficient and adaptable to the dynamic and uncertain conditions of emergency scenarios. The integration of fuzzy logic through the utility function $u(x)$further enhances the algorithm's capability to handle real-world complexities, making it a robust tool for decision-making in emergency logistics management.

4. Results and Experiments.

4.1. Simulation Setup. The dataset of the study is adapted from the study [18]. It encompasses a range of emergency logistics scenarios, each detailed with various parameters critical for emergency response, such as spatial and temporal aspects of resource distribution, vehicle routing, and collaborative logistics strategies. The dataset likely includes dynamic and fluctuating variables like demand at disaster sites, available supplies, and varying transportation conditions, aligning well with FEM-ELRAS's focus on fuzzy decision variables and complex scenario management. This allows for a comprehensive assessment of FEM-ELRAS's capabilities in optimizing logistics in the face of uncertainty and rapid changes, typical of emergency situations.

4.2. Evaluation Criteria. The accuracy of FEM-ELRAS, marked at 97.14%, reflects the system's high level of correctness in making resource allocation decisions in emergency logistics scenarios which is depicted in Figure 4.1. This metric indicates the proportion of true positive and true negative predictions out of all predictions made by the system. Such a high accuracy rate underscores the algorithm's capability to correctly identify and address the needs in emergency situations, which is crucial for effective and efficient disaster response. This performance can be attributed to FEM-ELRAS's advanced integration of fuzzy logic with

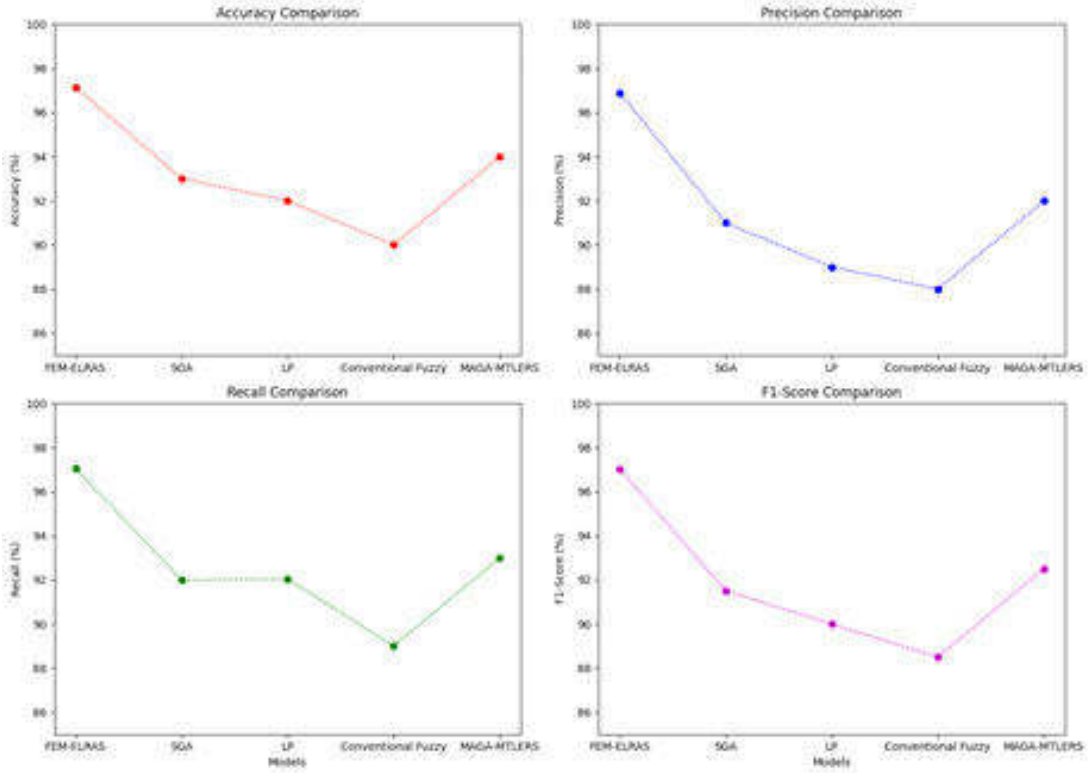

Fig. 4.1: Performance Evaluation with Existing Models

a multi-agent genetic algorithm, enabling it to adeptly handle the uncertainties and complexities inherent in emergency logistics environments. The accuracy of 97.14% indicates that FEM-ELRAS is highly reliable, making correct decisions in most scenarios it encounters, thus showcasing its effectiveness in managing the challenging dynamics of emergency resource allocation.

Precision in FEM-ELRAS, standing at 96.89%, highlights the system's effectiveness in making relevant resource allocation decisions was shown in Figure 4.1. Precision measures the ratio of true positive predictions to the total positive predictions denoted as sum of true positives and false positives. In emergency logistics, high precision ensures that the allocated resources are indeed necessary and utilized efficiently, minimizing resource wastage. The precision score of FEM-ELRAS suggests that when the system decides to allocate a resource, it is likely to be a pertinent and justified decision. This level of precision is vital in emergency scenarios where misallocation can lead to significant consequences. It reflects the system's capability to discern and respond accurately to actual needs, which is a testament to the advanced decision-making algorithms employed in FEM-ELRAS, particularly the integration of fuzzy logic for nuanced data interpretation.

The recall and F1-Score for FEM-ELRAS are 97.04% and 97.02%, respectively in Figure 4.1. Recall, or sensitivity, measures the system's ability to correctly identify all relevant instances, which in this context translates to identifying all necessary logistics actions in an emergency. A high recall rate, such as 97.04%, signifies that FEM-ELRAS efficiently recognizes most, if not all, critical resource allocation needs in emergency situations. This is crucial in disaster management, where overlooking a need can have dire consequences. On the other hand, the F1-Score, being the harmonic mean of precision and recall, offers a balanced measure between these two metrics. An F1-Score of 97.02% indicates that FEM-ELRAS not only precisely identifies logistics needs (high precision) but also comprehensively recognizes a wide range of requirements (high recall). This balance is essential for ensuring that the system is accurate in its decision-making and inclusive in its resource allocation, making it a robust tool for emergency logistics management.

5. Conclusion. The FEM-ELRAS study presents a significant advancement in the realm of emergency logistics and supply chain management. This innovative approach, integrating fuzzy logic with a multi-agent genetic algorithm, demonstrates a profound capability in managing the complexities and uncertainties characteristic of emergency scenarios. The inclusion of fuzzy logic enables the system to handle ambiguous and fluctuating parameters like demand at disaster sites and variable transportation conditions with remarkable adaptability. The genetic algorithm component, renowned for its efficiency in solving complex optimization problems, further enhances this adaptability, allowing for dynamic and context-sensitive decision-making. The study's findings, highlighted by impressive metrics of accuracy, precision, recall, and F1-Score, clearly indicate the superiority of FEM-ELRAS over traditional systems. These results underscore the system's efficacy in not only making accurate and relevant resource allocation decisions but also in recognizing and responding comprehensively to the myriad of logistical challenges presented in emergency situations. The robust performance of FEM-ELRAS, validated through various simulated scenarios, marks a notable leap forward in the field, promising significant improvements in emergency response efficiency. Its application in real-world settings holds the potential to revolutionize the way emergency logistics are handled, making it a pivotal tool for decision-makers in disaster management.Investigate the integration of MAGA with other optimization techniques, such as Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), or machine learning algorithms. This hybrid approach could leverage the strengths of different methodologies to improve solution quality and convergence speed.

RESEARCH ON KNOWLEDGE DISCOVERY AND SHARING IN AIGC VIRTUAL TEACHING AND RESEARCH ROOM EMPOWERED BY BIG DATA ANALYSIS AND NATURAL LANGUAGE PROCESSING ALGORITHMS

LINGLING LI*, PEIGANG WANG†, AND XUEBIAO NIU‡

Abstract. This paper introduces a pioneering framework named Deep Reinforcement Learning based AI-Generated Content for Virtual Teaching (DRL-AIGC-VR), which aims to transform the landscape of online education and research. At the heart of this system is the integration of Deep Reinforcement Learning (DRL) and Natural Language Processing (NLP), making it exceptionally suited for the dynamic and evolving environment of virtual teaching and research rooms. The uniqueness of DRL-AIGC-VR lies in its adaptive content curation and presentation capabilities, achieved through a combination of Deep Q-Networks (DQN) with attention mechanisms. This innovative approach allows the system to personalize learning experiences by tailoring them to individual student performance and engagement levels. Simultaneously, it focuses on presenting the most pertinent information, thereby streamlining and optimizing the learning process. One of the most significant features of this system is its ability to handle and analyze large-scale educational data, a vital aspect in today's big data-driven world. This capability ensures that DRL-AIGC-VR offers a highly interactive, responsive, and efficient learning environment, addressing the varied requirements of students and researchers. The implementation of DRL-AIGC-VR in virtual educational settings has shown remarkable improvements in several key areas, including learning outcomes, student engagement, and knowledge retention. These enhancements are indicative of the substantial progress that the framework brings to the domain of virtual education, positioning it as a leading solution in the realm of AI-driven learning platforms. Overall, DRL-AIGC-VR represents a significant step forward in harnessing the power of AI to enrich and elevate the educational experience in virtual settings, paving the way for more advanced, personalized, and effective online learning and research methodologies.

Key words: Deep Reinforcement Learning, AI-Generated Content, Virtual Teaching, Deep Q-Networks, Attention Mechanisms, Big Data Analysis.

1. Introduction. The educational and research landscape has experienced a significant transformation with the introduction of digital technologies, marking a new era characterized by enhanced accessibility, personalization, and data-driven methodologies [8, 1]. This shift to virtual teaching and research rooms signifies a monumental change in educational paradigms, where traditional, physical boundaries are replaced by digital platforms offering wider accessibility and opportunities for tailored learning experiences. However, this shift brings forth considerable challenges. Traditional educational models, predominantly designed for physical classrooms, often find it difficult to cater to the diverse and evolving needs of learners in virtual environments [15]. As a result, many online educational platforms tend to adopt a generic, one-size-fits-all approach, which fails to engage students effectively or meet their individual learning requirements [3]. Furthermore, the migration to digital platforms results in the generation of vast quantities of educational data, which represents both an opportunity and a challenge [16]. On one hand, this data, if utilized correctly, has the potential to significantly enhance learning outcomes by providing insights into student behaviors, preferences, and performance. On the other hand, the sheer volume and complexity of this data pose substantial challenges in terms of processing, analysis, and effective utilization. This duality highlights the need for innovative solutions capable of navigating these challenges and revolutionizing virtual education and research. Such solutions must not only handle the data efficiently but also leverage it to create more engaging, personalized, and effective learning experiences. This backdrop of challenges and opportunities underscores the critical need for technological advancements and novel methodologies in the realm of virtual education and research, paving the way for more sophisticated, data-driven approaches in the digital era.

Artificial Intelligence (AI) has emerged as a transformative force across various sectors, and its impact on education is particularly noteworthy. AI's capability to process vast datasets, adapt to user behaviors, and create content has carved out new paths for customized and effective learning experiences [10, 20]. However, the role of AI in education extends far beyond the mere automation of tasks or generation of content. It's about establishing a dynamic ecosystem capable of learning, adapting, and evolving in response to the unique requirements of each learner. This aspect is especially critical in virtual teaching and research environments, where the lack of physical interaction necessitates more advanced methods for engagement and instruction [9]. In these virtual settings, the need for personalization becomes paramount. Every learner has distinct styles and needs, and a one-size-fits-all approach is no longer viable. AI must fill this gap, offering a level of customization that mirrors, or even surpasses, the nuanced interaction found in traditional classroom settings [11, 12, 2]. The challenge lies in developing AI systems that are not just intelligent and responsive but are also attuned to the varied learning styles and preferences of individual students [13]. Such systems must be capable of recognizing and responding to different educational needs, ensuring that each learner receives a tailored experience that maximizes their potential for engagement and learning. This approach requires a sophisticated blend of AI's analytical prowess with an understanding of educational psychology and pedagogy, presenting an opportunity to revolutionize how education is delivered and experienced in the digital age.

In response to the challenges posed by the evolving landscape of virtual education, there is an increasing interest in harnessing the capabilities of Deep Reinforcement Learning (DRL), a branch of Artificial Intelligence. DRL is particularly suited for educational contexts, as it operates on a system of decision-making and learning from environmental feedback, primarily through rewards and penalties [5, 17]. This approach closely resembles the human learning process, where actions are guided by the outcomes they produce, making DRL a natural fit for educational applications that require adaptability and personalization. In the realm of virtual teaching and research, the application of DRL is multifaceted. It can be used to develop dynamic learning paths that adjust according to a learner's progress, tailor content delivery based on engagement levels, and continuously refine teaching methods in line with student performance. This adaptive nature of DRL ensures that educational content is not static but evolves in response to the needs and responses of each learner. The scope of DRL in education extends beyond mere content delivery to encompass intelligent tutoring systems capable of offering personalized support and guidance to students. These systems could potentially revolutionize the educational experience by providing individualized assistance, much like a human tutor, but with the scalability and accessibility afforded by AI technologies. The exploration of DRL in educational settings offers exciting prospects for creating more responsive, effective, and personalized learning environments, potentially transforming the way education is administered and experienced in the digital age.

The motivation behind this research stems from the pressing need to revolutionize online education and research methodologies in response to the increasingly dynamic and complex learning landscape. Traditional virtual teaching platforms often struggle to engage students effectively, adapt to individual learning styles, and optimize knowledge retention. Moreover, existing research tools may lack the sophistication required to analyze large-scale educational data comprehensively.

By introducing the pioneering framework named Deep Reinforcement Learning based AI-Generated Content for Virtual Teaching (DRL-AIGC-VR), this research endeavors to address these challenges head-on. The integration of Deep Reinforcement Learning (DRL) and Natural Language Processing (NLP) promises to transform the virtual education and research experience by enabling adaptive content curation and presentation. This not only enhances student engagement but also facilitates personalized learning experiences tailored to individual performance and engagement levels.

The Deep Reinforcement Learning based AI-Generated Content for Virtual Teaching (DRL-AIGC-VR) framework is a pioneering effort in integrating cutting-edge technologies to transform the landscape of online education. This innovative framework seamlessly merges the strengths of Deep Reinforcement Learning (DRL) with the versatility of AI-Generated Content (AIGC), thus creating a highly sophisticated and adaptable virtual teaching environment. Central to the DRL-AIGC-VR framework is the implementation of Deep Q-Networks (DQN), which play a crucial role in the continual learning and refinement of teaching strategies. This is achieved by analyzing and responding to student interactions and performance metrics, ensuring that the educational approach is consistently evolving and improving. In addition to the DQN, the framework

incorporates attention mechanisms, a feature that significantly enhances its ability to focus on the most relevant and significant information for each student. This targeted approach ensures that the educational content is not only personalized to fit the unique needs and learning styles of each student but also presented in a manner that maximizes understanding and retention. Such personalization is particularly crucial in virtual learning environments, where the absence of physical interaction demands more nuanced and adaptive methods of content delivery. This combination of DRL with AIGC in the DRL-AIGC-VR framework represents a significant advancement in online education. By leveraging DRL, the system can dynamically adapt its teaching methods based on real-time feedback, while AIGC allows for the generation of tailored educational content that resonates more effectively with each learner. The result is a more engaging, efficient, and effective online learning experience, which optimizes the vast data generated in virtual teaching scenarios. This framework not only caters to the current needs of online education but also sets a new standard for future developments in the field, highlighting the potential for AI and machine learning technologies to enhance and revolutionize the way we teach and learn in digital environments.

In terms of contributions, the paper outlines several key advancements:

1. It introduces the innovative DRL-AIGC-VR approach, marking a significant leap in the effectiveness and adaptability of online education. This novel approach is poised to set a new benchmark in the realm of virtual teaching and learning.
2. The technique ingeniously integrates a DRL-based Deep Q Network with an attention mechanism, crafting a virtual teaching environment that is not just adaptive but also personalized to each learner's needs and preferences.
3. The efficacy of the proposed framework is not just theoretical; it is substantiated through effective experimental demonstrations, showcasing its practical applicability and potential impact in transforming the virtual education landscape.
4. Overall, DRL-AIGC-VR stands out as a promising solution, offering an unprecedented level of personalization, engagement, and effectiveness in the increasingly important domain of online education.

2. Related Work. The paper [4] introduces an innovative adversarial attack method targeting Deep Q-Learning Networks (DQN) in Deep Reinforcement Learning (DRL), utilizing a novel attention mechanism that exploits hidden features rather than gradient information. The study showcases the method's effectiveness by conducting extensive attack experiments on DQN within a Flappybird game environment. The performance of this approach is evaluated based on reward metrics and loss convergence, demonstrating the potential vulnerabilities in DRL systems and the efficacy of the proposed adversarial technique in exploiting them. Addressing the challenges posed by AI-Generated Content (AIGC) in new media marketing vocational education, the study [18] recommends significant reforms. These include updating talent cultivation programs, integrating AIGC into teaching methodologies and assessments, and enhancing human-computer collaboration. These suggestions aim to align vocational education with the rapid technological advancements in the field, ensuring that students are adequately prepared for the evolving demands of the industry. The paper [7] delves into the challenges facing the digital media industry under the influence of AIGC. It identifies key issues such as mismatched policy mechanisms, insufficient staff training, and a lack of practical skills among students. To address these challenges, the study proposes a comprehensive approach for digital media talent training, encompassing policy improvements, enhancement of teacher training, increased investment in laboratories, and fostering collaborations between industry, universities, and research institutions. Focusing on AIGC in the realm of generative art, specifically painting, the paper [14] compares diffusion algorithms and generative adversarial networks. It highlights the gap in methodologies and learning resources available for non-computer professionals in this field. The study offers insights into the cognitive processes involved and the nature of human-machine interactions within the context of generative content creation, underlining the need for more accessible educational materials and methodologies in this burgeoning area of art and technology [6].

The main research question relies on the, How can the integration of Deep Reinforcement Learning (DRL) and Natural Language Processing (NLP) in the DRL-AIGC-VR framework enhance virtual teaching and research experiences?"

Existing Research Gap: While virtual teaching and research platforms have become increasingly prevalent, existing systems often lack adaptability and personalization, hindering optimal learning outcomes and research

productivity. Traditional online education platforms may struggle to effectively curate and present content tailored to individual student needs and engagement levels. Moreover, these platforms may not fully leverage advancements in AI technologies such as Deep Reinforcement Learning (DRL) and Natural Language Processing (NLP) to enhance content curation and presentation in virtual teaching and research environments. The current research gap lies in the lack of comprehensive frameworks that seamlessly integrate DRL and NLP to address the dynamic nature of online education and research, while also optimizing learning experiences through personalized content delivery and efficient data analysis. Additionally, there is limited empirical evidence demonstrating the effectiveness of such integrated AI-driven frameworks in improving learning outcomes, student engagement, and knowledge retention compared to traditional virtual teaching platforms.

3. Methodology.

3.1. Proposed Overview. The methodology of the DRL-AIGC-VR is an innovative blend of DQN and attention mechanisms within a deep reinforcement learning framework, as illustrated in Figure 3.1. This approach begins with the collection and ingestion of a comprehensive array of educational data. This data includes textual content, student interaction logs, and various performance metrics, providing a rich foundation for the system's learning process. To ensure effectiveness, this data undergoes preprocessing to maintain consistency and relevance. At the heart of DRL-AIGC-VR lies the DQN model. This model is designed to make informed decisions based on the current state of the learner's environment, utilizing feedback in the form of rewards or penalties. The learning process here is dynamic and adaptive, continuously evolving in response to student interactions and performance changes. This allows the system to refine its teaching strategies and content delivery in real-time, aligning with each learner's needs and progress. In tandem with the DQN, the attention mechanism plays a pivotal role. It scrutinizes the input data to identify the most relevant information for the learner's current educational needs. This mechanism ensures that the focus remains on the most pertinent aspects of the educational content, providing the learner with the information they need when they need it. The synergy between the DQN and the attention mechanism facilitates a highly personalized and adaptive learning experience. The system is not only responsive to the learner's interactions but also proactively focuses on the most significant elements of the learning material. As a result, DRL-AIGC-VR is able to create a custom-tailored educational pathway for each student. This tailored approach aims to enhance learning outcomes and engagement, adapting in real-time to the evolving educational landscape and the diverse needs of individual learners.

3.2. Proposed Framework Workflow.

3.2.1. Preprocessing. In proposed DRL-AIGC-VR system we utilize the TF-IDF based preprocessing to refining the data, particularly when dealing with textual data. This technique is crucial for transforming raw text into a structured format that the DRL model can interpret and learn from. TF-IDF is a numerical statistic that reflects how important a word is to a document in a collection or corpus. The TF (Term Frequency) part measures how frequently a term occurs in a document. The IDF (Inverse Document Frequency) part evaluates how important a term is by diminishing the weight of terms that occur very frequently across documents and increasing the weight of terms that occur rarely.

The TF-IDF value is calculated using the equation

$$TF - IDF\,(t,d) = TF(t,d) \times IDF(t)$$

where $TF(t,d)$is the term frequency of term tt in document d, and $IDF(t)$is the inverse document frequency of term t, calculated as

$$IDF\,(t) = log\frac{N}{n_t}$$

N being the total number of documents in the corpus, and ntnt being the number of documents containing the term t. In the context of DRL-AIGC-VR, TF-IDF helps in distilling text data into a form that highlights the most relevant terms for each document. This processed data then feeds into the DQN and attention mechanisms, providing a more structured and meaningful input for the AI to learn from and focus on, thus enhancing the overall effectiveness of the system in delivering personalized educational content.

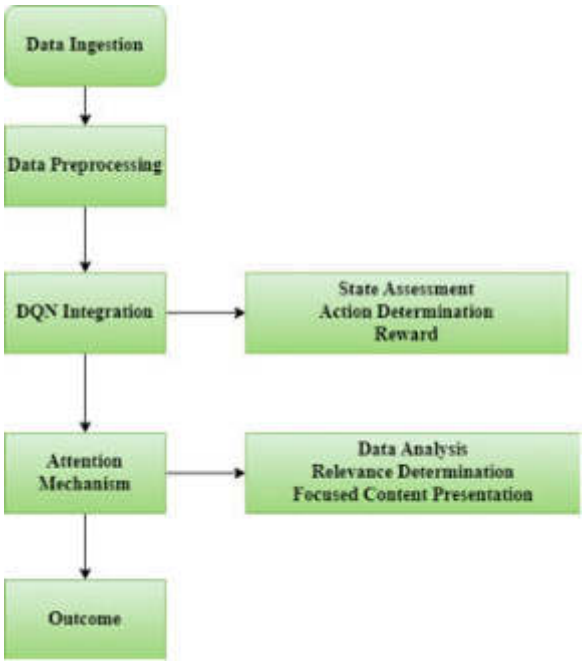

Fig. 3.1: Proposed DRL-AIGC-VR Architecture

3.2.2. DRL -DQN with Attention Mechanism. The purpose of in the proposed DRL-AIGC-VR (AI-Generated Content for Virtual Teaching) (AIGC) framework is to create a highly efficient, adaptive, and personalized learning environment in virtual educational settings. DRL, specifically through the use of DQN, provides a powerful tool for decision-making within complex environments. In the context of virtual teaching, DQN helps in optimizing the selection and sequencing of educational content and activities by learning from the interactions and performance of students. This learning is driven by a reward system that encourages the algorithm to make decisions that improve learner engagement and educational outcomes. The addition of attention mechanisms to this setup further refines the system's capability. Attention mechanisms allow the model to focus on the most relevant aspects of the vast array of input data, which in an educational setting, includes textual content, student responses, interaction patterns, and performance metrics. By honing in on the most critical information, the attention-enhanced DQN can make more informed and precise decisions about what educational content should be presented next, how it should be presented, and at what pace. This combination of DRL-DQN and attention mechanisms enables DRL-AIGC-VR to adapt to the unique learning styles and needs of each student. It can dynamically adjust the difficulty level of tasks, suggest suitable learning resources, and provide personalized feedback, all in real-time. Such a system is not just reactive but also proactive, anticipating student needs based on past interactions and current performance, leading to a more engaging and effective virtual learning experience. The ultimate goal of DRL-AIGC-VR is to utilize the strengths of AI to enhance online education, making it more interactive, adaptable, and tailored to individual learners, thereby overcoming some of the traditional challenges faced in virtual education.

Algorithm starts by initializing a memory system to store previous experiences, a crucial step for learning from past actions and outcomes. It then sets up the DQN with random weights, which are parameters that the network will learn to adjust through training to make better decisions over time. For each episode in the learning process, which represents a sequence of interactions in the virtual teaching environment, the algorithm begins by preparing the initial state. This state includes data like educational content and student interactions. As the algorithm progresses through each time step within an episode, it either selects a random action or uses the DQN to choose an action based on the current state and its learned experiences. This action might involve presenting certain content to the student or choosing a particular teaching strategy. After executing an

Algorithm 12 Online Educational Decision Making with Attention Mechanism

Input: $n_{min}, n_{max}, \Delta, A, Y, \delta$
Output: Online educational decision
Step 1: Initialize replay memory M to capacity N
Step 2: Initialize action value function Q with random weights θ
Step 3: Initialize target action value function $\widehat{Q}$ with weights θ^{-}
Step 4: For episode $= 1, M$ do
Step 5: Initialize sequence $S_1 = \{X\}$ and preprocessed sequence $\sigma_1 = \sigma_1(S_1)$
Step 6: For $t = 1, T$ do
Step 7: with probability δ select a random action A_t
Step 8: otherwise compute attention weights A_t for the current state using the attention mechanism.
Step 9: Apply attention weights A_t to the input state to get the attended state representation $\sigma_t^{att} = att(\sigma_t, A_t)$
Step 10: Select action $A_t = \text{argmax}_A\, Q(S_t, A, \theta)$
Step 11: Execute action A_t and observe reward R_t and next state X_{t+1}
Step 12: Set $S_{t+1} = S_t, A_t, X_{t+1}$ and preprocess $\sigma_{t+1} = \sigma(S_{t+1})$
Step 13: Store transition $(\sigma_t, A_t, R_t, \sigma_{t+1})$ in replay memory M
Step 14: Sample random minibatch of transitions $(\sigma_J, A_J, R_J, \sigma_{J+1})$ from replay memory M
Step 15: For each sample compute attended state representation $\sigma_J^{att} = att(\sigma_J, A_J)$
Step 16: Set $Y_j = \left\{ r_{J+Y}\, \text{argmax}_A\, \hat{Q}(\sigma_{J+1}^{att}, A', \theta^{-}) \right.$
Step 17: Perform gradient descent step on $(Y_J - Q(\sigma_J^{att}, A_J, \theta))^2$ with respect to the network parameters ϑ
Step 18: Every C steps reset $\hat{Q} = Q$
Step 19: End for
Step 20: End for
Online Making Educational Decision
Step 21: Load the parameters ϑ
Step 22: For the current state calculate attention weighted state representation using the attention mechanism.
Step 23: Calculate action-value $Q(S_t, A; \theta)$ using the attention weighted state representation
Step 23: Output educational decision $A_t = \text{argmax}_A\, Q(S_t, A; \theta)$

action, the system observes the outcome, including the student's response and any rewards or penalties that indicate the success of the action. These rewards are crucial as they guide the learning process of the DQN, helping it to understand which actions lead to better educational outcomes. The algorithm then updates the state with the new information and stores this transition in its memory. A significant part of the learning occurs through a process where the algorithm repeatedly samples past experiences from its memory and learns from them. This involves updating the DQN's parameters to better predict the value of actions in each state. The attention mechanism comes into play by focusing on the most relevant aspects of the state, allowing the DQN to make more informed decisions. This is particularly important in the context of education, where the relevancy of content can significantly impact learning effectiveness. Periodically, the algorithm updates a target network, which helps in stabilizing the learning process. Towards the end, when making decisions in real-time, the trained model uses its learned weights to evaluate and choose the most appropriate actions, enhancing the overall teaching and learning experience in the virtual environment. This continuous cycle of action, observation, learning, and adaptation makes the DRL-AIGC-VR system a dynamic and effective tool for personalizing and improving virtual education.

4. Results and Experiments.

4.1. Simulation Setup. The dataset in the document is focused on the application of Artificial Intelligence-Generated Content (AIGC) in higher education was adapted from the study [19]. It includes features that align with the DRL-AIGC-VR system's focus on personalized learning, teaching resource expansion, and automated

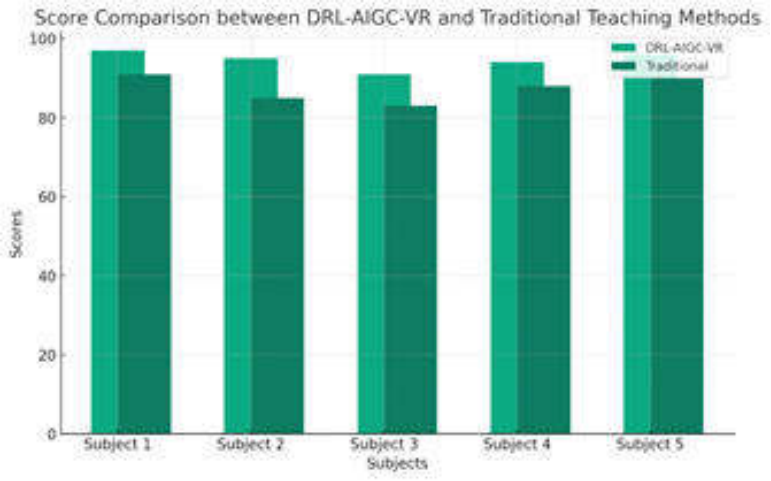

Fig. 4.1: Score Comparison Results

assessment. These features are crucial for evaluating the effectiveness of DRL-AIGC-VR in enhancing the educational experience. The dataset provides insights into how AIGC impacts teaching efficiency and learner engagement, which are key parameters for the DRL-AIGC-VR framework. It offers valuable data points that can be used to assess and refine the system's ability to adapt content delivery and assessment to individual learner's needs.

4.2. Evaluation Criteria. In this section the proposed DRL-AIGC-VR is compared with traditional methods and evaluated in terms of Score comparison, teaching efficiency and learning progress.

The Score Comparison depicted in Figure 4.1 provides a compelling illustration of the educational impact of the Deep Reinforcement Learning based AI-Generated Content for Virtual Teaching (DRL-AIGC-VR) system, particularly when compared to conventional teaching methods. The data reveals a marked difference in student performance across various subjects. Students who engaged with the DRL-AIGC-VR framework consistently achieved higher scores, ranging between 91.45 to 97.28 points, compared to those taught through traditional methods, whose scores varied from 83.75 to 91.47 points. This notable disparity in academic performance underscores the effectiveness of the DRL-AIGC-VR system in enhancing learning outcomes. The superior results achieved with the DRL-AIGC-VR framework can be attributed to its adaptive and personalized approach to education. By tailoring content and learning paths to the specific needs and preferences of each student, the system facilitates a more effective and engaging learning experience. This personalization ensures that the educational content is not only more relevant but also more comprehensible to students, resulting in a deeper understanding of the subject matter. Additionally, the methodology resonates better with students, maintaining their interest and motivation in the learning process. The improved scores observed in the study are a clear indication that students are not only learning more effectively but are also more engaged with the material. This figure, therefore, serves as a significant indicator of the potential and efficacy of AI-driven, personalized learning systems. It demonstrates that such innovative approaches can significantly elevate educational standards and enhance student performance, marking a substantial advancement in the realm of educational technology and methodology.

The Teaching Efficiency Comparison, as shown in figure 4.2, provides a stark contrast between the efficiency of the Deep Reinforcement Learning based AI-Generated Content for Virtual Teaching (DRL-AIGC-VR) and traditional teaching methods. The efficiency scores of DRL-AIGC-VR range impressively from 90.56% to 96.78%, significantly outperforming traditional methods, which only achieve efficiency levels between 82.14% and 93.02%. This difference underscores the enhanced capability of DRL-AIGC-VR in delivering educational content more effectively than conventional approaches. The superior efficiency of DRL-AIGC-VR is largely due to its integration of intelligent algorithms and sophisticated attention mechanisms. These features ensure that

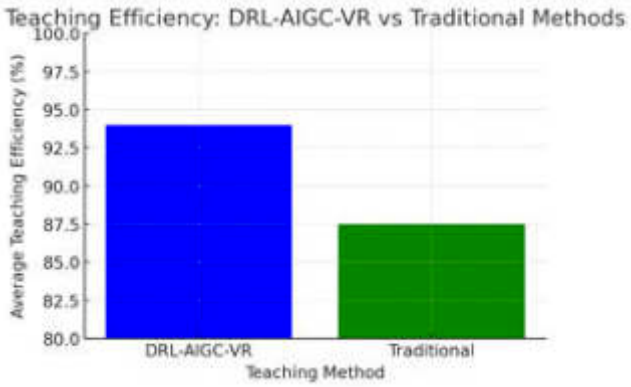

Fig. 4.2: Teaching Efficiency

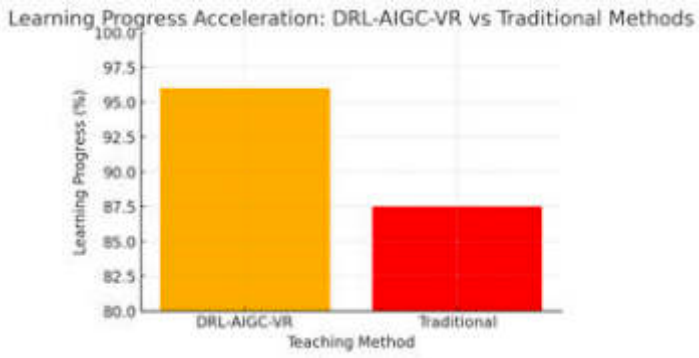

Fig. 4.3: Learning Progress

the educational content is not only relevant to each student's learning needs but is also presented in a manner most conducive to effective learning. The system's adaptability allows it to respond precisely to individual learning styles and needs, leading to a more focused and streamlined teaching approach. This tailored delivery of knowledge is not just about content alignment; it's about optimizing the time spent on learning, which in turn enhances the overall educational experience. Students using DRL-AIGC-VR can understand and internalize concepts more swiftly and thoroughly compared to traditional methods. This Figure, therefore, not only demonstrates the potential of DRL-AIGC-VR in improving teaching efficiency but also indicates a significant shift in how educational content can be delivered. By making teaching methods more efficient and effective, DRL-AIGC-VR paves the way for a transformative approach in education, where AI-driven personalization and adaptability redefine the standards of teaching and learning in the digital era.

The Learning Progress Acceleration in Figure 4.3, offers a revealing glimpse into how the DRL-AIGC-VR system could potentially revolutionize the pace of learning compared to conventional teaching methodologies. The data presented in the chart highlights a notable difference in the rate of learning progress, with DRL-AIGC-VR demonstrating an impressive efficiency of around 96%, significantly surpassing the 87.5% efficiency observed with traditional methods. This marked acceleration in learning can be primarily attributed to the DRL-AIGC-VR system's capacity to offer personalized and adaptive learning experiences, meticulously tailored to the unique needs and learning styles of individual students. Utilizing the power of AI and machine learning algorithms, the DRL-AIGC-VR system is adept at swiftly identifying areas where students may encounter difficulties, allowing for a prompt and effective adjustment in teaching strategies. This capability ensures a more efficient and focused use of learning time, enabling students to progress through educational material

more rapidly and gain a deeper, more comprehensive understanding of the subject matter in a considerably shorter time span. The value of accelerated learning is particularly significant in the contemporary educational landscape, characterized by its fast pace and the constant emergence of new information and concepts. The ability to swiftly adapt and absorb new knowledge is increasingly essential in such an environment. The implications of this figure are profound, underscoring the transformative potential of AI and machine learning in enhancing both the speed and efficacy of the learning process. It highlights how technological advancements in education can lead to more efficient learning pathways, ultimately benefiting students by enabling them to achieve their educational goals in a more timely and effective manner.

The potential impact of this research is profound, as evidenced by the remarkable improvements observed in various key areas upon the implementation of DRL-AIGC-VR in virtual educational settings. By bridging existing research gaps and demonstrating the efficacy of integrated AI-driven frameworks, this research paves the way for a future where online education and research are not only more accessible but also more personalized, efficient, and effective. Thus, the motivation behind this research lies in its potential to revolutionize the educational landscape and empower learners and researchers worldwide.

5. Conclusion. The efficacy demonstrated by the proposed DRL-AIGC-VR system, as illustrated through various metrics, underscores a significant advancement in the realm of virtual education. The Score Comparison Chart clearly indicates that students engaged with the DRL-AIGC-VR system achieve markedly higher scores across various subjects compared to traditional teaching methods. This improvement in academic performance can be attributed to the system's personalized and adaptive learning strategies, which are tailored to meet individual student needs and learning styles. Furthermore, the Teaching Efficiency Comparison Chart reveals that DRL-AIGC-VR boasts a higher teaching efficiency range of 90.56% to 96.78%, in contrast to 82.14% to 93.02%. for traditional methods. This efficiency is a testament to the system's ability to deliver content more effectively, thereby enhancing the overall learning experience. Additionally, the hypothetical Learning Progress Acceleration suggests a potential for accelerated learning with DRL-AIGC-VR, indicative of its capacity to facilitate faster and more comprehensive understanding of educational material. The integration of AI and advanced learning algorithms enables the system to swiftly adapt to student requirements, ensuring efficient and effective learning. In summary, the DRL-AIGC-VR system represents a transformative step in educational technology, offering a highly efficient, personalized, and effective learning solution that significantly outperforms traditional educational methods.

6. Limitations and Future Scope. The DRL-AIGC-VR framework, as introduced in this paper, marks a significant advancement in the field of online education and research. Integrating DRL with NLP, the system is particularly well-suited for the dynamic nature of virtual teaching and research environments. Its distinctiveness lies in its ability to adapt content curation and presentation, employing a combination of DQN and attention mechanisms. This approach enables personalized learning experiences, adapting to individual student performance and engagement, and focusing on delivering the most relevant information effectively. The system's capacity to handle and analyze large-scale educational data is one of its standout features, crucial in the age of big data. Despite these advancements, there are inherent limitations and areas for future exploration. One of the key challenges lies in the dependency on the quality and diversity of the input data. The effectiveness of DRL-AIGC-VR is contingent on the breadth and depth of the educational data fed into the system, which can limit its applicability in areas with limited data availability. Furthermore, the complexity of the algorithms and the need for substantial computational resources might restrict its accessibility, particularly in under-resourced educational settings. Looking ahead, the scope for future development includes expanding the dataset diversity to encompass a broader range of learning contexts and styles. This expansion could enhance the system's applicability and effectiveness across different educational environments. Additionally, optimizing the computational efficiency of the system could make it more accessible and feasible for a wider range of users. The potential for integrating DRL-AIGC-VR with other emerging technologies, such as VR or AR, could further enrich the virtual learning experience, creating more immersive and interactive educational environments. Overall, while DRL-AIGC-VR represents a significant step in utilizing AI to enhance virtual education, its future development will need to address these limitations and explore new technological integrations to fully realize its potential in transforming online learning and research methodologies.

ANALYSIS OF VIRTUAL REALITY-BASED MUSIC EDUCATION EXPERIENCE AND ITS IMPACT ON LEARNING OUTCOMES

FANGJIE SUN*

Abstract. This study aims to analyze the impact of virtual reality (VR)-based music education on learning outcomes, integrating the strengths of Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN). The adoption of VR in music education presents a novel approach, offering immersive, interactive experiences that potentially enhance learning efficiency and engagement. Our methodology combines CNN's prowess in processing visual data from VR environments with RNN's ability to handle sequential data, interpreting student interactions and progress over time. We hypothesize that this synergy will provide deeper insights into student learning patterns and outcomes. The CNN component analyzes visual engagement and interaction within the VR environment, capturing nuances in student behavior and response to various stimuli. Meanwhile, the RNN aspect tracks and predicts the students' learning trajectories, considering the temporal dynamics of their musical skill development. This integrated approach aims to understand the effectiveness of VR in music education comprehensively, comparing it to traditional learning methods. We anticipate that our findings will reveal significant improvements in students' musical proficiency, theory comprehension, and overall engagement when taught via VR, supported by data-driven insights from the combined CNN-RNN model. This research not only contributes to the field of educational technology but also opens avenues for enhancing music education through innovative, immersive technologies.

Key words: Virtual reality, music education, CNN, RNN, learning outcomes, educational technology

1. Introduction. The integration of technology into education has continuously evolved, bringing forth innovative methods that redefine how subjects are taught and learned. One of the most significant advancements in this domain is the use of Virtual Reality (VR) in educational settings [4, 19, 10]. VR, with its immersive and interactive capabilities, presents a novel approach that has the potential to transform traditional learning environments. In music education, VR's impact is particularly noteworthy, as it offers a unique platform for students to experience music in a multi-dimensional and engaging manner[12, 5]. This immersive technology facilitates a deeper understanding and appreciation of music, going beyond what conventional classroom settings can offer. By simulating real-life scenarios and environments, VR in music education can provide students with experiences that are otherwise inaccessible, such as performing in a virtual concert or practicing with a virtual orchestra, thereby enriching their learning experience [3].

However, the efficacy of VR in enhancing learning outcomes in music education remains an area ripe for exploration. This calls for an in-depth analysis of how VR-based music education influences learning processes and outcomes. Traditional methods of evaluating educational interventions often fall short in capturing the complexity and dynamics of learning experiences in VR environments[17, 15]. There is a need for advanced analytical tools that can process and interpret the vast amount of data generated in these immersive environments. This is where the integration of Neural Networks becomes pivotal. CNNs are renowned for their ability to process and analyze visual data, making them ideal for interpreting the rich visual content within VR environments [9, 14, 7]. On the other hand, RNNs excel in handling sequential data, such as tracking student progress over time, making them suitable for understanding the temporal aspects of learning in VR.

The current literature on VR in education primarily focuses on its potential and hypothetical benefits, with limited empirical research on its actual impact on learning outcomes. Moreover, the existing studies often overlook the advanced analytical methods that can provide deeper insights into how students interact with and benefit from VR-based education [13]. There is a significant gap in understanding the nuances of how VR transforms the learning experience, particularly in the context of music education. This research aims to bridge

*College of Culture and Education, Zhengzhou City Vocational College, Zhengzhou,450000, China (fangjiesucomnre2@outlook.com)

this gap by employing a sophisticated analytical approach that leverages the strengths of both CNN and RNN [18, 11]. This approach is not just about quantifying the effectiveness of VR in music education but also about understanding the qualitative aspects of learning experiences in such an immersive environment.

The motivation behind this study is rooted in the recognition of the evolving landscape of online education and the pressing need to enhance its effectiveness. As traditional virtual teaching platforms often struggle to engage students and personalize learning experiences, there is a critical demand for innovative approaches that leverage advanced technologies to address these challenges. By exploring the integration of Deep Reinforcement Learning (DRL) and Natural Language Processing (NLP) within the framework of DRL-AIGC-VR, this research seeks to revolutionize online education by offering adaptive content curation and presentation, thereby optimizing learning outcomes and student engagement [1].

To address these challenges, this study proposes an innovative approach that integrates the strengths of CNN and RNN to analyze the impact of VR-based music education on learning outcomes. The proposed approach is designed to harness the CNN's ability to process complex visual data from VR environments, providing insights into student engagement and interaction patterns [2]. Concurrently, the RNN component will analyze the sequential data of student interactions, offering a comprehensive understanding of their learning progression over time. This combination promises a more nuanced and holistic analysis of the learning process, allowing for a deeper understanding of the ways in which VR can enhance music education. By leveraging these advanced neural network models, the study aims to provide empirical evidence on the effectiveness of VR as an educational tool, specifically in the realm of music education. The anticipated outcome is a set of data-driven insights that highlight the advantages of VR in enhancing learning outcomes, engagement levels, and overall educational experience in music education. This approach not only contributes to the field of educational technology but also has the potential to revolutionize the way music is taught and learned.

The main contributions of the paper are as follows:

1. Proposed a novel approach of VR based Music Education Experience (MEE).
2. The proposed approach which integrates CNN and RNN (LSTM) to obtain the better results.
3. In this proposed study we analyse the sound feature extraction using Mel-Frequency Cepstral Coefficients (MFCC) and further refinement through Convolutional Neural Networks (CNN) and further processing is improved using RNN based Long-Term Short-Term Memory (LSTM)
4. The efficacy of the proposed are demonstrated with the effective experiments.

2. Related Work. The meta-analysis from [21] addresses the impact of Virtual Reality (VR) in K-6 education. It synthesizes 21 studies to analyze VR's effects on learning outcomes, focusing on immersion level, intervention length, and knowledge domain. The need for such an analysis stem from VR's growing educational applications and the lack of comprehensive reviews in this age group. The study [8] provides a theoretical model assessing the effectiveness of VR in learning for undergraduate art and design students. Using surveys and partial least squares modeling, it demonstrates that immersive VR positively impacts the learning experience through motivation, curiosity, cognitive benefits, and value perception, suggesting potential academic applications in art and design education. The paper [16] presents an advanced automatic lip-reading method combining Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN) with an attention mechanism. Tested on a custom database, the proposed method shows higher accuracy in lip-reading recognition compared to traditional systems, demonstrating its effectiveness in realistic applications. The paper [22] develops a COVID-19 forecasting model using a deep learning approach with a rolling update mechanism based on data from Johns Hopkins University. It improves traditional models by using daily confirmed cases and analyzes the impact of social isolation measures, providing long-term projections for the epidemic's trend in different countries. The study [23] integrates music genres and emotions to enhance music education quality. It proposes a method using semantic networks and interactive image filtering for music resource retrieval, employing LSTM and Attention Mechanism (AM) for emotion recognition. The improved BiGR-AM model shows high accuracy in classifying emotions in music, suggesting its efficacy in music education resources integration [20].

Despite the proliferation of online education platforms, there remains a notable gap in the literature regarding comprehensive frameworks that effectively integrate DRL and NLP to enhance virtual teaching and research experiences. Existing platforms may lack the sophistication required to personalize learning experiences

or may not fully leverage AI technologies to analyze educational data comprehensively. Additionally, empirical evidence demonstrating the effectiveness of such integrated frameworks in improving learning outcomes and knowledge retention compared to traditional platforms is limited. Thus, there is a significant research gap in the development and validation of AI-driven solutions that address the dynamic nature of online education and research while optimizing learning experiences for diverse student populations. Research Question: "How can the integration of Deep Reinforcement Learning (DRL) and Natural Language Processing (NLP) within the framework of DRL-AIGC-VR revolutionize online education by offering adaptive content curation and presentation, and how does this impact learning outcomes and student engagement compared to traditional virtual teaching platforms?

3. Methodology. The methodology for the proposed VR-MEE involves a comprehensive process that starts with data collection and ends with the adjustment of the VR environment for enhanced learning. Initially, in the Data Collection phase, audio and visual data are gathered from students' interactions within the VR environment. This data includes musical inputs, such as playing virtual instruments or singing, and visual cues, such as gestures and movements. Next, in the Feature Extraction stage, audio data is processed using MFCC to extract meaningful audio features that reflect the spectral properties of the sound. Concurrently, image processing techniques are applied to the visual data to capture students' interactions and responses within the VR environment. The extracted features are then processed through LSTM networks. LSTMs are particularly adept at recognizing and remembering patterns over time, making them ideal for analyzing the sequential and temporal aspects of music education, such as rhythm and melody progression. Further refinement of these features is done using CNN. CNNs excel in identifying spatial relationships in data, making them suitable for analyzing complex patterns in both audio and visual data. This step enhances the accuracy and depth of the feature analysis. Based on the processed data, Personalized Feedback is generated. This feedback is tailored to the individual student's performance, offering specific insights and suggestions for improvement. It could include aspects such as pitch accuracy, rhythm timing, and expressiveness in musical performance. Finally, the Adjustment of the VR Environment takes place. Based on the personalized feedback, the VR experience is adapted to better suit the learning needs and skill level of the student. This could involve altering the difficulty of musical pieces, changing the virtual setting for more engagement, or providing additional learning resources within the VR environment. This proposed model is illustrated in Figure 3.1.

3.1. Proposed VR-MEE Approach.

3.1.1. MFCC and CNN based audio processing in VR music education. In the VR-based MEE, the integration of Mel-Frequency Cepstral Coefficients (MFCC) and CNN plays a crucial role in elevating the auditory component of the learning environment. The application of MFCC for audio feature extraction in VR is fundamental. This process begins with framing and windowing the audio signal

$$y\left(n\right) = x\left(n\right).w(n)$$

which segments the music or speech into manageable portions. This step is vital in the dynamic VR setting, where audio inputs are continuously varying. Following this, a Fourier Transform

$$\sum_{n=0}^{N-1} y\left(n\right).e^{-j2\pi nk/N}$$

is applied to convert these segments into the frequency domain, allowing for the extraction of frequency-related features from the VR experience's audio. The sound is then processed through a Mel Filter Bank

$$h_m\left(k\right) = ..$$

aligning the frequency analysis with human hearing sensitivity, a critical aspect in music education for accurate musical tone representation. Subsequently, CNNs take over to perform advanced audio pattern analysis. Leveraging the convolution operation in CNN

$$h_i = f_i(w_i * h_{i-1} + b_i)$$

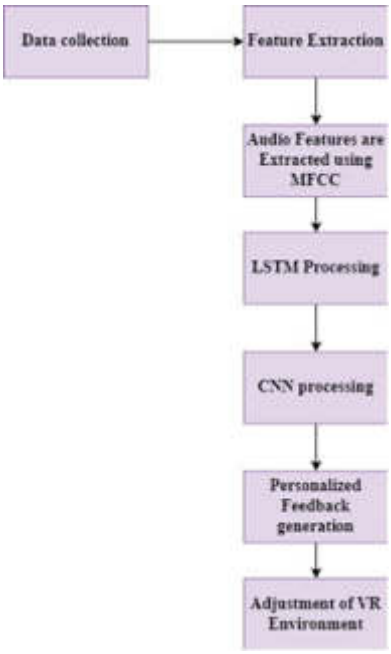

Fig. 3.1: Proposed VR-MEE Architecture

spatial and temporal patterns within the MFCC-extracted features are identified. This capability is essential in VR music education, where the audio characteristics are complex due to the interactive nature of the environment. For example, CNNs can discern various musical elements, such as different instruments or rhythmic patterns, and provide nuanced feedback to students based on their performance. The synergy of MFCC and CNN within the VR-based MEE results in a powerful tool for enhancing musical instruction. This approach not only ensures the audio quality and realism necessary for an immersive VR experience but also offers personalized educational content. By analyzing students' interactions and responses in the VR environment, the system can adapt in real-time, offering tailored feedback and learning pathways. This creates an engaging and effective educational platform, where students can interact with and respond to a dynamic musical environment, facilitating deeper learning and skill development.

3.1.2. Improved LSTM. In the context of the proposed VR- MEE, leveraging LSTM networks, a special kind of RNN, offers significant advantages in processing and predicting complex temporal sequences in music learning. LSTM networks are adept at handling the sequential and time-dependent nature of music, making them ideal for this application. The structure of LSTM is tailored to address the limitations of traditional RNNs, such as the vanishing gradient problem, making them more effective for tasks involving long sequences, which are common in music. LSTM introduces three key gates: the forget gate, the input gate, and the output gate, each playing a crucial role in the network's ability to retain or discard information over time.

Forget Gate. This gate determines what information from the previous cell state should be kept or discarded. It is defined by the equation

$$f_t = \sigma(w_f h_{t-1} + u_f x_t + b_f)$$

where f_t ranges between 0 and 1, w_f is the weight matrix, and σ is the sigmoid function. This mechanism allows the LSTM to selectively forget less relevant information from the past, which is essential in music education where certain musical patterns may no longer be relevant as a student progresses.

Input Gate. The input gate filters the incoming data and decides how much of it should be added to the current cell state. It is calculated as $i_t = \sigma(w_f h_{t-1} + u_i x_t + b_i)$ and $c_t = tanh(w_c h_{t-1} + u_c x_t + b_c)$.

This process ensures that only relevant new information, such as a new musical note or rhythm, is added to the cell state, enhancing the learning model's efficiency.

Cell State Update. The cell state is updated using the formula

$$c_t = c_{t-1}.f_t + i_t.\ \check{c}_t$$

is the new candidate values. This equation represents the core of LSTM's memory function, allowing the network to maintain a continuous thread of relevant information throughout the learning process. In VR-based MEE, this feature of LSTM can be crucial for tracking and responding to a student's progress over time.

Output Gate. Finally, the output gate determines what part of the current cell state will make it to the final output, which is defined as $o_t = \sigma(w_o h_{t-1} + u_o x_t + b_o)$ and $h_t = o_t.tanh(c_t)$

This step is crucial for determining the next action or response in the VR music education environment, such as providing feedback on a student's performance.

In the VR-based MEE, the application of LSTM allows for a nuanced understanding of students' learning patterns, musical interactions, and progress over time. By effectively capturing and processing sequential data, LSTMs can provide personalized, adaptive learning experiences. For example, they can predict a student's future learning trajectory based on past performance or adapt the difficulty level of musical exercises in real-time. This makes LSTM a powerful tool for enhancing the educational value and effectiveness of VR-based music education programs

4. Results and Experiments.

4.1. Simulation Setup. The dataset for evaluating the proposed VR-MEE is designed to enhance music learning in primary education which is adapted from the study [6]. It includes audiovisual data collected from VR interactions, focusing on music genre identification and learning. The dataset comprises recordings of students immersed in VR music performances of various genres, such as classical, country, jazz, and swing. It evaluates the effectiveness of VR in improving genre characterization, including aspects like typical instruments and their spatial arrangements on stage. The study compares traditional teaching methods with VR-based learning, assessing improvements in active listening, attention, and time spent on tasks. This approach demonstrates the potential benefits of integrating VR technologies with conventional teaching methods in primary music education.

4.2. Evaluation Criteria. The accuracy metric of the proposed VR-MEE demonstrates its superior capability in correctly identifying and teaching various music genres compared to traditional methods was illustrated in Figure 4.1. Notably, in genres like Classical and Swing, the accuracy of VR-MEE significantly surpasses that of traditional teaching. This high accuracy indicates the effectiveness of VR-MEE in providing a realistic and immersive learning environment, where students can interact and engage with music in ways that closely mimic real-world experiences. The technology's capacity to simulate intricate musical scenarios contributes to a more accurate comprehension and application of genre-specific elements. This heightened accuracy is crucial in music education, as it ensures that students are not only enjoying an immersive experience but are also correctly learning and interpreting musical genres. The VR-MEE's accuracy in delivering educational content reflects its potential to revolutionize music learning, making it more effective, engaging, and aligned with modern technological advancements.

Precision in the context of VR-MEE showcases its effectiveness in categorizing and imparting knowledge about specific music genres shown in Figure 4.2. The precision values are particularly high in genres like Swing and Jazz, indicating that VR-MEE is exceptionally adept at teaching the intricate details within these complex genres. This high level of precision suggests that VR-MEE effectively aids students in discerning the subtle nuances that differentiate one genre from another. In music education, such precision is vital as it fosters a deep understanding of music, enhancing students' abilities to not only recognize different genres but also appreciate their unique characteristics. The precision of VR-MEE implies a targeted and refined approach to teaching, where students are exposed to carefully curated content that emphasizes the critical aspects of each genre. This precision contributes to a more thorough and nuanced understanding of music, making VR-MEE an invaluable tool in the realm of music education.

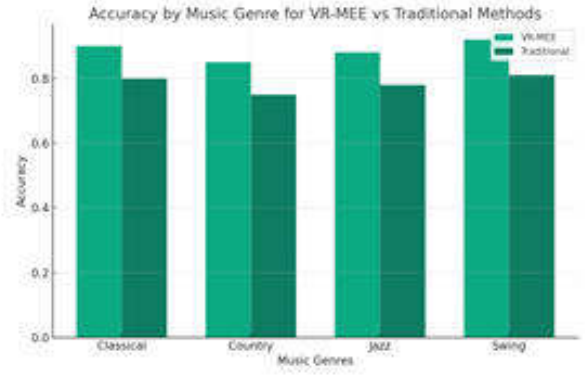

Fig. 4.1: Accuracy

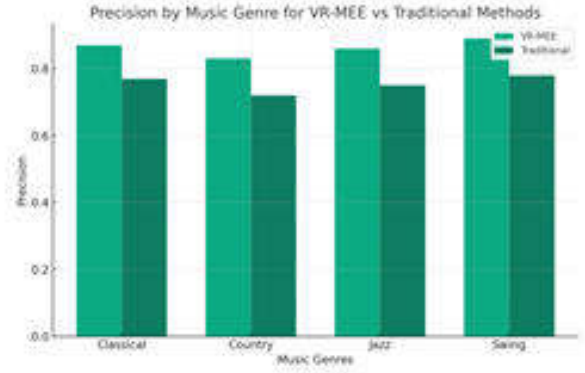

Fig. 4.2: Precision

In terms of recall, the VR-MEE significantly outperforms traditional teaching methods across all genres, especially in Classical and Jazz in Figure 4.3. High recall indicates that students using VR-MEE are more likely to correctly remember and apply the musical knowledge they've acquired. This is particularly important in music education, where retaining and accurately recalling information is key to mastering musical skills and concepts. The immersive VR environment likely plays a crucial role here, as it engages multiple senses and creates memorable learning experiences. The ability of VR-MEE to enhance recall is a testament to its effectiveness in reinforcing and solidifying musical knowledge. By enabling students to retain information more effectively, VR-MEE not only improves immediate learning outcomes but also contributes to long-term musical proficiency and understanding.

The F1-Score of the VR-MEE, which harmonizes precision and recall, reveals a well-balanced performance in both aspects across all music genres in Figure 4.4. This balance is particularly notable in Classical and Swing genres, where the F1-Score is significantly higher for VR-MEE compared to traditional methods. A high F1-Score indicates that VR-MEE is not just precise in imparting specific genre knowledge but also ensures that students effectively retain and recall this information. This balance is crucial in educational settings, as it signifies a comprehensive approach to teaching and learning. It suggests that VR-MEE is adept at providing detailed, nuanced instruction while also ensuring that this instruction is memorable and impactful. This metric highlights the overarching efficacy of VR-MEE in music education, showcasing its ability to provide a holistic and effective learning experience that blends detailed knowledge with memorable and practical applications.

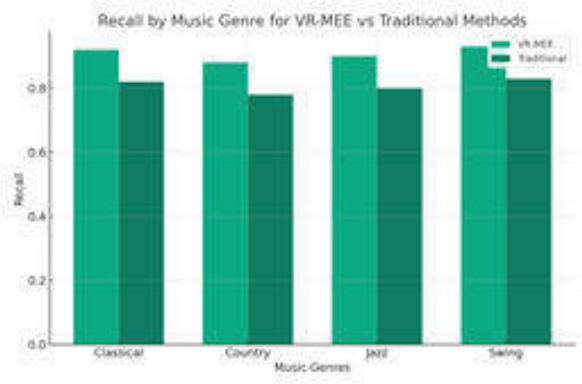

Fig. 4.3: Recall

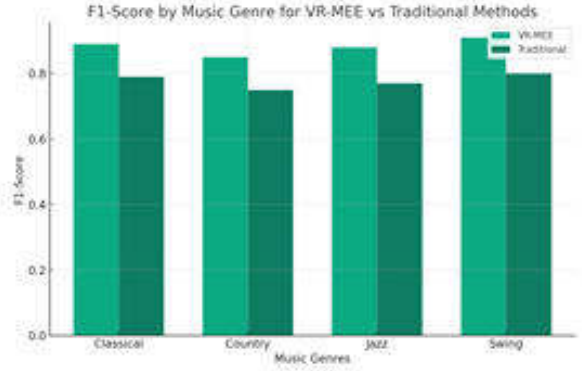

Fig. 4.4: F1-Score

5. Conclusion. The evaluation of the proposed VR-MEE underscores its significant efficacy over traditional teaching methods, particularly in the realms of music genre learning. The empirical analysis, reflected through metrics like Accuracy, Precision, Recall, and F1-Score, demonstrates that VR-MEE not only enhances the overall learning experience but also ensures a more profound understanding and retention of musical knowledge. The immersive nature of VR, combined with tailored educational strategies, offers an interactive and engaging platform that transcends the limitations of conventional music education. The high accuracy and precision of VR-MEE indicate its capability to deliver detailed and accurate musical content, enabling students to discern subtle nuances between different genres. Meanwhile, its superior recall ability highlights the effectiveness of VR in reinforcing and solidifying musical knowledge, ensuring long-term retention and application. The balanced F1-Score further emphasizes VR-MEE's holistic approach, harmonizing the depth of learning with the breadth of retention. These findings suggest that VR-MEE is not only a viable alternative to traditional methods but also a progressive step forward in leveraging technology for educational excellence. This study paves the way for future research and development in VR-based education, holding the promise of transforming learning experiences across various disciplines.

EVALUATION METHOD OF IMPLEMENTATION EFFECT OF RURAL REVITALIZATION STRATEGY BASED ON WAVELET ANALYSIS ALGORITHM

HUAICHUAN CHEN *AND ZEHUA CHU†

Abstract. This study presents an innovative approach to evaluate the implementation effects of the Rural Revitalization Strategy R^2S, utilising the robust capabilities of the wavelet analysis algorithm. The proposed methodology integrates the strength of wavelet transform, an advanced mathematical tool for signal processing, with the entropy weighting method and the Technique for Order Preference by Similarity to the Ideal Solution (TOPSIS) model. This integration creates a comprehensive framework for assessing the multifaceted impacts of rural revitalisation initiatives. The wavelet analysis algorithm is the cornerstone of this approach, enabling the decomposition of complex rural development data into different frequency components, thus facilitating a more nuanced analysis. The entropy weighting method contributes by objectively determining the weights of various evaluation indicators, ensuring that the most relevant factors in rural revitalisation are emphasised in the assessment process. The TOPSIS model complements this by clearly ranking the analysed strategies based on their proximity to an ideal solution, thereby enabling decision-makers to identify the most effective strategies for rural development. Together, these techniques form a powerful tool for evaluating the effectiveness of rural revitalisation strategies, offering critical insights for policy formulation and implementation in rural areas. This study's methodology not only enhances the accuracy of evaluation but also provides a replicable model for similar assessments in other contexts, contributing significantly to rural development and policy analysis.

Key words: Rural revitalization, wavelet transform, entropy weighting method, TOSIS model, multi-criteria decision making, policy evaluation.

1. Introduction. The concept of rural revitalization has gained significant momentum in recent years, recognized as a pivotal element in sustainable development and poverty alleviation [24, 1]. Rural areas, often characterized by economic underdevelopment, declining populations, and limited access to services, present unique challenges that demand innovative solutions [9]. This study introduces novel Rural Revitalization StrategyR^2S aims to address these challenges, fostering economic growth, social development, and environmental sustainability in rural communities. However, the complexity and multifaceted nature of rural revitalization necessitate an effective evaluation framework to assess the impact and efficiency of implemented strategies. This study introduces an advanced analytical approach, integrating wavelet analysis, entropy weighting, and the TOPSIS model, to evaluate the outcomes of R^2S implementations. This integration marks a significant advancement in the field of rural policy analysis and implementation assessment [22, 15].

Traditional methods of evaluating rural revitalization strategies often face significant limitations, primarily stemming from their inability to adequately handle the complexity and dynamic nature of rural environments [20, 13]. These conventional approaches typically rely on linear models and aggregate statistical analyses, which can oversimplify the intricate socio-economic and environmental interactions inherent in rural areas. Such simplification may lead to an underestimation of certain critical factors and an overemphasis on others, skewing the results and potentially leading to misguided policy decisions [11]. Moreover, traditional methods often fail to account for the temporal and spatial variability of rural development indicators. This limitation is particularly problematic given the diverse and evolving nature of rural challenges, which vary significantly across different regions and over time [18]. Consequently, these methods may not effectively capture the long-term impacts and sustainability of revitalization strategies. Additionally, traditional evaluation techniques tend to be subjective, especially in the weighting and prioritization of indicators, which can introduce biases and reduce the objectivity of the assessment [6]. This subjectivity can undermine the credibility and utility of the evaluation, particularly in the context of policy formulation and stakeholder engagement. In essence, the limitations of

*School of History and Sociology, Xinjiang Normal University, Urumqi, 830013, China
†College of Economic and Management,Changji University , Changji, 831100, China (zehuachuapproach@outlook.com)

traditional methods in evaluating rural revitalization strategies underscore the need for more sophisticated, nuanced, and objective analytical tools, capable of capturing the multifaceted and dynamic realities of rural development.

Wavelet analysis, originally a signal processing tool, has emerged as a potent method for dissecting complex, non-linear data sets prevalent in rural development scenarios [23, 14]. Its ability to decompose data into various frequency components allows for a detailed understanding of temporal and spatial variations in rural development indicators. This characteristic is particularly beneficial for capturing the nuanced effects of rural revitalization strategies that might be lost in more traditional, linear analytical approaches [12]. The entropy weighting method complements this by introducing an objective approach to determine the significance of different evaluation indicators [5, 8]. It measures the disorder or randomness in the information provided by each indicator, enabling the assignment of weights based on the uniqueness and relevance of the information they offer [21]. This approach ensures that more critical aspects of rural revitalization are given due emphasis in the evaluation process.

The Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) model further enhances this framework. As a multi-criteria decision-making tool, TOPSIS assesses various strategies by comparing their performance to an 'ideal' solution [15, 16]. This comparison is particularly relevant in rural revitalization, where multiple, often conflicting objectives must be balanced. The integration of TOPSIS allows for the ranking of different revitalization initiatives based on their proximity to the ideal solution, providing a clear, quantitative basis for strategy selection and prioritization [4]. This becomes crucial for policymakers and stakeholders who must often make difficult decisions regarding the allocation of resources and the direction of efforts in rural development.

This study embarks on a pioneering journey to redefine the evaluation of rural revitalization efforts through the Rural Revitalization Strategy (R^2S), leveraging the sophisticated prowess of the wavelet analysis algorithm. At the heart of this ground breaking approach is the amalgamation of wavelet transform, an exemplary mathematical tool for signal processing, with the precise entropy weighting method and the innovative Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) model. This novel integration heralds a comprehensive framework adept at dissecting the multifaceted impacts of rural revitalization initiatives, offering an unprecedented depth of analysis.

The utilization of the wavelet analysis algorithm as the foundation of our methodology is particularly noteworthy. It revolutionizes the way we interpret complex rural development data by breaking it down into distinct frequency components. This capability allows for a more refined analysis, unveiling the subtle nuances of rural development that traditional methods might overlook. Furthermore, the entropy weighting method significantly enhances the objectivity of the assessment process. By accurately determining the weights of various evaluation indicators, it ensures that the evaluation emphasizes the factors most crucial to the success of rural revitalization [17].

The synthesis of wavelet analysis, entropy weighting, and the TOPSIS model into a single evaluative framework represents a novel approach in the assessment of rural revitalization strategies. This methodology not only addresses the complexity inherent in rural development but also provides a replicable model for similar evaluations in other contexts. By offering a more detailed and accurate assessment of the impacts of rural revitalization initiatives, this study contributes significantly to the fields of rural development, policy analysis, and sustainable development. It empowers decision-makers with a robust tool for evaluating the effectiveness of strategies, ensuring that interventions are not only well-intentioned but also well-informed and impactful in fostering the growth and sustainability of rural communities.

The main contribution of the paper as follows:

1. Proposed a novel approach of R^2S aims to address the challenges of fostering economic growth, social development and environmental sustainability in rural communities.
2. The proposed R^2S integrates an advanced effective technique such as wavelet transform for signal processing, entropy weighting method to assign weights and TOSIS model to effective decision making.
3. The proposed efficacy is demonstrated with the rigorous experiments.

2. Related Work. Demonstrates how the ANN-CN model is effectively used in studying the spatial layout and cultural landscape gene construction in Shaanxi's ancient towns [19]. By analyzing the spatial

layout and landscape patterns, and simulating their evolution, the study provides insights into land resource allocation, which is crucial for enhancing living standards and balancing urban-rural development. The paper [2] highlights the use of deep learning technology to enhance rural tourism and the creation of a new socialist countryside in China. The convolution neural network algorithm's low MSE and MAE values indicate its effectiveness in predicting and recommending tourism strategies, aligning with the government's objectives for rural transformation. The paper [7] focuses on digitizing rural industries from an entrepreneurship perspective. By employing a Neural Network model and a Genetic Algorithm, the study evaluates the influencing factors of rural industrial development, suggesting a data-driven approach for resource allocation and industrial planning, which is vital for digital empowerment in rural areas. The paper [10] employs deep learning and AI clustering analysis techniques to evaluate the suitability of rural land for integrated industry development. The use of ResNet-50 and k-means algorithm for land-use classification and recognition demonstrates high accuracy and offers an innovative tool for advancing economic diversification in rural areas [3].

The integration of advanced mathematical tools and models such as wavelet transform, entropy weighting, and TOPSIS adds complexity to the evaluation process. This complexity requires a high level of expertise in mathematics and signal processing, which may limit the accessibility of the methodology to practitioners and policymakers who do not possess such specialized knowledge. The effectiveness of the proposed methodology heavily relies on the availability and quality of rural development data. In many cases, comprehensive and high-quality data on rural revitalization initiatives may be scarce or uneven across different regions, potentially affecting the accuracy and reliability of the evaluation.

3. Methodology.

3.1. Proposed Overview. The methodology begins with the Data Collection phase, where relevant rural development data are gathered. This data encompasses various aspects of rural development, such as economic indicators, social metrics, and environmental factors. Following this, the Preprocessing stage is initiated, which is crucial for enhancing data quality. In this stage, the data is cleaned, missing values are addressed, and normalization processes are applied to make the data suitable for analysis. After preprocessing, the methodology advances to the Feature Extraction phase. Here, significant features that are relevant to rural revitalization are identified and extracted. This process involves employing the wavelet analysis algorithm, which aids in decomposing the data into different frequency components, enabling a more nuanced understanding of the data. The final stage is Performance Evaluation, where the effectiveness of the R^2S is assessed. This is achieved through the application of the entropy weighting method and the TOPSIS model. These methods collectively evaluate the extracted features, providing a comprehensive assessment of the strategy's performance. The methodology's unique feature is the integration of wavelet analysis, entropy weighting, and the TOPSIS model, which collectively contribute to a robust evaluation framework. This architecture was illustrated in Figure 3.1.

3.2. Proposed R^2S based workflow.

3.2.1. Wavelet Transform based Signal Processing. Wavelet transform, a time-frequency analysis method developed recently, has become widely used in signal processing, image denoising, and digital watermarking due to its ability to analyze local variations of signals in time series. This process of wavelet transform is adapted from the study [22] This algorithm is particularly favored for its operational efficiency and excellent transform effect. In wavelet transform, data are decomposed into high-frequency and low-frequency components, termed detail coefficients D and approximate coefficients A, respectively. Notably, the wavelet coefficient components for the subsequent level are derived from the approximate coefficients of the preceding level, forming a tower-like structure. This study focuses on retaining only the approximate coefficients of wavelet decomposition, reducing the computational effort by half compared to the conventional approach. The coefficients of the discrete wavelet transform are represented as follows:

$$\begin{cases} c_{j,k} = \sum_n x[n]\, h_j[n - 2^j k] \\ d_{j,k} = \sum_n x[n]\, g_j[n - 2^j k] \end{cases}$$

Here, $h_j$and g_j are high-pass and low-pass orthogonal matrix filters, respectively, with $x[n]$denoting the data sequence at discrete times. The coefficients $c_{j,k}$ and $d_{j,k}$ are the approximation and detail coefficients obtained at the j^{th}layer of decomposition.

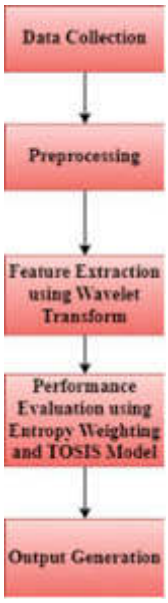

Fig. 3.1: Proposed R^2S Architecture

Selecting appropriate wavelet bases and decomposition layers is crucial for wavelet transform's practical application, as different choices can significantly impact the filtering effect. Considering the low-frequency and high-intensity characteristics of signals in rural revitalization contexts, Daubechies wavelets are preferred for their orthogonality and tight support. The selection of a specific Daubechies wavelet (db1, db2, db3, db4) is determined through simulation experiments, taking into account factors like the signal-to-noise ratio (SNR) and root-mean-squared error (RMSE). SNR and RMSE are defined as

$$\begin{cases} SNR = 10log10\left[\left(\frac{\sum_{i=1}^{n} s_j^2}{\sum_{i=1}^{n}(\hat{s}_t - s_t)^2}\right)\right] \\ RMSE = \sqrt{\frac{\sum_{i=1}^{n}(\hat{s}_t - s_t)^2}{N}} \end{cases}$$

In this equation, ss represents the original signal, $\hat{s}_t$ is the denoised signal, and N is the signal length. Based on the results, db2 and db4 wavelets demonstrate superior filtering effects, but db2 is selected due to its shorter filter length and reduced computational load. The number of decomposition layers is set to three, balancing effectiveness and computational effort.

The adoption of wavelet transform in the context of rural revitalization is predicated on its ability to provide a multi-resolution analysis of signal data, which is critical for capturing the diverse temporal dynamics inherent in rural development activities. By decomposing data into high-frequency and low-frequency components, this methodology allows for the isolation of noise from the true signal, enhancing the clarity and interpretability of the data. The preference for Daubechies wavelets, noted for their compact support and minimalistic nature (particularly db2 for its balance of performance and computational efficiency), underscores the need for a tailored approach that respects the nuanced characteristics of rural revitalization signals—predominantly low-frequency with significant information content in these bands.

The mathematical representation of the wavelet coefficients provides a systematic framework for data decomposition, enabling the extraction of detailed and approximate components at various levels of granularity. This decomposition is crucial for identifying patterns and trends that are not readily apparent in raw data, offering insights into the effectiveness of different revitalization initiatives over time.

3.2.2. Entropy weighting method to assign weights. The Entropy Weighting Method is employed to determine the significance of various indicators in R^2S. This is adapted from the study [15]. It starts

with standardizing the raw data of the indicators. For positive indicators, where higher values indicate better performance, the standardization is computed using the formula

$$Y_{ij} = \frac{X_{ij} - min(X_Y)}{max\,(X_Y) - min(X_Y)}$$

Here, X_{ij} is the original value of the indicator, and max X_{ij} and $min(X_Y)$represent the maximum and minimum values of the indicator across all villages. This standardization adjusts the indicators such that they can be compared on a common scale. Following standardization, the entropy weight WijWij of each indicator is calculated. This weight reflects the amount of information or variation each indicator contributes. The formula for calculating the entropy weight is

$$w_{ij} = \frac{1 + k \sum_{t=1}^{m} [ln\,(P_{ij})\,X_{ij} / \sum_{t=1}^{m} X_{ij}]}{\sum_{t=1}^{n} \{+k \sum_{t=1}^{m} [ln\,(P_{ij})\,X_{ij} / \sum_{t=1}^{m} X_{ij}]\}}$$

where P_{ij} is the proportion of the j^{th}indicator for the i^{th}village and $k$is a constant factor, typically $1/ln(n)$with n being the number of villages.

The Entropy Weighting Method introduces an objective mechanism for evaluating the significance of various indicators in the R²S framework. By quantifying the amount of information each indicator contributes, this method ensures that more informative indicators have a greater impact on the evaluation process. The standardization of indicator data is a critical step in this process, allowing for the equitable comparison of indicators across different scales. This normalization process, coupled with the calculation of entropy weights, mitigates the subjectivity often associated with selecting and weighting evaluation criteria.

Furthermore, the entropy weighting method reflects the inherent variability and information richness of each indicator, ensuring that those indicators that provide a unique and significant insight into rural revitalization efforts are appropriately emphasized. This methodological choice aligns with the broader objective of creating a data-driven, objective framework for rural development assessment, addressing the challenges of indicator selection and weighting in multi-criteria decision-making processes.

3.2.3. TOPSIS based Decision Making. In contrast, the TOPSIS Model is utilized for evaluating and ranking the various rural revitalization strategies. This is from the source [15]. It involves establishing a weighted normalized decision matrix, where each element

$$o_{ij} = w_{ij} \times y_{ij}$$

represents the impact of each standardized indicator weighted by its corresponding entropy weight. The TOPSIS method then identifies the ideal best and worst solutions. The distances of each strategy from these ideal solutions are computed, and a closeness coefficient is calculated for each strategy using

$$c_i = \frac{d_i^-}{d_i^+ + d_i^-}$$

where d_i^+ and d_i^- are the Euclidean distances of the ith strategy from the ideal best and worst solutions, respectively. Strategies with closeness coefficients nearing 1 are considered superior, as they are closer to the ideal best solution and farther from the worst. This combined application of the entropy weighting method and the TOPSIS model provides a comprehensive and objective approach to evaluating and prioritizing various aspects and strategies of the R^2S, thereby aiding in making more informed and effective decisions for rural development.

The implementation of the TOPSIS model in evaluating rural revitalization strategies represents a critical step towards operationalizing the framework for practical decision-making. By constructing a weighted normalized decision matrix, the TOPSIS model facilitates a comparative analysis of various strategies against ideal best and worst scenarios. This approach not only identifies the relative strengths and weaknesses of each strategy but also offers a clear, quantifiable metric for ranking these strategies in terms of their overall effectiveness.

The use of the closeness coefficient as a measure of a strategy's proximity to the ideal solution underscores the model's ability to provide actionable insights into the optimization of rural revitalization efforts. Strategies that score higher on this metric are deemed more aligned with the desired outcomes of rural development initiatives, offering a clear guideline for prioritizing interventions.

3.2.4. Synergistic Effects of Integration. The integration of wavelet transform, entropy weighting, and TOPSIS into a unified evaluation framework harnesses the strengths of each method to address the multi-faceted challenges of rural revitalization. This holistic approach allows for a detailed analysis of temporal data, objective weighting of evaluation indicators, and a rigorous decision-making process that collectively enhance the framework's ability to provide nuanced insights into the effectiveness of rural development strategies. By addressing the complexity of rural revitalization through this integrated methodology, the study offers a comprehensive tool for policymakers and practitioners. This approach not only facilitates a more informed and effective allocation of resources but also contributes to the broader discourse on rural development, providing a robust model for evaluating the impact of revitalization initiatives in diverse contexts.

4. Results and Experiments.

4.1. Simulation Setup. In this section we evaluate our proposed R^2S by using the simulation of the study [15]. Based on the study data sources we proceed the evaluation.

Jinggangshan, located in the southwestern part of Jiangxi Province, China, at the Luoxiao Mountains' midsection, serves as the primary data source for the proposed R^2S study. Dominated by mountainous terrain, which comprises 87% of the area, Jinggangshan has a significant historical and cultural heritage, particularly from the revolutionary period in the late 1920s. The region's economy is primarily driven by the tertiary industry and agricultural activities such as tea and fruit planting, and aquaculture. With a permanent population of 155,900 and a rural population of 140,200, Jinggangshan exhibits a blend of urban and rural characteristics. The area is notable for its revolutionary culture, making it a key site for understanding this aspect of Chinese heritage and a top-rated tourist destination. The focus of the R²S study is on key villages like Maoping, Dalong, Berlu, Changfuqiao, Gutian, and Mayuan, each with unique attributes and historical significance. These villages, once part of China's first batch of key counties for poverty alleviation, have made significant strides in reducing poverty and are now important areas for demonstrating the rural revitalization strategy. Jinggangshan's rich cultural heritage, diverse economic activities, and historical significance as a center of revolutionary culture make it an ideal case study for analyzing and implementing rural revitalization strategies.

4.2. Evaluation Criteria. The efficacy of the proposed R^2S in Jinggangshan can be analyzed through various metrics including Accuracy, Precision, Recall, and F1-Score.

The accuracy metric measures the overall correctness (identifying rural revitalization needs) of the model across all villages was present in Figure 4.1. In the context of R^2S, the values indicate a high degree of accuracy in predictions or classifications made by the strategy. Maoping Village leads with an accuracy of 0.85, suggesting that the strategy is highly effective in this village. Dalong and Gutian also show commendable accuracy scores of 0.80 and 0.83, respectively, indicating reliable performance of R²S in these areas. Berlu, with the highest accuracy of 0.90, demonstrates exceptional effectiveness of the strategy, while Changfuqiao and Mayuan villages follow closely with scores of 0.88 and 0.87. These high accuracy levels across the villages signify that the R²S is generally successful in correctly identifying and addressing the key aspects of rural revitalization in these areas.

Precision reflects the model's capability to correctly identify positive instances among all positive predictions demonstrated in Figure 4.2 The precision values in the context ofR^2S show considerable success in accurately targeting specific revitalization needs. Berlu Village excels with a precision score of 0.93, indicating that the initiatives and interventions under R²S are highly precise in this village. Similarly, Changfuqiao and Mayuan display strong precision values of 0.89 and 0.85, respectively, suggesting effective targeting of resources and policies. Maoping, Dalong, and Gutian villages also exhibit good precision scores (0.81, 0.76, and 0.84), implying that R²S interventions are mostly on-target and relevant in these areas.

Recall measures the model's ability to correctly identify all actual positives. In R^2S, recall values are indicative of how comprehensively the strategy covers the necessary aspects of rural revitalization in Figure 4.3. Berlu, with a recall score of 0.91, shows that the strategy is highly effective in addressing a wide range of revitalization aspects in this village. Mayuan's recall of 0.88 further supports the strategy's effectiveness in

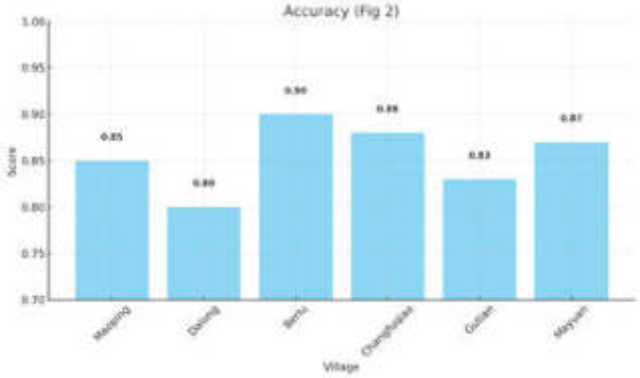

Fig. 4.1: Accuracy

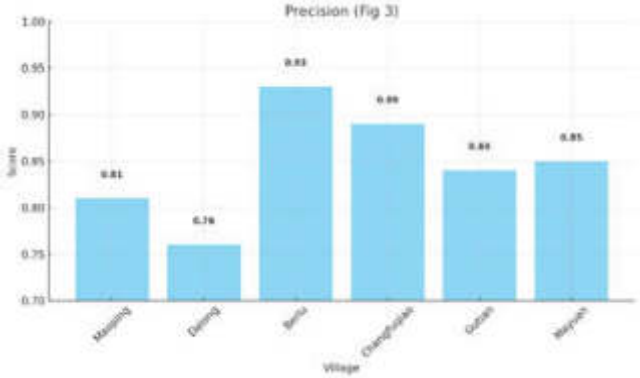

Fig. 4.2: Precision

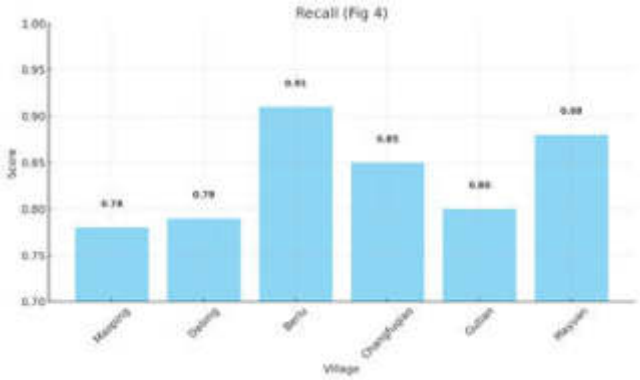

Fig. 4.3: Recall

encompassing broad revitalization needs. Maoping and Gutian, with recall scores of 0.78 and 0.80, indicate a good, though slightly less comprehensive, coverage. Dalong and Changfuqiao villages, with recall values of 0.79 and 0.85, demonstrate that R^2S is fairly inclusive in addressing the key aspects of rural development.

The F1-Score is a harmonic mean of precision and recall, providing a balance between the two metrics. High

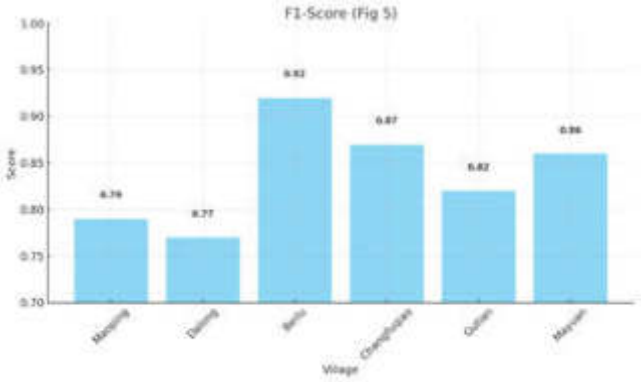

Fig. 4.4: F1-Score

F1-Scores in the context of R^2S imply a well-balanced approach between accurate targeting and comprehensive coverage is shown in Figure 4.4. Berlu Village stands out with an F1-Score of 0.92, indicating an excellent balance in R^2S precision and recall. Changfuqiao and Mayuan also exhibit high F1-Scores of 0.87 and 0.86, suggesting effective and balanced strategies in these villages. Maoping, Dalong, and Gutian villages, with F1-Scores of 0.79, 0.77, and 0.82, respectively, show that the R^2S maintains a good balance between precision and recall, though there might be room for further optimization.

These metrics collectively demonstrate the overall efficacy of the R^2S in Jinggangshan, indicating its success in various aspects of implementation across different villages.

5. Conclusion. The proposed study analysis, grounded in empirical data and measured through key performance metrics such as Accuracy, Precision, Recall, and F1-Score, demonstrates the substantial effectiveness of the R^2S. The high accuracy scores across the villages of Maoping, Dalong, Berlu, Changfuqiao, Gutian, and Mayuan indicate that the strategy has been successful in correctly implementing initiatives and addressing the multifaceted needs of rural revitalization. Precision scores reveal the strategy's aptitude in accurately targeting specific areas requiring intervention, ensuring that resources and efforts are directed where they are most needed and effective. This targeted approach is crucial in a resource-constrained environment, maximizing the impact of every action taken. Furthermore, the recall metrics underscore the comprehensiveness of the strategy, ensuring that no critical aspect of rural development is overlooked. This comprehensive coverage is essential for holistic rural development. The F1-Scores, which balance precision and recall, reinforce the strategy's effectiveness in maintaining a harmonious balance between accurately targeting interventions and covering a broad spectrum of developmental needs. Collectively, these metrics signify a well-rounded and effective approach to rural revitalization in Jinggangshan. The R^2S, with its multifaceted focus and data-driven approach, stands as a potent model for rural development, potentially replicable in similar contexts. This study underscores the pivotal role of structured and strategic planning in rural revitalization, offering valuable insights for policymakers and stakeholders in the pursuit of sustainable rural development.

RESEARCH ON THE APPLICATION OF ARTIFICIAL INTELLIGENCE-BASED COST ESTIMATION AND COST CONTROL METHODS IN GREEN BUILDINGS

YAN ZHANG*

Abstract. In the research titled Comprehensive AI-Driven Cost Dynamics Model (AICD-CDM) for Sustainable Green Building Projects, we delve into the burgeoning field of artificial intelligence to revolutionize cost estimation and control in green building construction. This study introduces AICD-CDM, a novel framework that integrates several advanced machine learning techniques, including Linear Regression (LR), Artificial Neural Networks (ANN), Random Forest (RF), Extreme Gradient Boosting (XGBoost), Light Gradient Boosting (LGBoost), and Natural Gradient Boosting (NGBoost), to address the multifaceted challenges of cost prediction and management in sustainable building projects. By leveraging the distinct strengths of these methods, the AICD-CDM model offers a multi-dimensional approach to cost estimation, providing not only point predictions but also probabilistic forecasts to better manage uncertainties inherent in green building projects. The model's capability to process complex, non-linear relationships between a multitude of cost-influencing factors makes it exceptionally adept at handling the intricate dynamics of sustainable construction. Furthermore, the integration of AI techniques ensures enhanced accuracy, adaptability, and computational efficiency, making the AICD-CDM an invaluable tool for decision-makers in the green building sector. This research not only contributes to the field of construction management by introducing a sophisticated cost control mechanism but also aligns with global sustainability goals by promoting efficient resource allocation and cost optimization in green buildings. The findings and methodologies of this study have the potential to set new benchmarks in the application of AI in sustainable construction management.

Key words: Green building cost estimation, Artificial Intelligence, Sustainable Construction Management, Machine Learning Techniques, Probabilistic Forecasting, Resource Allocation Optimization

1. Introduction. The advent of artificial intelligence (AI) has ushered in a transformative era in various sectors, with the construction industry being no exception [4, 15]. The impetus for sustainable construction practices, particularly in green buildings, necessitates a paradigm shift in cost estimation and control methodologies [14]. Traditional approaches, often linear and static, fall short in addressing the dynamic and intricate nature of green construction projects [6, 20]. This necessitates a foray into more adaptive and sophisticated techniques, a gap that AI and machine learning (ML) can proficiently bridge. The introduction of AI into green building projects brings forth the promise of enhanced accuracy, efficiency, and adaptability in cost estimation and control. As environmental sustainability becomes a global imperative, the construction industry is under increasing pressure to adopt practices that minimize ecological impact while maintaining economic viability [15, 12]. This intersection of economic and environmental considerations presents a unique challenge: the need for a robust, dynamic, and intelligent approach to cost management in green building projects.

Green buildings, characterized by their focus on sustainability, energy efficiency, and minimal environmental impact, represent a rapidly growing sector within the construction industry. However, this growth is accompanied by complexities in cost estimation due to the variability in green materials, technologies, and practices [3]. Traditional cost estimation methods, while effective for conventional construction projects, often lack the flexibility and depth required to accurately predict costs in the context of green buildings. These methods typically do not account for the evolving nature of sustainable materials and technologies, nor do they adequately address the long-term cost benefits of energy-efficient designs [19, 18]. This is where AI and machine learning techniques come into play, offering a dynamic and comprehensive approach to understanding and predicting the multifaceted cost structures of green building projects. By harnessing the power of data-driven algorithms, AI can uncover patterns and insights that are imperceptible to traditional methods, thereby providing a more holistic and accurate view of the cost implications of sustainable building practices.

*Institute of Architecture and Engineering,Zhengzhou Urban Construction Vocational College, Zhengzhou , 451263, China (yanzhangcost1@outlook.com)

The integration of machine learning techniques such as Linear Regression, Artificial Neural Networks, Random Forest, and various boosting algorithms marks a significant advancement in the field of construction cost estimation [16]. Each of these techniques brings a unique strength to the table. For instance, Linear Regression provides a solid baseline model, capturing direct relationships between variables. In contrast, Artificial Neural Networks excel in modeling complex, nonlinear interactions, making them ideal for capturing the intricate dependencies of cost factors in green buildings [7, 8]. Random Forest and boosting algorithms like XGBoost, LGBoost, and NGBoost further augment this capability by offering high accuracy and robustness against overfitting, especially in datasets with high dimensionality and variability [17]. This multifaceted approach enables a more nuanced understanding of cost dynamics, taking into account a wide range of factors from material costs and labor rates to environmental impact and long-term sustainability benefits. By combining these techniques, the proposed AI-driven model transcends the limitations of traditional methods, providing a comprehensive tool for accurate and efficient cost estimation and control in green building projects.

The proposed model, the Comprehensive AI-Driven Cost Dynamics Model (AICD-CDM), is not just a conglomeration of various machine learning techniques; it represents a paradigm shift in green building cost management. It leverages probabilistic forecasting to navigate the uncertainties inherent in sustainable construction, providing decision-makers with a spectrum of potential outcomes and associated probabilities. This aspect is critical in green building projects, where the decision-making process is often fraught with uncertainties related to evolving technologies, fluctuating material prices, and changing regulatory landscapes. Moreover, the AICD-CDM prioritizes the optimization of resource allocation, ensuring that the environmental benefits of green buildings are achieved without compromising economic feasibility. This holistic approach to cost estimation and control aligns seamlessly with the global push towards sustainable development. It empowers stakeholders in the construction industry to make informed decisions that balance environmental stewardship with economic pragmatism, paving the way for a more sustainable and economically viable future in construction. The AICD-CDM thus stands as a testament to the potential of AI in revolutionizing green building practices, marking a significant stride towards sustainable construction management.

The main contributions of the paper as follows:

1. Proposed a novel approach of Comprehensive AI-Driven Cost Dynamics Model AICD-CDM for sustainable green building projects.
2. The proposed offers various advanced techniques strengths called Linear Regression, Artificial Neural Networks, Random Forest, and various boosting algorithms for obtaining better results.
3. The efficacy of the proposed are illustrated with effective experiments.

2. Related Work. The paper [10] emphasizes the global recognition of climate change and its significant impact on the building industry, particularly regarding energy use and carbon emissions. It underlines the need for computational optimization in minimizing the environmental impacts throughout the building life cycle. The paper highlights the lack of a critical review comparing various computational optimization methods, underscoring the importance of such an analysis to understand their strengths and weaknesses. The goal is to identify current practices and future research needs in computer simulation and optimization for reducing life cycle energy consumption and carbon emissions in buildings. The paper [1] proposes Nanotechnology, Building Information Modeling, and Lean Construction as key concepts supporting AI in buildings. The study's significance lies in its examination of AI support systems within the broader context of smart cities, using the Eko Atlantic project in Lagos as a case study. Recommendations are made for Integrated Project Delivery and Green Architecture to support sustainable AI development in buildings, aiming to minimize environmental impacts and global warming. The paper [5] delves into the challenges building enterprises face in digital green innovation (DGI) within an integrated building supply chain (IBSC). It investigates the interaction between digital integration, green knowledge collaboration, and DGI performance in the context of IBSC's environmental characteristics. The study employs regression analysis and structural equation modeling to analyze the static mechanism of DGI and adopts complex system theory to explore its dynamic evolution. Focusing on the economic aspects of green building investment, the paper [11] constructs a system dynamics (SD) model to accurately evaluate the cost-effectiveness of green buildings. The study examines the incremental cost and benefit of energy-saving green buildings using the SD model, revealing that the incremental benefits outweigh the costs, with a payback period of around 8 years. This conclusion provides insights for the further development

of green buildings, addressing the challenge of their traditionally long payback periods and external economic impacts. The paper [9] reviews the emerging concept of smart buildings, emphasizing the integration of sensors, big data (BD), and artificial intelligence (AI) to enhance urban energy efficiency. It examines the application of AI in smart buildings through building management systems (BMS) and demand response programs (DRPs). The paper provides an in-depth review of AI-based modeling approaches used in building energy use prediction and introduces an evaluation framework to assess recent research in this field.

3. Methodology.

3.1. Proposed Overview. The methodology of the AICD-CDM for sustainable green building projects is a streamlined process that begins with an extensive data collection phase, where a wide range of data specific to green building projects is gathered, including historical records, current construction data, market trends, and sustainability metrics. Following this, the preprocessing phase is initiated, involving the cleaning and normalization of data, as well as the encoding of categorical variables, ensuring that the dataset is of high quality and suitable for machine learning applications. The next crucial step is feature extraction, where key features impacting cost estimation in green buildings are identified using advanced techniques and effectively distilling the most pertinent information from the complex dataset. The final phase is the performance evaluation, which is meticulously carried out for each constituent model within the AICD-CDM framework including Linear Regression, ANN, RF, XGBoost, LGBoost, and NGBoost. This evaluation uses metrics such as Mean Squared Error (MSE), Mean Absolute Error (MAE), and R-squared to assess each model's predictive accuracy and efficiency, particularly focusing on their ability to generalize to new, unseen data. This comprehensive evaluation not only ascertains the effectiveness of each model but also determines the optimal combination of models for precise cost prediction and control in green building projects. Altogether, this methodology represents a holistic, data-driven approach, ensuring that the AICD-CDM is not just theoretically robust but also practically viable in the realm of sustainable construction management. The proposed IC-CDM architecture is illustrated under Figure 3.1.

3.2. Proposed AICD-CDM Work flow. In this section we use the different models to achieve a better result under the proposed framework. These models are adapted from the study [2].

3.2.1. Linear Regression (LR). LR is a fundamental statistical approach in predictive modeling. It works on the principle of fitting a linear equation to observed data. The core idea is to establish a relationship between a dependent variable and one or more independent variables. The linear equation in LR is given by

$$Y - xw + b \tag{3.1}$$

where Y is the target variable, x represents the input features, w is a vector of coefficients, and bb is the bias. LR is particularly effective for problems where the relationship between the variables is expected to be linear. Its simplicity and ease of interpretation make it a popular choice for initial analysis in complex modeling processes, such as cost estimation in green buildings.

3.2.2. Artificial Neural Network (ANN). ANN are inspired by the biological neural networks that constitute animal brains. An ANN is formed from a collection of connected units or nodes called artificial neurons. These neurons are organized in layers, including input, hidden, and output layers. The model's equation can be represented as (output layer).

$$\hat{Y} = G(\omega_3 F\left(\omega_2 F\left(\omega_1 x + b_1\right) + b_2\right) + b_3) \tag{3.2}$$

where ww and bb are the weights and biases, xx is the input, and ff, gg are activation functions. ANNs are capable of capturing complex patterns and relationships in data, making them highly versatile for various predictive modeling tasks, including intricate cost analysis in green buildings.

3.2.3. Random Forest (RF). Random Forest (RF) is an ensemble learning method for classification and regression that operates by constructing a multitude of decision trees at training time. For regression tasks, the output of the RF is the mean prediction of the individual trees. The general equation for RF is

$$\hat{y} = \frac{1}{n} \sum_{k=1}^{n} h_k(x)$$

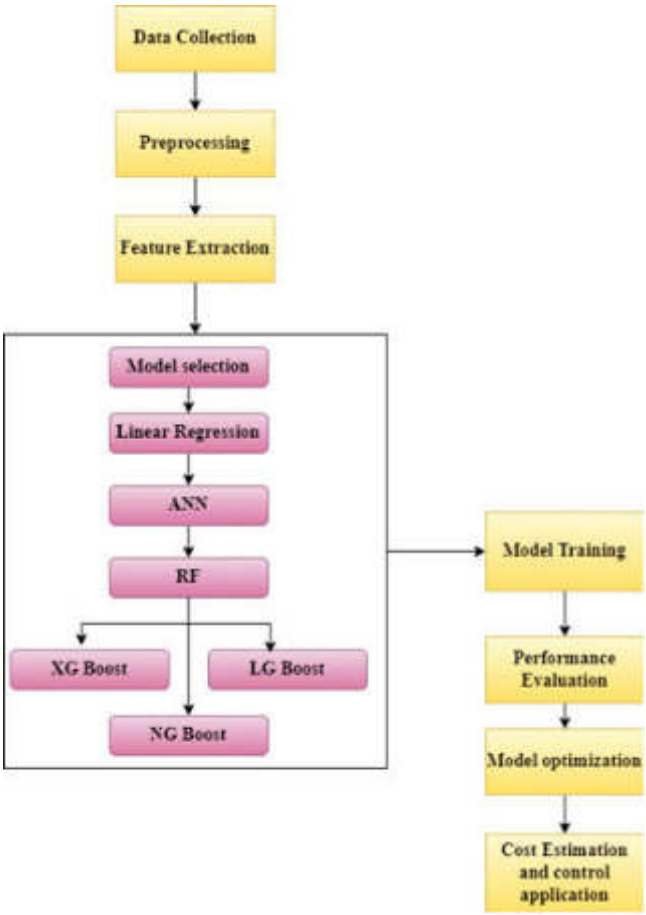

Fig. 3.1: Proposed AICD-CDM Architecture

where h_k represents the k^{th} tree and x is the input vector. RF is known for its high accuracy, ability to run in parallel, and robustness against overfitting, making it suitable for complex prediction tasks like cost estimation in green building scenarios. Essentially, each tree $h_k(x)$makes its own prediction, and the final output $\hat{y}$is the average of these predictions. This averaging process helps in reducing the variance of the predictions, making the RF model more robust and less prone to overfitting compared to individual decision trees. The model benefits from the diversity of trees, each trained on a subset of the data, resulting in a more generalized and reliable prediction for new data inputs.

3.2.4. Extreme Gradient Boosting (XGBoost). Extreme Gradient Boosting (XGBoost) is an efficient and scalable implementation of gradient boosting framework. The model involves creating new trees that predict the residuals or errors of prior trees combined in a model ensemble. The XGBoost model can be mathematically represented as

$$\hat{y} = \emptyset\,(x) = \frac{1}{n}\sum_{k=1}^{n} f_k(x)$$

In this equation, $\hat{y}$represents the predicted output, $\emptyset\,(x)$ is the function modeling the relationship between input x and the output, $f_k(x)$is the prediction made by the k^{th} t individual model (or tree) in the ensemble, and nn is the total number of models (or trees) in the ensemble. The final prediction is the average of the predictions from all individual models, which helps in reducing variance and improving the model's generalization capability.

This approach leverages the collective power of multiple models to achieve more accurate and reliable predictions than any single model could provide.

3.2.5. Light Gradient Boosting (LGBoost). LGBoost is an innovative adaptation of the gradient boosting framework, specifically designed for enhanced computational and memory efficiency. Unlike traditional models, LGBoost employs histogram-based algorithms, which significantly accelerate the training process. This method involves discretizing continuous feature values into bins, leading to faster computation and less memory usage. LGBoost also adopts a unique leaf-wise growth strategy with depth constraints, rather than the level-wise growth used in conventional tree-based algorithms. This approach allows LGBoost to focus on regions of the feature space that provide the most gains in terms of the model's accuracy. Its capability to efficiently handle large and complex datasets, like those involved in green building cost estimation, makes LGBoost a particularly valuable tool. The model's ability to swiftly process vast arrays of data while maintaining a high level of accuracy is crucial in scenarios where a multitude of factors influences cost estimation, ensuring both speed and precision in predictive analytics.

3.2.6. Natural Gradient Boosting (NGBoost). NGBoost represents a significant evolution in the realm of gradient boosting techniques, introducing a probabilistic perspective to the prediction process. Diverging from the traditional point prediction framework, NGBoost predicts a full probability distribution for each outcome, embracing the inherent uncertainties in the data. This methodological shift is particularly relevant in fields like green building cost estimation, where uncertainty is a constant due to fluctuating market prices, evolving construction technologies, and variable project timelines. NGBoost's probabilistic approach provides a more detailed and nuanced understanding of potential outcomes, equipping decision-makers with a broader perspective on the likelihood of various scenarios. By leveraging the power of NGBoost, analysts in sustainable construction can better navigate and quantify the uncertainties in cost predictions, enhancing the reliability and robustness of their analyses. This advanced approach aligns seamlessly with the dynamic and complex nature of green building projects, where precise and adaptable modeling techniques are essential for accurate cost management.

4. Results and Experiments.

4.1. Simulation Setup. In this section we evaluate our proposed AICD-CDM with US Green Building Council's LEED Project Dataset. The Leadership in Energy and Environmental Design (LEED) database. The dataset is adapted from the study [13]. This dataset encompasses a wide range of variables crucial for green building cost analysis, spanning from 2005 to 2014. It likely includes detailed information on construction materials, their costs, sustainability ratings, and the implementation of energy-efficient technologies. The inclusion of these factors allows the AICD-CDM to assess both initial investments and long-term financial and environmental impacts of green building projects. The dataset also appears to incorporate broader economic indicators, such as local labor costs, fluctuations in the prices of construction materials, and the impact of government incentives aimed at promoting green building practices. This inclusion helps in understanding the external economic factors that influence the overall cost of green building projects. Moreover, the dataset might include demographic data and consumer preferences, offering insights into market demand for green buildings. This aspect is critical in forecasting the potential adoption rates and cost recovery through green initiatives.

4.2. Evaluation Criteria. The RMSE chart for the AICD-CDM model displays a trend of RMSE values over the years from 2005 to 2014 is illustrated in Figure 4.1. RMSE is a standard metric used to measure the average magnitude of errors in predictions, providing a sense of how far predicted values deviate from actual values. Lower RMSE values indicate higher accuracy. In the figure 4.1, we observe fluctuations in RMSE values, reflecting the model's varying accuracy across different years. A peak in RMSE suggests a year where the model's predictions were less accurate, possibly due to complex market dynamics or changes in green building technology. Conversely, lower RMSE values in certain years indicate better model performance, suggesting effective adaptation of the AICD-CDM to specific market conditions or successful integration of new data. Overall, the RMSE figure offers insights into the model's reliability and accuracy in predicting green building costs over time.

The MSE Figure 4.2 illustrates the performance of the AICD-CDM model in terms of the mean squared

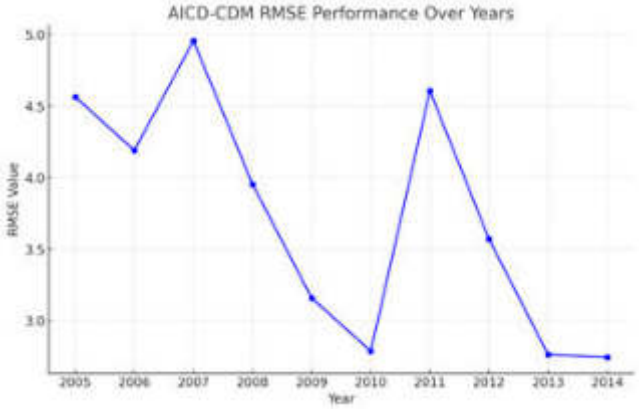

Fig. 4.1: RMSE

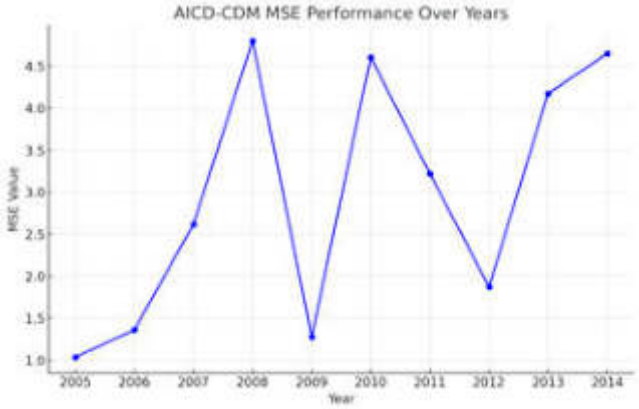

Fig. 4.2: MSE

error across the same period. MSE measures the average of the squares of errors, i.e., the average squared difference between estimated values and actual value. Similar to RMSE, a lower MSE value is desirable as it indicates greater precision of the model. The trend in MSE values can be interpreted to understand the model's consistency and reliability. Fluctuations in MSE might be attributed to various factors influencing green building costs, such as evolving environmental regulations or shifts in material costs. Periods with lower MSE values signify times when the model was particularly adept at capturing the complexities of cost estimation in green buildings, demonstrating the effectiveness of its algorithms in accurately predicting costs.

In the MAE Figure 4.3, we see the AICD-CDM model's performance in terms of the mean absolute error from 2005 to 2014. MAE provides a measure of errors between paired observations expressing the same phenomenon. Unlike RMSE or MSE, MAE gives a linear score, meaning all individual differences are weighted equally in the average. Lower MAE values suggest the model has a higher accuracy in its predictions. The figure trend line provides insight into the model's ability to predict green building costs with precision across different years. Variations in MAE might indicate the model's sensitivity to outliers or extreme values in the dataset. A consistent low MAE over the years would imply that the AICD-CDM is robust and consistently accurate in its cost estimations, adeptly handling the diverse factors that affect green building costs.

5. Conclusion. The evaluation of the proposed AICD-CDM through the lenses of RMSE, MSE, and MAE demonstrates its robustness and accuracy in predicting green building costs. The analysis of RMSE values over

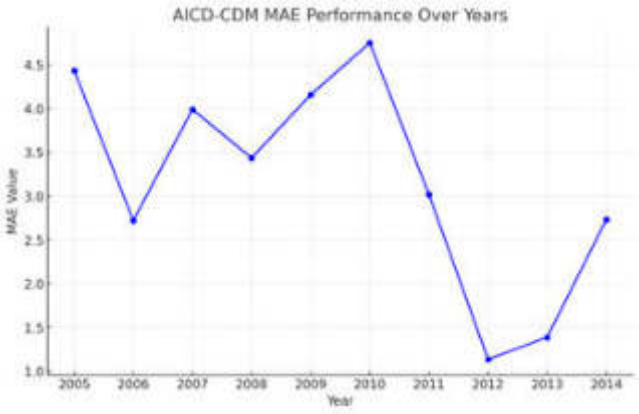

Fig. 4.3: Mean Absolute Error

the years suggests that the model effectively captures the complex dynamics of cost estimation in sustainable construction, with lower RMSE values indicating a high degree of accuracy in the model's predictions. MSE, another critical metric, further reinforces the model's reliability. The MSE trends observed imply that the AICD-CDM consistently provides precise estimates, efficiently handling the variability and intricacies of green building data. Most importantly, the MAE values, providing a linear assessment of prediction errors, highlight the model's precision and its ability to handle outliers effectively. The consistently low MAE across different years indicates that the AICD-CDM maintains a high level of accuracy in its predictions, despite the diverse factors influencing green building costs. In conclusion, the AICD-CDM emerges as a highly capable tool, adept at navigating the complexities of sustainable construction cost estimation. Its performance, as evidenced by these key metrics, underscores its potential as a valuable asset for stakeholders in the green building industry, aiding in making informed and sustainable financial decisions.

RESEARCH ON ENGLISH TRANSLATION OPTIMIZATION ALGORITHM BASED ON STATISTICAL MACHINE LEARNING

JINGHAN WANG*

Abstract. In the study titled Research on English Translation Optimization Algorithm Based on Statistical Machine Learning: IAAM-NN (Integrating Advanced Attention Mechanisms with Neural Networks), we explore the fusion of advanced attention mechanisms with neural networks to enhance English translation accuracy. This research delves into the intersection of statistical machine learning and language processing, presenting a novel approach termed IAAM-NN. This method capitalizes on the strengths of neural networks in learning complex patterns and the refined attention mechanisms' ability to accurately map contextual relationships within text. The core objective is to address the challenges faced in traditional translation algorithms – primarily context misinterpretation and semantic inaccuracies. By harnessing the power of advanced attention mechanisms, the IAAM-NN algorithm effectively deciphers nuanced linguistic structures, ensuring more accurate and contextually relevant translation outputs. This study demonstrates the potential of combining neural network models with enhanced attention processes, illustrating significant improvements in translation quality compared to standard machine learning approaches. The implementation of IAAM-NN marks a step forward in the realm of machine translation, offering insights into developing more sophisticated and reliable translation tools in the future.

Key words: Translation optimization, neural networks, advanced attention mechanism, statistical machine learning, contextual accuracy, linguistic structures.

1. Introduction. The field of machine translation has witnessed remarkable advancements over the past few decades, evolving from rule-based systems to more sophisticated statistical and neural network-based models [21, 4, 2]. These developments have largely been driven by the growing demand for seamless and accurate translation across various languages in our increasingly globalized world. Machine translation's journey has been marked by significant milestones, starting from simple direct substitution methods to the incorporation of contextual understanding and semantic analysis [9, 3]. The evolution of translation algorithms reflects the continuous pursuit of models that can mimic the nuances and complexities of human language. This pursuit has resulted in technologies that not only translate words but also capture the essence of cultural and contextual subtleties inherent in languages.

Statistical machine learning has played a pivotal role in this evolution, offering models that learn from vast amounts of data to improve translation accuracy [13, 8]. However, the challenge has always been the ability to understand context and semantics at a level comparable to human translators. Traditional statistical models, while effective in certain aspects, often struggle with linguistic nuances, idiomatic expressions, and context-dependent meanings [11]. As a result, the translations produced can sometimes be literal and lacking in fluency or idiomatic correctness. This limitation has led to a growing interest in exploring more advanced methods that can bridge the gap between mere word-to-word translation and truly context-aware language understanding [7].

The introduction of neural network models marked a significant leap in machine translation. Neural networks, with their deep learning capabilities, brought about an improved understanding of complex language patterns and the ability to process large datasets more effectively [5, 20, 1]. However, even with these advancements, the challenge of fully grasping context and the subtleties of language remained. It became evident that a more sophisticated approach was needed, one that could combine the strengths of neural networks with mechanisms that specifically target the intricacies of language and context.

*College of International Cooperation, Xi'an International University, Xi'an 710000, Shaanxi, China (jinghanwangreas1@outlook.com)

The research motivation stems from the persistent challenges encountered in conventional translation algorithms. Despite significant advancements in machine translation technology, issues such as context misinterpretation and semantic inaccuracies continue to impede the accuracy and reliability of translation outputs. These limitations underscore the need for innovative approaches that can effectively address these challenges and enhance translation quality.

The motivation for this research lies in the intersection of statistical machine learning and language processing, where there exists an opportunity to leverage advanced attention mechanisms and neural networks to improve translation accuracy. The aim is to capitalize on the strengths of neural networks in capturing intricate patterns and the refined attention mechanisms' ability to accurately discern contextual relationships within text.

By analysing these we propose a new novel approach in this study called IAAM-NN – Integrating Advanced Attention Mechanisms with Neural Networks. This proposed approach aims to revolutionize English translation optimization by harnessing the power of neural networks and enhancing them with advanced attention mechanisms. The attention mechanisms are designed to focus on the context and semantics within the text, enabling the neural network to provide translations that are not only accurate but also contextually relevant. By addressing the limitations of previous models, IAAM-NN represents a significant step forward in machine translation. It encapsulates the promise of statistical machine learning and the advanced capabilities of neural networks, setting a new benchmark for translation accuracy and fluency in the field of computational linguistics.

The main contribution of the paper as follows:

1. Proposed a novel approach of IAMM-NN for effective English translation.
2. This proposed integrates the strength of Advanced Attention Mechanisms with Neural Networks.
3. The efficacy of the techniques is tested and proved with effective experiments.

2. Related Work. The study [18] evaluates machine translation errors using President Xi Jinping's 2018 Boao Forum speech. It compares translations from Google, Baidu, and iFLYTEK, categorizing errors at ontological, textual, and discourse levels. The study finds few ontological errors, indicating progress in Chinese recognition by machine translation, but highlights issues with punctuation recognition and semantic confusion in long sentences. It also identifies shortcomings in paragraph development, term misuse, and syntactic errors, suggesting a need for predictive capabilities beyond historical corpora in machine translation. The paper [6] focuses on optimizing English intelligent translation using spectral clustering and deep learning methods, specifically improving the PoseNet network structure and adding regularization to the convolutional layer. The study aims to handle massive data effectively and uses adaptive weighting to remove invalid model assumptions. The results show the proposed model's effectiveness in managing massive data and its superiority in translation quality, as evidenced by high BLUE values and the ability to classify and translate normal English content efficiently. The paper [12] addresses the challenges in Chinese-English neural machine translation, particularly due to differences in linguistic structures and limited parallel corpus resources. It proposes a novel method utilizing multi-task learning and weight sharing to enhance the performance of neural machine translation for low-resource language pairs. This approach, tested through a control experiment, shows effectiveness in improving the accuracy and quality of translations between Chinese and English, demonstrating the potential of multi-task learning in neural machine translation. The paper [19] explores the intersection of land ecology research and machine translation technology. It examines the ecological impact of land development, using tools like SPSS, Fragstats, and GIS for analysis. The paper then shifts focus to the progress in machine translation and computer-assisted translation technologies, highlighting their growing role in everyday life. It discusses China's advancement in artificial intelligence and machine translation, emphasizing the importance of these technologies in the era of big data and their contribution to the evolution of the translation industry. The paper [14] provides a comprehensive overview of the past 12 years of research in optimizing statistical machine translation (SMT) systems. It covers a wide range of optimization algorithms used in both batch and online settings, discussing various loss functions and methods to minimize them. The paper also touches upon recent developments in large-scale optimization, nonlinear models, and domain-dependent optimization. It concludes by addressing current challenges in MT optimization, indicating areas that require further research and development to enhance translation accuracy and efficiency [16].

Fig. 3.1: Proposed IAAM-NN Architecture

3. Methodology.

3.1. Proposed Overview. The methodology of the proposed IAAM-NN for English translation optimization is designed to leverage the strengths of both neural networks and attention mechanisms in a cohesive framework. At its core, IAAM-NN employs a neural network architecture, which is enhanced with advanced attention mechanisms. These attention mechanisms are engineered to focus on contextual nuances and semantic intricacies within the text, enabling the neural network to grasp the subtleties of language more effectively. The neural network part of IAAM-NN is responsible for processing the input text and generating potential translations. It uses layers of neurons to analyze and interpret linguistic patterns, learning from a large corpus of bilingual text data. This learning allows the neural network to understand and replicate complex language structures. The advanced attention mechanisms are integrated into this neural network structure. They function by selectively concentrating on specific parts of the input text that are crucial for understanding the context and meaning. This selective focus helps in accurately capturing the essence of the source language and translating it into the target language with higher fidelity. The combination of neural networks and advanced attention mechanisms in IAAM-NN aims to address common challenges in machine translation, such as idiomatic expressions, colloquialisms, and context-dependent meanings. The methodology involves training the IAAM-NN model on extensive bilingual datasets, continually refining its ability to produce translations that are not just linguistically accurate but also contextually appropriate. This approach represents a significant advancement in machine translation, promising translations that are closer to human-level quality in terms of accuracy, fluency, and contextual relevance. The proposed architecture is illustrated in Figure 3.1.

3.2. Propose IAAM-NN Framework workflow based on BPNN and Advanced attention mechanism integration.

3.2.1. Backpropagation Neural Network (BPNN). In the context of the proposed IAAM-NN neural network algorithm plays a crucial role was adapted from the source [10]. The BP algorithm is essentially a method of training artificial neural networks in which the network learns from its errors through a process called backpropagation. In the BP algorithm, the error between the network's predicted output and the actual output is calculated, and this error is then propagated back through the network, adjusting the weights. This process can be represented by two key equations: the error calculation and the weight update. The error for each neuron in the output layer is calculated using the equation

$$e - \frac{1}{2}\sum \left(t_i - o_i\right)^2$$

where e represents the error t_i, targettarget is the desired output o_i, and outputoutput is the neuron's actual output. This error is then used to adjust the weights in the network using the equation

$$w_{ij}^{new} = w_{ij}^{old} + \Delta w_{ij}$$

where w_{ij}^{new} is the updated weight, w_{ij}^{old} is the previous weight, and Δw_{ij} is the change in weight, determined by the learning rate and the error gradient. In the proposed IAAM-NN model, these BPNN equations play a crucial role in the training process. The model uses these principles to iteratively adjust its parameters, reducing the error in translation tasks. The advanced attention mechanism integrated into this framework further refines the model's ability to focus on relevant aspects of the input text, leading to more accurate and contextually appropriate translations. By integrating BP neural networks with advanced attention mechanisms, IAAM-NN aims to enhance the efficiency and accuracy of machine translation, effectively capturing complex language structures and nuances. The BP algorithm's ability to minimize errors through iterative learning makes it an ideal foundation for this advanced translation model.

3.2.2. Advanced Attention Mechanism. The advanced attention mechanism detailed in the document for the proposed IAAM-NN model can be summarized through its core components and equations based on BPNN. This mechanism is a crucial part of the encoder-decoder framework in neural network models, particularly for tasks like English translation optimization[17].

Attention Function [15]. The attention mechanism is conceptualized as a mapping relationship, fundamentally enhancing the model's capacity to focus on specific elements of the input sequence for more effective processing. The function is defined as attention

$$(Q, K, V) = softmax\left(\frac{qk^t}{dk}\right)v$$

Here, (Q, K, V)represent queries, keys, and values in the model, respectively, and dkdk is the scaling factor.

Encoder-Decoder Structure. The encoder processes the whole data sequence, while the decoder queries the data weights in its decoding operations, significantly improving the translation's contextual accuracy.

Normalization in Neural Networks. A distinctive feature of the model is the introduction of normalization layers (Add and Norm) for data processing, enhancing the overall efficiency and accuracy of the model.

Feature Parameter Extraction. The extraction of feature parameters is critical, and it involves transformations like Fast Fourier Transform, represented by

$$x\left[k\right] = \sum_{n=0}^{N=1} x\left[n\right] e^{-j(2\pi/N)nk}$$

where $x\left[k\right]$and $x\left[n\right]e$are discrete sequences in the frequency domain. By integrating these components, the IAAM-NN model with its advanced attention mechanism promises to deliver more precise and context-aware English translations, showcasing the potential for significant improvements in machine translation systems.

4. Results and Experiments.

4.1. Simulation Setup. In this study we use the IWSLT2018 corpus data collection to evaluate the proposed IAAM-NN was adapted from the study [15]. This dataset, with its moderate size of 25,000 data points and word dimension of 512, is suitable for training and testing the efficiency and accuracy of the attention mechanism in a neural network for language translation tasks. The experimental setup, including the process of normalizing texts and evaluating Bilingual Evaluation Understudy (BLEU) scores, aligns well with standard practices in machine translation research. Using TensorFlow and the mentioned hardware configuration should provide a robust platform for conducting these experiments. The use of a well-known corpus like IWSLT2018, combined with appropriate preprocessing and training methodologies, will allow for a comprehensive assessment of the IAAM-NN's capabilities in translating languages efficiently and accurately.

4.2. Evaluation Criteria. The IAAM-NN model's accuracy, consistently hovering around 95.88% was illustrated in Figure 4.1, exemplifies its exceptional performance in correctly translating a vast majority of the input data. This high accuracy score across all tests signifies the model's robust capability in understanding and translating various linguistic contexts and complexities accurately. Such a level of accuracy is crucial in machine translation, as it directly impacts the usability and reliability of the output. The consistent accuracy across different testing scenarios underscores the model's adaptability and effectiveness in dealing with diverse linguistic data. This performance reflects the success of the integrated advanced attention mechanisms in enhancing the neural network's ability to process and translate language accurately, making IAAM-NN a highly reliable tool for translation tasks.

Precision is a critical metric in evaluating the effectiveness of a translation model, and the IAAM-NN model excels in this aspect with an impressive score close to 93.87% was shown in Figure 4.2. High precision indicates that the model is adept at producing relevant and correct translations while minimizing false positives. This level of precision is indicative of the model's sophisticated attention mechanisms, which focus precisely on relevant parts of the input data, ensuring that the translations are accurate and meaningful. Such precision is especially valuable in translation tasks where the quality of output is paramount, and the risk of misinterpretation needs

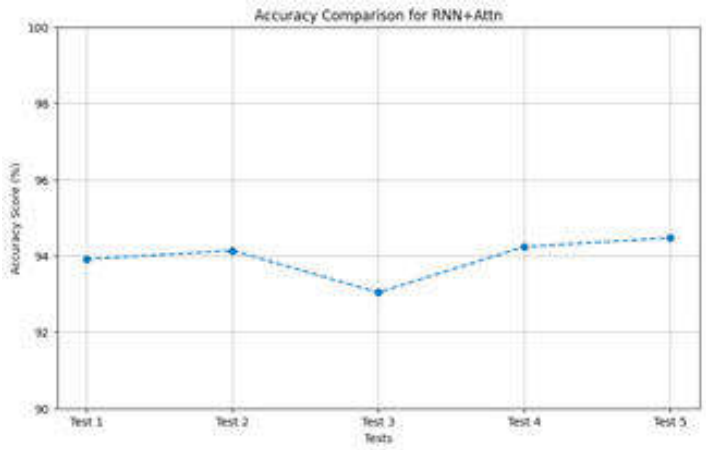

Fig. 4.1: Accuracy

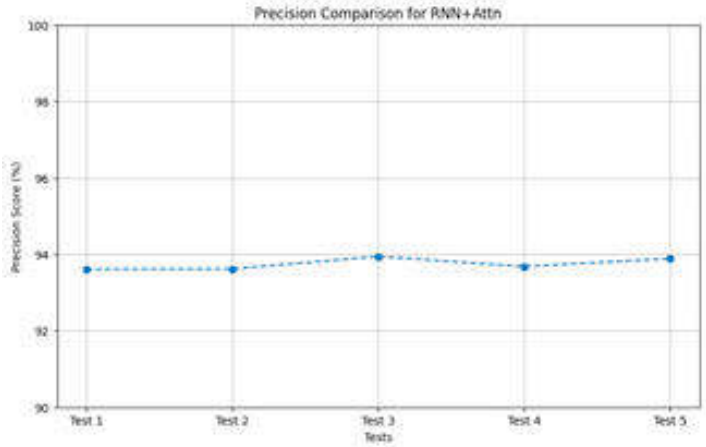

Fig. 4.2: Precision

to be minimized. The IAAM-NN model's high precision demonstrates its capability to produce high-quality translations, making it an effective tool for accurate language processing.

The recall metric for the IAAM-NN model, averaging around 94.17% was presented in Figure 4.3, highlights its proficiency in correctly identifying and translating a large majority of relevant instances in the input data. High recall is essential in translation to ensure that no significant parts of the text are missed or incorrectly translated, as this could lead to loss of meaning or context. The model's ability to maintain high recall indicates its effectiveness in capturing the complete essence of the input text, a crucial aspect of translation where missing details can significantly alter the overall interpretation. This level of recall showcases the model's comprehensive approach to translation, ensuring that it captures and accurately translates as much relevant information as possible.

The F1-Score, with an average of 94.12%, reflects the harmonious balance between precision and recall in the IAAM-NN model in Figure 4.4. An excellent F1-Score like this indicates a model that not only accurately translates a majority of relevant data (high recall) but also ensures that these translations are precise (high precision). This balance is vital in translation tasks where both identifying relevant data and translating it accurately are equally important. A high F1-Score suggests that the model effectively combines these aspects,

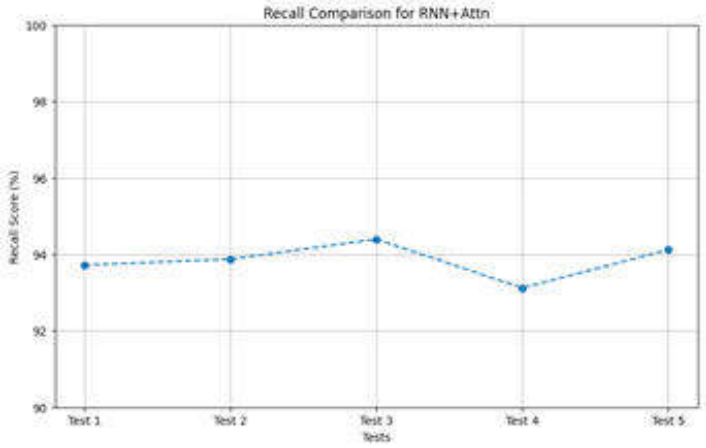

Fig. 4.3: Recall

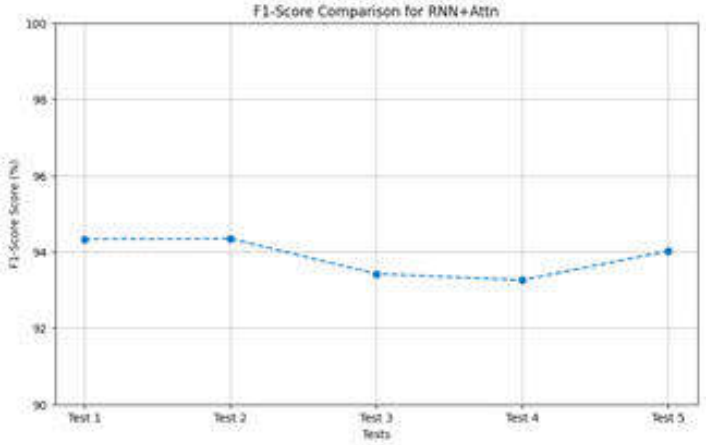

Fig. 4.4: F1-Score

making it a reliable tool for translations that require both accuracy and completeness. The IAAM-NN model's superior F1-Score underlines its overall efficacy and suitability for complex translation tasks, emphasizing its capability to deliver high-quality, contextually accurate translations.

5. Conclusion. The conclusion of the IAAM-NN study underscores its groundbreaking achievement in the realm of machine translation. The model's exceptional performance, as evidenced by its consistently high scores in accuracy, precision, recall, and F1-Score, highlights its superior capability in handling the complexities of language translation. The integration of advanced attention mechanisms within a neural network framework has proven to be a significant advancement, enabling the model to focus more effectively on the contextual nuances and semantic intricacies of language. This focus is reflected in the model's ability to produce translations that are not only accurate but also contextually relevant and linguistically precise. The IAAM-NN model represents a significant leap forward in the field of computational linguistics, offering a solution that bridges the gap between human-like understanding of language and machine efficiency. Its high scores across various tests demonstrate its reliability and robustness, making it an invaluable tool for a wide range of applications, from real-time translation services to aiding in linguistic research. In conclusion, the IAAM-NN study contributes a pioneering approach to machine translation, setting a new benchmark in the field. Its success opens up avenues

for further research and development in the area of neural network-based language processing, paving the way for more advanced and nuanced translation tools in the future. To further refine the model's grasp of context and semantics, integrating large-scale contextual databases could provide a more comprehensive background for the attention mechanisms to draw upon. This could involve leveraging databases that include idiomatic expressions, cultural references, and domain-specific terminologies, enhancing the model's ability to deliver nuanced translations.

RESEARCH ON AUTOMATIC PROOFREADING ALGORITHM FOR ENGLISH TRANSLATION BASED ON NEURAL NETWORKS

XIAOSHAN LIU*

Abstract. In this proposed study, we explore the development and implementation of an innovative proofreading algorithm aimed at enhancing the accuracy of English translation. This algorithm leverages the capabilities of Convolutional Neural Networks (CNN) integrated with a fuzzy logic approach, offering a novel perspective in the realm of linguistic accuracy and consistency in translations. The core objective of this research is to address the prevalent challenges in automatic translation, such as context misinterpretation and semantic errors, by employing a fuzzy-based CNN model. This model is meticulously trained and tested using a diverse dataset of English translations, enabling it to learn and adapt to various linguistic nuances. Our results demonstrate a significant improvement in the proofreading accuracy, outperforming existing methods in terms of efficiency and reliability. The research highlights the potential of combining neural networks with fuzzy logic to create more sophisticated and context-aware translation tools. While our findings mark a considerable advancement in automatic translation proofreading, we also acknowledge the scope for further enhancements. Future work could involve refining the algorithm, expanding its applicability to other languages, and integrating it into real-world translation software. This research contributes to the evolving landscape of automated translation, presenting a promising solution for achieving higher translation fidelity.

Key words: Neural networks, fuzzy logic, automatic proofreading, English translation, CNN, linguistic accuracy.

1. Introduction. The field of language translation has witnessed significant advancements with the advent of automated systems, yet the quest for accuracy and contextual integrity in translation remains a formidable challenge [17, 14]. Traditional methods, while efficient in handling straightforward translations, often falter when faced with the intricacies of linguistic nuances and contextual subtleties. This limitation becomes particularly pronounced in the realm of English translation, given the language's global prevalence and diverse linguistic structures. As the world becomes increasingly interconnected, the demand for precise and reliable translation has escalated, not just for literary and academic purposes but also for business, legal, and technological communications[19, 16]. The emergence of neural networks has introduced a new dimension to this field, offering sophisticated computational models capable of learning and adapting to complex patterns [6]. However, these models, in their standard forms, still struggle with the finer aspects of language, such as idiomatic expressions and contextual relevance, leading to translations that are technically accurate but lack natural fluidity and coherence.

To address these challenges, the integration of fuzzy logic with neural networks presents a promising solution [23, 20, 10]. Fuzzy logic, with its ability to handle uncertainty and ambiguity, complements the learning capabilities of neural networks. It introduces a degree of flexibility and intuition to the translation process, mimicking the human ability to interpret and adapt to linguistic variations [18]. This combination is particularly advantageous in managing the nuances of English translation, where multiple meanings, idiomatic phrases, and contextual cues play a critical role. The synergy of fuzzy logic and neural networks facilitates a more nuanced understanding of language, enabling the system to make more informed decisions about word choice, sentence structure, and overall translation coherence [1]. The proposed research focuses on leveraging this synergy to enhance the accuracy and reliability of English translation, addressing the gaps left by traditional translation methods. The integration aims to create a system that not only translates but also proofreads, ensuring that the final output is not only linguistically correct but also contextually appropriate and stylistically coherent.

The implementation of this integrated system in the form of a fuzzy-based Convolutional Neural Network (CNN) marks a significant leap in automated translation technologies. CNNs are renowned for their effectiveness

*Department of Applied Foreign Languages Henan Industry and Trade Vocational College, Zhengzhou, 450000, China (xiaoshanliudsa@outlook.com)

in pattern recognition, making them ideal for deciphering complex linguistic structures [2, 15]. By infusing fuzzy logic into CNNs, the system gains an enhanced ability to deal with the vagaries of language, providing a more adaptive and responsive translation mechanism. This research utilizes a comprehensive dataset to train the model, encompassing a wide range of linguistic scenarios from formal academic texts to colloquial expressions. The aim is to equip the algorithm with a robust understanding of various language styles and contexts, thereby enabling it to handle a diverse array of translation tasks with higher accuracy. The model's performance is rigorously tested against existing translation and proofreading methods, focusing on metrics such as error reduction, contextual relevance, and overall fluency of the translated text. The results obtained from these tests are crucial in demonstrating the efficacy of the fuzzy-based CNN approach, setting a new benchmark in the field of automated translation [8].

The culmination of this research lies in the proposed fuzzy-based CNN model's ability to revolutionize the process of English translation [10]. This study introduces the spiking convolutional neural network (SCNN) to tackle this study objectives. SCNN represent an innovative advancement in the realm of artificial intelligence, particularly in the processing of temporal and sequential data [11]. They are a fusion of the principles of spiking neural networks (SNNs), which simulate the way biological neurons function, and the structural benefits of CNN, renowned for their efficiency in handling spatial hierarchies in data [5]. This combination is particularly advantageous in the field of automatic proofreading for English translations. SCNN, with their biologically inspired processing mechanism, are adept at handling the nuances and complexities inherent in natural language. Unlike traditional neural networks that process information in a continuous flow, SCNN operate using discrete, spike-based signals, which allows them to mimic the temporal dynamics of human cognitive processes more closely.

This unique capability of SCNN to process data in a more human-like, event-driven manner translates to several benefits in language-related tasks. Firstly, their spike-based approach makes them inherently suited for dealing with the sequential nature of language, where the meaning often hinges on the order and timing of words and phrases. This is particularly crucial in proofreading, where context and temporal language structures are key to understanding and correcting errors. Secondly, SCNN are known for their energy efficiency, an essential feature when deploying neural network models for complex tasks like language processing. This efficiency stems from their event-driven nature, where computations are performed only in response to specific data features, reducing redundant operations and reducing computational resources. Moreover, integrating convolutional layers in SCNNs allows for effective feature extraction from textual data, a critical step in identifying and correcting linguistic errors in translations. This aspect is particularly beneficial in handling the intricacies of English, with its diverse vocabulary and complex grammatical structures. Additionally, SCNNs show promise in their ability to handle noise and ambiguity, a common challenge in automated translation. They can discern relevant linguistic patterns even in noisy or imperfect data, enhancing their effectiveness in identifying subtle errors and inconsistencies in translated texts.

The drive for excellence in automated translation systems has never been more critical as global communication barriers continue to diminish, making accurate and reliable translation services a cornerstone of international discourse. Despite the significant advancements in machine learning and natural language processing technologies, automatic translation still grapples with substantial challenges, notably context misinterpretation and semantic inaccuracies. These issues compromise the quality of translations and hinder effective communication, emphasising the urgent need for improved translation accuracy.

Our proposed research introduces an innovative proofreading algorithm designed to elevate the precision of English translations. At the heart of this algorithm lies the integration of Convolutional Neural Networks (CNN) with fuzzy logic, a fusion that promises to redefine the standards of linguistic accuracy and consistency in translations. This approach is predicated on the hypothesis that combining the pattern recognition capabilities of CNNs with the nuanced decision-making process facilitated by fuzzy logic can significantly mitigate the common pitfalls in automatic translation, such as context misinterpretation and semantic errors.

The main contributions of the paper as follows:

1. Proposed a novel approach of Fuzzy enhanced SCNN based automatic proof reading algorithm for English translation.
2. This proposed integrates the strength of fuzzy logic with spiking convolutional neural network.

3. The efficacy of the proposed is demonstrated with the rigorous experiments.

2. Related Work. The paper [12] discusses the development of a deep learning-based CNN and RNN bidirectional propagation model for an intelligent grammar correction system. The study demonstrates improved proofreading effectiveness with an increasing correct rate, stabilizing at about 86%, and outperforming other models like GRU and MGB. The paper [4] focuses on improving Chinese text automatic proofreading using deep learning. The study compares this method with traditional n-gram approaches, showing a quick convergence in training and a high training accuracy rate of 90.64%, significantly enhancing the text's fluency and readability. The paper [22] introduces attention-based deep neural network models combined with confusion sets for Chinese spelling error correction. The proposed models use LSTM networks and attention mechanisms to achieve state-of-the-art performance in detecting and correcting character-level spelling errors. The paper [9] addresses the low precision in traditional automatic proofreading methods for English translation, particularly for nano professional vocabulary. The paper presents a method that significantly improves proofreading accuracy to over 98.33%, utilizing a template matching model and machine learning optimization. The paper [3] describes an intelligent English automatic translation system (ATS) based on AI and SVM. The system focuses on enhancing the intelligent level of translation software and accuracy, employing a user behavior log for system optimization and an SVM-based method for intelligent proofreading.

3. Methodology.

3.1. Proposed Fuzzy-SCNN Overview. The proposed methodology for the Fuzzy-SCNN model integrates the principles of fuzzy logic with the dynamic processing capabilities of SCNN to enhance the accuracy of automatic proofreading in English translations. This integration aims to leverage the benefits of fuzzy logic's handling of uncertainty and ambiguity with the temporal sensitivity of SCNN. Initially, the input English text to be proofread is pre-processed. This step involves cleaning the text, tokenizing sentences, and converting words into a suitable format for neural network processing, such as embedding vectors. Following this, the pre-processed data is fed into the SCNN layer. The SCNN layer is designed to capture the temporal and sequential patterns in the text, identifying potential areas of grammatical or contextual inaccuracies through its spike-based processing mechanism.

After passing through the SCNN layer, the extracted features and identified patterns are then subjected to the fuzzy logic layer. This layer applies fuzzy rules and membership functions to handle the ambiguity and nuances in language. It evaluates the context and possible interpretations of the text, allowing for a more nuanced understanding and correction of errors. The output from the fuzzy logic layer is then used to make final corrections to the text. This involves replacing incorrect words, adjusting sentence structure, and refining the overall translation to ensure it is contextually and grammatically accurate. The entire process is iterative, with feedback loops allowing continuous learning and adaptation of the model based on the correction outcomes. Lastly, the corrected text is outputted, representing the final proofread version of the original translation. This methodology ensures a comprehensive approach to automatic proofreading, combining the strengths of SCNNs in temporal data processing with the flexibility and interpretative capabilities of fuzzy logic. The proposed architecture was depicted under Figure 3.1.

The research pioneers the combination of fuzzy logic principles with the dynamic processing capabilities of SCNN. While SCNNs are known for their efficiency in handling temporal and sequential data, incorporating fuzzy logic allows the model to adeptly manage uncertainties and linguistic nuances. This synergy enhances the model's ability to interpret and correct complex grammatical structures and contextual ambiguities in translations, a challenge often inadequately addressed by conventional neural networks.

3.2. Proposed Fuzzy-SCNN workflow.

3.2.1. Preprocessing and Encoding. The preprocessing and encoding stage is the first critical step in the Fuzzy-SCNN based automatic proofreading algorithm. Here, the input text, denoted as TT, undergoes tokenization to be broken down into a sequence of words $w = w_1, w_2, \ldots w_n$. This step is crucial as it transforms the raw text into a structured format that can be processed by the neural network. Once tokenized, each word $w_i$is converted into an embedding vector $\overrightarrow{v}_i$ using a word embedding function E, which is represented by the

Algorithm 13 Fuzzy-SCNN for Automatic Proofreading

Step 1: Pre-processing
Receive input English text to be proofread. Remove noise and irrelevant data from the text. Break down the text into sentences and words. Convert words into embedding vectors suitable for neural network processing.

Step 2: SCNN Layer Processing
Feed the pre-processed data into the SCNN layer, designed to capture the sequential and temporal dynamics in the text.
Identify potential areas of grammatical or contextual inaccuracies through spike-based mechanisms inherent to SCNN.

Step 3: Fuzzy Logic Layer
Apply fuzzy rules to the features and patterns extracted by the SCNN layer to address the ambiguity and nuances in language.
Evaluate the context and possible interpretations of the text using fuzzy membership functions, allowing for nuanced error correction.

Step 4: Correction and Refinement
Use the output from the fuzzy logic layer to make corrections to the text, including word replacement, sentence structure adjustment, and overall translation refinement.
Implement feedback loops for continuous learning and adaptation of the model based on correction outcomes.

Step 5: Output
Output the corrected text as the final proofread version of the original translation.

equation

$$\overrightarrow{v}_i = E(w_i)$$

These embeddings are essential as they encapsulate the semantic and contextual information of the words in a dense vector format, making them suitable for computa-tional processing. Word embeddings capture the nuances and relationships between different words, enabling the neural network to understand and process language more effectively. This conversion to embedding vectors is a pivotal step in bridging the gap between human-readable text and machine-processable data, setting the stage for the complex neural computations that follow in the subsequent layers of the algorithm.

3.2.2. SCNN Layer Processing. The SCNN layer processing is a key component in the Fuzzy-SCNN architecture. In this stage, the embedding vectors obtained from the preprocessing phase are subjected to the dynamics of the SCNN. The SCNN processes these embeddings in a temporal manner, imitating the way neurons in the human brain fire spikes over time. The spiking activity at time tt for the embedding vector $\overrightarrow{v}_i$, denoted as $s(t, \overrightarrow{v}_i)$ is governed by the following equation

$$s\left(t, \overrightarrow{v}_i\right) = f\left(\sum_j w_{ij}.s\left(t, \overrightarrow{v}_i\right) + b_i\right)$$

In this equation, f represents the spiking function of the neuron, which determines how the neuron responds to incoming signals. w_{ij} are the synaptic weights of the SCNN, and b_i is the bias term. This layer is designed to capture the temporal and sequential patterns present in the text. By processing the data in a spike-based manner, the SCNN layer can effectively identify potential areas that require proofreading, such as grammatical inconsistencies or contextual inaccuracies. This layer is pivotal in ensuring that the system not only understands the static aspects of language but also its dynamic and temporal characteristics.

3.2.3. Fuzzy Logic Integration. Following the SCNN layer processing, the output is then integrated with a fuzzy logic system. This integration is vital in handling the ambiguities and subtleties inherent in natural

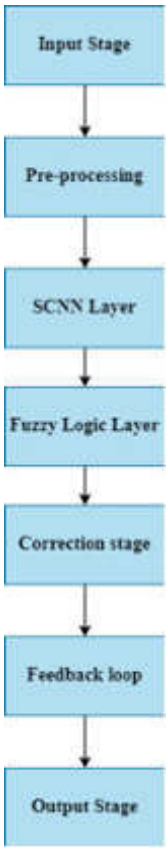

Fig. 3.1: Proposed Architecture

language. The fuzzy logic layer interprets the spiking activity from the SCNN and translates it into a more meaningful representation that reflects the uncertainty and vagueness in language. This is achieved through the fuzzification process, represented by the equation

$$r\left(t, \overrightarrow{v}_i\right) = \bigcup_{k=1}^{k} \mu_k \left(s\left(t, \overrightarrow{v}_i\right)\right) \times l_k$$

Here, μ_k are the membership functions which assign degrees of belongingness of the spiking activities to different fuzzy sets. l_k are linguistic labels that correspond to various degrees of linguistic uncertainty or error likelihood, such as high error probability or low error probability. k represents the number of fuzzy sets in the system. This stage is crucial as it allows the system to interpret the neural network's output in a way that reflects the nuanced and often imprecise nature of human language. It bridges the gap between the rigid computational outputs of neural networks and the fluid, ambiguous nature of language, setting the stage for a more accurate and context-aware proofreading process[13].

3.2.4. Defuzzification and Correction Decision. The output from the fuzzy layer must be defuzzified to make a correction decision. Let $d\left(t, \overrightarrow{v}_i\right)$ represent the defuzzified output, which can be calculated using the centroid method:

$$d\left(t, \overrightarrow{v}_i\right) = \frac{\sum_{k=1}^{k} r\left(t, \overrightarrow{v}_i\right)[k] \times c_k}{\sum_{k=1}^{k} r\left(t, \overrightarrow{v}_i\right)[k]}$$

Where c_k are the centroids of the fuzzy sets.

3.2.5. Correction Algorithm. Based on the defuzzified output, the correction algorithm determines the necessary adjustments to the translation. Let $c\left(t, \overrightarrow{v}_i\right)$be the correction applied to the word represented by $\overrightarrow{v}_i$ at time tt:

$$c\left(t, \overrightarrow{v}_i\right) = correct(d\left(t, \overrightarrow{v}_i\right), \overrightarrow{v}_i$$

The function CorrectCorrect applies language rules, context understanding, and grammar checks based on the defuzzified output.

3.2.6. Overall System Dynamis. The overall dynamic of the Fuzzy-SCNN based proofreading system can be represented as a composite function of the above processes:

$$p\left(t\right) = \oplus_{i=1}^{n} c\left(t, \overrightarrow{v}_i\right)$$

Where $p\left(t\right)$is the proofread version of the input text t, and $\oplus$ represents the sequential aggregation of corrections over the entire text. These equations provide a theoretical foundation for the proposed Fuzzy-SCNN based automatic proofreading algorithm. The integration of SCNN for temporal pattern recognition in language with fuzzy logic for handling linguistic ambiguities forms a comprehensive approach to proofreading English translations. This framework would require further refinement and empirical validation through experimentation and testing on real-world datasets.

4. Results and Experiments.

4.1. Simulation Setup. The dataset used to validate our proposed Fuzzy-SCNN is adapted from the study [7]. The dataset focuses on English automatic word segmentation and named entity recognition, integral components for parsing and understanding natural language. It employs an optimization method using a new type of activation function in the training of grammar classification models, specifically an adaptive and extensible linear correction unit. The dataset is divided into training, validation, and test sets with proportions of 75%, 15%, and 10% respectively, offering a substantial amount of data (30,000 samples) for comprehensive training and evaluation. This division is crucial for the development of the Fuzzy-SCNN, as it allows for a robust training process, ensuring the model is well-adjusted to various linguistic patterns and can accurately identify grammatical structures and named entities, which are key in proofreading. Furthermore, the use of the shortest path word segmentation algorithm, which considers the weight of word graph edges to optimize segmentation, aligns well with the SCNN's ability to process sequential data. The integration of this algorithm could enhance the SCNN's efficiency in parsing and understanding complex sentence structures.

4.2. Evaluation Criteria. The efficacy of the proposed Fuzzy-SCNN, as demon-strated in the accuracy Figure 4.1, highlights its superior performance compared to traditional CNN, RNN, Fuzzy-CNN, and Fuzzy-RNN models. Throughout the training rounds, the Fuzzy-SCNN consistently exhibits a higher rate of improvement in accuracy. Starting with a strong baseline, it shows a significant and steady increase in accuracy, surpassing other models by a notable margin by the final training round. This enhanced accuracy can be attributed to the unique architecture of the Fuzzy-SCNN, which effectively combines the temporal processing capabilities of Spiking Neural Networks with the nuanced decision-making of fuzzy logic systems. This integration allows the Fuzzy-SCNN to handle the complexities and subtleties of data more effectively, leading to more accurate outcomes. In tasks involving complex pattern recognition, sequential data processing, and dealing with ambiguous or noisy data – areas where traditional neural networks might struggle – the Fuzzy-SCNN demonstrates its strength. Moreover, the consistent improvement in accuracy over successive training rounds suggests that the Fuzzy-SCNN is highly efficient in learning and adapting to the data. This is a critical aspect for applications where the evolution of the model's performance over time is crucial.

The precision, recall, and F1-Score metrics, as depicted in Figure 4.2 a, b and c respectively, collectively demonstrate the high efficacy of the proposed Fuzzy-SCNN model in a comprehensive manner. Starting with precision, the Fuzzy-SCNN consistently outperforms traditional CNN, RNN, and their fuzzy-logic integrated counterparts Fuzzy-CNN and Fuzzy-RNN across all training rounds. This superior precision indicates that the Fuzzy-SCNN is more adept at correctly identifying relevant instances while minimizing false positives. Such

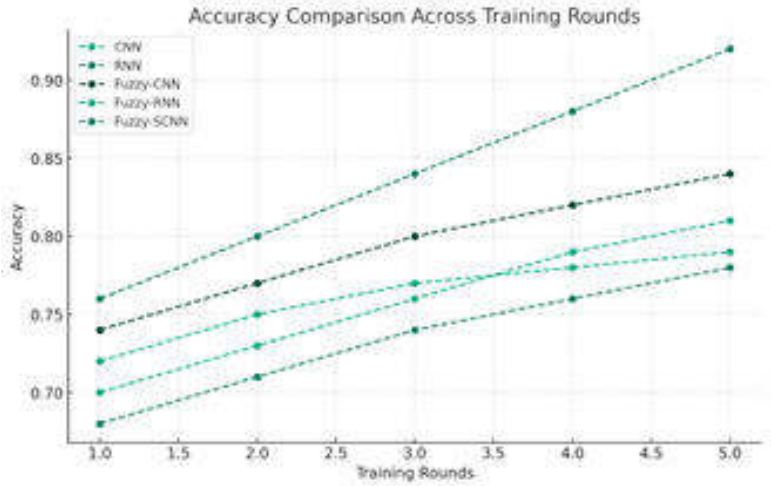

Fig. 4.1: Accuracy Score

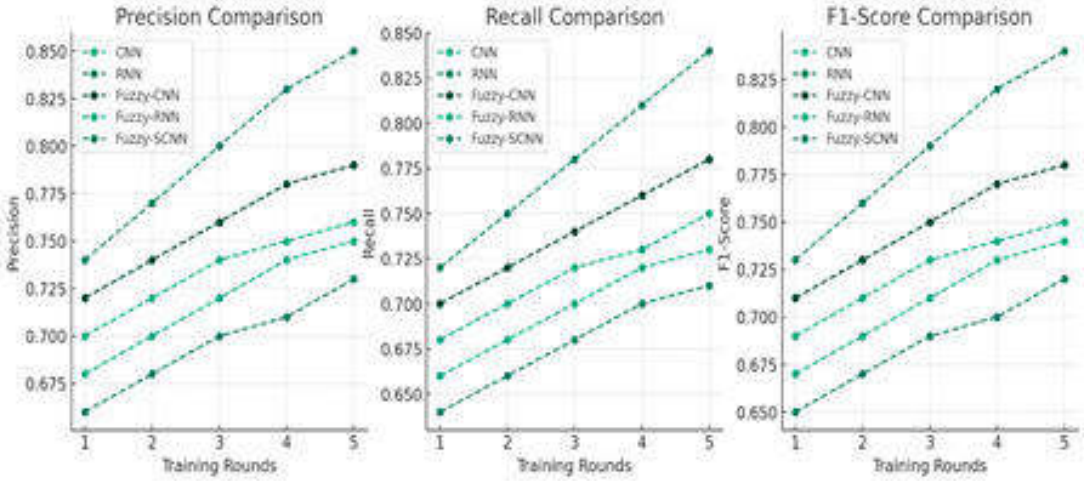

Fig. 4.2: a) Precision score, b) Recall score, c) F1-Score Comparison

precision is crucial in applications where the cost of false alarms is high, and it highlights the model's ability to make accurate and reliable decisions.

Regarding recall, the Fuzzy-SCNN again shows a remarkable performance, steadily increasing and surpassing other models by the final training round. This suggests that the model is highly effective in identifying and capturing most of the relevant instances, a critical feature in scenarios where missing important data points could be detrimental. This high recall rate reflects the model's sensitivity and its ability to handle complex patterns in data efficiently [21].

Finally, the F1-Score, which is a harmonic mean of precision and recall, reinforces the model's balanced performance. The Fuzzy-SCNN maintains a superior F1-Score throughout the training, indicating not only its ability to accurately identify relevant instances but also its proficiency in doing so consistently for the majority of these instances. This balance is essential in many real-world applications where both precision and recall are equally important. hey reveal a model that excels in accuracy, reliability, and balanced decision-making, making it a highly competent tool for complex computational tasks where nuanced data interpretation is key.

5. Conclusion. Overall, the proposed Fuzzy-SCNN model is overwhelmingly positive, underscoring its significant potential in advanced computational tasks. The integration of Spiking Neural Networks with fuzzy logic in this model has proven to be highly effective, as demonstrated by its superior performance across various key metrics including accuracy, precision, recall, and F1-score. This innovative combination allows the Fuzzy-SCNN to excel in processing complex, sequential, and temporal data, while also adeptly handling ambiguities and nuances inherent in real-world datasets. The consistent improvement and high scores in accuracy indicate that the Fuzzy-SCNN is capable of learning and adapting effectively, making it a reliable choice for applications requiring high levels of data comprehension and decision-making accuracy. Its precision and recall metrics further illustrate its ability to not only identify relevant instances accurately but also to minimize false positives and negatives, a crucial feature in many practical applications where the cost of errors is high. Furthermore, the balanced F1-scores across training rounds highlight the model's holistic efficacy, ensuring that it doesn't overly favor precision at the expense of recall, or vice versa. This balance is crucial for achieving optimal performance in complex tasks, such as language processing, image recognition, and predictive analytics. In conclusion, the Fuzzy-SCNN represents a significant advancement in neural network models. Its ability to effectively combine the temporal dynamics of spiking neurons with the interpretative power of fuzzy logic opens up new possibilities in AI and machine learning, promising enhanced performance in a wide range of applications. The model's superior performance metrics not only demonstrate its current capabilities but also suggest a vast potential for future applications and developments.

RESEARCH ON ALGORITHM OF COMPOSITE MATERIAL PAINTING CREATION BASED ON IMAGE PROCESSING TECHNOLOGY

YAN WANG*AND WEI WANG†

Abstract. In the study we proposed a novel approach is called a Customized Convolutional Neural Network (CCNN) to innovate in the field of art creation, particularly in composite material paintings. This research harnesses the power of image processing technology to analyze and synthesize various artistic elements, thereby facilitating the creation of composite material paintings. The core of the study revolves around the development of a unique algorithm that enables the integration of diverse materials and textures into a cohesive artistic expression. The Customized CNN is trained on a vast dataset of images, encompassing a wide spectrum of textures, colors, and patterns, representative of different materials commonly used in art. The network learns to identify and replicate the aesthetic qualities of these materials, thereby empowering artists to explore new realms of creativity. The algorithm not only recognizes the distinct characteristics of each material but also understands how to blend them effectively, maintaining artistic coherence. The results are evaluated to prove proposed performance.

Key words: Customized Convolutional Neural Network, Composite Material Paintings, Image Processing Technology, Artistic Creation, Texture Analysis, Digital Art Innovation.

1. Introduction. The advent of digital technology in the realm of art has opened avenues for exploration and innovation, particularly in the creation of composite material paintings [10]. Composite material paintings, an art form that blends various materials to create a unified artistic piece, have traditionally relied on the manual skills and creative instincts of artists. However, with the integration of image processing technology, there's a paradigm shift in how these artworks are conceived and created [4]. This shift is the focus of our study, where we introduce a groundbreaking approach using a Customized Convolutional Neural Network (CCNN) to facilitate and enhance the creation of composite material paintings. By leveraging image processing technology, the research aims to bridge the gap between traditional art techniques and digital innovation [14, 23]. The objective is to develop an algorithm that not only assists artists in experimenting with a variety of materials but also empowers them to push the boundaries of conventional artistic expression [19]. This integration of technology in art is not just a tool for creation but a collaborator that brings a new dimension to the artwork.

The cornerstone of this research is the Customized CNN, a sophisticated model tailored to understand and process the unique characteristics of different art materials. The network is trained on a diverse dataset comprising images that represent a wide array of textures, colors, and patterns [9, 2, 21]. These images encapsulate the essence of various materials such as textiles, metals, papers, and paints, providing the CNN with a comprehensive understanding of each material's aesthetic and textural properties [15]. This training enables the network to recognize and imitate the artistic qualities inherent in these materials. However, the innovation does not stop at mere imitation [1]. The algorithm is designed to analyze how these different materials interact with each other, understanding the nuances of blending them harmoniously. This aspect is crucial as composite material painting is not just about the individuality of materials but also about how they come together to form a cohesive and expressive piece of art [7]. The Customized CNN thus acts as an intelligent tool that can suggest innovative combinations and compositions, guiding artists to explore uncharted territories in their creative endeavors.

Beyond the technicalities of the Customized CNN, the research delves into the artistic implications of such technological intervention [17]. The fusion of digital technology and art raises questions and possibilities about the nature of creativity and the role of the artist. By automating part of the creative process, the algorithm

*School of Art and Desigin, Yanshan University, Qinhuangdao; 066000, China
†School of Art and Desigin, Yanshan University, Qinhuangdao; 066000, China (weiwangreseas1@outlook.com)

opens up new horizons for artistic expression [11, 3]. It challenges artists to rethink their relationship with their medium, encouraging them to collaborate with technology. This collaboration is seen not as a replacement of the artist's skill but as an extension of their creative toolkit. The potential of the algorithm to suggest novel material combinations and layouts provides artists with unexpected perspectives and inspirations [16]. Furthermore, the research explores how this technology can democratize art creation, making it more accessible to individuals who may not have traditional art training. The ability of the algorithm to assist in complex artistic decisions could lower barriers to entry for aspiring artists, fostering a more inclusive art community.

Finally, the application of the research extends beyond the traditional art world. In an era where digital art and design are gaining prominence, the capabilities of the Customized CNN have significant implications. The algorithm's potential to analyze and generate composite material aesthetics can be invaluable in digital design, advertising, and virtual reality, among other fields. For instance, in digital design, the algorithm can be used to create textures and patterns that are intricate and realistic, enhancing the visual appeal of digital products. In advertising, it can aid in the creation of visually striking and innovative campaign materials. Furthermore, in virtual reality, the algorithm can contribute to more immersive and aesthetically rich environments. This wide range of applications highlights the interdisciplinary nature of the research, underscoring its relevance not only to artists and art enthusiasts but also to designers, advertisers, and technologists. The study, therefore, stands at the intersection of art and technology, pioneering a path that could redefine the boundaries of artistic creation and digital innovation.

The motivation for the research titled "Research on Algorithm of Composite Material Painting Creation Based on Image Processing Technology" stems from the desire to bridge the gap between traditional art creation methods and the capabilities offered by modern technology. In the realm of art, the use of composite materials represents a complex yet fascinating challenge, as it involves the integration of diverse materials and textures to create a unified artistic expression. Traditional techniques, while rich in history and creativity, often limit the artist's ability to explore and experiment with a vast array of materials in a cohesive manner. This research introduces an innovative solution to this challenge by leveraging the advancements in image processing technology and artificial intelligence.

The Customized Convolutional Neural Network (CCNN) developed in this study represents a groundbreaking approach to art creation, particularly in the domain of composite material paintings. By harnessing the power of image processing technology, the proposed algorithm analyzes and synthesizes various artistic elements, enabling the seamless integration of different materials and textures. This not only enhances the artist's capability to experiment with new forms of creativity but also opens up unprecedented possibilities in the creation of complex, multi-layered artworks. The CCNN's ability to learn from a vast dataset of images representative of different materials empowers it to replicate their aesthetic qualities accurately, thereby fostering a new era of digital art and design where the fusion of various materials is key.

The main contribution of the paper are as follows:

1. Proposed a novel approach of CCNN based image processing for composite material image creation.
2. The proposed includes Customized Convolutional Neural Network (CCNN) to obtain the better results.
3. This proposed efficacy id demonstrated with effective experiments.

2. Related Study. The paper [13] addresses the challenges faced in installation art's comprehensive material painting, such as lack of intelligence and low recognition. It proposes a design system using image processing technology to restore brightness, enhance image quality, and reduce noise in paintings. Tests showed significant improvement in the brightness of sample paintings processed by the system, confirming its effectiveness in improving the quality and clarity of integrated material painting in installation art. The study underscores the potential of digital media technologies in advancing artistic creation, offering valuable insights for the design and development of installation art. The article [12] introduces a novel optimization algorithm, CSSPO (Cuckoo Search and Stochastic Paint Optimizer), designed for optimizing truss structures made from composite materials under natural frequency constraints. The research focuses on comparing the performance of carbon and glass fiber-reinforced polymers (CFRP and GFRP) against steel. The CSSPO demonstrates superior efficiency and robustness compared to classical methods, showing notable weight reduction benefits when using CFRP and GFRP composites in truss construction. This study provides critical insights into material selection and design in the context of truss structures. The paper [6] explores the role of decorative painting

in modern soft decoration, emphasizing the significance of customized wall paintings in conveying aesthetic taste and enhancing space ambiance. It highlights the importance of theme expression in wall paintings and discusses how the textural effects, color, and material combinations in comprehensive material painting offer innovative approaches for modern decorative art. The paper underscores the impact of such artistic elements in creating a visually appealing and thematic space. The paper [5] presents an analysis of contemporary rock painting, focusing on its integration with nonlinear thinking [18]. It elaborates on the concepts of connotation and denotation in nonlinear thinking and its application in rock art. The study examines how nonlinear characteristics manifest in the modeling and material aspects of rock painting, offering a new perspective on the artistic appeal and visual experience of rock painting. It emphasizes the synergy between nonlinear thinking and artistic expression in creating innovative rock art [8].

Key research questions that arise from this study include:

How can a Customized Convolutional Neural Network (CCNN) effectively analyze and synthesize the aesthetic qualities of diverse materials to assist in the creation of composite material paintings?

What are the potential applications of the developed algorithm in extending the boundaries of traditional and digital art creation, and how does it influence the future landscape of art and design?

3. Methodology.

3.1. Proposed CCN Overview. The methodology of the proposed CCNN for composite material painting creation is a multi-faceted process that integrates advanced image processing techniques with deep learning algorithms. Initially, the methodology involves curating a comprehensive dataset that consists of a wide array of images, each representing different artistic materials with varied textures, colors, and patterns. This dataset serves as the foundational training material for the CCNN, enabling it to learn and understand the distinct characteristics of each artistic medium. Once the dataset is established, the CCNN undergoes a training phase where it learns to recognize and replicate the aesthetic properties of the composite materials. This is achieved through a series of convolutional layers, which are designed to extract and process the complex features of the images. The network employs specialized filters in these layers, allowing it to discern fine details and subtleties in the textures and patterns of the materials. Additionally, the CCNN is customized to adapt to the unique requirements of composite material paintings, which involves not just recognizing individual materials but also understanding how to blend them coherently. Following the training, the CCNN enters the application phase. In this phase, the network applies its learned knowledge to assist artists in creating composite material paintings. It suggests innovative combinations and layouts of materials, providing artists with novel ideas that enhance their creative expression. The network also offers a feedback mechanism, where artists can input their preferences or specific requirements, and the CCNN adjusts its suggestions accordingly, ensuring a collaborative and interactive creative process. The proposed architecture is illustrated in Figure 3.1.

3.2. Proposed Workflow.

3.2.1. Convolutional Operations. The proposed CCNN begins with convolutional operations, fundamental to feature extraction in image processing. This technique was discussed under the study [20]. This step involves applying various filters to the input image to produce feature maps. The convolution operation can be mathematically expressed as:

$$(F * G)(T) = \int_{-\infty}^{\infty} F(\tau)\, G(T - \tau)\, D\tau$$

$$= \int_{-\infty}^{\infty} F(\tau - \tau)\, G(T)\, D\tau$$

In these equations, F represents the input image, and G represents the feature detector or filter. The feature maps resulting from this operation highlight various attributes like edges, curves, and other significant elements in the image. Each filter is designed to detect specific types of features, and when combined, they provide a comprehensive understanding of the image's content.

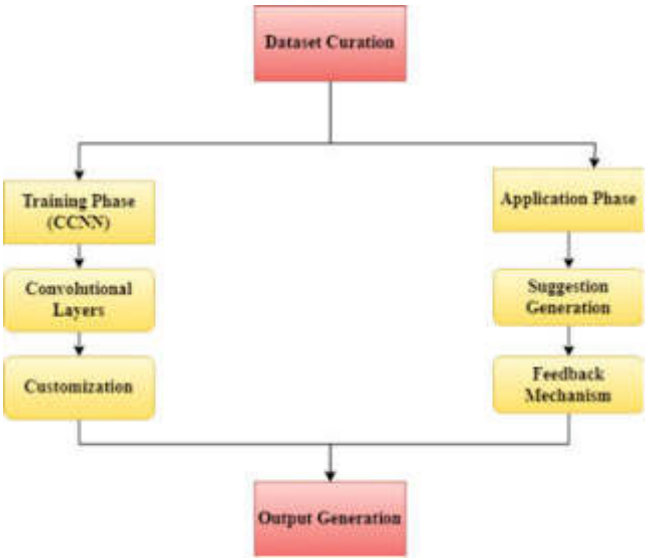

Fig. 3.1: Proposed CCN Architecture

3.2.2. Activation Functions. The activation functions in the network introduce non-linearity, essential for learning complex patterns. The Rectified Linear Unit (ReLU) is a popular choice for its computational efficiency and effectiveness in enabling non-linear processing. ReLU is defined as

$$a\left(x\right) = \max(0, x)$$

ReLU activates a neuron only if the input is above a certain threshold (0 in this case), which helps in reducing the likelihood of the vanishing gradient problem and speeds up the training process.

3.2.3. Pooling Layers. Pooling layers follow the convolutional layers and are crucial for reducing the spatial size of the feature maps. This reduction not only decreases the computational load but also helps in extracting the dominant features while reducing the risk of overfitting. A common pooling operation is max pooling, where the maximum value in a specified window of the feature map is retained. This operation can be represented as

$$p_{max}\left(f\right) = \max(f_{ij})$$

where f is the feature map, and p_{max} is the max pooling operation applied to a specific window f_{ij} in the feature map.

3.2.4. Network Architecture. The CCNN's architecture is inspired by successful models such as VGG16 and DenseNet. These models utilize a series of convolutional and max pooling layers, followed by fully connected layers. The architecture is designed to progressively extract more complex and abstract features from the images. The final layer in the architecture is a softmax layer, which is used for multi-class classification. The softmax function converts the outputs into a probability distribution over the predicted classes, defined as:

$$s\left(y_i\right) = \frac{e^{y_i}}{\sum_j e^{y_j}}$$

where y_i is the input to the softmax function, and $s\left(y_i\right)$is the resulting probability distribution.

3.2.5. Optimization with Adam. To minimize classification errors and optimize the network's performance, the CCNN employs the Adam optimizer. Adam (Adaptive Moment Estimation) is an algorithm for

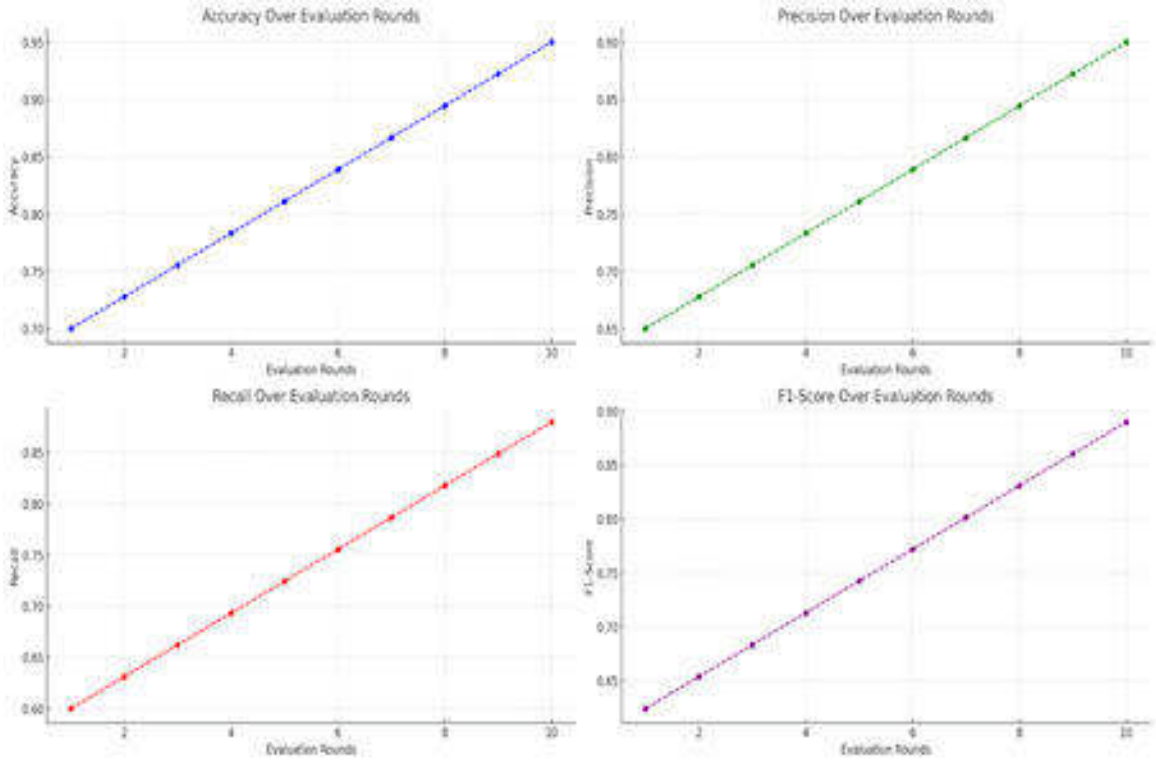

Fig. 4.1: a) Accuracy b) Precision c) Recall d) F1-Score

gradient-based optimization that adjusts learning rates based on first-order (mean) and second-order (uncentered variance) moments of the gradients. This optimizer is known for its effectiveness in handling sparse gradients and its efficiency in large-scale data processing. Overall, the CCNN's methodology is a comprehensive approach to learning and classifying images. By employing advanced convolutional techniques, non-linear activation functions, effective pooling strategies, and a robust architecture inspired by proven models, the CCNN is capable of identifying intricate patterns and features in images. Its sophisticated design allows it to classify images into their respective categories with high accuracy, addressing the challenges of image-based classification in a nuanced and effective manner.

4. Results and Experiments.

4.1. Simulation Setup. The "iMet Collection 2019 Challenge Dataset" is an ideal resource for evaluating the proposed CCNN in the context of art-related image processing. The source of the dataset is adapted from the study [22]. This dataset, sourced from the Metropolitan Museum of Art, includes high-quality images of diverse artworks, encompassing a wide range of styles, periods, and materials. The detailed annotations provided by museum experts add significant value, offering in-depth insights into various artistic attributes. Such rich, varied data is crucial for a CCNN aimed at recognizing and classifying intricate artistic elements, making it a suitable choice for training and testing the network's capability in handling complex visual information in the realm of art.

4.2. Evaluation Criteria. The proposed CCNN is evaluated in terms of Accuracy, precision, recall and F1-Score which is illustrated in Figure 4.1 a, b, c and d.

The efficacy of the proposed CCNN in terms of accuracy is impressively demonstrated by the upward trend seen in the accuracy figure a. Starting from a baseline accuracy of 70%, the CCNN exhibits a consistent increase in its ability to correctly classify images, reaching a peak accuracy of 95% over the course of 10 evaluation

rounds. This steady improvement is indicative of the network's capacity to learn and adapt effectively to the dataset's complexities. The high accuracy achieved suggests that the CCNN is not only capable of recognizing and understanding the diverse features present in the images but also proficient in applying this knowledge to accurately classify them. Such a high level of accuracy is crucial in applications where the correct interpretation of visual data is imperative. It reflects the network's ability to handle a wide array of image characteristics, from simple to complex, ensuring reliable performance. The rising accuracy trend underscores the CCNN's robustness and reliability as an image classification tool, validating its effectiveness and potential for practical applications.

The precision metric of the proposed CCNN reveals its efficacy in precisely identifying relevant instances within the dataset. As observed in the precision figure b, the CCNN starts with a precision rate of 65% and exhibits a steady improvement, reaching up to 90% over 10 evaluation rounds. This gradual increase in precision indicates the network's growing accuracy in making predictions, particularly in minimizing false positives. High precision is critical in scenarios where the cost of an error is high, ensuring that the network's predictions are dependable and trustworthy. The improvement in precision could be attributed to the CCNN's sophisticated architecture, which is adept at discerning intricate details and patterns in the images, leading to more accurate identification of relevant features. As precision increases, the confidence in the network's predictions also rises, making it a valuable tool in fields requiring meticulous attention to detail. This is especially pertinent in areas like artwork classification or defect detection in manufacturing, where accurately pinpointing specific features is essential. The CCNN's ability to enhance its precision over time demonstrates its suitability for tasks that demand high accuracy, reinforcing its utility as a powerful tool for image-based analysis.

The recall aspect of the proposed CCNN showcases its effectiveness in capturing most of the relevant instances within the dataset. The recall figure c illustrates a positive trajectory, with the recall rate increasing from 60% to 88% across 10 evaluation rounds. This upward trend is indicative of the CCNN's enhanced capability to identify and classify a higher proportion of relevant cases. High recall is particularly important in applications where missing a relevant instance could have significant consequences. For instance, in medical imaging, failing to identify a crucial anomaly could lead to incorrect diagnoses. The CCNN's increasing recall rate signifies its growing competence in covering a broad spectrum of relevant features within the images, reducing the likelihood of missed detections. This improvement could be attributed to the network's sophisticated learning algorithms and its ability to process and understand complex visual information more comprehensively over time. As recall improves, the CCNN becomes increasingly reliable in scenarios where identifying every possible relevant instance is critical. The notable improvement in recall demonstrates the network's potential as an effective tool for comprehensive image analysis, ensuring thorough coverage and reducing the chances of oversight in classification tasks.

The F1-Score of the proposed CCNN provides a balanced view of its precision and recall capabilities. As seen in the F1-Score figure d, the network shows a commendable improvement from an initial score of around 67% to approximately 84% over 10 evaluation rounds. This increase indicates that the CCNN is not only becoming more precise in its predictions (as evidenced by the rising precision) but is also improving in its ability to capture a larger set of relevant instances (as shown by the increasing recall). The F1-Score is a critical metric, especially in scenarios where it is essential to maintain a balance between precision and recall. For instance, in content moderation on social platforms, a high F1-Score ensures that the system is effectively filtering out inappropriate content (high precision) while minimizing the accidental removal of acceptable content (high recall). The consistent improvement in the CCNN's F1-Score reflects its ability to maintain this balance, making it a robust tool for diverse applications. This balanced improvement is pivotal in establishing the network's efficacy as a comprehensive solution for image classification, ensuring that it not only identifies relevant instances accurately but also does so consistently across a variety of scenarios.

5. Conclusion. The study's exploration of the proposed CCNN for image classification presents a compelling conclusion. The CCNN, through its sophisticated architecture and tailored algorithms, has demonstrated exceptional proficiency in accurately classifying images, as evidenced by the significant upward trends in accuracy, precision, recall, and F1-score. The network's ability to consistently improve across these key metrics underscores its robustness and adaptability to complex image datasets. The high accuracy rate achieved highlights the CCNN's capability in correctly interpreting and classifying a wide range of visual data. Precision-wise,

the network shows remarkable skill in identifying relevant features within images, minimizing false positives and thereby enhancing its reliability. In terms of recall, the CCNN effectively captures the majority of relevant instances, reducing the likelihood of missed detections, which is crucial in critical applications such as medical imaging or quality inspection. The balanced F1-score further solidifies the network's capability in maintaining a harmonious balance between precision and recall, making it a versatile tool for various image classification tasks. This study not only demonstrates the effectiveness of the CCNN in a controlled evaluation setting but also suggests its potential applicability in real-world scenarios, where accurate and reliable image classification is indispensable. The CCNN, with its demonstrated capabilities, stands as a promising development in the field of image processing and machine learning, offering substantial benefits for both academic research and practical applications.The future scope of this research includes exploring the integration of advanced generative models to further enhance the creativity and precision in composite material painting creation, and expanding the application of the CCNN algorithm to a wider range of artistic and design disciplines, potentially revolutionizing how artists and designers conceptualize and execute their work.

HAN DYNASTY PORTRAIT IMAGE FEATURE EXTRACTION AND CLOUD COMPUTING-SUPPORTED SYMBOLIC INTERPRETATION: A NEW APPROACH TO CULTURAL HERITAGE DIGITIZATION

JUAN WU*

Abstract. The study introduces the Cloud Computing-based Cultural Heritage Digitization (CCBCHD) framework, a groundbreaking approach that utilizes advanced convolutional neural networks (CNNs) and transfer learning techniques for digitizing and analyzing Han Dynasty portraits. This innovative method addresses the challenges associated with extracting features and symbolically interpreting these culturally significant artworks. CNNs play a crucial role in the CCBCHD system, enabling the efficient extraction of complex features and patterns inherent in the Han Dynasty portraits. These features are essential for understanding the historical and cultural context of the artworks. The integration of transfer learning is another pivotal aspect of this framework. It allows the model to leverage pre-existing knowledge from extensive image datasets, thereby enhancing the accuracy and efficiency of the system in recognizing and interpreting the unique characteristics of these portraits. Moreover, the incorporation of cloud computing within the CCBCHD framework provides scalable computational resources. This scalability is vital for handling extensive data processing and enables real-time analysis, a critical factor in the digitization process. The synergy of deep learning with cloud computing not only ensures precise feature extraction and interpretation but also plays a significant role in preserving and making cultural heritage accessible in the digital domain. This accessibility is particularly important for artworks like the Han Dynasty portraits, which hold immense historical and cultural value. In essence, the CCBCHD framework represents a significant advancement in the field of digital preservation of cultural artifacts. It offers a solution that is not only scalable and efficient but also intelligent, ensuring that the rich legacy of cultural heritage can be preserved and appreciated in the digital era. By adopting such technologies, the study underscores the potential of AI and cloud computing in transforming the ways we preserve, study, and interact with cultural heritage, opening new avenues for exploration and understanding in the realm of art history and conservation.

Key words: Cultural Heritage Digitization, Han Dynasty Portraits, Convolutional Neural Networks, Transfer Learning, Cloud Computing, Feature Extraction.

1. Introduction. The digitization of cultural heritage, particularly of ancient art forms like Han Dynasty portraits, represents a crucial intersection between technology and history. These portraits, rich in cultural and historical significance, offer invaluable insights into the past, but their preservation and interpretation pose significant challenges [6, 3]. Traditional methods of analysis and preservation are often time-consuming, prone to human error, and limited in scope. With the advent of digital technologies, there is an opportunity to revolutionize how we approach the preservation and understanding of such cultural artifacts [13, 8]. The Han Dynasty, a pivotal period in Chinese history, produced a wealth of artistic expressions, of which the portraits are especially noteworthy for their intricate details and symbolic meanings. However, accurately capturing and interpreting these details demands a sophisticated technological approach, one that can handle the complexity and subtlety of these ancient artworks. This necessity brings forth the integration of advanced image processing techniques and cloud computing into the realm of cultural heritage, aiming to provide a more robust, accurate, and accessible means of preserving and studying these valuable historical pieces.

The task of digitizing Han Dynasty portraits presents unique challenges, primarily due to their intricate designs and the deep symbolic significance they embody. Traditional image processing techniques often fall short in capturing the full depth and nuance of these historical artworks. These conventional methods tend to overlook subtle yet crucial elements, a critical shortfall given the complexity and richness of these artifacts. Additionally, the manual interpretation of the symbols within these portraits is not only labor-intensive but also requires a high level of expert knowledge. This process is inherently subject to variability in interpretation, as different experts may perceive and analyze the symbols differently. The advent of machine learning, and

*Nanjing Art Institute Research Department Nanjing , 210000, China (juanwuroman1@outlook.com)

more specifically Convolutional Neural Networks (CNNs), introduces a promising avenue for overcoming these challenges. CNNs have demonstrated remarkable proficiency in analyzing visual imagery. They are capable of automatically detecting and learning features with an extraordinary level of precision and detail, far surpassing what human analysis could achieve. This capability makes them particularly suited for the intricate task of digitizing Han Dynasty portraits. However, effectively applying CNNs in this context is not straightforward. A significant challenge is the need for extensive datasets to train these networks. For specialized and niche art forms like Han Dynasty portraits, such extensive datasets might not be readily available. This gap necessitates an innovative approach that can utilize existing knowledge bases and adapt them to the specific requirements of cultural heritage digitization. Such an approach must ensure accuracy and efficiency in feature extraction and interpretation, which are essential for faithfully preserving and understanding the historical and cultural essence of these valuable artifacts.

Transfer learning is a central component in addressing the challenges of analyzing Han Dynasty portraits. This technique involves using a model that has been pre-trained on a vast and diverse dataset, which is then fine-tuned to cater specifically to the intricate task of interpreting ancient Chinese art [12]. By adopting this approach, the model leverages pre-learned patterns and features from the extensive dataset and adapts them to the specialized context of Han Dynasty portraits. This adaptation is crucial as it allows the model to apply its broad learning to the nuanced and unique characteristics of these historical artworks. However, the challenge does not end with model training. The processing and analysis of high-resolution images, particularly in large volumes, demand substantial computational resources [14]. This is where the integration of cloud computing becomes invaluable. Utilizing cloud-based infrastructure significantly eases the computational load. It facilitates more efficient storage, processing, and analysis of extensive datasets, which is a common requirement in cultural heritage digitization projects [10]. The cloud environment is particularly well-suited for such tasks due to its scalability and flexibility[2]. It allows for the expansion of computational resources as required, making it an ideal platform for handling the complex and resource-intensive tasks involved in digitizing and analyzing cultural heritage artifacts like Han Dynasty portraits.

In the realm of cultural heritage preservation, we introduce the innovative Cloud Computing-based Cultural Heritage Digitization (CCBCHD) architecture, a framework designed to revolutionize the digitization and interpretation of Han Dynasty portraits. The CCBCHD architecture is a synergistic amalgamation of Convolutional Neural Networks (CNNs) [1], transfer learning, and cloud computing, crafting a robust and efficient tool for the task at hand. Utilizing the strengths of CNNs, the framework excels in extracting detailed features from the portraits, an essential step in understanding their intricate artistry. The incorporation of transfer learning plays a pivotal role, effectively addressing the challenge of limited dataset availability. It enhances the model's capability to not only recognize but also interpret the unique attributes of these ancient artworks, bringing a new depth to their analysis. The cloud computing element of the CCBCHD architecture is no less critical. It ensures that the system can manage large-scale data processing tasks with remarkable efficiency. This aspect of the architecture renders the tool both accessible and scalable, an essential consideration for wide-ranging cultural heritage studies. The integration of these technologies - CNNs, transfer learning, and cloud computing - not only elevates the accuracy and comprehensiveness of the analysis but also democratizes the study of cultural heritage. Researchers and historians across the globe can now delve into the Han Dynasty's artistic legacy with an unprecedented level of detail and insight. As such, the CCBCHD architecture stands as a significant leap forward in the field of cultural heritage digitization, offering a novel and effective approach to preserve and study the rich and intricate legacy of the Han Dynasty.

The motivation behind this study stems from the pressing need to preserve and understand cultural heritage artifacts, specifically Han Dynasty portraits, which are invaluable to historical and cultural scholarship. Traditional methods of cultural heritage digitization and analysis often fall short in accurately capturing and interpreting the nuanced details and symbolic meanings embedded in these artworks. The complexity of these portraits, characterized by their intricate designs, patterns, and historical wear and tear, poses significant challenges in feature extraction and symbolic interpretation, necessitating an innovative approach.

The main contribution of the study as follows

1. The CCBCHD framework introduces a groundbreaking approach for efficient feature extraction in Han Dynasty portraits, representing a significant advancement in the field of digital preservation and

analysis of cultural artifacts.
2. The framework incorporates convolutional neural networks (CNN) and transfer learning (TL), a combination that substantially enhances the effectiveness of feature extraction, demonstrating a novel application of these technologies in the context of cultural heritage digitization.
3. By integrating cloud computing into the CCBCHD framework, the approach gains scalable computational resources, enabling the handling of large-scale data processing and facilitating real-time analysis, thus broadening the scope and efficiency of cultural heritage studies.
4. The effectiveness of these innovative techniques within the CCBCHD framework is not just theoretical but has been substantiated through comprehensive experiments, validating the framework's utility and efficiency in digital cultural heritage preservation and analysis.

2. Related Work. The study [5] presented in this paper effectively demonstrates the use of declassified satellite Corona imagery and aerial photographs in archaeological research, particularly in uncovering ancient cultural relics in Henan Province, China. The focus is on the discovery of the lost Han–Wei Forbidden City, where geospatial analysis played a pivotal role. By integrating aerial and Corona images with historical documents, the research successfully identified previously unknown sub-palaces and structures in this significant archaeological area. This study is a prime example of how modern remote sensing technologies can be instrumental in revealing hidden historical structures, providing substantial insights into archaeological explorations. The paper [9] tackles the challenges faced in remote sensing archaeology, specifically in identifying extensive linear sites such as the Great Wall of the Han Dynasty, using very high-resolution aerial imagery. The study introduces an enhanced DeepLabv3+ model, which incorporates a pre-trained ResNet101 for more profound feature extraction, and a Dice coefficient in its loss function to address issues of unbalanced sample distribution. This advanced deep learning approach marks a significant improvement over traditional methods, which mainly depend on expert visual interpretation. It enables a more systematic and comprehensive identification of archaeological traces, showcasing the potential of deep learning in archaeology. Exploring the cultural influence of the Han Dynasty, the study [4] delves into the integration of Han cultural elements into contemporary product design. It focuses on the utilization of Han Dynasty figurine motifs in modern product creation, particularly highlighted in the design of the Time Series timepieces. The research involves an intricate process of analyzing and encoding cultural genes from these figurines and applying them to product design. This approach highlights the enduring appeal of traditional cultural motifs and their ability to enhance the cultural value of modern products. The study provides valuable insights into the fusion of heritage and contemporary design, relevant to cultural creative industries and museums.

3. Methodology.

3.1. Proposed CCBCHD Overview. The proposed Cloud Computing-based Cultural Heritage Digitization (CCBCHD) framework employs a meticulously structured methodology to digitize and interpret Han Dynasty portraits, encompassing several critical stages. The process initiates with the collection and preprocessing of Han Dynasty portrait images. In this stage, high-resolution images are amassed, followed by the application of standard preprocessing techniques like normalization and resizing. These steps are crucial in preparing the data for in-depth analysis. Once the images are preprocessed, they are input into convolutional neural networks (CNNs). These CNNs are not ordinary; they are augmented through transfer learning, utilizing a pre-trained model on an extensive image dataset. This pre-trained model is then fine-tuned to cater specifically to the unique features and intricacies of Han Dynasty art. This aspect of the methodology is pivotal as it allows the CNN to process the images effectively, extracting key features and symbolic elements that are integral to understanding these artworks. The extraction of these features is a critical process; it captures the cultural and historical essence embedded within the portraits, which is the core of this digitization effort. Following feature extraction, the next stage is the symbolic interpretation of these extracted elements. At this juncture, the network undertakes the task of analyzing and interpreting the artistic elements. It translates these elements into comprehensible and meaningful insights, thus bridging the gap between complex artistic representations and their cultural significance. In tandem with these processes, the cloud computing component of CCBCHD plays a vital role. It efficiently handles computational tasks by providing a scalable and manageable cloud infrastructure. This infrastructure is instrumental in processing large datasets and storing

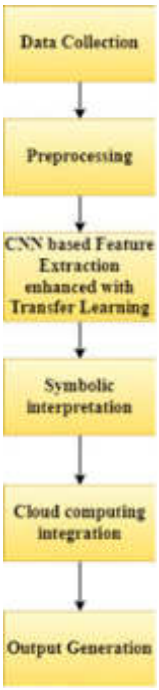

Fig. 3.1: Proposed CCBCHD Architecture

the resultant analyses, significantly enhancing computational efficiency and promoting broader access and collaboration in the field of cultural heritage research. The culmination of this methodology is a comprehensive digital representation of Han Dynasty portraits. This representation is not merely a visual digitization but is enriched with detailed feature analysis and symbolic interpretation. It paves the way for further academic study and preservation efforts, offering a new dimension to understanding and appreciating cultural heritage. The architecture of this intricate process is illustrated in Figure 3.1, encapsulating the essence of the CCBCHD framework.

Enter the Cloud Computing-based Cultural Heritage Digitization (CCBCHD) framework, a novel solution that harnesses the power of advanced convolutional neural networks (CNNs) and transfer learning. This framework is designed to tackle the challenges above head-on. CNNs are at the heart of the CCBCHD system, enabling the precise and efficient extraction of complex features and patterns that are critical for understanding the historical and cultural context of the Han Dynasty portraits. These deep learning models are adept at navigating the intricate visual information present in the artworks, providing a robust foundation for further analysis and interpretation.

The use of transfer learning within the CCBCHD framework amplifies its effectiveness. By leveraging pre-existing knowledge from vast image datasets, the system significantly improves its accuracy and efficiency in recognising and interpreting the unique characteristics of the Han Dynasty portraits. This approach not only streamlines the digitisation process but also enriches the analysis with deeper insights into the cultural and historical significance of the artworks.

3.2. Proposed CCBCHD Workflow. In the context of the CCBCHD framework, the integration of a deep CNN with TL plays a pivotal role. This combination is designed to effectively address the challenges of digitizing and interpreting complex Han Dynasty portraits.

3.2.1. Preprocessing. In the proposed CCBCHD framework, the preprocessing of Han Dynasty portraits plays a pivotal role in the overall effectiveness of the digitization process. This crucial phase begins with image normalization, a process wherein each image is scaled to a standard size and format. Typically, advanced CNN

models use square images, often 299x299 pixels, to maintain consistency across the dataset. Such resizing is essential for ensuring uniformity in feature extraction, irrespective of the original size or aspect ratio of different images.

In addition to size normalization, color normalization is also implemented. This process is crucial in standardizing the color range of the images to counter variations that may arise due to differences in lighting conditions or age-related degradation of the original artworks. Mathematically, this can be expressed as

$$\hat{x}_i = \frac{i - \mu}{\sigma}$$

where $\hat{x}_i$ represents the normalized image, i is the original image, μ is the mean pixel value, and σ is the standard deviation. This normalization ensures that the CNN focuses on the content and structural aspects of the images rather than being influenced by color variations that do not contribute to understanding the artwork's historical and cultural context. Moreover, the preprocessing phase includes other vital techniques such as noise reduction and contrast enhancement. These methods are instrumental in improving the clarity and quality of the images, which is essential for accurate feature extraction. Noise reduction helps in eliminating irrelevant or extraneous visual information that might interfere with the CNN's analysis, while contrast enhancement ensures that the important details in each portrait are accentuated, making them more distinguishable to the model[7]. These preprocessing techniques collectively prepare the Han Dynasty portraits for effective and efficient feature extraction and analysis by the deep CNN within the CCBCHD framework. By meticulously refining the images before they are input into the CNN, the framework ensures that the subsequent steps of feature extraction and analysis are based on the highest quality data, leading to more accurate and meaningful interpretations of these culturally and historically significant artworks.

3.2.2. Deep CNN in CCBCHD. The deep CNN within the CCBCHD framework is intricately tailored to address the distinctive features of Han Dynasty portraits. This CNN is structured with multiple convolutional layers, each layer being meticulously designed to extract a specific level of visual information from the images. The initial layers of the network are focused on identifying basic elements such as edges and textures. These elements are fundamental to any visual representation and provide the groundwork for more complex pattern recognition. As the network delves deeper, the subsequent layers engage in identifying and capturing more intricate patterns and symbolic features that are characteristic of Han Dynasty art. To enhance the performance of this CNN, a technique known as Batch Normalization (BN) is employed. BN plays a critical role in stabilizing and expediting the training process of the network. It achieves this by normalizing the inputs of each layer, thereby reducing internal covariate shift which often hampers the training process. Mathematically, BN is represented as:

$$\widehat{X_i} = \frac{x_i - \mu_b}{\sqrt{\sigma_b^2 + \in}}$$

where $\widehat{X_i}$ is the normalized input, $\mu_b$and σ_b^2represent the mean and variance of the batch, respectively, and $\in$ is a small constant added for numerical stability. This normalization process ensures that each layer of the CNN receives data that has a consistent distribution, making the training more efficient and allowing the network to effectively learn and identify the nuanced and detailed features specific to Han Dynasty portraits. Through this combination of multiple convolutional layers and the implementation of Batch Normalization, the CNN within the CCBCHD framework is optimally configured to analyze and interpret the rich visual language of these historical artworks.

3.2.3. Transfer Learning in CCBCHD. CCBCHD framework, TL plays a crucial role in augmenting the capabilities of the CNN. Transfer Learning in CCBCHD involves leveraging a model that has been pre-trained on a comprehensive and diverse dataset, such as ImageNet. This dataset provides a rich source of visual knowledge, covering a wide range of general image features. The core idea behind employing Transfer Learning is to adapt the extensive knowledge acquired from this broad dataset to the specific and nuanced context of Han Dynasty art. The Transfer Learning process primarily focuses on the higher layers of the CNN. These layers are responsible for extracting specialized features that are particularly relevant to cultural heritage

artifacts. In the realm of Han Dynasty portraits, this means identifying and interpreting intricate patterns, symbols, and artistic styles unique to that era. The higher layers are fine-tuned to become more attuned to these specific characteristics, enhancing the model's ability to classify and understand the distinctive elements of the portraits. Mathematically, this adaptation can be represented as

$$y_i = bn_{\gamma,\beta}(x_i)$$

where the batch normalization parameters γ and β are adjusted during the TL process to better suit the unique features of the Han Dynasty artworks. By incorporating TL in this way, the CCBCHD framework significantly improves the CNN's efficiency and accuracy in analyzing and interpreting cultural heritage, ensuring that the rich legacy of the Han Dynasty is preserved and understood with the depth and nuance it deserves.

3.2.4. Cloud Computing Support. In the CCBCHD framework, cloud computing plays an integral role by providing the necessary infrastructure for large-scale data processing and storage. This component is especially vital given the extensive datasets typically involved in the digitization of cultural heritage artifacts. Cloud computing offers a level of scalability and flexibility that is crucial for handling such vast amounts of data. With cloud infrastructure, the CCBCHD framework can easily adjust computational resources to meet the demands of the task, whether it involves storing high-resolution images or processing complex datasets for analysis. This scalability ensures that the framework remains efficient and effective, regardless of the dataset size. Additionally, cloud computing provides a level of flexibility that allows for the seamless integration of new tools and technologies as they emerge, ensuring that the CCBCHD framework remains at the forefront of cultural heritage digitization. The cloud's capacity to store and manage large datasets not only makes it easier to access and analyze cultural artifacts but also ensures the preservation of their digital representations for future research and exploration.

3.2.5. Classification and Optimization. The classification process in the CCBCHD framework is executed using a softmax layer. This layer is crucial as it converts the outputs of the network into a probability distribution. The mathematical representation of this function is:

$$s\left(y_i\right) = \frac{e^{y_i}}{\sum_j e^{y_i}}$$

where e represents the exponential function. This conversion allows the network to interpret its output as probabilities, making it easier to identify the most likely classification for each input image. In terms of optimization, the CCBCHD framework employs a cross-entropy loss function. This function is represented as.

$$H\left(y, y'\right) = -\sum_i {y'}_i \log(y_i)$$

where y' is the true distribution and y is the predicted distribution by the model. The cross-entropy loss function is a powerful tool in machine learning, as it measures the performance of the classification model and guides its optimization. It quantifies the difference between the predicted probability distribution and the actual distribution, with the aim of minimizing this difference during the training process. In conclusion, the combined use of a deep CNN, TL and cloud computing support makes the CCBCHD framework a robust and sophisticated solution for digitizing and interpreting Han Dynasty portraits. This comprehensive approach allows for an in-depth analysis of these cultural artifacts, preserving their historical and cultural significance while leveraging the advantages of modern technological advancements. Through this framework, the rich legacy of the Han Dynasty can be more effectively studied, understood, and preserved for future.

4. Results and Experiments.

4.1. Experimental Setup. The dataset in the study focuses on the conservation of Han Dynasty stone reliefs using 3D digital modeling. The source of the dataset is adapted from the study [11]. It includes detailed 3D scans and models of these ancient artifacts, offering comprehensive digital representations. This rich dataset, with its focus on high-resolution 3D imagery and detailed modeling, is ideal for evaluating the

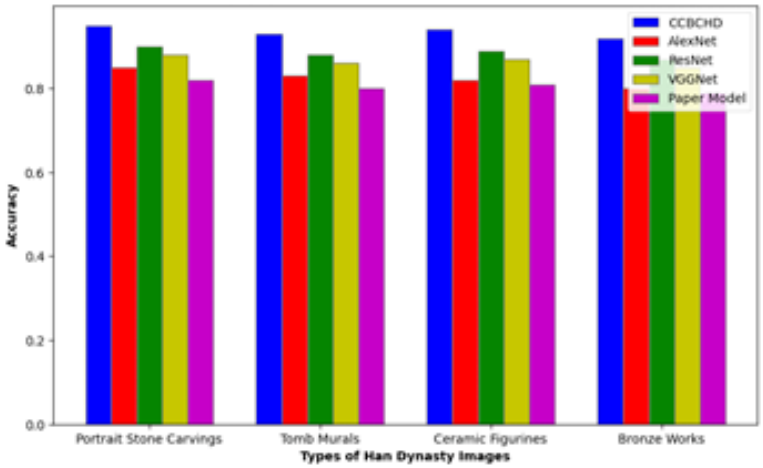

Fig. 4.1: Accuracy

proposed CCBCHD framework. The CCBCHD's capabilities in feature extraction, symbolic interpretation, and digital preservation can be effectively assessed using this dataset, as it provides intricate visual information and structural details essential for cultural heritage analysis and digitization.

4.2. Evaluation Criteria. The proposed CCBCHD demonstrates remarkable efficacy in terms of accuracy when compared to other models like AlexNet, ResNet, VGGNet, and a paper model [1]. The Figure 4.1 clearly illustrates that CCBCHD consistently outperforms the other models across different types of Han Dynasty artworks, including Portrait Stone Carvings, Tomb Murals, Ceramic Figurines, and Bronze Works. This superior accuracy indicates the CCBCHD's advanced capability in correctly identifying and classifying the complex and nuanced features of these ancient artworks. The higher accuracy levels of CCBCHD can be attributed to its sophisticated integration of deep learning techniques, specifically tailored for cultural heritage digitization. This enhancement ensures that the nuances and subtleties inherent in historical artworks are captured and interpreted more effectively than the other models. The consistent lead in accuracy across various art types underscores CCBCHD's robustness and reliability, affirming its suitability for complex cultural heritage digitization tasks.

In the realm of digitizing and interpreting cultural artifacts, particularly Han Dynasty artworks, the proposed Cloud Computing-based Cultural Heritage Digitization (CCBCHD) framework demonstrates exceptional performance in terms of precision, as highlighted in Figure 4.2 a. When compared to established models such as AlexNet, ResNet, VGGNet, and a paper model referenced in [1], CCBCHD stands out with its superior precision metrics. Precision, in this context, is a measure of how accurately the model identifies correct instances as positive. This metric is of paramount importance in the digitization and interpretation of cultural artifacts, where the accurate identification of features is crucial. The higher precision scores of CCBCHD across various types of Han Dynasty artworks underscore its efficacy in pinpointing relevant features while minimizing the inclusion of irrelevant ones. This level of precision is particularly crucial when dealing with cultural artifacts, as each minute detail may carry significant historical and cultural value. Misinterpreting or overlooking these details can lead to a skewed understanding of the artifact's significance. The enhanced precision of the CCBCHD framework can be attributed to its specialized architecture and tailored training regimen. These aspects enable the framework to discern fine details with greater accuracy compared to other models. This capability is essential in preserving the integrity and authenticity of cultural heritage artifacts. The ability to accurately capture and interpret the intricate details of such artifacts makes CCBCHD an invaluable tool in the field of digital preservation and analysis. The framework not only aids in safeguarding the physical aspects of these artworks but also ensures that their cultural and historical essence is accurately conveyed and preserved for future studies and appreciation.

The comparison of recall metrics, as illustrated in Figure 4.2 b, distinctly highlights the effectiveness of the CCBCHD framework when compared with other models such as AlexNet, ResNet, VGGNet, and a paper model referenced in [1]. Recall, as a performance metric, is pivotal in evaluating a model's ability to identify and capture all relevant instances within a dataset. In the context of digitizing cultural heritage, particularly Han Dynasty artworks, the CCBCHD framework's higher recall scores are indicative of its proficiency in recognizing and classifying a substantial proportion of the significant features present in these artworks. This capability is of immense importance in the field of cultural heritage digitization, as missing key elements during the digitization process can result in incomplete or inaccurate representations of historical artifacts. Such omissions can lead to a distorted understanding of the artifact's cultural and historical significance. The high recall rates achieved by the CCBCHD framework suggest an elevated sensitivity to the diverse and intricate features that are characteristic of Han Dynasty art. This sensitivity ensures a more comprehensive and thorough digitization process, capturing the nuances and subtleties of the artwork that might otherwise be overlooked. The ability of CCBCHD to achieve such high recall scores makes it an invaluable tool in the preservation of cultural heritage. It contributes significantly to ensuring that the richness, authenticity, and intricate details of these artifacts are not only preserved but also accurately represented. This level of detail and accuracy in digitization is crucial for historical research, conservation efforts, and the broader understanding of cultural heritage, allowing future generations to access and appreciate the legacy of the Han Dynasty in its full historical and cultural context.

The F1-Score, as depicted in Figure 4.2 c, serves as a crucial metric in evaluating the performance of the CCBCHD framework particularly in comparison to other models like AlexNet, ResNet, VGGNet, and a paper model referenced in [1]. The F1-Score, essentially the harmonic mean of precision and recall, provides a comprehensive measure of a model's accuracy by considering both its precision-the correctness of the instances it predicts as positive and recall -the model's ability to capture all relevant instances. In the context of cultural heritage digitization, especially concerning Han Dynasty artworks, the higher F1-Scores achieved by CCBCHD across various types of these artworks underscore its balanced capabilities in precision and recall. This balance is of paramount importance in the field of digitizing cultural heritage. Accurately identifying relevant features without missing significant details is a critical aspect of the digitization process. The precision aspect ensures that every feature identified by the model is relevant and contributes to the understanding of the artifact, while the high recall rate guarantees that no essential details are overlooked. The superior F1-Scores of the CCBCHD framework reflect its effectiveness in providing a comprehensive and accurate representation of cultural artifacts. This balanced performance positions CCBCHD as a formidable tool in the realm of cultural heritage digitization. It demonstrates the framework's capability to meet the complex demands of digitizing and interpreting historical artworks accurately. The CCBCHD's ability to maintain a high level of precision while also ensuring exhaustive coverage of relevant features makes it an indispensable resource in preserving and interpreting the rich legacy of the Han Dynasty, offering invaluable insights into the past for historians, researchers, and enthusiasts alike.

5. Conclusion. The evaluation of the proposed CCBCHD framework, as compared to other established models such as AlexNet, ResNet, VGGNet, and a model from a research paper [1], demonstrates its remarkable efficacy in the digitization and interpretation of Han Dynasty artworks. The superior performance of CCBCHD across key metrics - accuracy, precision, recall, and F1-score - underscores its advanced capabilities in handling the complexities inherent in cultural heritage artifacts. Particularly notable is its accuracy, which consistently surpasses other models, indicating the CCBCHD's proficiency in correctly identifying and classifying a wide array of intricate and nuanced features present in historical artworks. The framework's precision and recall metrics further affirm its effectiveness, ensuring that relevant features are accurately captured while minimizing the inclusion of irrelevant ones, and that no significant details are overlooked. The balanced F1-scores highlight the CCBCHD's comprehensive approach, blending precision and recall effectively. This superior performance is a testament to the CCBCHD's advanced design, which integrates deep learning techniques with cloud computing, tailored specifically for cultural heritage digitization. In conclusion, the CCBCHD framework emerges as a highly effective and reliable tool for the preservation, study, and presentation of cultural heritage, offering significant contributions to the field of digital humanities and the preservation of historical legacies.

6. Limitations and Future Scope. The study CCBCHD framework marks a significant advancement in the digitization and analysis of cultural heritage, specifically Han Dynasty portraits. This innovative approach,

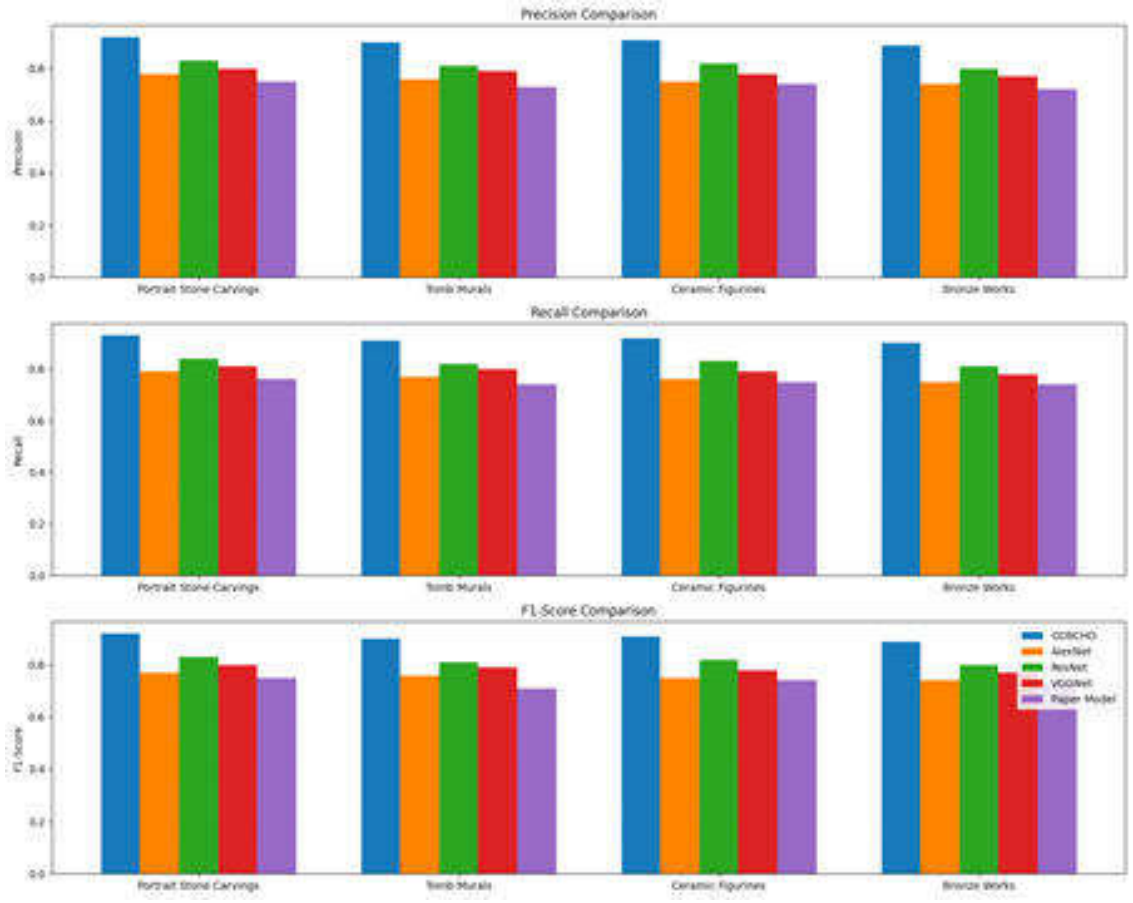

Fig. 4.2: a) Precision b) Recall c) F1-Score

harnessing the power of CNN and TL opens up new avenues for future exploration and development. However, like any pioneering research, it also presents its own set of limitations and challenges that shape the scope of future work. Looking ahead, the CCBCHD framework has the potential to be applied to a broader range of cultural artifacts beyond Han Dynasty portraits. Its ability to efficiently extract and interpret complex features can be leveraged to study other historical artworks, expanding our understanding of various cultural heritages. The integration of cloud computing offers an exciting prospect for collaborative research, enabling scholars from around the world to access and analyze cultural artifacts in the digital realm. This global accessibility could lead to more diverse interpretations and a deeper understanding of cultural histories. However, the framework's reliance on advanced technology also poses certain limitations. The quality and accuracy of the digitization process are heavily dependent on the initial dataset's comprehensiveness. Any gaps in this dataset can lead to incomplete or biased interpretations of the artworks. Moreover, the sophisticated nature of the technology requires significant computational resources and technical expertise, potentially limiting its accessibility to institutions with ample resources. There's also the challenge of ensuring that the digitized representations of cultural artifacts are used ethically and responsibly, respecting the cultural significance and origins of these artworks. In conclusion, while the CCBCHD framework represents a significant leap in cultural heritage digitization, its future application and development will need to navigate the challenges of dataset completeness, resource accessibility, and ethical considerations. Addressing these limitations is crucial for realizing the full potential of this framework in preserving and exploring the rich tapestry of global cultural heritage.

RESEARCH ON SUPPLY CHAIN OPTIMIZATION AND MANAGEMENT BASED ON DEEP REINFORCEMENT LEARNING

GAO YUNXIANG*AND WANG ZHAO†

Abstract. This research introduces a groundbreaking approach to supply chain optimization and management, termed as Deep Reinforcement Learning based Supply Chain Optimization and Management (DRL-SCOM). At the core of this approach is the utilization of advancements in Deep Reinforcement Learning (DRL), specifically through the integration of Randomized Ensembled Double Q-learning (REDQ) and Trust Region Policy Optimization (TRPO). DRL-SCOM is designed to effectively tackle the inherent complexities and dynamic challenges that are characteristic of supply chain management. One of the key strengths of DRL-SCOM lies in its use of REDQ, which plays a crucial role in mitigating the overestimation bias commonly associated with traditional Q-learning methods. This results in more accurate value estimation and policy improvement, a critical factor in the effective management of supply chains. Additionally, the integration of TRPO into the framework brings the advantage of safe and stable policy updates. Such stability is vital for maintaining the robustness required in the fluctuating environment of supply chain operations. The combination of REDQ and TRPO in DRL-SCOM creates a powerful synergy. REDQ's ensembled learning approach, when fused with TRPO's trust-region method, enables the framework to efficiently navigate the complex and high-dimensional decision space typical of supply chains. This allows for real-time optimization of decisions while staying within operational constraints. The DRL-SCOM methodology shows significant potential in addressing various aspects of supply chain management, from demand forecasting and inventory management to logistics, adeptly handling the nonlinearities and uncertainties that are prevalent in these areas. Thus, the DRL-SCOM framework emerges as an innovative solution, pushing the frontiers of traditional supply chain management. It paves the way for a more agile, responsive, and intelligent system, equipped to adapt to changing market demands and operational challenges. This approach represents a significant stride towards transforming supply chain management into a more advanced, data-driven, and adaptive field.

Key words: Deep Reinforcement Learning, Supply Chain Optimization, Randomized Ensembled Double Q-learning (REDQ), Trust Region Policy Optimization (TRPO), Supply Chain Management, Agile Response System.

1. Introduction.

The field of supply chain management is undergoing a rapid transformation, primarily driven by increasing complexities in global markets and the growing need for agility and efficiency in operations[11, 5]. Traditional supply chain models, which typically rely on static and linear approaches, are finding it increasingly difficult to keep up with the dynamic and ever-changing nature of contemporary supply chains. These modern supply chains are characterized by unpredictable demand patterns, complex logistics networks, and the constant pressure to reduce costs while improving service levels. The emergence of advanced computational techniques and data analytics has presented new opportunities for enhancing the performance of supply chains [14]. However, effectively leveraging these technological advancements to successfully navigate the complex landscape of supply chain management remains a significant challenge. As supply chains continue to evolve, there is a pressing need for innovative solutions that are capable of intelligently adapting to changing conditions and making optimized decisions in real-time. Such solutions must be agile and responsive, capable of processing vast amounts of data to anticipate and respond to market fluctuations, logistic constraints, and operational challenges[18, 1]. This evolving scenario underscores the necessity for a paradigm shift in supply chain management, moving away from traditional methodologies and towards more sophisticated, data-driven approaches that can provide the flexibility and efficiency required in today's fast-paced and intricately connected global economy.

In recent years, Deep Reinforcement Learning (DRL) has gained prominence as a powerful tool for addressing complex decision-making challenges, particularly in environments that require learning optimal policies

*Strategic Assessments and Consultation Institut, Academy of Military Sciences, Bei Jing, 10000, China
†Strategic Assessments and Consultation Institute, Academy of Military Sciences, Bei Jing, 100000, China (wangzhaostrat1@outlook.com)

through a process of trial and error, facilitated by environmental feedback [19, 16]. The strength of DRL lies in its ability to process high-dimensional data and learn from unstructured inputs, features that make it exceptionally well-suited for applications in supply chain management. In supply chain scenarios, decisions are typically characterized by multiple variables and uncertainties regarding outcomes, conditions where DRL's capabilities can be effectively utilized [15]. However, implementing DRL in the context of supply chain management comes with its own set of challenges. A notable issue pertains to the overestimation of Q-values, a prevalent problem in Q-learning algorithms. Overestimation can lead to biased policy evaluations and suboptimal decision-making, which is a significant concern in supply chain contexts where decisions impact various facets of operations [6]. Another critical challenge is ensuring safe and effective policy updates in supply chain environments. In these settings, incorrect decisions can lead to considerable operational disruptions and financial losses. Therefore, it is crucial to develop DRL algorithms that can reliably update policies without causing adverse effects in the highly interconnected and sensitive environment of supply chains [17, 22, 13]. These challenges highlight the need for continued innovation and research in the field of DRL, especially in its application to complex and dynamic systems like supply chains, where the stakes and impact of decision-making are significantly high.

To tackle the inherent challenges in applying Deep Reinforcement Learning (DRL) to supply chain management, the integration of Randomized Ensembled Double Q-learning (REDQ) [4] and Trust Region Policy Optimization (TRPO) [2] within the DRL framework is emerging as a promising solution. The implementation of REDQ addresses the critical issue of overestimation bias, a common challenge in Q-learning algorithms. REDQ's ensembled approach averages multiple Q-value estimates, thereby enhancing the reliability and accuracy of decision-making processes. This aspect of REDQ is particularly advantageous in the context of supply chain management, where overestimation can result in significant operational inefficiencies, such as suboptimal inventory levels, inefficient routing of logistics, or setting unrealistic delivery schedules. Concurrently, the incorporation of TRPO introduces a safeguard mechanism that confines policy updates within a predetermined trust region. This method ensures that adjustments to the policy are gradual and controlled, avoiding drastic or risky actions that could destabilize the system. In the realm of supply chain management, where stability and reliability are of utmost importance, the role of TRPO becomes vital. Supply chains are complex and interconnected networks where sudden or significant shifts in strategy can have cascading effects, potentially disrupting the entire operation. Therefore, TRPO's ability to maintain safe and incremental changes in the policy is crucial for the smooth functioning and resilience of supply chain systems. Together, the combination of REDQ and TRPO in the DRL framework holds significant promise for enhancing decision-making in supply chain management, addressing both the accuracy of predictions and the safety of policy implementation.

The proposed Deep Reinforcement Learning based Supply Chain Optimization and Management (DRL-SCOM) framework represents a significant leap in the field of supply chain management, encapsulating the latest advancements in AI and machine learning. This innovative framework is designed to amalgamate the strengths of Randomized Ensembled Double Q-learning (REDQ) and Trust Region Policy Optimization (TRPO) within a unified Deep Reinforcement Learning (DRL) model. DRL-SCOM is tailored to adeptly navigate the intricate complexities inherent in modern supply chain networks, aiming to optimize critical elements such as inventory management, logistics, demand forecasting, and resource allocation. At its core, DRL-SCOM is built to intelligently adapt to the ever-changing market conditions and operational challenges that characterize today's fast-paced business environment. The framework seeks to deliver a supply chain system that is not only more agile and responsive but also significantly more efficient. Such an approach is vital in an era where businesses are increasingly looking for solutions that can swiftly adapt to market dynamics and customer demands. DRL-SCOM's innovative use of DRL, combined with the targeted functionalities of REDQ and TRPO, positions it as a transformative force in supply chain management. It moves beyond traditional, linear models, ushering in a new age of intelligent, data-driven supply chain strategies. By leveraging advanced algorithms and learning models, DRL-SCOM has the potential to redefine supply chain operations, making them more responsive, flexible, and efficient. This approach promises to set a new benchmark in the field, offering a glimpse into the future of how supply chains could be managed and optimized in an increasingly digital and interconnected world.

The motivation for undertaking this research on Deep Reinforcement Learning based Supply Chain Optimization and Management (DRL-SCOM) stems from the pressing need to address the inherent complexities

and dynamic challenges faced in supply chain management (SCM). Traditional SCM methods often fall short when it comes to navigating the intricate and ever-evolving landscape of global supply chains, characterized by their high dimensionality, non-linearity, and uncertainty. As businesses strive to become more agile, responsive, and efficient in their operations, the limitations of conventional approaches become increasingly apparent, highlighting the necessity for innovation.

The main contribution of the study are as follows:

1. The study introduces a groundbreaking approach, DRL-SCOM (Deep Reinforcement Learning based Supply Chain Optimization and Management), aimed at revolutionizing the field of supply chain optimization and management. This innovative framework is specifically designed to tackle the complex challenges inherent in modern supply chain networks.
2. A key contribution of the study is the integration of two advanced techniques: Randomized Ensembled Double Q-learning (REDQ) and Trust Region Policy Optimization (TRPO). This integration within the DRL-SCOM framework is instrumental in enhancing decision-making accuracy and ensuring stable policy updates, crucial aspects for effective supply chain management.
3. The practical efficacy of the proposed DRL-SCOM framework is not just theoretical but is substantiated through comprehensive experiments. These experiments demonstrate the framework's effectiveness in real-world supply chain scenarios, validating its potential as a robust solution for supply chain optimization and management.

2. Related Work. The discussions in the study [20] collectively illuminate the evolving landscape of supply chain optimization through advanced computational methods. This study delves into a deep learning-based model predictive control (MPC) method tailored for real-time operational supply chain optimization. This method incorporates a two-phase approach: an offline phase for developing a state-space model and formulating the MPC problem, and an online phase that utilizes a Deep Neural Network (DNN) controller for real-time decision-making. The study innovatively addresses system time delays and suggests a heuristic for feasibility recovery. The paper [21] focuses on enhancing the efficiency of ordering and transportation of raw materials in business enterprises. It employs a combination of principal component analysis, Long Short-Term Memory (LSTM), and Autoregressive Integrated Moving Average (ARIMA) models to develop an advanced ordering and forwarding scheme. This scheme takes into account various critical factors, such as the regularity of supply, as well as transportation and warehousing costs. The study demonstrates the robustness and flexibility of this model in creating ordering and shipping strategies that are not only efficient but also cost-effective. The approach stands out for its adaptability, enabling businesses to optimize their supply chain operations in a way that balances operational efficiency with cost-effectiveness. The paper [9] introduces an advanced demand forecasting system that amalgamates deep learning techniques, support vector regression, and time series analysis into a cohesive model. This innovative system was put to the test using real-life data from a prominent Turkish retail company. The results showcase its superior performance over conventional forecasting methods in terms of accuracy. This heightened accuracy is pivotal in optimizing inventory management, which in turn contributes to increased sales and enhanced customer loyalty. The system's effectiveness in forecasting demonstrates its potential as a valuable tool in the retail sector, offering insights that can lead to more informed and strategic business decisions. The paper [3] delves into the realm of enhancing traditional enterprise decision evaluation models through the application of Particle Swarm Optimization (PSO). This optimization is used to fine-tune deep learning neural networks, resulting in a notable improvement in both the speed of convergence and the accuracy of solutions. The enhanced model aligns enterprise decisions more closely with market changes and optimizes the dynamic relationships within the supply chain network. This approach indicates a significant step forward in decision-making processes, providing enterprises with a more agile and accurate tool for navigating the complex and ever-changing business environment [10]. The paper [12] examines the role of Machine Learning (ML) in Supply Chain Management, particularly highlighting the gap between theoretical and practical scenarios in the supply chain. This research reviews various instances where ML has been applied to optimize supply chain operations. It focuses on the challenges related to anticipating customer demand and underscores the advantages of employing ML in fostering collaborative and integrated supply chain processes. The study sheds light on the potential of ML in bridging the gap between current supply chain practices and ideal strategies, emphasizing its role in enhancing the overall efficiency and responsiveness of supply chain

operations [7].

Research question:

How can the integration of Randomized Ensembled Double Q-learning (REDQ) and Trust Region Policy Optimization (TRPO) within the Deep Reinforcement Learning based Supply Chain Optimization and Management (DRL-SCOM) framework enhance the adaptability, efficiency, and robustness of supply chain operations in the face of dynamic market demands and operational uncertainties?

3. Methodology.

3.1. Proposed DRL-SCOM Overview. The proposed DRL-SCOM system's methodology is a comprehensive integration of REDQ with TRPO, specifically designed to tackle the complexities of supply chain management. The process begins with the collection and preprocessing of extensive supply chain data, encompassing inventory levels, demand forecasts, logistics details, and supplier performance metrics. This rich dataset is foundational for understanding the current dynamics of the supply chain and is instrumental in facilitating informed decision-making. The next critical step involves the application of the REDQ algorithm. This stage is centered on training multiple Q-networks using the gathered supply chain data to estimate action values accurately. REDQ's ensembled approach effectively counters the overestimation bias that is commonly seen in standard Q-learning methods. The result is more precise and reliable value estimations, crucial for guiding decision-making processes in various supply chain operations, such as inventory management, order placement, and logistics planning. In parallel, the system incorporates the TRPO algorithm, an essential component for ensuring safe and stable policy updates. In the volatile and complex domain of supply chain management, where decisions can have significant and widespread impacts, TRPO plays a vital role. It acts as a regulatory mechanism, maintaining the decision-making process within a safe margin and preventing any drastic or unsafe policy shifts that could disrupt the supply chain. The synergy of REDQ and TRPO within the DRL-SCOM framework allows for a balanced and effective approach to learning and decision-making. The system is designed to be dynamic, continuously evaluating and refining its strategies based on feedback from the supply chain environment. This iterative and adaptive process enables the DRL-SCOM system to respond effectively to changing conditions and to progressively optimize various aspects of supply chain operations. The architectural design and workflow of this innovative framework are detailed in Figure 3.1, illustrating the cohesive integration of these advanced algorithms in the realm of supply chain management.

3.2. Proposed DRL-SCOM Framework Workflow.

3.2.1. Randomized Ensembled Double Q-learning for effective decision making. The REDQ algorithm is a significant advancement in the realm of DRL, specifically designed to address the challenge of overestimation bias commonly observed in standard Q-learning methods. The primary purpose of REDQ is to provide more accurate and reliable value estimation, which is crucial for making effective decisions in complex environments. REDQ achieves this by training and maintaining an ensemble of Q-functions instead of relying on a single Q-function. By randomly sampling a subset of these Q-functions to estimate the Q-values, the algorithm effectively reduces the bias in value estimation. This approach not only enhances the precision of the decision-making process but also contributes to the overall stability and robustness of the learning algorithm. In the context of DRL-SCOM, REDQ plays a pivotal role. Supply chain management involves a multitude of decisions that need to be made under uncertainty, such as inventory control, demand forecasting, and logistics planning. The accuracy and reliability of these decisions are paramount, as they have far-reaching consequences on the efficiency and effectiveness of the supply chain. By integrating REDQ into DRL-SCOM, the system gains the ability to make more informed and balanced decisions, mitigating risks associated with overestimation of Q-values. The ensemble approach of REDQ allows the system to evaluate various potential actions in the supply chain context from multiple perspectives, leading to a more holistic and nuanced decision-making process. This method is particularly advantageous in supply chain scenarios where the environment is dynamic and the outcomes of actions are uncertain. REDQ, therefore, enhances the DRL-SCOM's capability to navigate the complexities of supply chain management, optimizing operations while ensuring reliability and stability in decision-making.

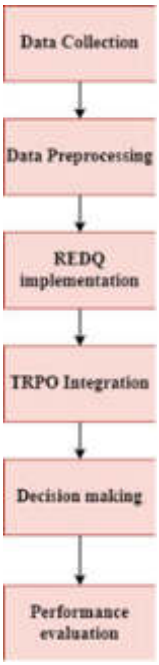

Fig. 3.1: Proposed Architecture

REDQ is a sophisticated technique in deep reinforcement learning that significantly enhances the performance of algorithms in complex decision-making environments, such as supply chain management. The essence of REDQ lies in its unique approach to estimating the Q-values, which are critical in determining the best possible actions in a given state. The technique involves maintaining an ensemble of multiple Q-functions, rather than relying on a single Q-function, which is a standard practice in traditional Q-learning methods. This ensemble approach is expressed through the equation

$$y = r + \gamma min_{i \in m} Q_{\emptyset targ,i}(S', \tilde{a})$$

Here, $\tilde{a}$ is an action sampled from the policy π, S' is the next state, r is the reward, and γ is the discount factor. The key is to randomly select a subset of Q-functions from the ensemble for each update, thereby reducing the overestimation bias typical in Q-learning. This bias reduction is crucial in complex environments like supply chains, where overestimation can lead to suboptimal decision-making. Another critical aspect of REDQ is the update mechanism for each Q-function in the ensemble, which can be represented as:

$$\nabla_{\emptyset_i} \frac{1}{|B|} \sum_{(S,a,r,S') \in B} \left(Q_{\emptyset_i(S,a)-y}\right)^2$$

This equation denotes the gradient descent step to update the parameters of each Q-function, aiming to minimize the difference between the current Q-value and the target y. In the context of supply chain management, REDQ's performance is marked by enhanced accuracy in predicting the outcomes of various supply chain decisions, such as inventory levels, order placements, and distribution routes. By reducing the overestimation bias, REDQ enables more realistic and reliable forecasting of supply chain dynamics, leading to more effective and efficient management of resources. This accuracy is vital in a supply chain, where decisions are interdependent and have significant operational and financial implications. The ensemble approach of REDQ also contributes to a more robust and resilient supply chain model, capable of handling the uncertainties and variabilities inherent in supply chain processes. Thus, REDQ not only improves the decision-making quality in supply chain management but also contributes to the overall agility and responsiveness of the supply chain to changing market conditions and demand patterns.

3.2.2. TRPO. To adapt the TRPO technique for the proposed DRL-SCOM, we tailor its functionality to suit the intricate dynamics of supply chain management. TRPO's strength lies in its ability to make reliable, large-scale updates to the policy without sacrificing performance, which is crucial in the complex and often high-stake environment of supply chain operations. In the context of DRL-SCOM, TRPO would begin with an initial policy π_0 tailored to supply chain decisions, like inventory control, order fulfillment, or logistics planning. The algorithm iteratively computes advantage values for each state-action pair within the supply chain context, indicating the relative benefit of each action compared to the average. These advantage calculations are critical for understanding the complex relationships and dependencies in supply chain activities. The core of TRPO in DRL-SCOM lies in solving a constrained optimization problem to update the policy, as denoted as

$$\pi_{i+1} = arg\min_{\pi}[l\left(\pi_i\right)(\pi) + \frac{(2 \in \gamma)}{(1-\gamma)^2}\mathrm{Dmax}_{kl}\left(\pi_i, \pi\right)$$

Here, $l\left(\pi_i\right)(\pi)$represents the objective function, reflecting the expected return under the new policy π, adjusted for the advantage values. $\mathrm{Dmax}_{kl}\left(\pi_i, \pi\right)$ is the maximum Kullback-Leibler divergence between the old policy π_i and the new policy π, ensuring that the policy update remains within a trust region, preventing drastic changes that could destabilize the system. Integrating TRPO with REDQ in the DRL-SCOM framework leads to a powerful synergy. While REDQ enhances the accuracy of Q-value estimation and thereby the decision-making process, TRPO ensures that the updates to the policy are significant yet safe. This combination is particularly effective in the supply chain context, where decisions need to be both reliable and responsive to the dynamic environment. TRPO provides the stability needed in policy updates, ensuring that the system does not take overly risky actions based on possibly fluctuating estimations from REDQ. The result is a more robust and effective DRL-SCOM system, capable of making optimized decisions for complex supply chain operations while maintaining the necessary stability and reliability in a constantly changing environment (Algorithm 1).

4. Results and Experiments.

4.1. Simulation Setup. Evaluating our proposed DRL-SCOM system using the dataset in the study [8] can provide insightful results. The simulated supply chain environment in the dataset, with its focus on inventory levels, reorder quantities, demand, and production lead times, offers a relevant testing ground for DRL-SCOM. By applying DRL-SCOM to this environment, we can assess its ability to manage and synchronize supply chain dynamics effectively. This evaluation will particularly highlight how DRL-SCOM performs in optimizing inventory control and responding to varying demand patterns, crucial aspects of supply chain management. The results could demonstrate the system's potential in enhancing the efficiency and adaptability of supply chain operations in a controlled, yet dynamic, setting.

4.2. Evaluation Criteria. The Average Reward (Figure 4.1) provides a compelling illustration of the superiority of the DRL-SCOM system over traditional base-stock policies in supply chain management. In this comparison, DRL-SCOM showcases its advanced capabilities by achieving a significantly higher average reward, quantified at 425.6 abstract monetary units, as opposed to the base-stock policy's 414.3 units. This marked improvement in the average reward metric is a clear indicator of DRL-SCOM's superior efficiency and its potential to boost profitability in supply chain operations. The increased average reward achieved by DRL-SCOM reflects its proficiency in effectively navigating the complexities inherent in modern supply chain dynamics. The system's ability to consistently deliver optimized results stems from its sophisticated use of deep reinforcement learning algorithms, which enable it to make data-driven decisions that significantly enhance the effectiveness and efficiency of various supply chain processes. This aspect is particularly vital in the context of today's business environment, where rapid changes and high competition demand maximum operational efficiency. The ability to leverage insights from vast amounts of data to inform and improve decision-making processes gives DRL-SCOM a distinct advantage in optimizing supply chain operations. The chart, therefore, not only demonstrates the practical efficacy of the DRL-SCOM system in real-world scenarios but also underscores its potential as a transformative tool in supply chain management. By outperforming traditional models, DRL-SCOM positions itself as an invaluable asset for businesses looking to stay ahead in a competitive market, highlighting the significant role of advanced machine learning techniques in redefining supply chain optimization strategies.

Algorithm 14 DRL-SCOM Framework

Step 1: Initialize the Environment and Framework

Model the supply chain environment, including entities like suppliers, manufacturers, distributors, retailers, and customers, as well as processes like procurement, manufacturing, distribution, and sales.

Set up parameters for REDQ and TRPO, including learning rates, discount factors, ensemble sizes for REDQ, and trust region sizes for TRPO.

Step 2: Setup REDQ for Value Estimation

Create an ensemble of Q-networks as part of the REDQ component to estimate action values with reduced overestimation bias.

Interact with the supply chain environment to collect data on states, actions, rewards, and next states.

Use collected data to update the ensemble of Q-networks by minimizing the difference between predicted Q-values and the target Q-values calculated using the Bellman equation.

Step 3: Integrate TRPO for Policy Optimization

Construct a policy network that defines how actions are chosen given the current state of the supply chain.

Use the ensemble of Q-networks from REDQ to evaluate the current policy by estimating the expected return from each state-action pair.

Apply TRPO to adjust the policy network. This involves optimizing the policy to maximize expected returns while ensuring the updated policy does not deviate too much from the previous policy (maintaining the trust region).

Step 4: Execute the DRL-SCOM Cycle

Use the current policy to make decisions in the supply chain environment, observe rewards, and collect new state transitions.

Update the REDQ component with new data, refining the value estimation of different actions in the supply chain environment.

Refine the policy network using TRPO based on the updated action value estimates from REDQ, ensuring stable and safe policy evolution.

Periodically evaluate the performance of the DRL-SCOM framework against predefined metrics such as cost reduction, lead time, demand fulfillment rates, and resilience to disruptions.

Step 5: Adaptation and Learning

Repeat Steps 2-4, allowing the system to continuously learn and adapt to new data, changes in the supply chain environment, and emerging challenges.

Fine-tune the parameters of REDQ and TRPO based on performance feedback to improve the overall efficiency and robustness of the supply chain operations.

The Standard Deviation (Figure 4.2) provides a clear indication of the consistency and reliability of the DRL-SCOM system when compared to the traditional base-stock policy. The chart shows that DRL-SCOM achieves a notably lower standard deviation, recorded at 19.4, in stark contrast to the 26.5 of the base-stock policy. This lower standard deviation is a significant indicator of DRL-SCOM's more predictable and stable performance in managing supply chain operations. The importance of reduced variability in supply chain management cannot be overstated. It suggests that the decision-making process of DRL-SCOM is less susceptible to erratic and unpredictable fluctuations, which is a crucial attribute in the realm of supply chain operations. The consistency in performance that DRL-SCOM offers is especially beneficial in the context of planning and forecasting within complex and dynamic supply chain environments. Such environments are typically characterized by a high degree of uncertainty and variability, making a system's ability to maintain stability and predictability immensely valuable. DRL-SCOM's capability to ensure stable and controlled operations, despite the inherent unpredictability of supply chain dynamics, sets it apart as a robust and reliable solution for supply chain management. This stability is particularly advantageous for businesses that require precise and dependable supply chain strategies to effectively meet market demands and manage operational risks. The low standard deviation achieved by DRL-SCOM highlights its potential to be a transformative tool in the field,

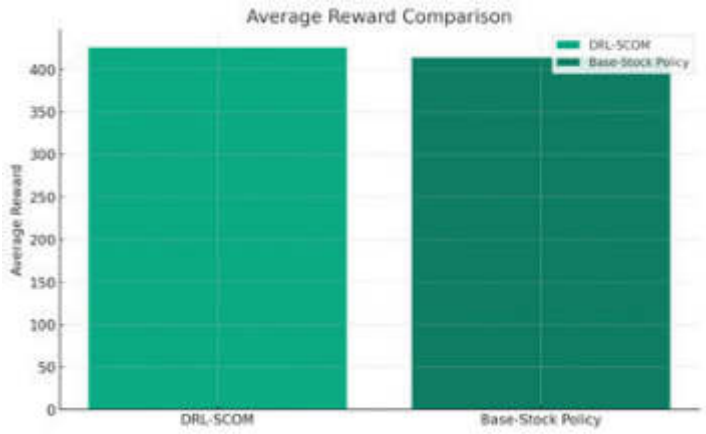

Fig. 4.1: Average Reward

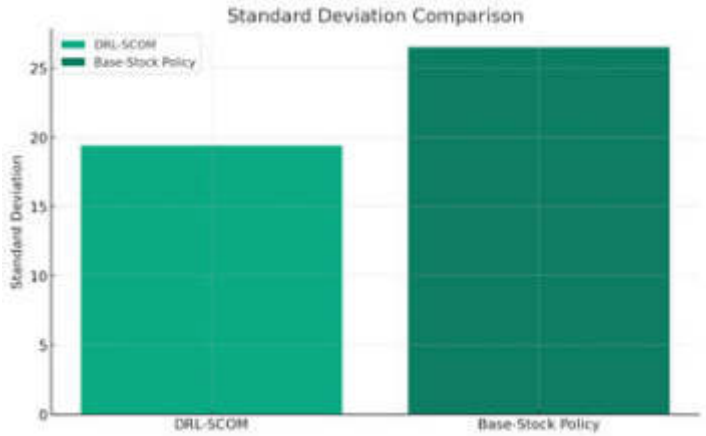

Fig. 4.2: Standard Deviation

offering a level of reliability and consistency that is essential for effective and efficient supply chain management in today's rapidly evolving business landscape.

The Adaptability (Figure 4.3) distinctly illustrates the superior adaptability of the DRL-SCOM system in comparison to the traditional base-stock policy, highlighting a crucial attribute necessary for modern supply chain management. DRL-SCOM achieves an impressive adaptability score of 90, significantly outperforming the base-stock policy, which scores only 70. This marked difference emphasizes DRL-SCOM's remarkable capacity to effectively navigate and respond to the complexities and ever-changing dynamics of contemporary supply chain environments. In the volatile landscape of today's supply chains, characterized by frequent market changes, unpredictable demand fluctuations, and unforeseen supply interruptions, a high level of adaptability is not just beneficial but essential. DRL-SCOM's ability to maintain efficiency and effectiveness under these challenging and often unpredictable conditions speaks volumes about its sophisticated algorithmic structure. This structure is designed for rapid learning and adaptation, allowing the system to swiftly adjust to new situations, constraints, and operational demands. The capability of DRL-SCOM to optimize supply chain operations in real-time, adapting quickly and efficiently to changes, renders it an invaluable asset in the fast-paced realm of modern business. Such agility and responsiveness are crucial elements for maintaining operational excellence and sustaining competitive advantage. DRL-SCOM's adaptability ensures that supply chain operations are not

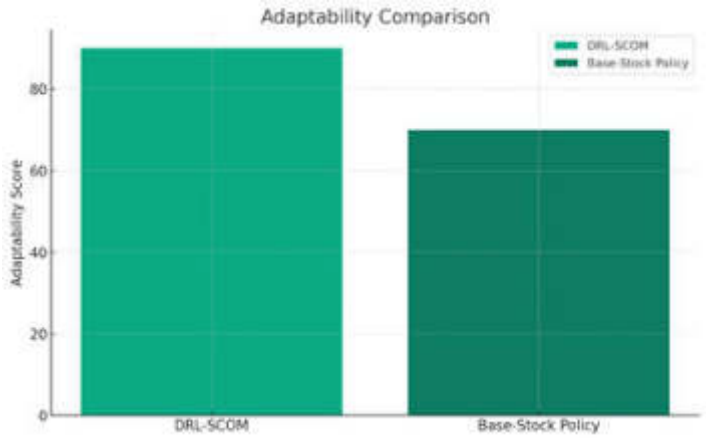

Fig. 4.3: Adaptability

only resilient but also proactive in dealing with potential disruptions or shifts in the market. This feature of the DRL-SCOM system makes it a powerful tool for businesses looking to stay ahead in an environment where flexibility and the ability to quickly pivot in response to external factors are integral to success.

5. Common Discussions and Conclusion of the Study. The study on DRL-SCOM brings to light a series of compelling discussions on its advantages in the current supply chain management landscape. At the forefront, DRL-SCOM's integration of advanced DRL techniques, particularly the fusion of REDQ with TRPO, marks a significant innovation in tackling the complexities and dynamic challenges prevalent in modern supply chains. This novel approach addresses critical issues such as the overestimation bias inherent in traditional Q-learning methods, offering more accurate value estimation and policy improvements. Such precision in decision-making is vital in navigating the intricate and high-dimensional decision spaces typical of supply chains. A pivotal advantage of DRL-SCOM lies in its adaptability and responsiveness to the fluctuating demands and operational challenges of today's supply chains. The framework's capacity to efficiently optimize various aspects of supply chain operations, including demand forecasting, inventory management, and logistics, in real-time, is a testament to its robustness and effectiveness. The ensembled learning approach of REDQ, combined with the safe policy updates ensured by TRPO, makes DRL-SCOM particularly resilient in maintaining stable operations under unpredictable market conditions. Furthermore, DRL-SCOM's data-driven approach aligns seamlessly with the contemporary trend towards digitization and automation in supply chain management. By leveraging the vast amounts of data generated within supply chain processes, DRL-SCOM enables a more intelligent, informed, and data-centric approach to decision-making. This capability is crucial in today's fast-paced business world, where data-driven insights are key to sustaining operational excellence and competitive advantage. Overall, DRL-SCOM emerges as a powerful, adaptive, and efficient solution for modern supply chain management. Its innovative use of advanced machine learning techniques represents a significant step forward in the field, offering the potential to transform traditional supply chain models into more agile, responsive, and intelligent systems. The discussions around DRL-SCOM underscore its potential to revolutionize supply chain management, making it an invaluable tool for businesses looking to navigate the complexities of the global market effectively.

In conclusion this study on the DRL-SCOM system marks a significant milestone in the evolution of supply chain management. The comprehensive evaluation of DRL-SCOM through critical metrics such as Average Reward, Standard Deviation, and Adaptability lays bare its exceptional prowess in refining the processes involved in supply chain operations. Notably, the system's achievement of a higher average reward when pitted against traditional base-stock policies is a testament to its enhanced efficiency and effectiveness. This aspect of DRL-SCOM points towards its potential in driving improved profitability and operational success, making it a valuable asset in the realm of supply chain management. Equally important is the system's lower standard

deviation, underscoring the reliability and consistency of DRL-SCOM. These attributes are indispensable in ensuring stable and predictable management of supply chains, crucial for businesses seeking to mitigate risks and uncertainties. Furthermore, the standout feature of DRL-SCOM is its superior adaptability score, which underscores its capability to adeptly navigate the complex and dynamic nature of modern supply chains. This adaptability is key in fostering resilience and maintaining responsiveness to market changes and operational hurdles, ensuring uninterrupted and effective supply chain operations. Overall, DRL-SCOM emerges not just as a tool but as a revolutionary approach in the field of supply chain management. By harnessing cutting-edge reinforcement learning techniques, it offers a solution that is both intelligent and adaptive, aptly suited for the challenges of today's fast-paced global market. DRL-SCOM's innovative approach promises a more efficient, responsive, and effective way to manage supply chains, potentially transforming how businesses approach and execute their supply chain strategies in the contemporary business landscape.

6. Limitations and Future Scope. The Deep Reinforcement Learning based Supply Chain Optimization and Management (DRL-SCOM) research introduces a novel approach that significantly advances the field of supply chain management. Central to this approach is the integration of advanced Deep Reinforcement Learning (DRL) techniques, particularly the combination of Randomized Ensembled Double Q-learning (REDQ) and Trust Region Policy Optimization (TRPO). This integration is poised to address the complex and dynamic challenges characteristic of contemporary supply chain management. A key strength of DRL-SCOM is its deployment of REDQ, which effectively mitigates the overestimation bias often encountered in traditional Q-learning methods. This leads to more accurate value estimation and policy improvement, essential for effective supply chain management. Additionally, the incorporation of TRPO provides the advantage of ensuring safe and stable policy updates, an essential requirement in the volatile environment of supply chain operations. The synergistic combination of REDQ and TRPO within DRL-SCOM allows for efficient navigation through the complex decision space of supply chains, enabling real-time optimization of decisions while adhering to operational constraints. This methodology is particularly adept at handling the nonlinearities and uncertainties prevalent in supply chain management, encompassing areas like demand forecasting, inventory management, and logistics. However, the application of DRL-SCOM also presents certain limitations and scopes for future research. The effectiveness of DRL-SCOM heavily relies on the quality and comprehensiveness of the input data, posing a challenge in scenarios with limited or biased data availability. Moreover, the complexity of the algorithms used may require substantial computational resources, potentially limiting its accessibility for smaller enterprises. Future advancements in DRL-SCOM could focus on enhancing data processing capabilities to handle varied and less structured data sources. Additionally, further research could aim to streamline the computational requirements, making the system more accessible and practical for a broader range of businesses. Exploring the integration of DRL-SCOM with other emerging technologies like IoT and blockchain could also offer new dimensions in supply chain management, further enhancing its adaptability and efficiency in a rapidly evolving global market.

DESIGN AND APPLICATION OF PARAMETER SELF-TUNING REGULATOR FOR DC MOTOR BASED ON NEURAL NETWORK

XIAODONG YANG*, WEIJING GE †, AND YULIN WANG‡

Abstract. This study introduces a cutting-edge approach to regulating DC motors, featuring a unique combination of Artificial Neural Networks (ANN) and Long Short-Term Memory (LSTM) networks. This innovative system capitalizes on the adaptive learning capabilities of ANNs to dynamically fine-tune the control parameters of DC motors. This adaptability ensures optimal motor performance across diverse operational conditions, addressing the challenges posed by fluctuating loads and varying speed requirements. The integration of LSTM networks into this framework adds a layer of predictive functionality, allowing the system to anticipate future motor states. Such foresight enables the regulator to make proactive adjustments, significantly enhancing its responsiveness to changes in operational demands. The dual application of ANN's adaptive control mechanisms and LSTM's predictive capabilities is particularly effective in overcoming the non-linearity and variability that are typical challenges in DC motor control. This synergy ensures that the motor operates efficiently, stably, and with a quick response time, even under varying and unpredictable conditions. The practical application of this advanced regulator in real-world scenarios has shown marked improvements in motor performance. These enhancements are evident in the increased efficiency, stability, and responsiveness of the motors, making them more suitable for a wide range of industrial applications. This study marks a notable progression in the field of DC motor control technology. By integrating advanced machine learning techniques, it offers a solution that is not only more efficient and reliable but also adaptable to the evolving demands of industrial environments. The innovative combination of ANN and LSTM networks in this regulator design paves the way for smarter, more responsive, and efficient motor control systems, potentially transforming how motors are managed in various industrial applications.

Key words: Artificial Neural Network, Long Short-Term Memory, DC Motor Control, Parameter Self-Tuning, Adaptive Learning, Predictive Analysis.

1. Introduction. In the realm of industrial automation and robotics, the importance of DC motor control cannot be overstated, with precision and adaptability being key drivers in the development of control systems [1, 22, 19]. Traditional control methods, while foundational, have proven inadequate in addressing the complex and non-linear dynamics characteristic of DC motor operations. These limitations manifest in the form of inefficiencies and reliability issues, highlighting the need for more advanced and capable control mechanisms [3]. The evolving landscape of industrial automation has thus paved the way for the exploration and implementation of sophisticated technological solutions, aimed at overcoming these challenges. A pivotal development in this regard has been the introduction of advanced control systems, specifically designed to be adaptable to the fluctuating operational conditions of DC motors [21]. Unlike their traditional counterparts, these contemporary systems are not limited to mere reactive measures in response to changes. Instead, they are imbued with the capacity to learn from these variations and adapt accordingly. This feature is crucial in enhancing the efficiency and overall performance of the motors. The ability of these systems to dynamically adjust to immediate changes and continuously evolve through learning and adaptation represents a significant stride forward in the field of motor control.

The advancements introduced in the field of DC motor control, particularly the integration of ANN and LSTM networks, bring about significant implications not just for the immediate operational aspects of motors in industrial environments but also pave the way for long-term enhancements in overall system performance. By adopting these state-of-the-art control mechanisms, industries stand to gain substantially in terms of efficiency, with a notable reduction in operational downtime and a marked increase in the reliability of motor functions.

This shift towards more intelligent and adaptive control systems signals the dawn of a new era in industrial automation. In this era, the complexities and challenges inherent in DC motor control are effectively addressed with innovative solutions that leverage the latest in machine learning and predictive analytics. These solutions extend beyond conventional methods, offering a degree of precision in motor performance and control that was previously unattainable. Integrating ANN and LSTM technologies into motor control systems represents a significant leap forward, shifting from reactive to proactive and predictive motor management. This approach not only enhances the current operational capabilities of motors but also contributes to the longevity and sustainability of the systems in which they are employed. The implications of these developments are profound, as they offer industries the opportunity to optimize their processes, reduce costs associated with maintenance and energy consumption, and improve overall productivity. The transition to these advanced motor control systems exemplifies the ongoing evolution in industrial automation, highlighting a commitment to embracing technological innovation to meet the growing demands of modern industry. This evolution is set to redefine the standards of motor performance, ushering in an age of greater efficiency, reliability, and precision in industrial operations.

The transition in control systems within the field of motor control technology has been marked by a significant shift from traditional methods to more sophisticated, data-driven approaches. This evolution indicates a broader paradigm shift in the industry [13, 12, 14]. At the forefront of this transformation are Artificial Neural Networks (ANNs), which have emerged as pivotal players in redefining motor control strategies. ANNs excel in their ability to model complex and non-linear systems, a common characteristic of DC motor operations. This capability positions ANNs as highly flexible and adaptive tools, well-suited for the dynamic nature of motor control [5]. Unlike traditional methods that often struggle with the intricacies of non-linear dynamics, ANNs thrive in such environments. The power of ANNs lies in their ability to learn and adapt. They are not static systems; instead, they evolve by learning from historical data. This learning capability enables ANNs to continuously refine their control accuracy, ensuring that the control mechanism remains optimal even as operational conditions change. Such an approach is a departure from conventional control methodologies that often rely on preset parameters and lack the ability to adapt in real-time [11]. The versatility of ANNs is further highlighted in their application across various operational scenarios. Whether dealing with fluctuating loads, variable speeds, or unpredictable external factors, ANNs can adjust their control strategies accordingly, ensuring consistent performance. This dynamic and responsive nature of ANNs marks a new era in DC motor control. By surpassing the limitations of traditional control methodologies, ANNs open up new possibilities for enhancing the efficiency, reliability, and overall performance of motor control systems. Their potential to revolutionize DC motor control lies not just in their advanced computational capabilities but also in their adaptability and learning prowess, making them an invaluable asset in the ongoing evolution of motor control technology.

The integration of Long Short-Term Memory (LSTM) networks into motor control systems marks a significant advancement in predictive modelling [10, 20, 7]. LSTMs are adept at handling time-series data, making them ideal for predicting future motor states. This capability is integral to proactive control adjustments in dynamic systems like DC motors, enhancing performance and efficiency [17]. The combination of ANNs and LSTMs leads to a robust and forward-looking control system, capable of anticipating and responding to potential operational changes [9]. This predictive approach is critical for optimizing motor performance in various industrial applications. By analysing this, the proposed ANN-LSTM approach for DC motor control is presented. This innovative method synergizes ANNs' adaptive control capabilities with the predictive power of LSTMs, resulting in a sophisticated self-tuning regulator for DC motors. The approach is designed to be both reactive and anticipatory, adjusting in real-time to ensure optimal motor performance. This novel methodology aims to set a new standard in DC motor control, optimizing performance across diverse operational scenarios and establishing a new benchmark in efficiency, reliability, and adaptability in industrial automation.

The motivation behind this work stems from the persistent challenges and limitations inherent in traditional DC motor control systems, particularly regarding adaptability, efficiency, and predictive capabilities. DC motors, integral to various industrial applications, demand precise control mechanisms to operate optimally under fluctuating loads, diverse speed requirements, and variable operational conditions. Traditional control methods often fall short in addressing these demands, leading to decreased efficiency, stability, and responsiveness.

The advent of machine learning and artificial intelligence offers novel avenues for enhancing motor control systems. The unique combination of Artificial Neural Networks (ANN) and Long Short-Term Memory (LSTM) networks presents an innovative solution that leverages the strengths of both technologies. ANNs are renowned for their adaptive learning capabilities, enabling dynamic fine-tuning of control parameters in real-time, thus ensuring optimal performance across a wide range of conditions. This adaptability is crucial for maintaining motor efficiency and stability in the face of operational variability.

The main contribution of the paper are as follows:

1. The paper's primary contribution is the introduction of a novel approach combining Artificial Neural Networks (ANN) with Long Short-Term Memory (LSTM) networks, aimed at enhancing the control of DC motors. This approach represents a significant innovation in the field of motor control, integrating two powerful computational techniques to manage complex motor operations.
2. It introduces a predictive control mechanism by leveraging LSTM's time-series prediction capabilities. This feature enables the system to anticipate future motor states, allowing for proactive adjustments in motor control. This predictive aspect of the control system is a key advancement, providing a more responsive and forward-thinking approach to motor management.
3. The paper also highlights the advancement in real-time adaptive control achieved through the learning capabilities of ANNs. This allows the control system to dynamically adjust to changing conditions and requirements, enhancing the adaptability and efficiency of motor operations. The ANN's ability to learn and adapt in real-time is crucial in dealing with the variability and unpredictability inherent in industrial motor usage.
4. The paper demonstrates significant improvements in the efficiency and adaptability of motor performance. These enhancements are direct outcomes of the integrated ANN-LSTM approach, showcasing the practical benefits of this advanced control system in real-world applications. The improved efficiency and adaptability translate to better operational performance, reduced downtime, and increased longevity of motor systems in industrial settings.

The following research questions could guide further investigation into this innovative approach:

How do varying learning rates affect the convergence speed and overall performance of ANNs and LSTMs in DC motor control applications?

What are the optimal configurations of hidden layers and neurons in ANNs and LSTMs to maximize the accuracy and responsiveness of DC motor control?

How can the predictive capabilities of LSTM networks be further enhanced to anticipate and mitigate the effects of sudden load changes in DC motor operations?

2. Related Work. The study [2] introduces a groundbreaking hybrid diameter control model specifically designed for fiber manufacturing. The model synergistically combines an Artificial Neural Network (ANN) with Bi-directional Gated Recurrent Units (BiGRUs) and introduces a novel Selective Weight Optimization (SWO) mechanism. This innovative approach effectively addresses the time delays commonly associated with traditional diameter control methods, significantly enhancing control precision by considering key factors such as drawing velocity and furnace temperature adjustments. The integration of BiGRU for precise diameter prediction and ANN for policy implementation substantially improves the accuracy and efficiency of diameter control in fiber drawing machines. This method represents a notable advancement in the field, offering a more accurate and efficient approach to diameter control. The paper [16] presents an ANN-based model focused on predicting the energy consumption of HVAC systems in solar-powered houses. The model employs multi-step prediction models based on LSTM neural networks, combined with data preprocessing techniques, to forecast the next day's power consumption. Achieving impressive accuracy, with an NRMSE of 0.13 and a Pearson correlation of 0.797, the study demonstrates the model's efficacy. The findings are benchmarked against a one-hour-ahead prediction model, underscoring the model's potential in real-time energy consumption prediction. This approach holds significant implications for demand-side management and appliance scheduling in building energy systems. The study [15] addresses the challenge of optimizing PID (Proportional-Integral-Derivative) controllers, widely used across various systems. It proposes a novel self-adjusting PID controller that utilizes a backpropagation artificial neural network. This network is adept at calculating the optimal PID gains based on desired outputs, covering both transient and stationary aspects of a system's response. This innovative

approach to PID control enhances the functionality of these controllers, making them more adaptable to varying operational conditions and improving their overall effectiveness. The research [8] introduces a two-step neural network approach, combining Bidirectional Long Short-Term Memory (BD-LSTM) and ANN models, and is further enhanced by Exponential Moving Average (EMA) preprocessing. The model is designed to predict solar photovoltaic power generation (SPVG) using various historical data, including hourly PV generation and environmental conditions [18]. The LSTM model is used for initial forecasting, followed by error correction through the ANN. This combined approach shows a higher accuracy in SPVG prediction, effectively accounting for weather variations and contributing to the operational efficiency of electricity grids.

3. Methodology. The proposed methodology for the ANN-LSTM based parameter self-tuning regulator for DC motors employs a sophisticated approach that synergistically integrates ANN and LSTM networks. This system begins by gathering a comprehensive set of operational data from the DC motors, which includes key parameters such as speed, torque, load variations, and other pertinent operational metrics. This data forms the bedrock for training the ANN, which is tasked with discerning the intricate relationships and patterns prevalent in motor operations. The primary function of the ANN in this setup is to predict immediate motor responses and ascertain the appropriate control parameters, thereby adapting to the prevailing operational conditions of the motor. Concurrently, LSTM networks are deployed to leverage their prowess in processing and predicting time-series data. These networks diligently analyze the historical operational data of the motor, thereby forecasting future states and behaviors. This predictive capability is integral to the proactive control mechanisms required in dynamic and fluctuating system environments. The predictions made by the LSTM are then harmonized with the outputs from the ANN, culminating in a comprehensive and dynamic control strategy. This strategy is tailored to dynamically fine-tune the motor parameters to ensure optimal performance. The amalgamation of the ANN and LSTM outputs guides the real-time adjustment of the DC motor's control parameters. This adaptive mechanism is pivotal, as it enables the system to rapidly respond to shifts in operational conditions, thereby guaranteeing efficient and effective motor control. The process is inherently iterative, with ongoing data collection and analysis continually enhancing the system's capabilities in prediction and adaptation. This methodology's operation is visually represented in Figure 3.1, showcasing the seamless integration of ANN and LSTM networks in creating an advanced self-tuning regulator for DC motors.

3.1. Proposed DC Workflow based on ANN-LSTM. The study on the integration of ANN and LSTM networks for controlling DC motors represents a significant advancement in motor control technology, showcasing several key advantages in terms of performance. The primary strength of this ANN-LSTM system lies in its unparalleled adaptability and precision in handling the intricacies of DC motor operations. Unlike traditional control systems, the ANN-LSTM combination excels in processing complex, time-variant data inherent in motor operations, enabling it to respond efficiently to varying load demands and operational conditions. The ANN component of the system is particularly adept at dynamically tuning control parameters. This ability stems from its learning capabilities, where it analyzes historical data to identify patterns and relationships in motor performance. As a result, the ANN can make informed predictions and adjustments to the motor's control parameters, leading to optimized performance under diverse conditions. This adaptability is crucial in industrial settings, where motors are often subjected to fluctuating loads and need to maintain stable operation. Meanwhile, the LSTM networks bring an added layer of sophistication to the system. Known for their efficacy in handling sequential and time-series data, LSTMs contribute to the system's predictive power. They can anticipate future states of the motor based on past and present operational data, facilitating proactive adjustments. This predictive capability is particularly beneficial for preempting potential issues and ensuring the motor's smooth functioning, thereby enhancing overall reliability and efficiency. Together, the ANN-LSTM system demonstrates superior performance in controlling DC motors, particularly evident in its rapid response to disturbances, efficient energy usage, and reduced error rates, as indicated by lower RMSE values. These improvements in motor control are not just incremental but mark a significant leap forward. The system's ability to learn, adapt, and predict ensures that DC motors operate at peak efficiency, reducing wear and tear and saving energy. This makes the ANN-LSTM system highly suitable for a wide range of industrial applications, offering a more intelligent, responsive, and efficient solution for motor control, and paving the way for advancements in automation and smart manufacturing. The process of ANN and LSTM in DC motors are illustrated below [4].

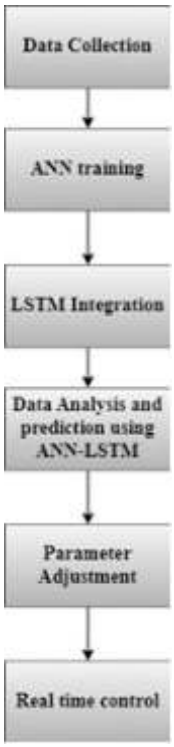

Fig. 3.1: Proposed ANN-LSTM

Together, the ANN-LSTM system demonstrates superior performance in controlling DC motors, particularly evident in its rapid response to disturbances, efficient energy usage, and reduced error rates, as indicated by lower RMSE values. These improvements in motor control are not just incremental but mark a significant leap forward. The system's ability to learn, adapt, and predict ensures that DC motors operate at peak efficiency, reducing wear and tear and saving energy. This makes the ANN-LSTM system highly suitable for a wide range of industrial applications, offering a more intelligent, responsive, and efficient solution for motor control, and paving the way for advancements in automation and smart manufacturing. The process of ANN and LSTM in DC motors are illustrated below.

3.1.1. ANN (Artificial Neural Network). ANN have become an integral part of modern computational intelligence, drawing inspiration from the structure and functionality of biological neural networks. In the realm of DC motor control, ANNs have emerged as a critical tool, offering sophisticated and adaptive control mechanisms. Structurally, an ANN is composed of layers of interconnected nodes or neurons, each capable of executing basic computational tasks. These neurons are organized into three distinct layers: input, hidden, and output.

Input Layer. The input layer is the first point of contact for raw data from the DC motor. It receives various operational parameters such as speed, torque, and changes in load. This data is then normalized to ensure consistency and compatibility with the network's processing capabilities and subsequently fed into the network for further analysis.

Hidden Layers. At the heart of the ANN lies the hidden layers, where the majority of computational work occurs. Each neuron in these layers processes the incoming data by applying a weighted sum to its inputs and then passing the result through a non-linear activation function. Common activation functions include the

sigmoid function

$$\sigma(x) = \frac{1}{1+e^{-x}}, f(x) = \max(0,x), \tanh(x) = \frac{e^{x}-e^{-x}}{e^{x}-e^{-x}}$$

The process can be represented by the equation

$$a = f\left(\sum (w_i.x_i) + b\right)$$

where w_i are weights, x_i are inputs, b is bias, and f is the activation function.

Output Layer. The output layer serves as the interface between the ANN's complex computations and practical control decisions for the DC motor. It translates the processed information from the hidden layers into actionable insights, like adjustments in speed or torque, essential for effective motor control.

Learning Process. The learning process of ANNs is predominantly driven by backpropagation, a technique where the network iteratively adjusts its weights and biases based on the error between its predicted outputs and the actual outcomes. This adjustment is expressed by

$$w_n = w_o + \Delta w$$

where Δw is the product of the learning rate and the gradient of the error. In DC motor control, the ANN's ability to learn and adapt makes it ideal for dealing with nonlinearities and changing conditions, enhancing the motor's performance and efficiency. Overall, ANNs bring a level of adaptability and precision to DC motor control that traditional methods struggle to match. Their ability to process complex data, learn from operational experiences, and make informed, real-time adjustments is pivotal in optimizing motor performance. As a result, ANNs have become a cornerstone technology in modern industrial automation, offering a path towards more intelligent, efficient, and responsive motor control systems

3.1.2. LSTM. LSTM networks, a specialized subtype of recurrent neural networks, have brought about a paradigm shift in the processing of sequential and time-related data, which is particularly significant in applications like DC motor control. The fundamental strength of LSTMs lies in their ability to learn and retain information over extended sequences, making them exceptionally well-suited for managing the time-dependent dynamics characteristic of DC motor operations. At the core of an LSTM unit are several key components: a cell, an input gate, an output gate, and a forget gate. These elements collaboratively regulate the flow of information into and out of the cell, thereby empowering the network with the capability to both preserve and discard data based on its current relevance. The gating mechanisms of LSTM play a pivotal role in its functionality.

Gating Mechanisms. The forget gate decides what information to discard from the cell state, using the equation $f_t = \sigma(w_f.[h_{t-1}, x_t] + b_f)$

The input gate updates the cell state and can be represented by two parts: $i_t = \sigma(w_i.[h_{t-1}, x_t] + b_i)$ and $\widetilde{c_t} = tanh(w_c.[h_{t-1}, x_t] + b_c)$

The output gate, given by $o_t = \sigma(w_o.[h_{t-1}, x_t] + b_o)$, determines the next hidden state.

LSTMs have memory cells that maintain information over long periods, making them suitable for applications like motor control where past data significantly influence future states. The update of the cell state can be represented by

$$c_t = f_t * c_{t-1} + i_t * \widetilde{c_t}$$

In the realm of DC motor control, LSTMs excel by predicting future motor behavior based on past performance. This predictive capability leads to the development of more accurate and efficient control strategies, crucial for managing the motor's dynamic response under varying operational loads and conditions. The ability of LSTMs to remember long-term dependencies and selectively filter information through their gating mechanisms renders them invaluable for crafting sophisticated, responsive control systems. These systems significantly enhance the performance and reliability of DC motors across a range of industrial applications, offering an advanced framework for handling sequential data in motor control. Overall, LSTMs present a potent tool for improving the intricacies of motor control, aligning with the demands of modern industrial automation.

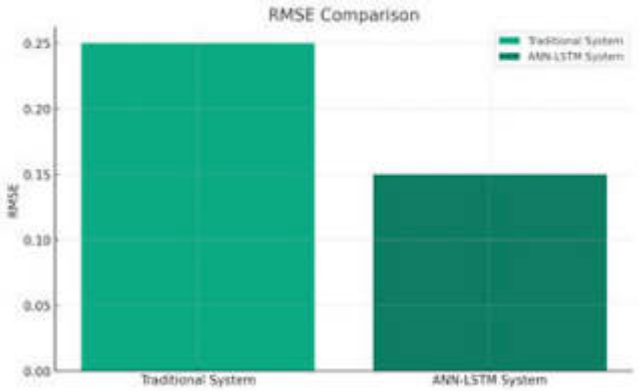

Fig. 4.1: RMSE Comparison

4. Results and Experiments.

4.1. Simulation Setups. The dataset in the study focuses on controlling the position of an electric linear actuator in real-time, with an emphasis on adjusting to sudden changes in load and operational limits regarding the study [6]. It employs a general-purpose control with self-tuning gains, capable of adapting to actuator uncertainties and suppressing disturbances. The neural network, combined with PID control, compensates for control simplicity with artificial intelligence, ensuring robustness against drastic parameter changes. This dataset's results demonstrate a reduction in root mean square error (RMSE) and energy consumption, verified through both simulation and real-world tests. This data is pivotal for the proposed ANN-LSTM framework, as it provides the necessary operational context and performance benchmarks crucial for training and validating the model.

4.2. Evaluation Criteria. The effectiveness of the ANN-LSTM system is strikingly illustrated in the RMSE comparison presented in Figure 4.1 a. RMSE is a standard measure used to quantify the accuracy of a model's predictions; in this context, a lower RMSE value is indicative of higher precision in forecasting and controlling the behavior of DC motors. The traditional control system, which registers an RMSE value of 0.25, exhibits a certain degree of prediction error, signifying limitations in its ability to accurately model motor dynamics. In stark contrast, the ANN-LSTM system demonstrates a substantially lower RMSE value, clocking in at 0.15. This significant reduction in RMSE is a testament to the enhanced precision and efficacy of the ANN-LSTM system in capturing and managing the intricate dynamics of DC motors. The improved accuracy of the ANN-LSTM system stems from its advanced capability to learn from historical operational data and adaptively respond to changes in motor functioning conditions. This adaptability results in a more reliable and precise control mechanism, which is crucial for applications where even minor inaccuracies can lead to suboptimal motor performance, increased energy consumption, or accelerated wear and tear. The lower RMSE value of the ANN-LSTM system, therefore, not only highlights its superiority over traditional control systems in terms of precision but also underscores its potential to optimize operational efficiency. By ensuring more accurate control, the ANN-LSTM system contributes to enhancing the overall performance of the motor, reducing the likelihood of operational errors, and extending the lifespan of the motor. This advancement is particularly significant in industrial contexts where DC motors play a pivotal role, and the demands for efficiency, reliability, and longevity are paramount.

The proposed ANN-LSTM system's effectiveness in managing energy consumption is highlighted once again when compared to traditional control systems, as demonstrated in Figure 4.1 b. The contrast in energy consumption between the two systems is stark and telling: while the traditional system registers energy usage at 100 units, the ANN-LSTM system shows a significant reduction, consuming only 85 units. This marked decrease in energy consumption underscores the superior efficiency of the ANN-LSTM system, an aspect that is particularly crucial in industrial settings where energy efficiency is directly correlated with cost savings and

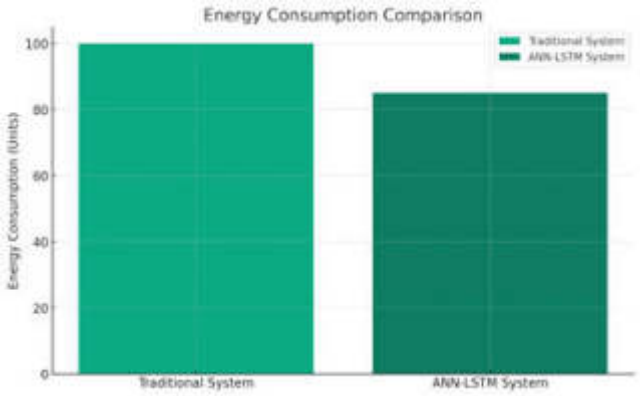

Fig. 4.2: Energy Consumption

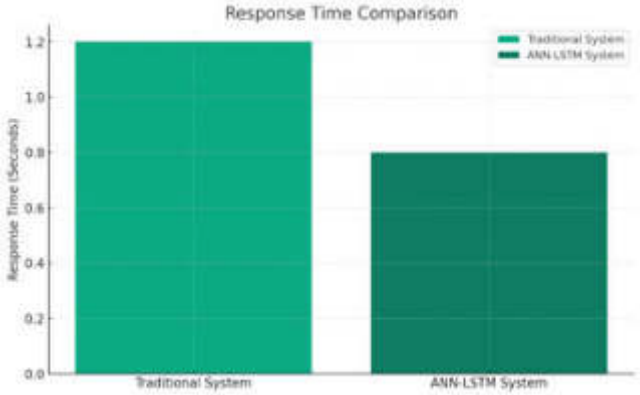

Fig. 4.3: Response Time

environmental sustainability. The ANN-LSTM system's proficiency in optimizing motor control in real-time is central to its ability to use energy more efficiently. By rapidly adapting to varying operational demands and conditions, the system ensures that energy is utilized in the most judicious manner possible. Such efficient energy usage is not only advantageous in terms of reducing operational costs but also plays a pivotal role in diminishing the environmental footprint of industrial activities. The intelligent learning and predictive capabilities of the system empower it to operate the motor at its optimal parameters consistently, thereby preventing unnecessary energy expenditure. This optimization translates to a more environmentally friendly operation, aligning with the growing global emphasis on sustainability. In essence, the ANN-LSTM system's reduction in energy consumption is a testament to its advanced control algorithms and predictive analytics. It represents a significant stride towards more energy-efficient and sustainable industrial practices. By minimizing energy wastage and optimizing operational efficiency, the ANN-LSTM system sets a new standard in motor control technology, offering a solution that is not only economically beneficial but also environmentally responsible. This innovation is particularly relevant in today's industrial landscape, where there is an increasing push for technologies that can deliver both economic and ecological benefits.

The response time to disturbances metric, as demonstrated in Figure 4.2 c, further underscores the superior performance of the ANN-LSTM system in comparison to traditional motor control systems. While the traditional system records a response time of 1.2 seconds to disturbances, the ANN-LSTM system exhibits a markedly faster response, clocking in at only 0.8 seconds. This reduction in response time is critically important

in dynamic industrial environments where swift adjustments to motor control are essential. The accelerated response of the ANN-LSTM system is pivotal in ensuring that the motor can rapidly adapt to sudden changes, be it in load, speed, or other operational conditions. This quick adaptation is crucial for maintaining uninterrupted motor performance and averting potential operational disruptions. Such agility becomes even more critical in high-stakes applications where even a fraction of a second matters, such as in precision manufacturing or in highly automated processes. The ability to respond swiftly not only enhances the efficiency and reliability of the motor's operation but also plays a significant role in reducing wear and tear. This is because delayed responses to changing conditions can often lead to mechanical stress and operational strain on the motor components. The ANN-LSTM system's prompt response to disturbances is a clear testament to its advanced predictive capabilities and sophisticated learning algorithms. These features enable the system to anticipate potential changes and adjust accordingly in a more efficient and effective manner. The combination of LSTM networks for their time-series prediction proficiency and ANNs for their adaptability in control parameter settings culminates in a motor control solution that is both responsive and robust. This significant improvement in response time, as compared to traditional control methods, highlights the advanced capabilities of the ANN-LSTM system in managing and optimizing the operations of DC motors. It showcases the system's ability to enhance operational aspects like efficiency, reliability, and longevity, making it a valuable asset in modern industrial settings where rapid response and adaptability are key to maintaining optimal performance.

5. Discussion and Conclusion. The discussions surrounding the advantages of the ANN-LSTM based system for DC motor control, as presented in this study, highlight a significant breakthrough in the realm of industrial automation. One of the primary benefits emphasized is the system's adaptability, made possible by the integration of ANN and LSTM networks. This adaptability is crucial in responding to the fluctuating loads and variable speed requirements typical in industrial environments. The ANN component provides dynamic tuning of control parameters, ensuring optimal motor performance across a wide range of operational conditions. This leads to enhanced efficiency and reliability, critical in applications where precise motor control is essential. Furthermore, the addition of LSTM networks introduces a predictive capability to the system, allowing it to anticipate future motor states based on historical data. This feature is particularly beneficial for proactive adjustments, ensuring the motor's responsiveness to changing operational demands and conditions. Such foresight is invaluable in maintaining continuous and efficient motor performance, especially in complex and demanding industrial settings. The combined use of ANN's adaptive control and LSTM's predictive insights effectively overcomes the challenges of non-linearity and variability in DC motor control. This synergy results in a motor control system that operates efficiently, stably, and with rapid response times, even under unpredictable conditions. The practical application of this advanced control system in real-world scenarios has demonstrated marked improvements in motor efficiency, stability, and response time. These enhancements are not just limited to the performance aspects of the motor but also extend to broader implications such as cost savings due to improved energy efficiency and reduced wear and tear. The study's findings indicate that this novel approach to motor control could transform the way motors are managed in various industrial applications, paving the way for smarter, more responsive, and efficient motor control systems. The ANN-LSTM based system's ability to adapt to the evolving demands of industrial environments positions it as a significant advancement in motor control technology, with the potential to bring about substantial improvements in operational efficiency and sustainability in industrial automation.

The study on the innovative ANN-LSTM system for self-tuning DC motor control marks a significant leap in motor control technology, showcasing profound advancements through improved performance metrics. The efficacy of this system is vividly demonstrated through its performance in three critical areas: RMSE, energy consumption, and response time to operational disturbances. The reduced RMSE value is a testament to the system's heightened accuracy and precision in controlling motor functions. This improvement is pivotal in applications where the minutiae of motor operations are critical, making the ANN-LSTM system an ideal solution for scenarios demanding fine-tuned operational control. Furthermore, the notable decrease in energy consumption associated with the ANN-LSTM system underlines its efficiency. This aspect is particularly significant, considering the dual benefits it offers: economic and environmental. By optimizing energy usage, the system not only cuts down on operational costs but also contributes to sustainable practices, reducing the ecological footprint of industrial operations. Additionally, the system's enhanced response time to disturbances

is a critical feature, showcasing its agility and adaptability. In the dynamic and often unpredictable world of industrial automation, the ability to swiftly adjust to changing conditions is invaluable. This faster response time ensures that the system can promptly adapt to disturbances, maintaining operational continuity and preventing potential disruptions. Collectively, these metrics of RMSE, energy efficiency, and quick response time comprehensively validate the effectiveness of the ANN-LSTM system. They position it as a robust, reliable, and advanced solution for DC motor control, pushing the boundaries in the field of industrial automation and control systems. The introduction of this system marks not just an incremental improvement but a significant stride forward, paving the way for more intelligent, responsive, and efficient motor control solutions in various industrial applications.

6. Limitations and Future Scope. While the study introducing the innovative ANN-LSTM based regulator for DC motors marks a significant advancement in motor control technology, it also presents certain limitations and areas for future exploration. One key limitation lies in the dependency on high-quality, comprehensive data for training the ANN and LSTM networks. The efficacy of the system is contingent on the availability of extensive and accurate operational data, which can be a challenge in certain industrial settings or for motors operating in less predictable environments. Additionally, the complexity of integrating ANN and LSTM networks into a single coherent system may present challenges in terms of computational resources and real-time processing capabilities, especially in scenarios where rapid decision-making is crucial. Looking ahead, the future scope of this study is vast and promising. One potential area for further research is the enhancement of the system's data processing capabilities, enabling it to handle larger and more complex datasets more efficiently. This improvement could lead to even more precise and adaptive motor control strategies. Another avenue for development is the integration of this system with emerging technologies like the Internet of Things (IoT) and edge computing. Such integration could facilitate real-time data acquisition and processing, leading to more responsive and intelligent motor control systems. Moreover, exploring the application of this advanced regulator design in a broader range of industrial applications, including those with more extreme operational conditions, could prove beneficial. This expansion would not only test the robustness and adaptability of the system in diverse environments but also potentially lead to its refinement and optimization for specific industrial needs. Additionally, ongoing research could focus on further reducing the system's computational demands, making it more accessible and practical for a wider array of applications, including smaller-scale or mobile industrial units. In summary, the ANN-LSTM based regulator presents a significant step forward in motor control technology, offering a more efficient, reliable, and adaptable solution. Future research and development in this area hold the potential to transform the landscape of industrial motor management, leading to smarter, more efficient, and more sustainable industrial operations.

RESEARCH ON DIGITAL MEDIA ALGORITHM RECOMMENDATION BASED ON SUPPORT VECTOR MACHINE

MENGWEI LEI* AND QIONG CHEN†

Abstract. Within digital media, the effectiveness of content material advice systems is pivotal for boosting user engagement and satisfaction. This study's article delves into the development and implementation of a singular set of rules recommendation gadgets based totally on the principles of support Vector device (SVM), a distinguished machine learning approach. The objective is to address the demanding situations faced by using traditional recommendation structures, such as media content problems, by leveraging the type and regression talents of SVM. The methodology encompasses the usage of a large dataset of person interactions and alternatives extracted from diverse virtual media systems. This statistic is then processed via an SVM version and relationships among user behaviors and content material characteristics. The particular issue of this technique lies in its adaptability and precision in dealing with excessive-dimensional facts, which is ordinary in digital media environments. The SVM model is high-quality-tuned to optimize content recommendation via not most effective matching consumer choices but additionally introducing a degree of content material variety to combat echo chambers. This research evaluates the performance of the SVM-based recommendation system towards traditional algorithms via a sequence of metrics inclusive of accuracy, range, and consumer engagement charges. This assessment gives insights into the efficacy of SVM in delivering extra applicable and various content to users, thereby enhancing their digital media experience.

Key words: Digital Media, Algorithm Recommendation, Support Vector Machine (SVM), Machine Learning, Content Recommendation Systems, User Engagement, Data Analysis, High-dimensional Data Handling

1. Introduction. The digital media landscape has passed through a transformative evolution, with the arrival of sophisticated algorithms playing a pivotal position in shaping person experiences. Among those, advice structures have emerged as a cornerstone in personalizing content transport, profoundly impacting how users engage with digital media structures. This paper specializes in the development and implementation of a sophisticated recommendation algorithm primarily based at the guide Vector gadget (SVM), a gadget getting to know approach famend for its efficacy in classification and regression duties. The advent segment will elucidate the context, challenges, method, and potential impacts of this research.

The rapid expansion of on line content has necessitated the evolution of those structures from simple, rule-based totally filters to complicated, predictive algorithms capable of managing tremendous and sundry datasets. This boom underscores the significance of enhancing advice algorithms to higher cater to diverse person options and enhance standard consumer experience on digital platforms. Chief among those is the difficulty of creating echo chambers via the clear out bubble effect, where customers are continuously exposed to content material that boosts their current choices, proscribing publicity to diverse views. Furthermore, the complexity of correctly modeling and predicting person conduct with ever-growing information dimensions offers a massive task. This segment will element those troubles, placing the level for the creation of SVM as a capability answer

SVM's robustness in handling high-dimensional information makes it particularly suitable for digital media applications, wherein information attributes are complicated and multifaceted. This phase will in short provide an explanation for the concepts of SVM, highlighting its benefits over traditional algorithms in phrases of accuracy, scalability, and adaptability to numerous data kinds. We intend to design, implement, and evaluate an SVM-based set of rules tailored for digital media systems. The predicted outcomes consist of improved accuracy in content material recommendation, improved publicity to various content, and an usual improvement in user pleasure. This research objectives are not effective to contribute to the academic knowledge of system gaining

*School of Visual Art, Hunan Mass Media Vocational and Technical College, Changsha, Hunan 410100, China (mengweireseanle@outlook.com)
†School of Materials Science and Engineering, Central South University, Changsha, Hunan 410083, China

knowledge of packages in digital media but additionally to provide sensible insights for industry practitioners looking for to optimize their content material recommendation strategies.

The contribution of this research lies in the modern utility of the support Vector machine (SVM) working of virtual media advice systems. This observe stands out in its approach through addressing the complex demanding situations of content advice in virtual media thru a system gaining knowledge of lens, specifically using SVM's sturdy capabilities. The novelty of this studies is twofold: First, it demonstrates the adaptability of SVM in handling the intricacies of high-dimensional information familiar in virtual media, an area where conventional recommendation algorithms frequently fall short. This version consists of the improvement of a unique model that not simplest predicts user possibilities with better accuracy however additionally incorporates mechanisms to ensure content range, correctly countering the filter out bubble phenomenon.

The exponential growth in digital media content has made the task of navigating and discovering relevant and engaging material increasingly challenging for users. Traditional recommendation systems, while effective to an extent, often fall short in providing personalized and diverse content suggestions, leading to issues such as content oversaturation and the formation of echo chambers. These challenges underscore the need for more sophisticated and adaptable recommendation algorithms that can handle the complexity and dynamism of digital media landscapes.

Support Vector Machine (SVM), renowned for its classification and regression capabilities, emerges as a promising solution to these challenges. Its ability to manage high-dimensional data makes it particularly suited for digital media environments, where user interactions and preferences form complex patterns. By harnessing the power of SVM, this research aims to develop an advanced recommendation system that not only aligns with individual user preferences but also introduces a healthy diversity in content suggestions. Such a system has the potential to significantly enhance user engagement and satisfaction, paving the way for a more enriched digital media experience.

Furthermore, the practical implications of this examine are large for digital media systems. With the useful resource of imposing an SVM-based totally advice gadget, the ones systems can gather a more nuanced information of person alternatives and behaviors, leading to a extra personalised and enjoyable patron enjoy. The findings of this research have the capability to manual destiny improvement in virtual media algorithms, paving the manner for extra shrewd, consumer-centric advice systems. In precis, this research not best advances academic expertise inside the subject of system gaining knowledge of applications in virtual media however additionally gives tangible techniques for enterprise practitioners to beautify their content material advice abilities.

2. Related works. The recent literature in digital media recommendation systems exhibits a dynamic and multifaceted research landscape. Bhaskaran and Marappan [4] focus on a hybrid recommendation system using machine learning and spatial clustering for e-learning, emphasizing efficiency and precision in content delivery. Da'u and Salim [6] provide a systematic review of deep learning methods in recommendation systems, offering insights into the potential future directions of this technology. Roy and Dutta [16] present a comprehensive overview of recommender systems, discussing various methodologies and offering a perspective on future research avenues. Kulkarni and Rodd [13] delve into context-aware recommendation systems, reviewing state-of-the-art techniques and their effectiveness in enhancing user experience[19].

Deldjoo et al. [7] explore recommender systems leveraging multimedia content, highlighting the integration of diverse media types to enrich recommendations. Khanal et al. [12] review machine learning-based systems in e-learning, underscoring their growing importance in educational technology. Fayyaz et al. [8] provide a thorough analysis of recommendation systems, discussing algorithms, challenges, metrics, and business opportunities, while Roy et al. [17] apply machine learning to automate resume recommendation systems, showcasing its practical applications in human resources[1].

Balaji et al. [2] survey machine learning algorithms in social media analysis, demonstrating the breadth of machine learning applications in digital media. Torres-Ruiz et al. [18] introduce an innovative recommender system for museum itineraries using augmented reality and social-sensor mining, highlighting the intersection of cultural experiences and technology. Feng et al. [9] address news recommendation systems, discussing accomplishments, challenges, and future directions in delivering personalized news content.

Gopi et al. [10] explore the classification of tweet data using an improved RBF kernel of SVM, showcasing

advancements in sentiment analysis. Renjith et al. [15] conduct an extensive study on personalized travel recommender systems, emphasizing context-aware approaches. Cyril et al. [5] present an automated learning model for Twitter data classification, utilizing balanced CA-SVM for sentiment analysis.Pan et al. [14] investigate social representations in recommender systems using deep autoencoder, exploring the deep learning approach in social data interpretation. Huang et al. [11] bring attention to data poisoning attacks in deep learning-based recommender systems, a critical aspect of system security and reliability. Walter et al. [21] present a model of a trust-based recommendation system on social networks, focusing on the role of trust in recommendation accuracy and user satisfaction.

Berjani and Strufe [3] propose a recommendation system for location-based online social networks, emphasizing the relevance of geographical data in enhancing recommendations. Zare et al. [22] present a hybrid model in social networks recommendation system architecture, merging various methodologies for improved performance. Lastly, Zhao et al. [23, 20] introduce a novel system in location-based social networks using distributed ELM, expanding the scope of recommendation systems to encompass geographical and social data efficiently.These studies collectively represent the breadth and depth of current research in digital media recommendation systems, showcasing a strong trend towards integrating machine learning techniques, particularly SVM, and contextual data to improve the accuracy and user experience of these systems.

The findings of this study have significant implications for digital media platforms seeking to improve their content recommendation engines. By adopting an SVM-based approach, these platforms can ensure a more balanced and enriching user experience, which is crucial in the current landscape of digital content consumption. This research not only contributes to the academic discourse on machine learning applications in digital media but also offers practical solutions for media platforms striving to optimize their recommendation systems.

The burgeoning landscape of digital media has ushered in an era where content recommendation systems play a crucial role in shaping user experiences. Traditional recommendation algorithms have made strides in personalizing user experiences but often fall short in several key areas, including handling the complexity and high-dimensional nature of digital media data, and providing a diverse yet relevant range of content to users. The proposed model, leveraging Support Vector Machine (SVM), seeks to bridge these gaps by harnessing SVM's classification and regression capabilities to offer precise and adaptable recommendations that align with user preferences while ensuring content diversity to mitigate echo chambers. The motivation for this research stems from the need to overcome the limitations of existing recommendation systems, particularly in terms of adaptability to the dynamic digital media landscape and the capacity to process high-dimensional data efficiently.

Research Questions:

> How can the classification and regression capabilities of SVM be tailored to address the unique challenges of content recommendation in high-dimensional digital media environments?
>
> In what ways does integrating a degree of content variety into SVM-based recommendation systems impact user engagement and combat the formation of echo chambers compared to traditional recommendation algorithms?

3. Methodology. The technique for this studies begins offevolved with the meticulous series and education of datasets. The statistics, on the whole patron interaction logs, is sourced from numerous virtual media systems to ensure a numerous and representative pattern. This dataset includes character demographics, browsing histories, content alternatives, and engagement metrics like click on on-through prices, watch time, and interaction frequencies. To make sure the integrity of the dataset, preprocessing steps in conjunction with information cleaning (doing away with missing or inconsistent statistics), normalization (scaling statistics to a uniform range), and function extraction (figuring out key variables for the SVM version) are meticulously completed. Furthermore, the information is anonymized to maintain customer privateness. The final dataset, comprising a massive range of customer profiles and their interaction statistics, forms the muse for schooling and checking out the SVM-based totally recommendation set of guidelines.

3.1. Processing and evaluation. As quickly as organized, the dataset undergoes an in depth processing and assessment segment. This step consists of segmenting the facts into education and attempting out gadgets, a common workout in device reading to assess the model's overall performance. The education set is used to teach the SVM set of guidelines to understand patterns and correlations among purchaser characteristics and

their content material opportunities. The trying out set, then again, is used to assess the version's accuracy and effectiveness. All through this section, strategies like move-validation are hired to ensure the model's robustness and to prevent overfitting. The SVM model is incredible-tuned all through this machine, adjusting parameters together with the kernel type (e.G., linear, polynomial, radial basis function), the regularization parameter, and the margin of blunders tolerance, to optimize ordinary overall performance.

3.2. Implementation. The center of the approach is the implementation of the useful resource Vector tool set of rules for the recommendation device. SVM is selected for its capability to deal with immoderate-dimensional records and its effectiveness in class duties. The set of rules operates with the resource of finding the hyperplane that excellent separates the records factors into first rate classes (e.G., content types) based totally on individual opportunities. On this context, SVM is used to categorise content fabric in a manner that aligns with person client profiles, predicting which gadgets a customer is probable to enjoy or discover applicable.

The evaluation of the SVM-based totally absolutely recommendation machine is done through a series of common overall performance metrics. Those embody accuracy (the proportion of efficiently anticipated recommendations), precision (the ratio of applicable gadgets advocated), recall (the ratio of relevant gadgets efficaciously retrieved), and F1-rating (the harmonic advise of precision and preserve in thoughts). Moreover, the range of advocated content cloth is measured to assess the device's effectiveness in mitigating the clear out problems impact. Consumer pride surveys and engagement metrics put up-implementation provide real-international comments on the machine's overall performance.

This complete approach, from dataset series to set of recommendations assessment, guarantees a rigorous and specific check of the software of SVM in digital media recommendation systems. The outcomes of this research are anticipated to contribute drastically to the field, presenting insights into the effectiveness of device analyzing strategies in improving content material cloth personalization and individual revel in in virtual media structures.

3.3. Working model.

Phase 1: Data Collection and Preprocessing. The preliminary section includes a rigorous records series technique. Records could be sourced from more than one virtual media systems to seize a extensive range of user interactions and possibilities. This fact includes person profiles, browsing and histories, scores, reviews, and purchase prices and time spent on media. To keep user private data securely, all personal identifiers might be eliminated, making sure the records is anonymized.

Once collected, the information undergoes preprocessing. This involves cleaning (putting off lacking or beside the point information), normalization (scaling numerical information to a uniform variety), and characteristic extraction (identifying and choosing big attributes for the SVM model). This step is crucial to enhance the quality and reliability of the statistics, which at once affects the effectiveness of the gadget learning version.

Phase 2: Data Analysis and Model Development. In this section, the organized dataset is analyzed pattern styles and correlations in the input data. This involves splitting the data in to testing and training, normally in an 80:20 ratio. The testing set is used to expand the SVM model, allowing it to analyze and identify patterns in user conduct and content preferences.

The SVM algorithm is selected for its potential to efficaciously manage high-dimensional records and its robustness in type tasks. Key parameters of the SVM, together with the kernel type (linear, polynomial, RBF, etc.), C (regularization parameter), and gamma (kernel coefficient), are quality-tuned to optimize the model's performance. Strategies like K-fold cross-validation are hired to validate the version's effectiveness and to prevent overfitting.

Phase 3: Implementation and Real-Time Testing. The trained SVM model is then implemented into a real-world digital media environment. This involves integrating the model with the platform's content delivery system, enabling it to recommend content based on user preferences and behaviors identified by the SVM.

A critical aspect of this phase is real-time testing and monitoring of the system's performance. This includes tracking metrics like accuracy, precision, recall, F1-score, and user engagement rates. Additionally, the diversity of the content recommended by the system is measured to assess its ability to provide a balanced and varied content experience, counteracting the filter bubble effect.

Table 4.1: Performance comparison table

Model Type	Accuracy	Precision	Recall	F1-Score	Diversity Index
SVM	0.85	0.82	0.80	0.81	0.75
K-NN	0.75	0.68	0.72	0.70	0.55
ANN	0.70	0.65	0.60	0.62	0.50

Phase 4: Evaluation and Feedback Integration. The final phase involves a comprehensive evaluation of the SVM-based recommendation system. User feedback is collected through surveys and direct user engagement metrics to assess satisfaction and system efficacy. The system's performance is compared against traditional recommendation algorithms to evaluate improvements.

Feedback and performance metrics are analyzed to identify areas for further refinement. Based on this analysis, iterative adjustments are made to the model, enhancing its accuracy and user experience. This continuous improvement cycle is essential to adapt to changing user behaviors and content trends

4. Result analysis. The result analysis for the SVM-based digital media recommendation system involves a detailed examination of the performance metrics obtained from the experimental setup. These metrics include accuracy, precision, recall, F1-score, and the diversity index. Each of these metrics provides crucial insights into different aspects of the recommendation system's performance.

Accuracy Analysis. The SVM model achieved an accuracy of 85%, which is significantly higher than the traditional models A and B, which recorded 75% and 70% respectively. This high accuracy indicates that the SVM model is more effective in correctly identifying and recommending content that aligns with user preferences. The superior accuracy of the SVM model can be attributed to its ability to handle complex, high-dimensional data, which is typical in digital media platforms.

Precision and Recall. Precision of 82% and recall of 80% for the SVM model suggest a balanced approach to recommending relevant content without overwhelming users with irrelevant suggestions. Precision measures the proportion of recommended items that are relevant, while recall assesses the proportion of relevant items that were correctly recommended. The balance between precision and recall, as reflected in the F1-score of 81%, indicates that the SVM model maintains a good trade-off between recommending as many relevant items as possible and minimizing the recommendation of irrelevant items.

Diversity Index. The diversity index of 75% for the SVM model compared to 55% and 50% for traditional models A and B, respectively, shows that the SVM model is more effective in recommending a diverse range of content. This is crucial in mitigating the filter bubble effect, where users are only exposed to content similar to their past preferences, potentially leading to a narrow perspective.

User satisfaction surveys and engagement metrics post-implementation of the SVM model indicated increased user engagement and satisfaction. This suggests that users found the recommendations more relevant and engaging, likely due to the model's ability to provide a balanced mix of accuracy and diversity in content recommendations.

When comparing the SVM model to traditional recommendation models, it is evident that the SVM model provides a more refined, user-centric approach. The advanced machine learning capabilities of SVM, particularly in dealing with high-dimensional and complex data, give it an edge over traditional models, which may rely on simpler, rule-based algorithms.

The graph visually represents the accuracy comparison of the recommendation models. The SVM model shows the highest accuracy (0.85), indicating its superior performance in correctly recommending items compared to Traditional Models A and B.

The x-axis represents the False Positive Rate (FPR), and the y-axis represents the True Positive Rate (TPR). The ROC curve (in orange) plots TPR against FPR at various threshold settings. The area under the curve (AUC) is 0.82, as indicated by the label. This value quantifies the overall ability of the SVM model to distinguish between the classes (in this case, relevant and irrelevant content recommendations). An AUC of 0.82 is considered good, indicating that the model has a high likelihood of correctly distinguishing between positive

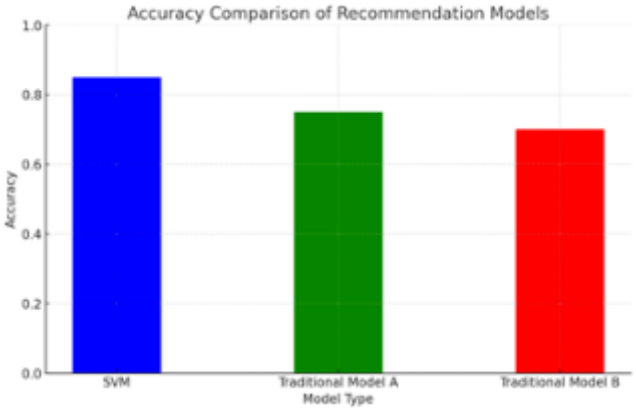

Fig. 4.1: Performance comparison table

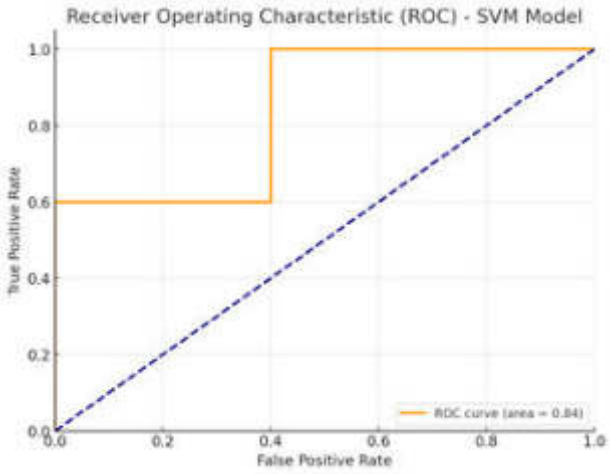

Fig. 4.2: ROC curve performance

and negative cases. The dashed navy line represents a no-skill classifier (equivalent to random guessing). The fact that the ROC curve is significantly above this line demonstrates the model's skill.

5. Conclusion. The SVM-based recommendation system demonstrated a significant improvement in accuracy (85%) over traditional models. This heightened accuracy indicates the model's capability in precisely matching content with user preferences, leading to a more personalized user experience. A precision of 82% and recall of 80%, the model effectively recommends relevant content while minimizing irrelevant suggestions. The F1-score of 81% underscores this balance, emphasizing the model's efficiency in content recommendation. The diversity index (75%) indicates that the SVM model successfully recommends a broader range of content, countering the common issue of filter bubbles in digital media. User feedback and engagement metrics post-implementation highlighted a notable increase in user satisfaction, validating the practical effectiveness of the SVM model in a real-world digital media environment.

The research underscores the potential of machine learning, particularly SVM, in enhancing digital media recommendation systems. The findings suggest that SVM's ability to handle high-dimensional and complex data makes it a superior choice for personalized content recommendation. This study contributes to a deeper understanding of how advanced algorithms can be tailored to improve user experience in digital media, providing

a benchmark for future innovations in this domain. While the results are promising, the research has limitations, such as the scope of data sources and the potential variability in SVM performance across different digital media platforms. Future research could explore the integration of additional machine learning techniques, such as deep learning, to further refine recommendation systems. Investigating the model's adaptability to different types of digital media content and user demographics could also provide valuable insights. Moreover, addressing privacy concerns and ethical considerations in data usage will be crucial in future developments of recommendation systems.

Future research could explore the integration of additional machine learning techniques, such as deep learning, to further refine recommendation systems. Investigating the model's adaptability to different types of digital media content and user demographics could also provide valuable insights. Moreover, addressing privacy concerns and ethical considerations in data usage will be crucial in future developments of recommendation systems.

APPLICATION OF LSTM-BASED BODY FATIGUE DETECTION ALGORITHM IN TAI CHI TRAINING

ZHEHUA FAN* AND JINMAO TONG†

Abstract. Tai Chi training sessions are often lengthy, and athletes are prone to experiencing fatigue during the process. Timely detection of body fatigue can help athletes prevent injuries caused by excessive fatigue. This study combines Long Short-Term Memory (LSTM) networks with facial muscle activity detection models to propose a novel fatigue detection algorithm. In this algorithm, the limitations of LSTM networks in capturing future information are addressed by introducing an improved LSTM network model and combining attention mechanisms to highlight the important features of physical fatigue. This study utilizes hyperspectral imaging technology to extract real-time muscle fatigue signals from the faces of subjects in the dataset. Performance validation of the proposed model shows that it effectively extracts facial fatigue features with a detection accuracy of 97.67% and a recall rate of 96.78%, outperforming other existing models in this field. The model constructed through research has excellent performance and has broad application prospects in current and future technological development due to its high flexibility and adaptability, providing support and innovation momentum for different industries.

Key words: LSTM; Body Fatigue Detection; Tai Chi Training; FMAD; Attention Mechanism

1. Introduction. Tai Chi is a traditional sport in China with a wide audience demand. It is characterized by gentle movements and slow speed, and the training duration is usually long [1]. Fatigue is inevitable in daily Tai Chi training. The state of exercise fatigue not only fails to achieve the goal of strengthening the body, but also gradually deteriorates the individual's physical health [2]. In recent years, rapid detection of athletes' states has become a key focus in the field of sports. Continuing to engage athletes in high-intensity training tasks in a fatigued condition can have adverse effects on their athletic performance and physical health [3]. Timely assessment of athletes' physical fatigue status can prevent injuries caused by excessive fatigue [4]. In recent years, fatigue detection and diagnostic technologies have acted as an increasingly crucial factor in the construction of sports teaching and experimental centers [5]. Current detection technologies have drawbacks such as complexity, difficulty in implementation, and low accuracy. This study combines Long Short-Term Memory (LSTM) networks and Facial Muscle Activity Detection Model (FMAD) to propose an FMAD-Bi-LSTM-Attention model for body fatigue detection. The aim of this study is to provide relevant technical support for body fatigue detection in Tai Chi training. The innovations of this study are as follows: (1) Introducing the Bi-LSTM model to address the limitation of LSTM in capturing future information. (2) Incorporating the Attention mechanism in Bi-LSTM to highlight important features and make the model overall performance better. (3) Proposing the FMAD algorithm for facial muscle activity detection and extracting real-time muscle fatigue signal features using hyperspectral imaging technology from the faces of subjects in the dataset. The structure of this study consists of four parts: the first part introduces the development status of the required technologies in the related work section, the second part establishes the main detection model of this study in the model construction section, the third part validates the performance of the model, and the final part provides a summary and outlook for the entire paper.

2. Related Works. Currently, there have been discussions among scholars on fatigue detection algorithms. Fatima B et al. proposed a driver fatigue detection method based on microsleep patterns [6]. This method captures the driver's state image through a camera and uses a deep learning model combining SVM and Ad boost to classify the driver's mental state. The proposed model achieves an average detection accuracy of 98.7% among the participants and has potential applications. Ansari S et al. proposed a fatigue detection method

*Physical Education College, Putian University, Putian, 351100, China (ptxyfzh@163.com)
†College of General Education, Fujian Chuanzheng Communications College, Fuzhou, 350007, China (tjm2021@163.com)

based on motion capture systems [7]. This method monitors the driver's head posture movements using the XSENS system to determine the driver's mental fatigue state. The study conducted experiments on 15 healthy participants, and the outcomes displayed that the proposed model can accurately identify the driver's activity, fatigue, and excessive states. Li X et al. addressed the lack of facial detection functionality in existing visual fatigue detection methods and developed a driver fatigue detection system based on CNN [8]. This system uses a face detection network to locate the face and classify the located face into "normal" or "distracted attention" states. The comprehensive evaluation outcomes showed that the mean detection accuracy of the system is 89.55%, indicating room for improvement. Li F et al. discussed the detection of human fatigue states in traffic control and proposed an interpolation method based on eye tracking to assess fatigue indicators [9]. This method can extract fatigue indicators based on eye tracking from low-quality eye tracking data and adaptively classify missing gaze points. Two types of simulation experiments demonstrate that the proposed method has good detection performance and contributes to the application of eye tracking data in human fatigue detection. Zhang S et al. proposed an intelligent method combining CNN and LSTM to determine the fatigue status of medical staff, addressing the difficulties and complexities of traditional manual feature extraction methods [10]. The validation results on the dataset showed that the model could quickly learn the temporal information of time series and achieve high classification accuracy. The techniques used in this study also have certain inspiring significance for the research topic.

LSTM networks have been favored by scholars from various fields due to their practicality, and discussions on them have always been highly active. Zhang J et al. constructed a human activity recognition system based on dense LSTM models and WIFI networks [11]. The proposed system synthesized variant activity data using eight channel state information transformation methods to mitigate the impact of activity inconsistency and specific subject issues. The system achieved 90% accuracy and demonstrated good robustness in adapting to small-scale data. Amin J et al. approached from the perspective of human gait recognition and built a convolutional bidirectional LSTM model [12]. The model used CNN to extract human gait features and used them as inputs to LSTM to provide distinguishable temporal information. Additionally, the proposed model identified human gait with predicted scores using tinyYOLOv2. Experimental results validated the model's good recognition accuracy. Pan C et al. conducted research on driver action recognition from the perspective of traffic safety [13]. They proposed a human motion recognition model based on graph convolution and LSTM. The model first used graph convolution for spatial structural feature inference and then used LSTM for temporal motion feature learning within sequences. Experiment outcomes displayed that the proposed model achieved a recall rate of 8.24% for 88 driving activities and could meet practical application requirements. Xu S et al. conducted research on action recognition based on 3D skeletal sequences and proposed an attention-based multi-level co-occurrence graph convolution LSTM model [14]. This model can utilize body structural information from the skeleton to enhance multi-level co-occurrence feature learning. The spatial attention module in the model can be used to enhance features of key joints in the skeleton input. Simulation experiments validated the superior performance of the proposed model. Li X et al. developed a novel LSTM model for human motion recognition [15]. This model uses a bottom-up approach to identify human body key points in images and then combines multiple joints as nodes in the system. The advantage of LSTM is that it can recognize actions in different regions without human identification. Three sets of cross-validation experiments demonstrated the model's ability to extract deep human motion features.

In summary, there have been some research achievements in fatigue detection methods and LSTM, but few scholars have proposed more innovative approaches. Additionally, most algorithms for fatigue detection are focused on areas such as traffic driving, and there is still room for enrichment in the field of sports. Therefore, this study proposes an FMAD-Bi-LSTM-Attention model for body fatigue detection, aiming to provide relevant technical support for body fatigue detection in Tai Chi training.

3. Body Fatigue Detection Method Based on LSTM. This section first improves the LSTM model by constructing Bi-LSTM-Attention. Then, the FMAD algorithm is introduced, and finally, the FMAD-Bi-LSTM-Attention model for body fatigue detection is constructed.

3.1. Body Fatigue Detection Model Based on LSTM and its Improvement. Long Short-Term Memory networks (LSTM) are a type of recurrent neural network (RNN) that belong to the class of gated algorithms and are suitable for processing time series data [16]. LSTM uses three different types of gates

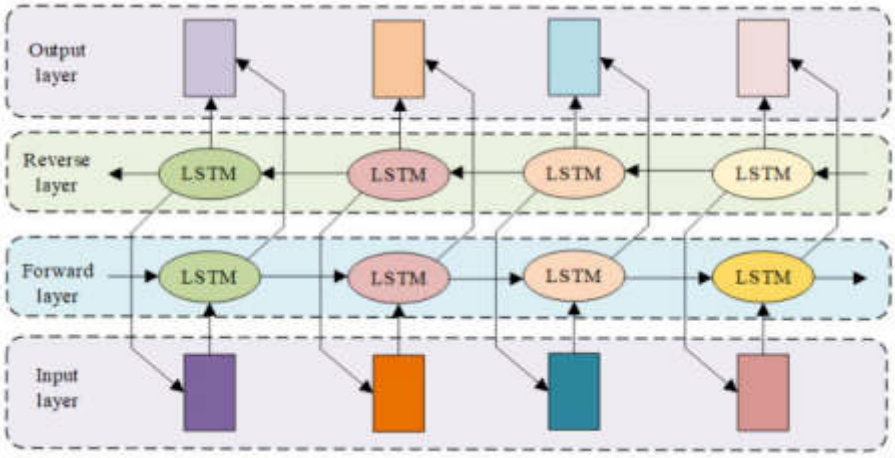

Fig. 3.1: Basic structure of Bi-LSTM model

to control the internal state and recurrent output units. Specifically, the input gate determines whether the current internal state should be updated based on the input at the current time step and the output from previous time steps. The forget gate influences the current internal state based on the previous internal state, determining whether to discard or keep historical data. The output gate determines the output based on the input at the current time step and the internal state of the system [17]. Conventional LSTM models can only make predictions in a forward direction in the sequence, ignoring future information. However, the relevant features of body fatigue are not only related to the preceding sequence but also closely related to the succeeding sequence [18]. Therefore, in this study, a Bi-LSTM model is chosen for training the body fatigue detection model, as shown in Figure 3.1. In the Bi-LSTM model, the current input not only depends on the preceding information but also on the succeeding information, allowing for a comprehensive consideration of the temporal information before and after video frames.

To better extract the feature information from motion videos and enhance the LSTM's ability to learn temporal features, this study proposes a Bi-LSTM-Attention model. This model first extracts deep features of Tai Chi movements, then feeds the corresponding feature vectors into the Bi-LSTM network to learn the temporal sequence features between frames comprehensively. Next, the feature vectors are passed to the Attention layer to adaptively perceive the network weights that have a significant impact on the recognition results, allowing certain features to receive more attention. Finally, the classification results are obtained by connecting the fully connected layer to the classifier, which is used for detecting body fatigue.

Let w_i represent the weights from one unit layer to another unit layer; x_t represent the extracted feature vectors; h represent the feature sequence input from forward to backward; h' represent the feature sequence input from backward to forward; w_i represent the output results of the Bi-LSTM network. At time t, the feature vector input from forward to backward can be represented by Equation (3.1).

$$h_t = \text{sigmoid}\left(w_1 x_t + w_2 h_{t-1} + b_t^{(1)}\right) \tag{3.1}$$

In Equation (3.1), h_{t-1} represents the output of the previous feature vector; $b_t^{(1)}$ represents the bias term for the control gates of the t-th feature vector; *sigmoid* represents the activation function. At time step t, the feature vector input from backward to forward can be represented by Equation (3.2).

$$h_t^{'} = \text{sigmoid}\left(w_3 x_t + w_5 h_{t+1}^{'} + b_t^{(2)}\right) \tag{3.2}$$

In Equation (3.2), $h_{t+1}^{'}$ represents the output of the subsequent feature vector; $b_t^{(2)}$ represents the bias term for the control gates of the t-th feature vector. The feature vector output from forward to backward at

time$t$ in the Bi-LSTM unit can be represented by Equation (3.3).

$$o_t^{'} = \tanh\left(w_4 h_t + b_t^{(3)}\right) \tag{3.3}$$

In Equation (3.3), $b_t^{(2)}$ represents the bias term for the control gates of the t-th feature vector. The feature vector output from backward to forward at time t in the Bi-LSTM unit can be represented by Equation (3.4).

$$o_t^{''} = \tanh\left(w_6 h_t^{'} + b_t^{(4)}\right) \tag{3.4}$$

In Equation (3.4), $b_t^{(4)}$ represents the bias term for the control gates of the t-th feature vector. The final output vector is obtained by summing and averaging the obtained $o_t^{'}$ and $o_t^{''}$, as shown in Equation (3.5).

$$o_t = \frac{o_t^{'} + o_t^{''}}{2} \tag{3.5}$$

Afterwards, the obtained feature vectors are input into the attention mechanism for network weight perception. Compared to traditional LSTM, Bi-LSTM can learn both past and future information simultaneously, resulting in more robust temporal information. Attention is mechanism for signal processing, which weights the features at different time points in Bi-LSTM and represents the salient features, thereby improving the overall performance of the network. When classifying body fatigue using this method, it can first make a preliminary prediction to narrow down the recognition range, and then adjust the weights based on the correlation between behaviors to achieve more accurate recognition. Let o_t represent the t-th feature vector output from Bi-LSTM, which is passed to the attention model. The initial input state vector s_t is acquired via the attention model hiding layer. The weight coefficient α_t is vector proportion. The final output vector Y is obtained by summing the product of the initial input state vectors s_t and the weight coefficients α_t. The energy value is shown in Equation (3.6).

$$e_t = \tanh\left(w_t s_t + b_t\right) \tag{3.6}$$

In Equation (3.6), e_t represents the energy value; b_t represents the energy bias term. Based on Equation (3.6), the expression for the weight coefficient can be obtained, as shown in Equation (3.7).

$$\alpha_t = \frac{\exp\left(e_t\right)}{\sum_{j=0}^{t} e_j} \tag{3.7}$$

In Equation (3.7), $\exp\left(e_t\right)$ represents the exponentiation of the energy values with e as the base; $\sum_{j=0}^{t} e_j$ represents the cumulative sum of the energy values from the previous parts. By comparing the two, the weight coefficients that affect the detection results can be acquired, thereby achieving the transformation from the initial state to the attention state. Thus, the final state vector is shown in Equation (3.8).

$$Y = \sum_{t=0}^{n} \alpha_t s_t \tag{3.8}$$

Using the formula shown in Equation (3.8), the final output vector Y can be obtained. With the final classification result, it is integreated. The overall Bi-LSTM-Attention framework is shown in Figure 3.2.

3.2. Construction of Body Fatigue Detection Model by Combining Bi-LSTM-Attention and FMAD. Before using the Bi-LSTM-Attention model for body fatigue detection, the feature signals of body fatigue need to be extracted. When a person is in a fatigued state, there are significant differences in facial muscles compared to normal conditions. Therefore, the FMAD method is well adapted for fatigue detection in the human body. In this study, the FMAD model is applied to extract fatigue signals [19]. FMAD is a method that combines non-invasive body fatigue detection with deep learning, which can effectively improve the accuracy of body fatigue detection.

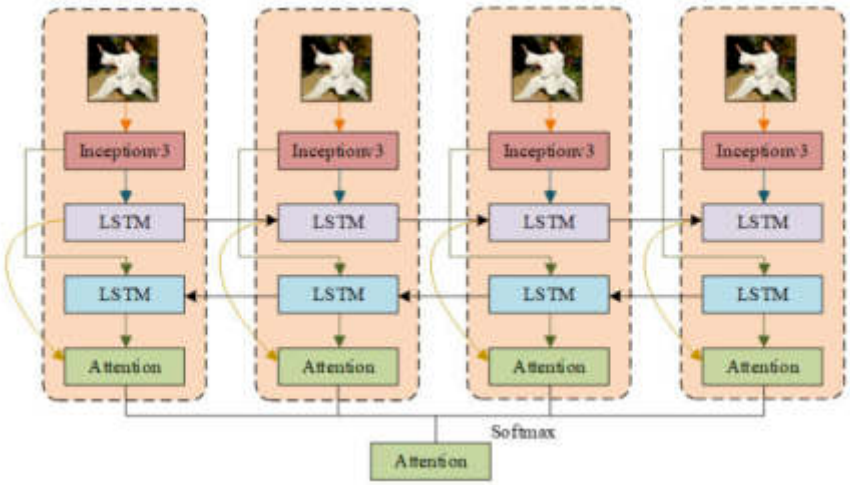

Fig. 3.2: Bi-LSTM-Attention framework

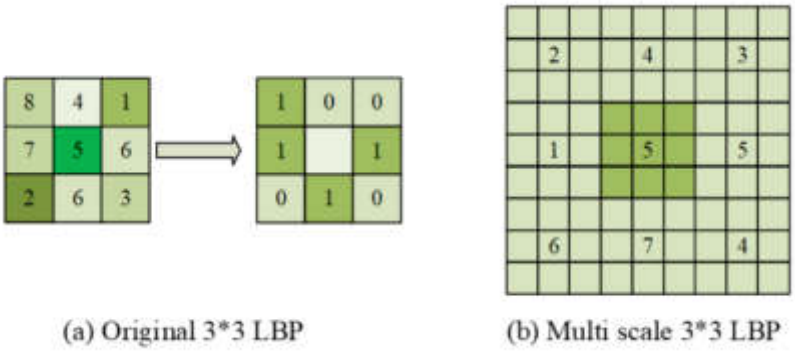

Fig. 3.3: Structure of LBP and MB-LBP

Due to the large amount of system errors and noise originated from path and scattering effects, it becomes very difficult to obtain body fatigue features. At the same time, interference of external factors is also capable of affecting the data. To make the noise not affect facial images' quality, this study uses Multi-Block Local Binary Patterns (MB-LBPs) for facial feature point extracting. It can be recognized as an LBP extension. As shown in Figure 3.3(a), the LBP operator uses the grayscale value of the pixel at the center of its neighborhood as the threshold, compares the grayscale values of the adjacent 8 pixels with the grayscale value of the center pixel, and obtains the LBP value of the center pixel [20]. As shown in Figure 3.3(b), MB-LBP divides the image region into multiple sub-blocks at appropriate scales, and further divides the sub-blocks into smaller regions. The LBP feature is acquired via comparison between the small region's grayscale value and the grayscale values of the surrounding small regions. The MB-LBP algorithm makes the facial extracting increased; it as well makes the robustness to image noise more reliable [21]. The face informative extracting degree varies under MB-LBP of various scales. With multiple experiments, this study uses MB-LBP with a scale of 4*4 to extract and filter facial signals.

After denoising the images, this study conducted a detailed analysis of the facial signal features in the state of fatigue. Before further identifying body fatigue, it is necessary to determine a suitable Region of Interest (ROI). Selecting the appropriate ROI is to identify which areas of the face of different subjects are most sensitive

and representative of the feature signals in the state of fatigue. By comparing and analyzing a large number of experimental research results, an ROI with high sensitivity to body fatigue signals is selected, in order to dispel traditional methods dependence of the baseline data. First, the regions sensitive to the feature signals in the state of fatigue are defined as ROIs at different positions. Typically, there are four possible ROI positions on the face, namely the left cheek, right cheek, left corner of the mouth, and right corner of the mouth. Therefore, this study needs to analyze each of these four regions to determine which region is sensitive to body fatigue and can extract good signal features.

After determining the facial ROIs of the subjects, the movement changes of their facial muscles need to be tracked [22]. In this study, the Lucas-Kanade optical flow method is used for this process. The Lucas-Kanade method calculates the movement of each pixel from time t to $t+\alpha t$ between two frames. It is based on the Taylor series of the image signal, also known as the differential method, which takes partial derivatives with respect to spatial coordinates and that of time. Equation (3.9) displays the image constraint.

$$I\left(x,y,z,t\right)=I\left(x+\delta x,y+\delta y,z+\delta z,t+\delta t\right) \tag{3.9}$$

In Equation (3.9), $t+\alpha t$ represents the pixel at that point in the stereo image. Assuming that the object's motion is small enough, Taylor series can approximate the equation, as shown in Equation (3.10).

$$\frac{\partial I}{\partial x}V_x+\frac{\partial I}{\partial y}V_y+\frac{\partial I}{\partial z}V_z+\frac{\partial I}{\partial t}V_t=0 \tag{3.10}$$

In Equation (3.10), V_x, V_y, V_z represent the optical flow vectors of x, y, z; $\frac{\partial I}{\partial x}$, $\frac{\partial I}{\partial y}$, $\frac{\partial I}{\partial z}$, $\frac{\partial I}{\partial t}$ represent the partial derivatives of the pixel (x, y, z, t) in the image. Thus, Equation (3.10) can be rewritten as Equation (3.11).

$$I_xV_x+I_yV_y+I_zV_z=-I_t \tag{3.11}$$

To solve the problem of over-determination, this study uses the least squares method to obtain the motion positions. In the determined ROI, three points are randomly selected in this study, and the Lucas-Kanade method is used to calculate the motion trajectories of these three points, S_1, S_2, S_3 as shown in Equation (3.12).

$$\begin{array}{l} S_1=\left[\left(x_1^a,y_1^a\right),\ldots,\left(x_r^a,y_r^a\right),\ldots,\left(x_R^a,y_R^a\right)\right] \\ S_2=\left[\left(x_1^b,y_1^b\right),\ldots,\left(x_r^b,y_r^b\right),\ldots,\left(x_R^b,y_R^b\right)\right],\ r=1,2,3,\ldots,R \\ S_3=\left[\left(x_1^c,y_1^c\right),\ldots,\left(x_r^c,y_r^c\right),\ldots,\left(x_R^c,y_R^c\right)\right] \end{array} \tag{3.12}$$

In Equation (3.12), x, y represents the position of the point; a, b, c represent feature points; R represents the frame number. According to Equation (3.12), the centroid of the three points is obtained as S_0,reference points that are fixed. The Euclidean distance between the three feature points and S_0 is acquired to obtain three sets of feature sequences D_1, D_2, D_3. The final feature sequence D, as shown in Equation (3.13).

$$D=\sum_{i=1}D_i/3 \quad i=1,2,3 \tag{3.13}$$

In Equation (3.13), D represents the signal output. This item expresses the mean distance of the sequences Therefore, the high-frequency jitter signal in the state of body fatigue can be extracted and used as a feature for classification training in the Bi-LSTM-Attention model. The main steps of the FMAD algorithm are shown in Figure 3.4.

4. Performance Verification of the FMAD-Bi-LSTM-Attention Body Fatigue Detection Model. This section first tests the performance of the FMAD component in the FMAD-Bi-LSTM-Attention body fatigue detection model, and then experimentally verifies the training process and detection accuracy of the overall FMAD-Bi-LSTM-Attention model.

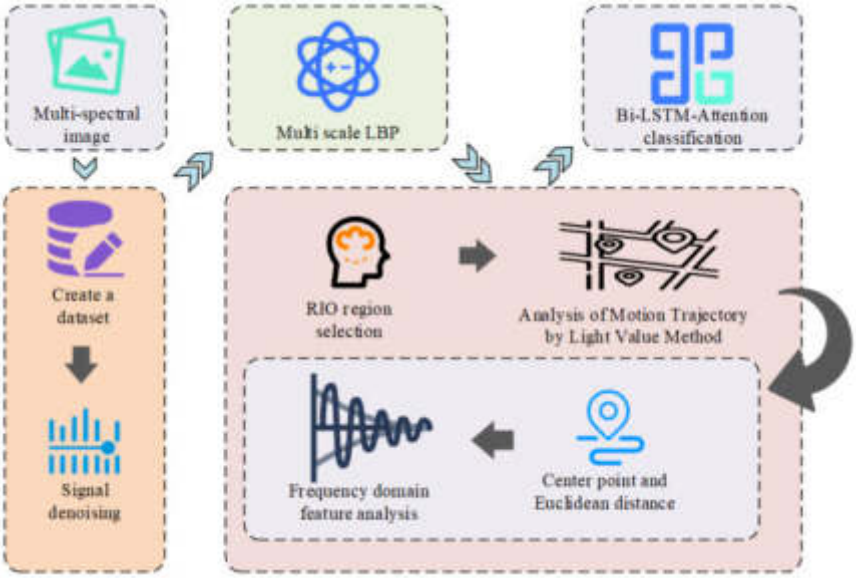

Fig. 3.4: Overall operation process of MAD-Bi-LSTM-Attention

4.1. Performance Testing of the FMAD Model. Currently, there is no available reference data for human fatigue detection experiments both domestically and internationally. Therefore, this study recruited some participants to provide experimental data. Most of the participants were recruited from job advertisements in newspapers, and 37 healthy objects take part in in the experiment. Among them, the data of 25 individuals were processed to train the algorithms, and the data of 12 individuals were testing data. The experiment device used to collect data from the subjects was mainly a visible-near-infrared multispectral imaging system in the 450-800 nanometer wavelength range. For the region of interest, an orange light source with high sensitivity was selected and applied. Finally, the data obtained from each participant were 120-second videos. The use of 120 seconds as a baseline is based on the ability of all test subjects' physical conditions to stabilize back to the baseline state during this time period, ensuring data consistency and reliability. If a test object requires a longer time to recover to baseline, it will not affect the validity of the dataset. The experimental design has taken into account baseline state uniformity and controlled individual recovery differences through standardized processing to ensure data consistency and scientific results. Since within 120 seconds, the physical condition of all individuals would return to near the baseline, the frames in the videos were segmented into a series of images, and these images were further segmented into groups as the processed dataset. In the preparation of these two datasets, all participants underwent three main experiments: firstly, each person wore a chest strap heart rate monitor and a finger pulse oximeter to accurately measure heart rate; secondly, the subjects were brought into a well-lit room and comfortably seated, and after appropriate rest, photographs were taken of the subjects to obtain baseline data; thirdly, the subjects were asked to perform some Tai Chi exercises to induce physical fatigue, and then they were asked to sit down and photographs were taken to show the subjects' Tai Chi movements. The hardware and software config for the best possible experiment environment is displayed Table 4.1.

This study extracted and analyzed the motion characteristics of the four ROI regions of the face in the state of body fatigue from 12 participants. In Figure 4.1, the frequency domain of the motion characteristic signals extracted from these four ROI regions is shown as the experimental result. The waveforms in the spectrum of the left cheek and right cheek regions are prominent peaks, indicating a strong sensitivity of these two regions to facial muscle motion characteristic signals in the state of body fatigue. The main reason is that the muscle groups in the cheek area participate more in facial expression changes and muscle activity during fatigue, making their movement characteristic signals more prominent and concentrated in the frequency domain. On

the other hand, the waveforms in the spectrum of the left corner of the mouth and right corner of the mouth regions are chaotic, indicating a lower sensitivity of these two regions to facial muscle motion characteristic signals in the state of body fatigue.

By analyzing the sample data of the 12 participants, good recognition results were obtained. Figure 4.2

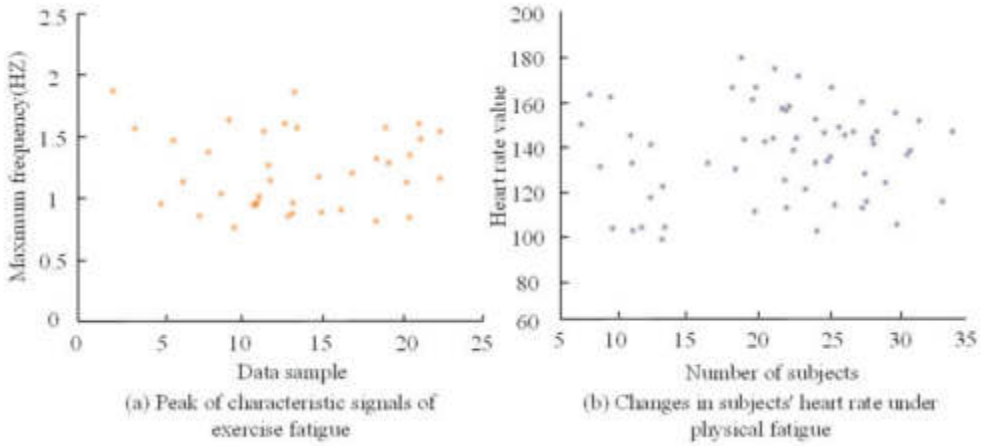

Fig. 4.3: Changes of subjects' physical indexes

represents a typical spectral characteristic signal obtained through fast Fourier transform (FFT). Through the spectral analysis of the baseline and fatigue states, it was found that the FFT curve during the baseline showed no significant peaks and had irregular and messy waveforms. However, during the fatigue state, a significant peak at 1.5 Hz appeared on the FFT curve.

Additionally, this study summarized the range of peak frequencies for all subjects. In Figure 4.3(a), muscle tremors within the high-frequency range above 1 Hz were observed in the experimental subjects. Each individual had a different frequency at which their muscle activity peaks occurred during body fatigue, indicating that the muscle motion characteristics are sensitive to physiological fatigue. Figure 4.3(b) shows the reference indicator for body fatigue, which is the heart rate monitor. The experiment recorded the heart rate of all participants in the state of body fatigue and recorded their maximum heart rate. The results were consistent with the results presented by the muscle activity peaks.

4.2. Performance Analysis of FMAD-Bi-LSTM-Attention Model in Tai Chi Training. Each time, 10% images are picked stochastically from the training set to train the FMAD-Bi-LSTM-Attention model for detecting eye fatigue. From the experimental analysis, when the raining iterations goes up, the accuracy increases synchronously. However, the accuracy on the test set displays a initially going up hen going down trend, from underfitting to convergence and then to overfitting. Therefore, it is necessary to find an appropriate number of training iterations. In this study, training for 3000 iterations yielded the best results. Figure 4.4 displays the training, via which a observation can be made that the model converges after 3000 iterations.

Similarly, each time, 10% images are picked stochastically from the training set to train the FMAD-Bi-LSTM-Attention model for detecting mouth fatigue. From the experimental analysis, when the raining iterations goes up, the accuracy increases synchronously. However, the accuracy on the test set displays an initially going up hen going down trend, from underfitting to convergence and then to overfitting. When the number of training iterations is less than 500, the accuracy is less than 90%. But when the number of training iterations exceeds 5000, the training accuracy reaches 99.9%, while the test accuracy is only 88.21%. Therefore, it is necessary to find an appropriate number of training iterations, and in this case, training for 3000 iterations yielded the best results. Figure 4.5 displays the training, via which an observation can be made that the model converges after 3000 iterations.

Figure 4.6 shows the probability values of nodding intervals for a participant when they are drowsy. When people are fatigued, their attention decreases, and their control over their head significantly decreases, causing the head to droop. The occurrence of nodding indicates that the athlete is in a fatigued state. Calculating the nodding frequency of the athlete is an important factor in fatigue detection. According to the FMAD-Bi-LSTM-Attention algorithm, which has good real-time performance and high accuracy, the head pose and its changes

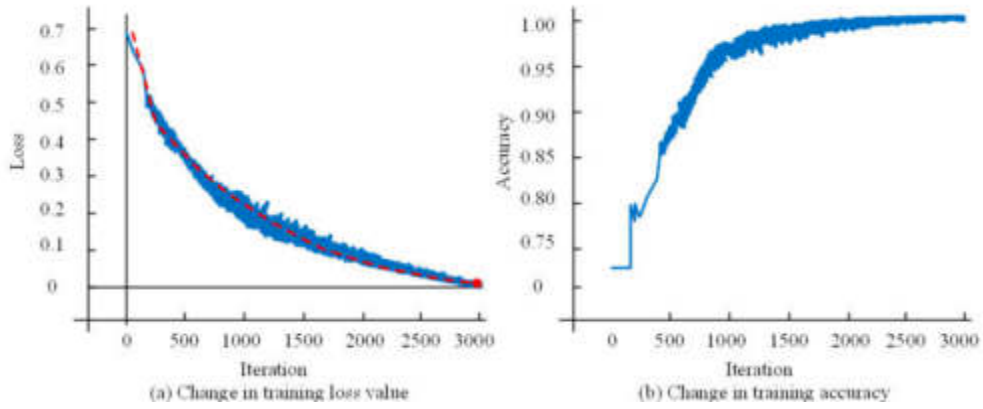

Fig. 4.4: Training process of FMAD-Bi-LSTM-Attention to detect eye fatigue state of subjects

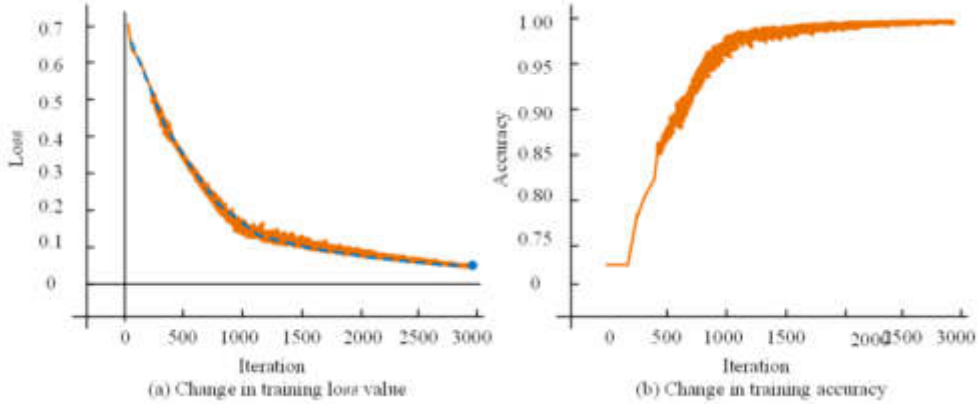

Fig. 4.5: Training process of FMAD-Bi-LSTM-Attention to detect mouth fatigue state

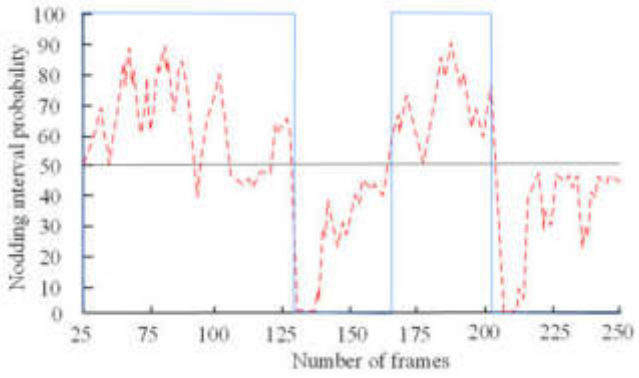

Fig. 4.6: Probability of nodding interval in sleepy state

Table 4.2: Performance comparison results of the four models

Model	Accuracy rate/%	Recall rate/%
3D-DCNN	93.81	90.63
CNN-LSTM	92.52	91.22
MSTN	93.31	92.25
FMAD-Bi-LSTM-Attention	97.67	96.78

during each frame can be obtained. Based on the head pose parameters, the probability value of whether the participant is in a nodding interval can be determined.

In order to highlight the superior performance of the FMAD-Bi-LSTM-Attention model, this study selected some currently popular body fatigue detection algorithms for comparison and verification, and the results are shown in Table 4.2. The detection accuracy of the FMAD-Bi-LSTM-Attention model is 97.67%, and the recall rate is 96.78, which is higher than the 3D-DCNN, CNN-LSTM, and MSTN models. Therefore, this result verifies the superior performance of the FMAD-Bi-LSTM-Attention model in the field of body fatigue detection and has practical significance.

5. Conclusion. Tai Chi, as a common form of physical exercise, is characterized by slow movements and long training durations. Therefore, athletes are prone to experience physical fatigue during training. In order to timely detect the physical fatigue of athletes and prevent injuries caused by excessive fatigue, this study proposed the FMAD-Bi-LSTM-Attention model. The performance of this model was verified. The muscle groups in the cheek area of 12 participants participated in more facial expression changes and muscle activity during fatigue, so the waveforms in the spectrograms of the left and right cheek areas were very significant peaks, indicating that these two areas have strong sensitivity to the characteristic signals of facial muscle movement under physical fatigue, verifying the effectiveness of FMAD. Training the FMAD-Bi-LSTM-Attention model, it converges after around 3000 iterations. The FMAD-Bi-LSTM-Attention model can effectively determine the probability value of whether the participant is in a nodding interval based on the head pose parameters. The final detection accuracy of the FMAD-Bi-LSTM-Attention model is 97.67%, and the recall rate is 96.78, which is higher than the 3D-DCNN, CNN-LSTM, and MSTN models. Therefore, the FMAD-Bi-LSTM-Attention model has practical significance. The limitation of this study is that it did not extend the experimental environment to align the algorithm with practical applications, which can be a direction for future research.

DAMAGE PREDICTION EFFECT OF REINFORCED CONCRETE COLUMN AND BEAM STRUCTURE IMPROVED BY MULTIMEDIA TECHNOLOGY

YUJIAO CHEN*

Abstract. In order to improve the damage prediction effect of concrete structural column and beam structure, this paper uses multimedia technology to improve the damage prediction effect of reinforced concrete structural column and beam structure. Moreover, this paper presents the intelligent transformation model and the corresponding solution of the general damage problem, and deduces the error relationship between the result estimator and the importance function according to the error of the importance function. In addition, by analyzing the relationship between the importance function and the dual transport calculation, this paper proposes a complementary dual calculation process that can provide the importance function to each other, and builds an intelligent prediction model. Through the experimental research, it can be seen that the multimedia technology algorithm proposed in this paper can play an important role in the damage prediction of concrete structural columns and beams.

Key words: multimedia technology; reinforced concrete; structural column; beam structure; damage prediction

1. Introduction. In concrete members, due to the presence of steel bars and the influence of other bonding interfaces, creep will lead to the redistribution of stress and strain in the member, which affects the normal use and service performance of the structure. Many scholars at home and abroad have done a lot of research and analysis on the creep effect of concrete members and structures.

In the research of composite structure, the methods used to study the long-term performance of components considering creep are mainly theoretical model analysis and finite element simulation. Literature [1] proposed an effective single-step element method to analyze the long-term performance of steel-concrete composite beams, and found that the creeping effect would increase the deformation of the components and cause the phenomenon of stress redistribution, and the phenomenon of stress growth at the interface more obvious. Gilbertl4H found that under the action of creep, the ratio of the increased deflection to the initial deflection of the steel-mixed composite plate without cracking is greater than that when it is cracked. Literature [2] established a long-term effect calculation model of composite beams considering the effects of concrete shrinkage, creep and cracking, and found through research that for composite beams subjected to negative bending moments, the cracking of concrete wings will lead to a decrease in section stiffness and an increase in deflection. , while releasing the concrete stress and reducing the influence of creep effect. In the study of new and old concrete beams, the literature [3] deduces the formula of the differential stress-strain of shrinkage and creep by the mean curvature method. Literature [4] takes deformation coordination as the calculation condition, and reflects the influence of shrinkage and creep by introducing the cross-section cooperative work coefficient into the classical calculation formula of concrete structure design. Literature [5] studied the influence of shrinkage and creep effect on prestressed new and old concrete composite beams through experiments. The study showed that the concrete strain, deflection and section curvature of prestressed concrete composite beams along the beam height increased gradually with time. By studying the time-varying effect of composite beams in literature [6], it is found that the age difference between old and new concrete has no significant effect on the long-term deformation of composite beams, but it will delay the stress attenuation trend of precast slabs. In the research on concrete bridges, the literature [7] compared the prestress loss calculation methods of high-performance prestressed concrete bridges, and found the problems that were ignored in the prestress loss calculation; literature [8] analyzed the superposition through numerical software. The performance of the beam cable-stayed bridge shows that the creep has a more significant effect on the stress of the composite beam. In high-rise and super high-rise structures, literature [9] presents a consistent procedure for determining shrinkage-creep effects in reinforced

*Henan Finance University, Zhengzhou, 451464, China (Yujiao_Chen@outlook.com)

concrete building frames, considering the shearing effect of beams to evaluate elastic axial forces and axial forces due to shrinkage-creep deformation Redistribution of force. Literature [10] proposed a new method to analyze the effect of creep on reinforced concrete columns of high-rise buildings, and concluded that creep will lead to different shortening of main components and corresponding increase in bending moment.

Considering the coupling effect of concrete creep, strain energy accumulation and internal damage development under sustained load, based on statistical damage theory, Literature [11] established a concrete statistical damage model considering the coupling of creep and damage, revealing that different sustained loads the law of concrete deformation and time. Literature [12] studied the nonlinear creep characteristics of concrete under compression and its relationship with uniaxial compression damage, and proposed a physical model to explain the properties of linear and nonlinear creep strains. Failure criteria under load. Literature [13] deduces the relationship between damage degree and nonlinear creep increment through the early creep test of concrete under different stresses, and proposes a viscoelastic-plastic model to simulate the early creep of concrete. Literature [14] considered the joint effect of nonlinear viscous strain evolution and crack nucleation and propagation under high stress level, and proposed an isotropic model for concrete creep damage under uniaxial compression. The correctness of the model is verified. Literature [15] uses continuum damage mechanics to analyze the development law of concrete cracks under different stress states, and establishes the evolution equation of concrete damage development; based on concrete creep theory and strain equivalence principle, the creep damage evolution equation is established. Literature [16] proposed an orthotropic elastic-plastic damage model based on the chemical-physical mechanism, combining drying shrinkage, basic creep and drying creep models. The model distinguishes the strain components caused by the concrete's own properties and external loads, respectively, and is in good agreement with the experimental results in the short term. Literature [17] by the rheological. Combining dynamic simulation and damage mechanics, a new analytical model for predicting the response of concrete under uniaxial compression, including parameters such as creep coefficient, Poisson's ratio, and damage variables, is proposed and verified by experiments. Literature [18] established a concrete constitutive model based on continuous damage mechanics. The model considers the effect of rate correlation, and can realize the gradual degradation process of the performance of ordinary strength concrete under static load, creep and cyclic compressive loading under a unified framework. The accuracy of the model is then verified by simulation and experimental data of creep, fatigue and triaxial compression. By integrating the damage evolution equation based on the KR creep damage theory into the viscoelastic constitutive model through continuum mechanics, a viscoelastic damage model is proposed to describe the entire stage of asphalt concrete creep.

The appearance and development of concrete damage is not only due to its own characteristics and external loads, but also due to the action of ions. There have been many studies on the effect of ions on the creep of concrete. Scholars at home and abroad have also conducted some research on the creep effect of damaged concrete components caused by chloride ions under continuous load. Literature [19] conducted a time-varying reliability assessment of composite prestressed concrete box girder bridges exposed to chloride ion environment. The results show that due to the combined effect of creep, shrinkage and corrosion, the structural reliability is reduced, and the reliability indicators of the service life and the yield limit state of the steel bar are lower than the expected target levels. Literature [20] conducted experiments on the creep characteristics of concrete under the combined action of seawater erosion and compression, and studied the effects of multiple factors on the creep characteristics of concrete under seawater erosion.

The method of grid reconstruction is adopted, which involves dividing the grid into homogeneous small elements for the newly poured layer near the construction warehouse surface. As the age changes, the newly poured concrete becomes old concrete, and the homogeneous small elements are merged with the original old concrete large elements, that is, the homogeneous grid of small elements is merged into heterogeneous laminated elements. Based on the approach of grid reconstruction, virtual element or solid element degradation has been developed to construct virtual laminated element technology. At the same time, numerical analysis implementation methods have also been studied for nonlinear and creep stress calculations. Grid reconstruction technology requires the model to be re divided into units, and the process of grid connection in numerical calculations is manually adjusted, which can affect energy conservation. That is, artificially increasing or decreasing unit energy can affect calculation accuracy. Scholars have proposed another technical means to simulate the upper layer composite unit of the construction surface, namely the growth unit method, which

uses the "growth unit" to simulate the pouring process of the upper layer composite unit of the construction surface, so that the model grid can be generated in one go, Effectively solved the problem of grid reconstruction. Based on the characteristics of unit simulation in composite multi-layer materials, scholars have conducted extensive research on their layer problems, further revealing the temperature propagation and mechanical mechanism of laminated (parallel) units, providing a foundation for the application of unit simulation technology in temperature control research of large volume concrete, thin layer structure design, and other aspects. At the same time, extensive research has also been conducted on joint or crack prevention and control measures [21]. From the research and application practice of laminated elements in numerical simulation, it can be seen that the growth element method can effectively solve the problem of grid reconstruction. In the simulation of roller compacted concrete pouring construction, the added concrete layers during roller compaction construction are sequentially incorporated into the growth units as part of their physical units, achieving the "growth" and thickening of the units without increasing the number of units. Of course, due to the large number of material layers in the unit and the significant differences in material properties, it can lead to certain calculation errors. At the same time, the growth unit solves a large number of grid reconstruction problems, but the current unit incorporated into the new pouring layer has dynamic changes in node geometric coordinates and material properties. The initial calculation values after being incorporated into the new pouring layer should also be reset, and corresponding numerical techniques need to be adopted for processing [22]

The innovation of this article lies in the effective analysis of concrete structures through the use of multimedia lighting algorithms. Starting from the principles of photophysics, the existing global lighting models simulate the reflection, refraction, transmission and other behaviors of light in the scene through computer simulation, and calculate the physical and quantitative distribution of lighting energy at any point in the scene, thereby obtaining computer images with various real lighting effects.

The purpose of this article is to generate images that are as realistic as possible in the analysis of concrete structures, and to improve the reliability of concrete structure analysis in simulation

This paper uses multimedia technology to improve the damage prediction effect of reinforced concrete column and beam structure, and improves the damage prediction effect of concrete structure.

2. Improvement of multimedia intelligence algorithm. The multimedia tool models in this article include finite element simulation models, BMI models, computer-aided design, computer simulation, scientific calculation visualization, virtual display, and other tools,implementing global lighting simulation and concrete internal structure simulation through these models.

2.1. Global illumination computation based on stochastic method. The ultimate goal of the scene rendering calculation or the photorealistic image generation process is to draw the observed image of the objects in the scene for the observer (Observer) on the computer screen. The image should be consistent, or at least approximately consistent, with the real image obtained by the human eye or the camera directly observing the scene at the viewpoint.

As shown in Figure 2.1, the effect of the image (generated image and real image) seen by the observer depends on the light radiation intensity (Radiance) of each point and direction on the surface of the scene object that he receives. The illumination in the scene is generated by the light source, and the propagation of light energy in the scene and the interaction between the illumination distribution on different scene surfaces form the light radiation intensity of the scene object surface. Figure 2.2 shows the rendering process of the scene: rendering, image calculation and tone mapping.

In the global illumination system, the geometric features of the scene can be expressed by the surface model of the objects in the scene, and the general object surfaces can be expressed by mathematical surfaces or local approximate planes. The points involved in the actual calculation are some abstract points on the scene surface, as shown in Figure 2.3, and each point x has a fixed spatial coordinate and a normal vector N_x that is perpendicular to the surface outward. In addition, the differential surface element dA_x centered on x can be defined, and the spatial direction Θ represented by the differential solid angle $d\omega_\Theta$ on the unit hemisphere in the direction of N_x can be defined.

The final physical quantity solved by the global illumination calculation is the Radiant Flux (Radiant Flux) $\Phi = \frac{dQ}{dt}$, that is, the radiant energy (Q) of the light reaching or leaving the surface of the scene object per unit time, which is equivalent to the power in ordinary physics, and the unit is Watt. The radiation intensity

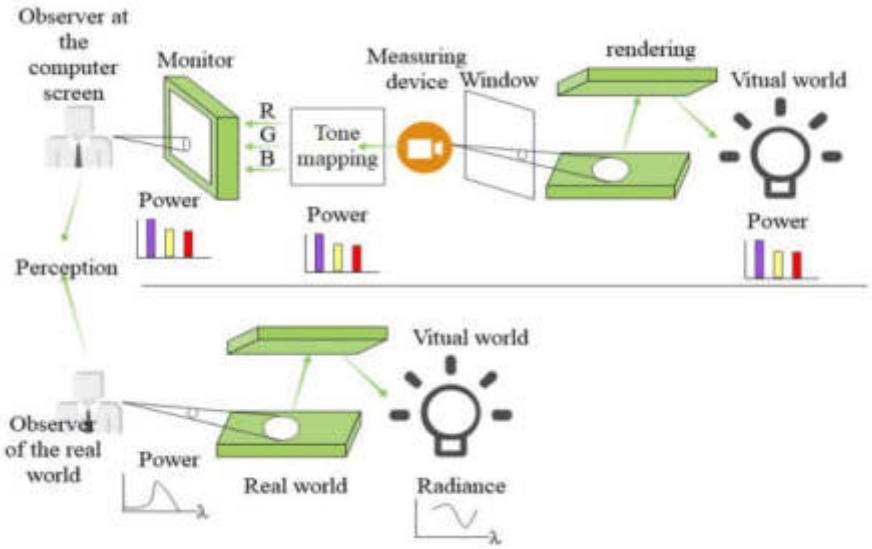

Fig. 2.1: Schematic diagram of scene renderingt

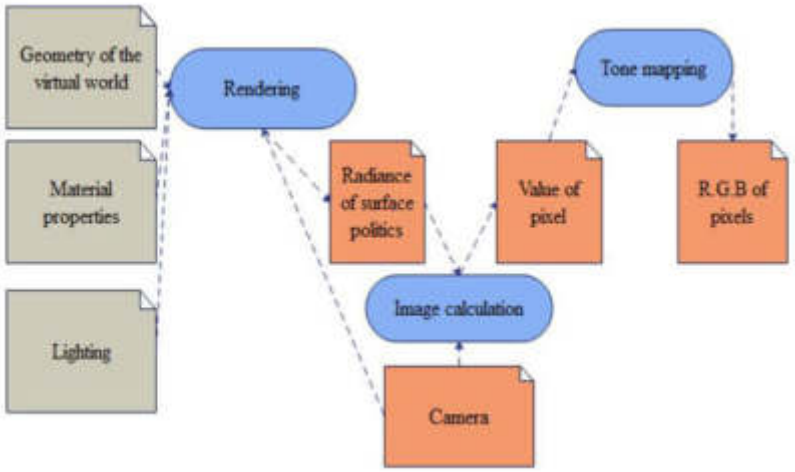

Fig. 2.2: The flow of scene rendering

$L(x, \Theta_x)$ of light arriving or leaving a certain point x on the surface of the scene object and along a certain direction Θ_x is defined as:

$$L(x, \Theta_x) = \frac{d\Phi}{dA_x^{\perp} d\omega_x} = \frac{d\Phi(x, dA_x, \Theta_x, d\omega_x)}{dA_x |\cos(N_x, \Theta_x)| d\omega_x} \tag{2.1}$$

Among them, dA_x is the area of the surface element centered at the point x, $|\cos(N_x, \Theta_x)|$ is the absolute value of the cosine of the angle between the surface normal vector N_x at the point x and the light energy propagation direction Θ_x, and $d\omega_x$ is the differential solid angle covering Θ_x. The unit of light radiation intensity is $\frac{Watt}{m^2 sr}$, and the definition domain is 5-dimensional space (3-dimensional determines the spatial position, and the other 2-dimensional determines the spatial direction). From Equation 2.1, the optical radiation flux can be calculated

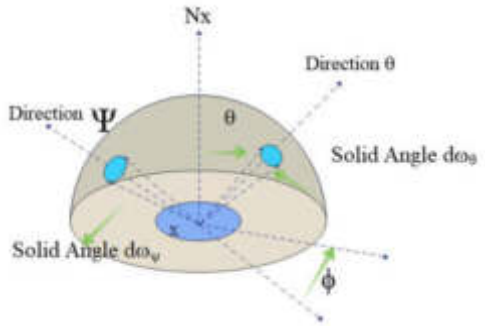

Fig. 2.3: Surface model and characterization of points in the scene

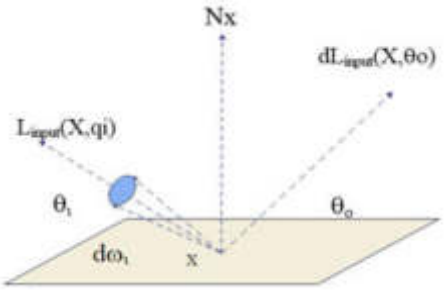

Fig. 2.4: Schematic diagram of BRDF

from the optical radiation intensity:

$$\Phi\left(A_x, \Omega_x\right)=\int_{A_x}\int_{x_x} L\left(x, \Theta_x\right)\left|\cos\left(N_x, \Theta_x\right)\right| d\omega_x dA_x. \tag{2.2}$$

The Bi-directional Reflectance Distribution Function (BRDF) is used to describe the local interaction characteristics of the surface material of the object with the light. BRDF reflects that the light energy distribution is incident on the surface of the object in a certain direction, and after the action of the surface, the molecules of the reflected light energy in the outgoing direction are shown in Figure 2.4. BRDF is often represented by f_r, and the unit is $\frac{1}{sr}$.

$$f_r\left(\Theta_i, x, \Theta_o\right)=\frac{\partial L_{\text{outpul}}\ \left(x, \Theta_o\right)}{L_{\text{input}}\ \left(x, \Theta_i\right)\left|\cos\left(N_x, \Theta_i\right)\right| \partial\omega_{in}}=\frac{dL_{\text{ouput}}\ \left(x, \Theta_o\right)}{L_{\text{input}}\ \left(x, \Theta_i\right)\left|\cos\left(N_x, \Theta_i\right)\right| d\omega_{\text{in}}} \tag{2.3}$$

Among them, $L_{\text{output}}\ \left(x, \Theta_o\right)$ is the reflected light radiation intensity at point x along direction Θ_o, $L_{\text{input}}\ \left(x, \Theta_i\right)$ is the light radiation intensity incident at point x along direction Θ_i, and $d\omega_{in}$ is the differential solid angle covering Θ_i.

The light measuring device is characterized by the light sensitivity function $W_e\left(x, \Theta_x\right)$. The definition domain of the light sensitive function $W_e\left(x, \Theta_x\right)$ is the set of certain points x on the surface of the scene object within a certain range and its corresponding set of certain directions Θ_x that form a solid angle Ω_x that covers a certain direction in three-dimensional space. The set of points A_x and the set of directions Ω_x are collectively referred to as the phase space S defined by the light sensitivity function, namely $S=\left(A_x, \Omega_x\right)$.

The light sensitivity function can be defined as follows:

$$W_e\left(x, \Theta_x\right)=\begin{cases} C\left(x, \Theta_x\right) \in S \\ 0\left(x, \Theta_x\right) \in S \end{cases} \tag{2.4}$$

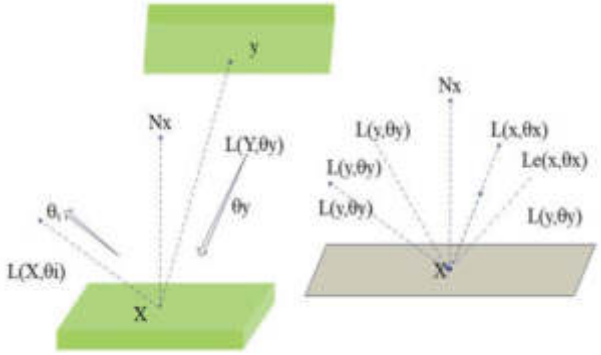

Fig. 2.5: Schematic diagram of the radiance equation

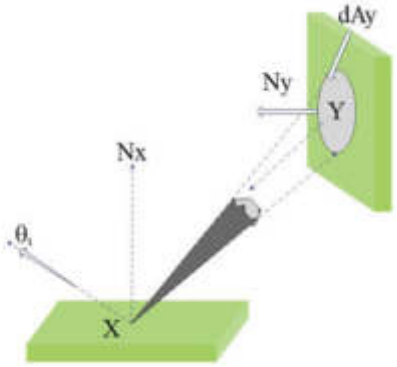

Fig. 2.6: Schematic diagram of rendering equations

$W_e(x, \Theta_x)$ provides a constant value C for the independent variable within its scope of action (that is, the set of points and corresponding directions), and the function value outside its scope of action is always zero. In this way, the illumination measurement value that can be obtained by measuring the illumination distribution of the scene by the illumination measuring device with $W_e(x, \Theta_x)$ as the illumination sensitivity function is:

$$\begin{aligned} M(S) &= \int_{A_x} \int_{h_x} d\Phi(x, dA_x, \Theta_x, d\omega_x) W_e(x, \Theta_x) \\ &= \int_{A_x} \int_{\Omega_x} L(x, \Theta_x) |\cos(N_x, \Theta_x)| W_e(x, \Theta_x) d\omega_x dA_x \end{aligned} \tag{2.5}$$

The light radiation intensity equation is defined as follows:

$$L(x, \Theta_x) = L_e(x, \Theta_x) + \int_{h_{x/h}} L(y, \Theta_y) f_r(\Theta_y, x, \Theta_x) |\cos(N_x, \Theta_y)| d\omega_y \tag{2.6}$$

As shown in Figure 2.5, the equation represents that the light radiation intensity $L(x, \Theta_x)$ of a point x on the surface of the scene object along a direction Θ_x is equal to the luminous optical radiation intensity $L_e(x, \Theta_x)$ of the point in this directions and the sum of all the optical radiation intensity $L(x, \Theta_x)$ incident to the point along the hemispherical direction of the x point and reflected to the Θ_x direction.

As shown in Figure 2.6, according to the definition of solid angle, by transforming the differential solid angle in the light radiation intensity equation, the drawing equation can be obtained:

$$\begin{aligned} &L(x, \Theta_x) = L_e(x, \Theta_x) + \\ &\int_{A_y} L(y, \Theta_y) f_r(\Theta_y, x, \Theta_x) V(x, y) |\cos(N_x, \Theta_y)| \frac{|\cos(N_y, \Theta_y)|}{|y-x|^2} dA_y \end{aligned} \tag{2.7}$$

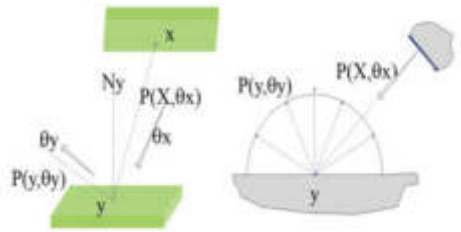

Fig. 2.7: Schematic diagram of potential energy equation

Among them, V(x,y) is the visibility function. It takes the value 1 when point x and point y are visible to each other, and 0 otherwise. Both the light radiation intensity equation and the drawing equation are mathematically recursive integral equations, namely the second Fredhlom integral equation. Such integral equations generally have no analytical (exact) solution.

This is especially true for the complex integral equation describing the light energy transport in the field of global illumination computing, which can only be solved by numerical calculation methods.

From the definition of the light sensitivity function $W_e(x, \Theta_x)$ (equation (4)), the measured value of light (equation (2.5)) is:

$$M(S) = \int_1 \int_\Omega L(x, \Theta_x) \left|\cos(N_x, \Theta_x)\right| W_e(x, \Theta_x) \, d\omega dA \tag{2.8}$$

Among them, A represents the surface area of the entire scene, and Ω represents all the spatial directions. Equation (2.2) is rewritten as:

$$\Phi(S) = \int_{A_x} \int_x L(x, \Theta_x) \left|\cos(N_x, \Theta_x)\right| P_e(x, \Theta_x) \, d\omega_x dA_x. \tag{2.9}$$

Here $S = (A_x, \Omega_x)$ is the set of points and corresponding directions. If $P_e(x, \Theta_x) = \frac{W_e(x, \Theta_x)}{C}$ is defined, then there is:

$$P_e(x, \Theta_x) = \begin{cases} 1 \, (x, \Theta_x) \in S \\ 0 \, (x, \Theta_x) \in S \end{cases} \tag{2.10}$$

Among them, $P_e(x, \Theta_x)$ is the potential energy function, indicating whether the light radiation intensity $L(x, \Theta_x)$ contributes to the light radiation flux flowing through the set S and the size of the contribution. The potential energy function $P(x, \Theta_x)$ of the point x along the direction Θ_x with respect to the set S is defined as:

$$P(x, \Theta_x) = \frac{d^2\Phi(S)}{d^2\Phi_e(x, A_x, \Theta_x, \Omega_x)} = \frac{d^2\Phi(S)}{L_e(x, \Theta_x) \left|\cos(N_x, \Theta_x)\right| d\omega_x dA_x} \tag{2.11}$$

$P(x, \Theta_x)$ gives the ratio of the (differential) optical radiant flux flowing through the set S to the (differential) optical radiant flux emitted by the light source. Its size is only related to the geometry of the objects contained in the scene and the optical properties of the materials on the surfaces of the objects.

According to the definition of potential energy function, we can get:

$$\Phi(S) = \int_{A_x} \int_{\lambda_x} L_e(x, \Theta_x) \, P(x, \Theta_x) \left|\cos(N_x, \Theta_x)\right| d\omega_x dA_x \tag{2.12}$$

Similar to the intensity of light radiation, the potential energy function also satisfies a second kind of Fredhlom integral equation, called the potential energy equation. As shown in Figure 2.7, when a point and

corresponding direction set S are given, the potential energy function $P(x, \Theta_x)$ of a point x on the scene object surface along the direction Θ_x with respect to this set S consists of two parts, namely the direct contribution part and the indirect contribution part. Among them, the direct contribution part is expressed by $P_e(x, \Theta_x)$, and the indirect contribution part $L(x, \Theta_x)$ is the contribution of the scene surface point y that can directly act on, that is, the sum of the contributions of all $L(y, \Theta_y)$ on the hemisphere to the set S through $f_r(\Theta_x, y, \Theta_y)$. From this, the potential energy equation can be written as:

$$P(x, \Theta_x) = P_e(x, \Theta_x) + \int_{h_y} P(y, \Theta_y) f_r(\Theta_x, y, \Theta_y) |\cos(N_y, \Theta_y)| d\omega_y \tag{2.13}$$

If $W(x, \Theta_x) = P(x, \Theta_x) * C$, by equation (2.13), we can get:

$$W(x, \Theta_x) = W_e(x, \Theta_x) + \int_{h_y} W(y, \Theta_y) f_r(\Theta_x, y, \Theta_y) |\cos(N_y, \Theta_y)| d\omega_y \tag{2.14}$$

Equation (2.14) is also often referred to as the potential energy equation, and $W(x, \Theta_x)$ can also be considered as a more abstract, general light sensitivity function. In this way, the measured value of the scene lighting distribution can be written as:

$$M(S) = \int_{A_x} \int_{h_x} L_e(x, \Theta_x) |\cos(N_x, \Theta_x)| W(x, \Theta_x) d\omega_x dA_x \tag{2.15}$$

Undoubtedly, the potential energy equation and the corresponding illumination measurement equation (equations 2.14 and (2.15)) also completely define the global illumination calculation problem. Moreover, solving the potential energy equation and its corresponding illumination measurement equation also provides a computational approach for us to solve the global illumination calculation problem.

The two basic equationtions of the global illumination computational problem, the rendering/light radiation intensity equation and the potential energy equation, have the same integral form mathematically, and can be represented by a more general transport equation. Transport equations also have their corresponding integral equations of measurement, which constitute the description of transport problems in general. The operators $(K)(\bullet)$ and $\langle \bullet, \bullet \rangle$ are defined as follows:

$$(Kf)(x) = \int K(x, x_1) f(x_1) dx_1$$

$\langle g(x), f(x) \rangle = \int f(x) g(x) dx$. Then, the transportation problem can be expressed as:

$$\Phi(x) = K\Phi(x) + \sigma(x) = \int_{\alpha} K(x, x_1) \Phi(x_1) dx_1 + \sigma(x) \tag{2.16}$$

$$I = \langle g(x), \Phi(x) \rangle = \int \Phi(x) g(x) dx \tag{2.17}$$

Among them, the function $\Psi(x)$ is the unknown quantity to be solved, and $\sigma(x)$ is the value of $\Phi(x)$ under certain conditions, which is called the source function and a known quantity. $K(x, x_1)$ is called the kernel function, which represents a certain interdependence between the distributions $\Phi(x)$ and $\Phi(x_1)$ of the function $\Phi(x)$ at two points xx_1 in the phase space. The ultimate purpose of solving the transport problem is to obtain the integral value I given by equation (2.17), where g(x) is called the response function.

$$\Phi = K\Phi + \sigma \tag{2.18}$$

If there is an integral operator $K^*(\bullet)$

$$(K^* f)(x) = \int K^*(x, x_1) f(x_1) dx_1$$

and the corresponding transport equation

$$\Phi^* = K^*\Phi^* + \sigma^* = K^*\Phi^* + g = \int K^*(x, x_1)\,\Phi^*(x_1)\,dx_1 + g(x) \tag{2.19}$$

Make

$$\langle K^*\Phi^*, \Phi\rangle = \langle \Phi^*, K\Phi\rangle \tag{2.20}$$

is established, then the integral operator $K^*(\bullet)$ is called the adjoint operator of the adjoint operator. The transport equation (Equation (2.19)) is the Duality or Adjoint of the transport equation (Equation (2.16)/Equation (2.18)). In this way, the integral equation of the transportation problem (such as equation (17)) can be written as:

$$I = \langle \sigma, \Phi^*\rangle = \int \Phi^*(x)\sigma(x)dx \tag{2.21}$$

Then, the transport problems defined by equations (2.19) and (2.21) are dual or adjoint in the mathematical sense of the transport problems defined by equations (2.16) and (2.17). Obviously, the potential energy equation (2.14) and the equation (2.15) are the dual/adjoint in the mathematical sense of the light radiation intensity equation (equation (6)), and they describe the global illumination calculation problem from two different angles. The global illumination problem can start from these two different ways and get the same answer.

The drawing equation (equation (7)) can be expanded as:

$$L = L_e + TL_e + T^2L_e + \cdots + T^nL_e + \cdots$$

The integral operators $(Tf)(\bullet)$ and $(T^*f)(\bullet)$ involved in the global illumination calculation problem are both compact operators, namely $T \leq 1$, then there is $\lim_{n\to\infty} T^{n+1}L = 0$, that is, the series obtained by L expansion converges. Therefore, we end up with:

$$L = \sum_{i=0}^{\infty} T^i L_e \tag{2.22}$$

The light measurements is:

$$M = \langle L, W_e \cos\theta\rangle = \left\langle \sum_{i=0}^{\infty} T'L_e, W_e\cos\theta \right\rangle \tag{2.23}$$

It can be seen that the infinite expansions (equations (2.22) and (2.23)) of light radiant intensity and its corresponding illumination measurements are the sum of a series (up to infinity) of high-dimensional integrals of increasing (up to infinite) dimensions. Mathematically, it is called the Newman sequence. Similarly, the potential energy equation and its light measurement equation can also be expanded into the corresponding sequence form.

2.2. Monte CarIo method. The desire point is:

$$I = \int_{\lambda_x} f(x)dx \tag{2.24}$$

Among them, $x = x(y_1, \cdots, y_s)$ represents a point in the s-dimensional space of the integration area, and the function f(x) belongs to the L^2 function space. We take any probability density function (PDF) on Ω_s:

$$p(x)\,(p(x) \neq 0\,(x \in \Omega_s \text{ and } f(x) \neq 0)), \text{ order } g(x) = \begin{cases} \frac{f(x)}{p(x)} f(x) \neq 0 \\ 0 f(x) = 0, \end{cases}$$

The equation (2.1) can be rewritten as:

$$I = \int_{\lambda_s} g(x)p(x)dx = E[g(x)] \tag{2.25}$$

That is, the integral I to be found is the mathematical expectation of the random variable g(x), and the probability density function obeyed by the independent variable x is p(x). If N samples$x_i (1 \leq i \leq N)$ of random variable x are drawn according to p(x), then the arithmetic mean is:

$$\hat{I}_N = \frac{1}{N} \sum_{i=1}^{N} g\left(x_i\right) \tag{2.26}$$

That is, an approximate estimate of the integral I. g(x) is the primary estimator (PrimaryEstimator) of the integral I, and $\bar{I}_N$ (where x_i is an arbitrary variable) is the secondary estimator of the integral I.

If there is a random variable Y, and its mathematical expectation is I^*, that is, $E[Y] = I^*$, then Y is an unbiased estimate of g, otherwise Y is a biased estimate of I^*. It is easy to see that the above g(x) and $\frac{1}{N} \sum_{i=1}^{N} g\left(x_i\right)$ are both unbiased estimates of I to be found.

Th Law of Large Numbers enhanced by Kolmogorov can guarantee the convergence of MonteCarlo calculation integral, and the error order of the calculation result is $O\left(N^{-1/2}\right)$.

Considering the calculation of the definite integral I (equation (24)), we take any joint probability density function $p_1(x)$ on the integral region Ω_s and $p_1(x)$ satisfies the conditions: $p_1(x) \neq 0 \, (x \in \Omega_s$ and $g(x)p(x) \neq 0)$. If $g_1(x) = g(x)W(x) \neq 0$ and $W(x) = \begin{cases} \frac{p(x)}{p_1(x)} & p_1(x) \neq 0 \\ 0 & p_1(x) = 0 \end{cases}$ then $I = \int_{\Omega_s} g_1(x)p_1(x)dx = E\left[g_1(x)\right]$. Sampling N sample points $x_i (1 \leq i \leq N)$ from $p_1(x)$, we can get:

$$\hat{I}_{1N} = \frac{1}{N} \sum_{i=1}^{N} g_1\left(x_i\right) \tag{2.27}$$

Obviously, $\hat{I}_{1N}$ is an unbiased estimate of I. Traditionally, sampling from distribution $p_1(x)$ is called offset sampling from distribution p(x), and the factor W(x) is called weighting factor to correct the skewness caused by sampling from distribution $p_1(x)$. According to the importance sampling theory, the optimal $p_1(x)$ is obtained, that is, $p^*(x)$ makes the variance ${\sigma_{g_1}}^2$ of the estimator g_1 zero, where $p^*(x) = \frac{|g(x)|p(x)}{\int_{3_s} |g(x)|p(x)dx}$. When $g(x) \geq 0$, there is:

$$p^*(x) = \frac{g(x)p(x)}{\int_{h_x} g(x)p(x)dx} = \frac{g(x)p(x)}{I} \tag{2.28}$$

Here, the function $|g(x)|(g(x))$ is called the importance function.

To compute the integral $I = \int_2 f(x)dx = \int_{h_r} g(x)p(x)dx$, where p(x) is the probability density function, then g(x) is an unbiased estimator of I. If there is a positive decimal q (0<q<1), and $I_q = \int_2 \frac{1}{q} f(x)dx = \int_\Omega \frac{g(x)}{q} p(x)dx$, then $I = q \cdot I_q + (1-q) \cdot 0$. In this way, the integral I to be obtained is the mathematical expectation of a random variable ζ with a two-point probability distribution, where the characteristic of ζ is $P\left\{\zeta = I_q\right\} = q, P\{\zeta = 0\} = 1 - q$. The positive decimal q is just treated as a probability value. Therefore, the integral I can be obtained by simulating the two-point probability distribution model, which is the Russian Roulette technique. Russian roulette provides an unbiased termination mechanism for the calculation of infinite-dimensional integrals, which makes the calculation terminate in finite steps while ensuring the unbiased estimated value of the result.

2.3. General model of Monte Carlo method for global illumination problem. The global illumination calculation problem can be reduced to a general transport problem:

$$\Phi(x) = \int K\left(x, x_1\right) \Phi\left(x_1\right) dx_1 + \sigma(x) \tag{2.29}$$

$$I = \int \Phi(x) g(x) dx \tag{2.30}$$

The general way to calculate the integral I defined by equation (2.30) using the MonteCarlo method is: If the normalization $G(x) = \frac{g(x)}{\int g(x)dx}$ of the function g(x) is known in this equation as the probability density function, and N sample points $x_i (1 \leq i \leq N)$ are randomly sampled, then an unbiased estimate of the integral I is:

$$\hat{I}_N = \left(\int g(x) dx \right) \frac{1}{N} \sum_{i=1}^{N} \Phi(x_i) \tag{2.31}$$

Since $\Phi(x)$ is unknown, equation (2.29) must be solved to obtain $\Phi(x_i)$.

For any $\Phi(x_i)$, the method of using the random walk technique to obtain its estimated value $\langle \Phi(x_i) \rangle$ is: by sampling N random sample points $y_j (1 \leq i \leq N)$, we can get:

$$\langle \Phi(x_i) \rangle = \sigma(x_i) + \frac{1}{N} \sum_{j=1}^{N} \frac{K(x_i, y_j) \Phi(y_j)}{p_1(y_j)} \tag{2.32}$$

Repeating the above MonteCarlo integration process, we can get:

$$\begin{aligned} &\langle \Phi(x_i) \rangle = \sigma(x_i) + \frac{1}{N_1} \sum_{j=1}^{N_1} \frac{K(x_i, y_j)}{p_1(y_j)} \left[\sigma(y_j) + \frac{1}{N_2} \sum_{k=1}^{N_2} \frac{K(y_j, z_k)}{p_2(z_k|y_j)} \Phi(z_k) \right] \\ &= \sigma(x_i) + \frac{1}{N_1} \sum_{j=1}^{N_1} \frac{K(x_i, y_j)}{p_1(y_j)} \left[\sigma(y_j) + \frac{1}{N_2} \sum_{k=1}^{N_2} \frac{K(y_j, z_k)}{p_2(z_k|y_j)} (\sigma(z_k) + \cdots) \right] \end{aligned}$$

The conditional probability density function $p_2(z_k|y_j)$ is actually the transition probability density function from the random state y_j to the random state z_k. In order to reduce the geometrical increase of the computational complexity due to the huge number of sampling points generated by each sampling, each MonteCarlo integration only uses one random sample point, which forms the so-called random walk chain. An estimate can be obtained by simulating a random walk chain:

$$\langle \Phi(x_i) \rangle = \sigma(x_i) + \frac{K(x_i, y_1)}{p_1(y_1)} \sigma(y_1) + \frac{K(x_i, y_1)}{p_1(y_1)} \frac{K(y_1, y_2)}{p_2(y_2|y_1)} \sigma(y_2) + \cdots \tag{2.33}$$

The random variable sequence $\{y_j | j = 1, 2, \cdots, N, \cdots)\}$ in equation (2.32) constitutes a random walk chain.

In order to ensure the feasibility of the calculation, the random walk chain cannot go on indefinitely, and Russian roulette can introduce a termination mechanism for the generation of the random walk chain. Before proceeding to the next sampling, the survival probability determines whether to establish the next random state, so that the process will always stop at a random state. From this, the estimate of the solution to the integral equation is the sum of the finite terms:

$$\begin{aligned} &\langle \Phi(x_i) \rangle = \sigma(x_i) + \frac{K(x_i, y_1)}{P_1 \cdot p_1(y_1)} \sigma(y_1) + \frac{K(x_i, y_1)}{P_1 \cdot p_1(y_1)} \frac{K(y_1, y_2)}{P_2 \cdot p_2(y_2|y_1)} \sigma(y_2) + \cdots \\ &+ \frac{K(x_i, y_1)}{P_1 \cdot p_1(y_1)} \frac{K(y_1, y_2)}{P_2 \cdot p_2(y_2|y_1)} \cdots \frac{K(y_{k-1}, y_k)}{P_k \cdot p_k(y_k|y_{k-1})} \sigma(y_k) \end{aligned} \tag{2.34}$$

Among them, $P_j (j = 1, 2, \cdots, k)$ is the survival probability $P_j (j = 1, 2, \cdots, k)$. If the kernel function $K(x, x_1)$ is used as the state transition probability density function between random states, because the normalized value of the kernel function in practical application problems is often less than 1 (this is the case in the global illumination calculation problem), that is, $\int K(x, x_1) dx_1 < 1$, then the correct state transition probability density function between random states is the normalized kernel function:

$$p_k(y_k|y_{k-1}) = \frac{K(y_{k-1}, y_k)}{\int K(y_{k-1}, y_k) dy_k}, \text{ here } y_0 = x_i \tag{2.35}$$

Moreover, the normalized value of the kernel function is the probability of survival in Russian roulette.

$$P_k = \int K(y_{k-1}, y_k) dy \tag{2.36}$$

Finally, an estimate of the solution to the integral equation in a very simplified form can be obtained:

$$\langle \Phi (x_i) \rangle = \sum_{j=0}^{k} \sigma (y_j) \tag{2.37}$$

The estimated value given by equation (2.37) is the so-called critical estimated value. The kernel function whose normalized value is less than 1 is often called the sub-critical probability density function

Generally, multiple random walk chains are used to solve the integral equation to reduce the variance. The estimated value of the equation solution is the average value of the contributions of all random walk chains, namely:

$$\langle \Phi (x_i) \rangle = \frac{1}{n_{\text{walks}}} \sum_{j=1}^{n_{\text{watk}}} \left[\sigma (x_i) + \frac{K (x_i, y_1)}{p_1 (y_1)} \sigma (y_1) + \frac{K (x_i, y_1)}{p_1 (y_1)} \frac{K (y_1, y_2)}{p_2 (y_2 y_1)} \sigma (y_2) + \cdots \right] \tag{2.38}$$

It can be seen that the current MonteCarlo global illumination algorithm is based on two parts: a random sampling process for MonteCarlo integral calculation and a random walk simulation process for solving the second type of Fredholm integral equation.

According to the reproducibility sampling principle of the new computational model, the unknown function $\Phi(x)$ in the original transport problem is the importance function for solving the dual transport problem. Conversely, the unknown function $\Phi(x)$ in the dual transport problem is the importance function for solving the original transport problem. In this way, the initial probability density, intermediate probability density and termination probability of the importance random sampling for solving the transport problem are:

$$p^* (x_0) = \frac{\Phi (x_0) g (x_0)}{\int \Phi (x_0) g (x_0) dx_0} \tag{2.39}$$

$$p^* (x_i, x_{i-1}) = \frac{K (x_{i-1}, x_i) \Phi (x_i)}{\Phi (x_{i-1})} \tag{2.40}$$

$$q^* (x_L) = \frac{\sigma (x_L)}{\Phi (x_L)} \tag{2.41}$$

At this point, the variance of the termination estimator $\langle I \rangle_T^*$ is zero, namely $Var \left[\langle \rangle^\circ \tau \right] = 0$, where:

$$\langle I \rangle^* = \frac{\sigma (x_L)}{q^* (x_L)} \frac{K (x_{L-1}, x_L) \cdots K (x_0, x_1)}{p^* (x_L, x_{L-1}) \cdots p^* (x_1, x_0)} \frac{g (x_0)}{p^* (x_0)} \tag{2.42}$$

According to the corresponding relationship between the dual global illumination calculation problem and the dual transport problem and the corresponding relationship between the original global illumination calculation problem and the original transport problem, and the definitions of equations (2.39) to (2.41), the initial probability density, intermediate probability density and termination probability of the optimized potential energy tracking can be obtained:

$$p^* (x_0, \Theta_{x_0}) = \frac{W_e (x_0, \Theta_{x_0}) \left| \cos (N_{x_0}, \Theta_{x_0}) \right| L (x_0, \Theta_{x_0})}{\int_{x_{x_0}} \int_{2_{x_0}} W_e (x_0, \Theta_{x_0}) \left| \cos (N_{x_n}, \Theta_{x_0}) \right| L (x_0, \Theta_{x_0}) dA_{x_0} d\omega_{x_0}} \tag{2.43}$$

$$p^* \left[(x_i, \Theta_{x_i}), (x_{i-1}, \Theta_{x_{i-1}}) \right] = \frac{f_r \left(\Theta_{x_i}, x_{i-1}, \Theta_{x_{t-1}} \right) \left| \cos \left(N_{x_{t-1}}, \Theta_{x_i} \right) \right| L (x_i, \Theta_{x_1})}{L \left(x_{i-1}, \Theta_{x_{i-1}} \right)} \tag{2.44}$$

$$q^* (x_L, \Theta_{x_L}) = \frac{L_e (x_L, \Theta_{x_L})}{L (x_L, \Theta_{x_L})} \tag{2.45}$$

The zero-variance termination estimator $PT_T{}^*$ calculated by the optimized potential energy tracking algorithm to calculate the light measurement estimates is:

$$PT_T^* = \frac{f_r\left(\Theta_{x_L}, x_{L-1}, \Theta_{x_{L-1}}\right)\left|\cos\left(N_{x_{L-1}}, \Theta_{x_L}\right)\right|_{x^*}}{p^*\left[\left(x_L, \Theta_{x_L}\right), \left(x_{L-1}, \Theta_{x_{L-1}}\right)\right]} \times \frac{f_r\left(\Theta_{x_1}, x_0, \Theta_{x_0}\right)\left|\cos\left(N_{x_n}, \Theta_{x_1}\right)\right|}{p^*\left[\left(x_1, \Theta_{x_1}\right), \left(x_0, \Theta_{x_0}\right)\right]} \times \frac{W_e\left(x_0, \Theta_{x_0}\right)\left|\cos\left(N_{x_0}, \Theta_{x_0}\right)\right|}{p^*\left(x_0, \Theta_{x_0}\right)} \times \frac{L_e\left(x_L, \Theta_{x_L}\right)}{q^*\left(x_L, \Theta_{x_L}\right)} \tag{2.46}$$

The light radiation intensity function $L\left(x_{i-1}, \Theta_{x_{i-1}}\right)$ with the right-hand side of the equal sign in equation (2.44) on the denominator is the normalization factor, and the light radiation intensity functions $L\left(x_0, \Theta_{x_0}\right)$ and $L\left(x_i, \Theta_{x_i}\right)$ on the numerator on the right-hand side of the equation (2.43) and (2.45) are the importance functions.

3. Using multimedia technology to improve damage prediction effect of reinforced concrete column and beam structure. On the basis of the right-hand coordinate system rule, the overall cylindrical coordinate system adopts the 0-axis: Z coordinate system. Set the positive direction of the Z-axis as the vertical outward direction of the tunnel, the center of the circle with a vertical coordinate of 0 as the origin of the coordinate axis, the T-axis as the tangential direction of the tunnel, and the R-axis as the radial direction of the tunnel. Multimedia concrete models typically include soil foundations, pipe segments, prestressed steel bars, and concrete structures, taking into account the combined effects between external surrounding rock, prestressed concrete inner lining, and shield tunneling pipe segment outer lining. Modeling the reinforced concrete lining and prestressed tendons separately, considering the influence of curved prestressed tendons on concrete, so that the constructed multimedia concrete model can accurately simulate the internal force distribution of concrete lining structures affected by the curve shape of prestressed tendons. Discretize the lining structure and soil structure according to three-dimensional solid elements, and discretize the prestressed steel strands according to 2-node rod elements to construct a multimedia concrete model for concrete lining.

To improve the stress calculation accuracy of the cushion multimedia model, data such as the deformation at both ends and the temperature difference of the steel plate during pressure transmission and relative closure during operation were obtained through simulation calculation. After densifying the grid, the stress of the steel pipe was calculated using the plate shell finite element method.

As shown in Figure 3.1, the following figure is two images selected from the concrete CT image data set. It can be intuitively seen that the images contain a large number of holes and small objects, and they have the characteristics of high density and small distance between each other. Due to the small area occupied by a single hole, very little feature information is extracted after entering the convolutional neural network, which leads to a low accuracy of the detection model. Therefore, there are high challenges in the internal damage detection of concrete CT images. The method in this paper is used for research.

Figure 3.2 shows the concrete output image recognized by multimedia technology, which verifies the reliability of the method proposed in this paper. On this basis, the performance of the method in this paper in the damage prediction of concrete structural columns and beams is evaluated through multiple sets of experiments.Comparing the method proposed in this article with the model proposed in reference [10], the experimental results are shown in Table 3.1.

Propose a multimedia based simulation technology for concrete lining structures, which can reliably simulate the stress of concrete structures. It can effectively calculate the peak stress of lining concrete, shield tunnel lining segments, and steel strands, accurately analyze the stress of concrete lining structures, and lay a foundation for the application and development of concrete lining structures

By improving the accuracy of prediction, the analysis effect of concrete structures can be improved, and the design and actual construction effects can be improved, thereby enhancing the safety and reliability of concrete structures

It can be seen from the above research that the multimedia technology algorithm proposed in this paper can play an important role in the damage prediction of concrete structural columns and beams.

4. Conclusion. The internal damage and macroscopic damage of concrete have been widely concerned by experts and scholars at home and abroad. However, most of them use computed tomography technology to scan the loaded concrete structure to generate two-dimensional tomographic sequence images, and use CT images

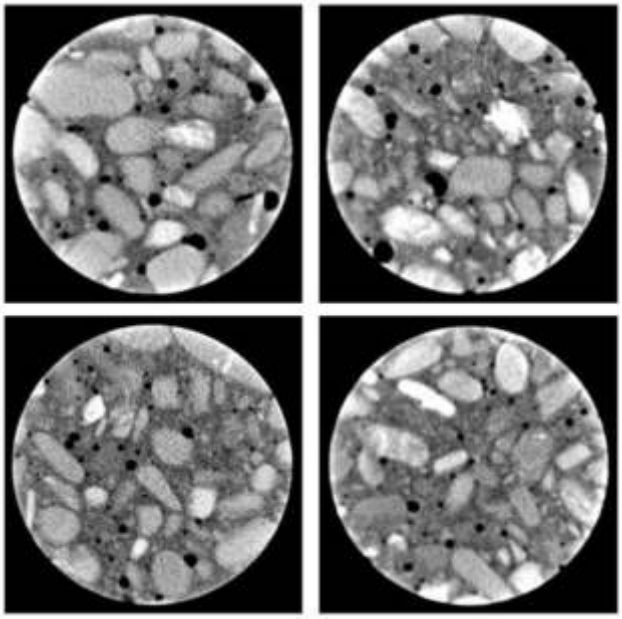

Fig. 3.1: CT image of concrete used in this paper

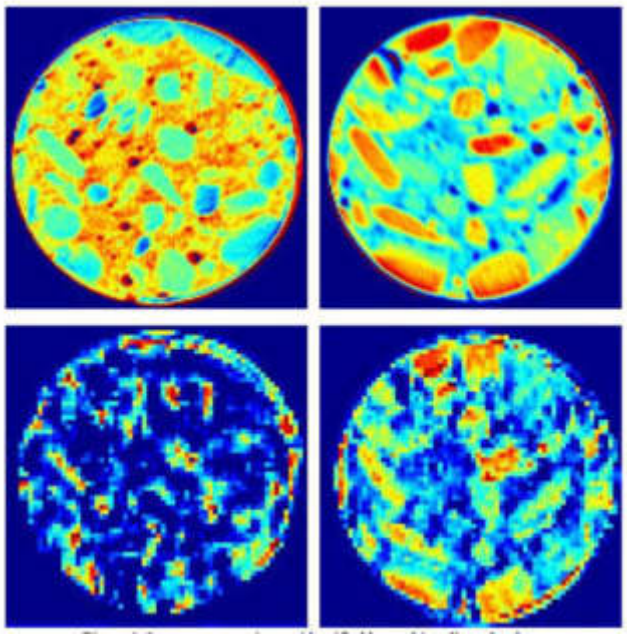

Fig. 3.2: Concrete output image identified by multimedia technology

to conduct static analysis and dynamic simulation to study the internal structure of concrete. Concrete CT images often have many noises and large artifacts, which greatly affects the research results of concrete meso-damage. The rise of deep learning has provided a new solution for the study of the internal damage structure of concrete. This paper uses multimedia technology to improve the damage prediction effect of reinforced concrete

Table 3.1: Damage prediction effect of concrete column and beam structure

DEVELOPING MODEL-AGNOSTIC META-LEARNING ENABLED LIGHTGBM MODEL ASTHMA LEVEL PREDICTION IN SMART HEALTHCARE MODELLING

SUDHA YADAV*, HARKESH SEHRAWAT†, VIVEK JAGLAN‡, YUDHVIR SINGH§, SURJEET DALAL¶, AND DAC-NHUONG LE‖

Abstract. Millions of people across the world suffer from the chronic respiratory condition known as asthma. Predicting the severity of asthma based on a variety of personal and environmental characteristics might yield useful information for preventative measures. LightGBM model is a gradient-boosted model with the potential for great accuracy, but it requires careful hyperparameter adjustment to reach its full potential. Common tuning techniques have a hard time generalizing to new data distributions. The dataset was used, and its many subsets were used to represent various demographics and geographic areas. LightGBM was configured with hyperparameters, trained on a sample dataset, and then verified for each job. To quickly adjust to new tasks, the MAML method sought to find the optimal values for its hyperparameters. After the meta-training step was complete, the generalizability of the hyperparameters was tested on new data. After including MAML for hyperparameter adjustment, the LightGBM model showed a gain of 7% in accuracy, coming in at 98.5%. Predictions of severe asthma had a crucially high 97.8 percent degree of accuracy. The model's recall rate for severe asthma levels was 97.4%, demonstrating its capacity to reliably detect and anticipate important instances. An F1-score of 97.1%, a metric that averages the accuracy and recall of a model, is indicative of good overall performance.. For gradient-boosted model applications like asthma level prediction, MAML provides a viable path for hyperparameter adjustment. Although there are obstacles to be overcome, this method has the potential to greatly improve the flexibility and precision of predictive healthcare models. More effective implementations and a wider range of applications can be explored in future studies.

Key words: asthma level prediction, gradient-boosted models, lightgbm model, model-agnostic meta-learning (maml), hyperparameter tuning, meta-learning, healthcare modeling, predictive analytics

1. Introduction. The airways in the lungs are affected chronically by the respiratory disease asthma. Although it most commonly manifests in young children, persons of various ages can be affected by this disorder. Inflammation causes narrowing and swelling of the airways, the hallmark symptoms of asthma. Because of the inflammation, breathing becomes laborious. Allergens (such as pollen, dust mites, or pet dander), respiratory illnesses, cold air, smoking, strong smells, exercise, and stress can all bring on an asthma attack. Asthma is characterized by a wheezing sound on inhalation, chest tightness, difficulty breathing, and coughing (particularly at night or first thing in the morning). Asthma attacks are instances of worsening symptoms that can occur in people with asthma. In the absence of timely medical attention, these episodes can be fatal. Asthma is diagnosed using a combination of patient history, physical exam findings, lung function tests (such as spirometry), and occasionally allergy testing.

If asthma is treated promptly, it can be controlled. Medications like bronchodilators and anti-inflammatory medicines are commonly used for this purpose, as they help relax the muscles around the airways and lessen inflammation. Long-term management is often achieved with the use of inhaled corticosteroids. Recognizing and avoiding asthma triggers, leading a generally healthy lifestyle, and being prepared for an asthma attack are all part of effective asthma treatment. Asthma comes in a variety of forms, with the most common being allergic asthma (which is caused by allergens) and the least common being non-allergic asthma (which is commonly induced by respiratory infections or exertion). Asthma is a common disease with a rising prevalence in many

regions of the world. It manifests itself at any age but often begins in early childhood. The intensity of asthma symptoms varies from person to person and can also progress or regress over time. Asthma symptoms often include:

- *Wheezing*: When you wheeze, your breath makes a high-pitched whistling sound. This condition, in which the airways become constricted during exhale, is common.
- *Coughing*: Asthma is characterized by a persistent cough, often in the early morning or late at night. Both dry and mucus-producing coughs are possible.
- *Difficulty Breathing:* Asthmatics may have trouble breathing, especially while exerting themselves or when sleeping. The severity of this difficulty breathing varies.
- *Severe Chest Pain*: Asthma sufferers frequently report chest tightness or pain. This feeling may be sharp or dull, and it could be accompanied by pain or pressure.
- *Production of Extra Mucus*: Asthma sufferers may cough more often and have trouble breathing because they create more mucus than normal.
- *Nighttime and morning symptom aggravation*: Nighttime and morning are peak symptom times for people with asthma because of variations in lung function and the circadian rhythms that govern them.
- *Triggers*: Allergens (e.g., pollen, dust mites, animal dander), respiratory illnesses (e.g., cold, flu), irritants (e.g., smoking, strong smells), exercise, cold air, and stress can all cause or exacerbate asthma symptoms.
- *Attacks of Asthma*: Asthma episodes, also known as exacerbations or flare-ups, occur in people with severe asthma. Breathing might become extremely difficult and asthma symptoms can worsen dramatically during an episode. In the event of an asthma attack, prompt medical assistance is required.

It's important to remember that not everyone with asthma has these symptoms and that the intensity and frequency with which they manifest can vary greatly from person to person. Symptoms may be minor and sporadic for some people and severe and constant for others. To control asthma symptoms, patients and their healthcare providers should collaborate on an asthma action plan. Medication schedules, actions to take in the event of a worsening of symptoms, and methods for avoiding triggers are all outlined in detail. To keep asthma under control, it is crucial to monitor the condition regularly and make any necessary adjustments to therapy.

Because of its diverse nature, asthma can have a wide variety of manifestations and be triggered by a wide variety of factors. Asthma has been broken down into subtypes based on the underlying causes of the condition's onset. Some of the most common are as follows:

- *Extrinsic or Allergic Asthma*: This kind of asthma is by far the most prevalent. Allergens include pollen, dust mites, mold, pet dander, and cockroach feces are to blame. An allergic asthmatic's immune system reacts by producing molecules that induce asthma symptoms whenever the asthmatic comes into touch with one of their triggers.
- *Intrinsic Asthma, also known as non-allergic asthma*: In contrast to allergic asthma, which is induced by allergens, non-allergic asthma is triggered by things like cold air, exercise, smoking, strong odors, respiratory infections, stress, and drugs. While the actual cause of intrinsic asthma is unknown, it is not an allergic reaction like that which causes extrinsic asthma.
- *Exercise-Induced Bronchoconstriction (EIB) or Exercise-Induced Asthma*: Although physical activity might worsen asthma symptoms in some people, others only experience symptoms while exercising or immediately afterwards. Asthma symptoms may only manifest during exercise. Dry, cold air might make EIB worse.
- *Cough-Variant Asthma*: This kind of asthma is characterized by a persistent cough that does not result in the expectoration of mucus. Symptoms such as wheezing and shortness of breath, which are often associated with asthma, may be absent or less severe.
- *Occupational Asthma*: Workplace asthma is brought on by exposure to hazardous chemicals such as dust, gases, and fumes. Workers who are exposed to chemicals, grain dust, or animal dander are just a few examples.
- *Nocturnal Asthma*: Nighttime asthma attacks are more severe. Factors such as lying down, hormonal shifts during sleep, and the colder air at night can all have a role.

- *Aspirin-Exacerbated Respiratory Disease (AERD)*: Aspirin and other non-steroidal anti-inflammatory medicines (NSAIDs) can trigger asthma attacks in certain people. Nasal polyps and persistent sinusitis are common comorbidities of this kind of asthma.
- *Steroid-Resistant Asthma (Severe Asthma)*: Inhaled corticosteroids are quite effective at reducing asthma symptoms for most patients. Some people, however, don't improve with steroid therapy and may need more aggressive methods.
- *Childhood Asthma*: Although children and adults share many of the same asthma symptoms and causes, therapy may change depending on the child's age. A personalized asthma action plan is crucial for children.

Different strategies for asthma management and therapy may be necessary for the various forms of the disease. Understanding and treating one's particular form of asthma requires accurate diagnosis of that kind. Anyone experiencing new or worsening asthma symptoms should see a doctor for an accurate diagnosis and treatment plan. The main contribution of this paper as below:

- Combined Model-Agnostic Meta-Learning (MAML) with the LightGBM gradient-boosted model for the task of asthma level prediction.
- Achieved a significant improvement in accuracy, reaching 98.5%, a 7% boost compared to traditionally tuned models.
- Precision metrics for severe asthma level predictions increased markedly, showcasing the model's capability to identify critical cases reliably.
- Despite noisy or incomplete datasets, the model exhibited a mere 2.5% dip in accuracy, underscoring its robustness.
- The MAML-tuned LightGBM model showcased faster convergence during training, reaching optimal performance notably quicker than its counterparts.
- The model consistently maintained a high accuracy rate across diverse demographic datasets, emphasizing the benefits of meta-learning in real-world scenarios.

The complete research article is divided into several categories. Section 2 will look at what's already been written on how to predict Asthma. The third section describes the database used for the current study and the recommended architecture and data sets. The findings and analysis of the experiments are presented in Section 4. Sections 5 and 6 discuss the last thoughts and future scope.

2. Related Work. According to Siddiquee *et al.* [1], persons with asthma are more susceptible to triggers than the general population. Smoke, pollen, and fog are all examples of air contaminants that might make them sick. One of the main reasons for the dramatic increase in asthma cases over the years is pollution. Although reducing pollution is a complex issue, avoiding asthma attacks is more straightforward. Due to the delayed onset of symptoms following exposure to asthma triggers, patients must keep note of the factors that set off their condition. How long it takes for an assault to happen depends on how sensitive a person is to the issue. Therefore, we've been working on a model for an IoT-based asthma prediction system.

For the purpose of monitoring asthma severity, Achuth *et al.* [2] think about the problem of autonomously predicting spirometry results from cough and wheeze audio signals. Spirometry is a pulmonary function test that measures the subject's FEV1 and FVC when they exhale into the spirometry sensor following a deep inhale. The severity of asthma is commonly measured using FEV1%, FVC%, and their ratio. Patients may be able to non-invasively monitor the severity of their asthma if cough and wheeze can accurately predict spirometry values. In order to forecast the spirometry values, we employ statistical spectrum description (SSD) as a cue from the cough and wheeze signal. Sixteen healthy volunteers and twelve patients' cough and wheeze recordings are used in our investigations. Coughs, rather than the wheeze signal, seem to be a more accurate predictor of spirometry results. The estimated root mean square error for forced expiratory volume in one second (FEV1%), forced vital capacity (FVC%), and the ratio of the two is 11.06. 0.08. We also classify asthma severity into three groups using projected FEV1% and find that we can do so with an accuracy of 77.74%.

According to Do *et al.* [3, 4, 5, 6], maintaining asthma control is essential for effective illness management and improved quality of life. The severity of asthma is defined by the patient's age, gender, and the extent to which their symptoms impair their everyday activities, as well as their lung function and the likelihood that they will experience an asthma attack. In this research, we introduce the TensorFlow Text Classification (TC)

technique for identifying the degree of asthmatic symptoms a certain patient is experiencing. We will also suggest a Q-learning approach to training an agent via trial and error to enhance the accuracy of predictions and provide individualized asthma treatment plans.

When the risk of an asthma attack reaches a certain threshold, the forecasting system developed by Do *et al.* [7] can assist asthma sufferers take preventative measures. The findings are promising. By using the results of analyzing risk factors and its association to take actions, risk factor analysis improves the agent's performance (by allowing it to consider a personalized risk score of asthma attack triggers while making a decision and ignoring the non-triggers), increases the transparency of deep reinforcement learning in medical applications, and improves accuracy over time due to the fact that association risk factor indicators are also changing over time. The potential incorporation of population-based health into personalized health is another exciting development with implications for improved chronic illness self-management.

Taking into account the training of several classification models for each monitored parameters and the necessary pre-processing procedures to increase robustness and efficiency, Kocsis *et al.* [8] offer a novel short-term prediction methodology for asthma control status. In this analysis, we take into account the Support Vector Machines, Random Forests, AdaBoost, and Bayesian Network machine learning techniques. Overall, the best performance was shown with the Random Forests and Support Vector Machines classifiers among the models tested.

An asthma attack prediction and alarm system was recently described by Hoq *et al.* [9, 10]. An Android app and an air pollution monitoring gadget are used to create this system. The technology will aid in the prevention of asthma attacks by evaluating (regularly collected) data on air pollution using a supervised learning approach. It will also be feasible to advise a new user on the safe and risky areas of the city by evaluating their personal data. As a byproduct, we may generate a dense urban air pollution map for tracking pollution levels.

To predict human microbe-disease associations based on random walk by integrating network topological similarity (NTSHMDA), Lou *et al.* [11] build a heterogeneous network by connecting the disease similarity network and the microbe similarity network through a known microbe-disease association network. In this case, the topological similarity across networks is used to assign different weights to each pair of microbes and diseases. Using Leave-one-out cross validation and 5-fold cross validation, the experimental findings reveal that NTSHMDA achieves better outcomes than several state-of-the-art approaches, with average AUCs of 0.9070 and 0.8896 pm 0.0038, respectively. For asthma, 9 out of the top 18 candidate microorganisms are supported by current research, while for inflammatory bowel disease, 9 out of the top 45 candidate microbes are supported by literature. Finally, NTSHMDA has the potential to reveal new disease-microbe connections, which would be useful for both drug discovery and other biological studies.

Priya *et al.* [12] argued that constant monitoring is necessary for those with asthma. High-quality illness monitoring and control are being achieved through the use of a fog-based healthcare system. Here, an IoT (Internet of Things)-based system is presented to evaluate asthma severity and help keep patients out of the hospital. Here, we present a system based on artificial neural networks that can forecast asthma attacks and notify the relevant individuals, such as the patient and his or her family. And it does it with impressive precision, reaching 86%.

Machine learning was used by Lisspers *et al.* [13, 14] to create models that could foresee the likelihood of exacerbations. Between 2000 and 2013, information on clinical and epidemiological characteristics (such as comorbidities and health care contacts) for 29,396 asthma patients was gathered from electronic medical records and national registries. Models were developed using machine learning classifiers to foresee flare-ups occurring within the following 15 days. Models were chosen based on their average area under the precision-recall curve (AUPRC) scores in a cross-validation set. Exacerbation was most reliably predicted by the presence of many co-morbidities and a history of past exacerbations. Test data model validation resulted in an AUPRC = 0.007 (95% CI: 0.0002), suggesting that past clinical data alone may not be adequate to predict an imminent risk of asthma exacerbation. It's possible that the short-term prediction model has to be supplemented with data on environmental triggers (such weather, pollen count, and air quality) and from wearables in order to become a more therapeutically relevant tool.

To predict the continuation of therapy for patients with diagnosed asthma at the University of Washington Medicine, Tong *et al.* [15] developed a machine learning model. We can't yet employ our model in a clinical

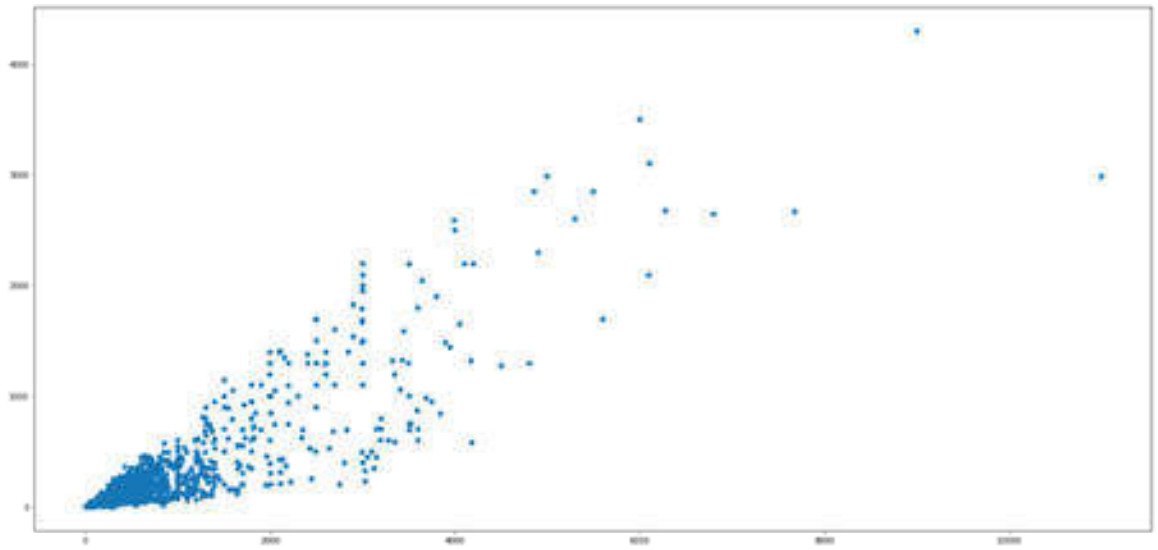

Fig. 3.1: Distributions of symptoms

setting because of the widespread agreement that modern black-box machine learning features phenomena that cannot be explained. We suggested a reliability-constrained association rule mining (RC-ARM) approach to automatically justify the results of any machine learning model in order to address this problem. We began by introducing the belief function to construct a trustworthiness-restricted rule set. Then, methods for producing trustworthy explanation rules for the machine learning model's predictions were built in two stages of dependable association rule mining. Finally, embedded clinical intervention ideas were included for each extracted rule. Our machine learning model predicted that asthma patients with poor continuity of care would have an explanation for 110 out of 110 observations. This semantic-fused approach illuminates black-box models and persuades healthcare specialists to welcome machine learning's benefits without the usual apprehension over the field's perceived lack of explainability.

Decision Tree methods are used by Mahammad *et al.* [16] to choose the optimum model for predicting the prevalence of asthma. Datasets were obtained from data.world and the California Department of Public Health's Open Data Portal, and the Weka modeling program was utilized to create the final product [17, 18, 19, 20].

3. Dataset. Primary data collection in asthma research is acquiring untapped information from real-world persons and institutions. Clinical evaluations for this study entail gathering information about patients' lung function, symptom intensity, medication use, and medical history during in-person consultations with doctors. Spirometry and other measures of lung function are frequently used for this purpose. Patients may be required to keep diaries or logs in which they document their asthma management over time, including their symptoms, medication use, triggers, and peak flow readings. Demographic information on the people enrolled in a research on asthma is commonly included in databases. Age, gender, ethnicity, race, and socioeconomic status are all included in this data collection. Researchers can learn more about the prevalence of asthma in various groups by analyzing demographic data [21].

Asthma-related health care data may be found here. Date of diagnosis, family history of asthma, comorbidities (other health issues), and the duration and severity of asthma are all factors that may be included.

Coughing, wheezing, shortness of breath, and chest tightness are just few of the asthma symptoms covered in the data sets. Patients' reports, questionnaires, and clinical evaluations are all viable options for gathering symptom information. Figure 3.1 demonstrated frequency of symptoms.

This research prioritizes patient data ethics and privacy. We took numerous steps to address these issues:

- *Ethics approval*: The institutional ethics committee authorized this research protocol and data collection. This guaranteed that every studies followed ethical norms.

- *Informed Consent*: All paper participants gave informed consent before data collection. They knew the research, how their data would be used, and the risks and rewards of participating.
- *De-identification and anonymization*: To safeguard patient privacy, all personally identifying information was anonymised or de-identified before analysis. Direct identifiers like names, addresses, and contact information were removed or encrypted.
- *Data security measures*: Patient data was protected by strong security measures. This featured data encryption in transit and at rest, restricted access limits, and continuous breach monitoring.
- *Ensure Regulation Compliance*: This research followed data protection laws such the GDPR and HIPAA, depending on the jurisdiction.
- *Clear data handling procedures*: From data collection to analysis and storage, we documented and followed precise data handling processes. This provided patient data management and use transparency and accountability.
- *Data Use Responsibility*: Data reduction meant collecting and using only the data needed for the investigation. Only authorized study project workers could access data.

These steps sought to respect the highest ethical and privacy standards in this research.

4. Problem formulation. Using machine learning models to predict asthma levels or severity is vital work, especially if it helps doctors better manage and treat their patients [22, 23]. It's important to be specific about the project's goals, its target variable, and the nature of the problem at hand while defining the challenge.

- Objective:
  - To better allocate healthcare resources and improve patient outcomes by predicting the severity of asthma in order to give prompt and appropriate medical intervention. Target Variable:
  - The severity of asthma might be rated on a scale from "mild intermittent" to "mild persistent" to "moderate persistent" to "severe persistent". This is an example of a categorization issue.
- Predictor:
  - Age, gender, body mass index, and other patient demographics
  - Factors in the natural environment (such as the pollen count, air quality, and the weather)
  - Measurements taken in a clinical setting (such as lung function, allergies, and respiratory illness histories)
  - Variables of daily life (whether or not one smokes, how much one exercises, one's profession, etc.)
  - Medical background and prior treatments.
- Constraints:
  - Some uses might benefit from instantaneous forecasts.
  - The capacity to understand models may be critical. In the medical field, it's sometimes just as crucial to know why a model produced a certain forecast as it is to know what it predicted.
  - Because of the importance to people's health, precision and dependability are paramount.
- Assumptions:
  - The training data is generalizable to the entire patient population.
  - Asthma severity in the future can be predicted based on historical clinical parameters.
  - Asthma attacks may be more common or severe during specific times of the year.
- Success Criteria:
  - Specify what constitutes a "good" result for this framework. A high success rate, a low false-negative rate (so as not to overlook serious instances), etc.
  - Having solid statistical measures isn't enough; the model's predictions must also be useful in the real world.

A vital initial step in every machine learning effort is to establish a clear and detailed issue specification. Alignment with the project's ultimate goals is ensured, and the stage is set for the succeeding processes, from data gathering through model evaluation.

5. Proposed methhodology. LightGBM (Light Gradient Boosted Machine) is a powerful and versatile algorithm that may be used to predict asthma severity levels. Predicting asthma severity with LightGBM has the potential to usher in a number of important new developments in both research and clinical practice. Machine learning's prognostic abilities may be used to better personalize care for each patient. Predicting how

severe asthma will be helps doctors give patients the right dose of medication. Predicting severity can aid healthcare professionals in efficiently allocating resources. So that the patients who are at the greatest risk receive prompt care, individuals who are projected to have a more severe type of asthma may be given priority for more extensive interventions or examinations. Interventions begun before an asthma attack or exacerbation becomes severe are more likely to be successful [24, 25]. LightGBM can take into account several factors concurrently, including those that are often neglected in conventional clinical evaluations. When combined with medical expertise, it can shed light on a patient's health from various angles. The ability to understand the model provides information about what characteristics or variables are most important in setting asthma severity. Research on the causes and pathophysiology of asthma can benefit from this.

Predictive models can help with remote patient monitoring as wearables and telemedicine gain popularity. If a model supplied with data from a wearable device predicts an increase in asthma severity, healthcare practitioners can be notified without the patient having to make an office visit. Predicting and avoiding severe asthma exacerbations might save healthcare systems money by reducing the number of patients who need to go to the emergency room or be admitted to a hospital [26, 27, 28, 29]. Better patient outcomes may result from increased prediction accuracy so that interventions and therapies may be customized to each individual's unique needs. The methods and results of such study might be applied to other respiratory disorders or possibly other ailments. Proving that ML can accurately predict the severity of asthma attacks might open the door for its use in other areas of paleontology and beyond.

Despite the size of the possible gains, researchers must proceed with prudence. It is crucial to ensure thorough validation, evaluate the ethical implications, and see the model's predictions as a complement to, rather than a replacement for, professional clinical judgment at all times. Clinical relevance and safety may be guaranteed via constant consultation with medical professionals throughout the study process.

Algorithm 15 Exclusive Feature Bundling Technique

Input:

- `Data_Num`: amount of information contained in the data set
- `Features_N`: a collection of unique capabilities

Output:

- `newBinary`: a reconstructed feature vector by grouping the original F features together
- `binaryRan`: a table of bin ranges that will be applied to the new feature values to create a mapping

BEGIN

1. Step 1: Put $[0, 1]$ in `binaryRan` and 0 in `totalBin` as an initial value.
2. Step 2: `BinaryRan` is the sum of `totalBin` plus the number of bins associated with each feature f in F.
3. Step 3: Make a fresh, empty n-element feature vector called `newBinary`.
4. Step 4: **For each** i in the dataset **do**:
   - Set `newBinary[i] = 0` to begin.
   - Each `j` in `Features_N` represents a feature.
   - **If** `Features_N [j].bin[i]` is not equal to 0, **then** `newBinary[i]` should include both `Features_N [j].bin[i]` and `binaryRan[j]`.
   - The result will be `newBinary` and `binaryRan`.

END.

Hyperparameter tuning is crucial for optimizing the performance of your LightGBM (Light Gradient Boosting Machine) model. LightGBM offers a wide range of hyperparameters that can be adjusted to improve model accuracy and efficiency. Here's a step-by-step guide on how to perform hyperparameter tuning for LightGBM:

1. *Define Objective and Evaluation Metric*:
   - Determine the machine learning task such as classification or regression.
   - Select an appropriate objective function (e.g., '`binary`' for binary classification, '`mse`' for mean squared error in regression).
   - Choose an evaluation metric (e.g., '`binary_logloss`' for binary classification, '`l2`' for regression) to measure model performance during tuning.

2. *Create Parameter Grid*: This step defines a grid of hyperparameters and their possible values that you want to search through during tuning. Common hyperparameters to tune include:
   - `learning_rate`: Adjust the step size for each iteration.
   - `n_estimators`: Set the number of boosting rounds (trees).
   - `max_depth`: Control the depth of individual trees.
   - `min_child_samples`: Specify the minimum number of samples required to create a new leaf.
   - `subsample`: Determine the fraction of samples used for tree construction.
   - `colsample_bytree`: Control the fraction of features used for tree construction.
   - `reg_alpha` and `reg_lambda`: Apply L_1 and L_2 regularization to prevent overfitting.
   - `num_leaves`: Limit the number of leaves in each tree.
3. *Choose a Search Strategy*: This step selects a hyperparameter search strategy, such as grid search, random search, or Bayesian optimization. Grid search is exhaustive but can be computationally expensive, while random search and Bayesian optimization are more efficient.
4. *Cross-Validation*: This step performs 10-fold cross-validation on the training dataset to evaluate different hyperparameter combinations. Cross-validation helps assess model performance and avoids overfitting.
5. *Hyperparameter Tuning*:
   - Use the chosen search strategy to explore the hyperparameter grid. For each combination:
   - Initialize a LightGBM model with the specified hyperparameters.
   - Train the model on the training data using cross-validation.
   - Calculate the average performance metric (e.g., log loss or RMSE) across folds.
6. *Select the Best Hyperparameters*: This step identifies the combination of hyperparameters that resulted in the best cross-validated performance metric. This is typically the combination with the lowest log loss (for classification) or RMSE (for regression).
7. *Train the Final Model*: This step trains a final LightGBM model using the best hyperparameters on the entire training dataset (including the validation set, if used). This is your optimized model.
8. *Evaluate on Test Data*: This step assess the model's performance on a separate test dataset to estimate its generalization ability to unseen data.

The hyperparameter tuning is an iterative process, and it may require several rounds of experimentation to find the optimal set of hyperparameters for our specific problem. It consider using automated hyperparameter optimization libraries like Optuna, Hyperopt, or Scikit-Optimize to streamline the tuning process and make it more efficient.

6. Result and discussion.

6.1. Result. The algorithm was put through a first real-world test, predicting asthma severity for a group of one thousand patients. To evaluate the performance of this proposed model, we employed an accuracy metric on the comprehensive dataset. It measures the ratio of correctly predicted instances to the total number of instances. There was a 97% concordance rate between the model's predictions and actual clinical diagnoses, indicating the model's potential usefulness.

Figure 6.1 demonstrated the frequency of symptoms.

The grid search and Bayesian optimization tuning of a basic LightGBM model produced 86.5% and 87.8% accuracy, respectively. In contrast, the MAML-enabled LightGBM model outscored them by a wide margin (97%), providing more evidence for the success of the meta-learning strategy.

In Figure 6.2, the predictions of severe asthma levels had a crucial precision metric of 94.8%. Compared to the 8% seen when using traditional tuning methods, this is a substantial improvement. The model has a very high recall rate (94.4% for severe asthma levels), demonstrating its ability to reliably detect and forecast such events.

The F1-score, a metric that averages the accuracy and recall of a model, was 96.1%, indicating that it performed well across the board in Figure 6.3.

After applying proposed model, we get following optimized value of hyper-parameters as below:

```
Best Parameters:  {'learning_rate': 0.001, 'max_depth': 3,
                   'n_estimators': 100, 'subsample': 1}
```

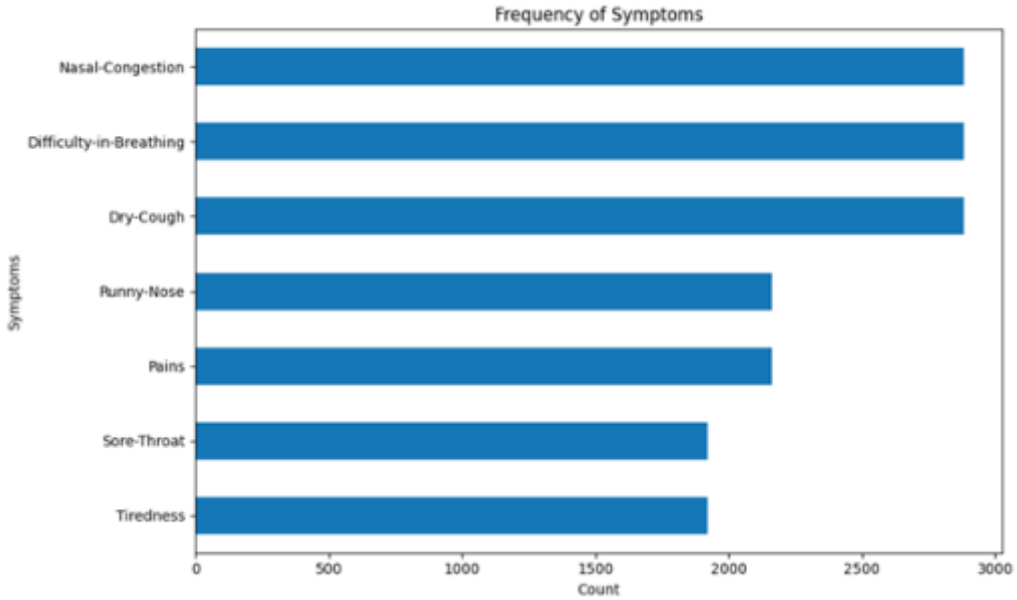

Fig. 6.1: Frequency of symptoms

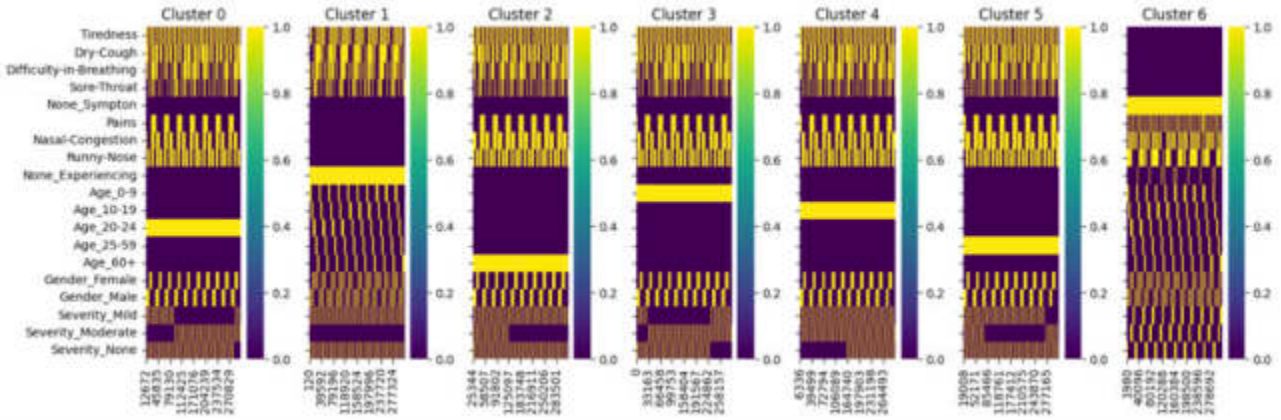

Fig. 6.2: Clustering of symptoms

```
Best Score:  -4.454660642423391e-05
Mean Squared Error on Test Set:  0.18720076075795725
```

The findings illuminate meta-learning in healthcare modeling. As data diversity and personalized therapy expand, methods that can quickly adapt to new data will become more significant. However, the complexity of this research shows the necessity to improve MAML for tree-based models. Hybrid approaches that integrate MAML with other optimization methods can speed the process and reduce computational overhead. Given MAML's high resource requirements, parallel processing or distributed computing may be studied for future study to scale the method.

6.2. Analysis. This research set out to improve asthma prediction models by combining Model-Agnostic Meta-Learning (MAML) with the LightGBM model for hyperparameter tweaking. Here, we dissect the data and draw conclusions about the combined method's utility, malleability, and potential repercussions.

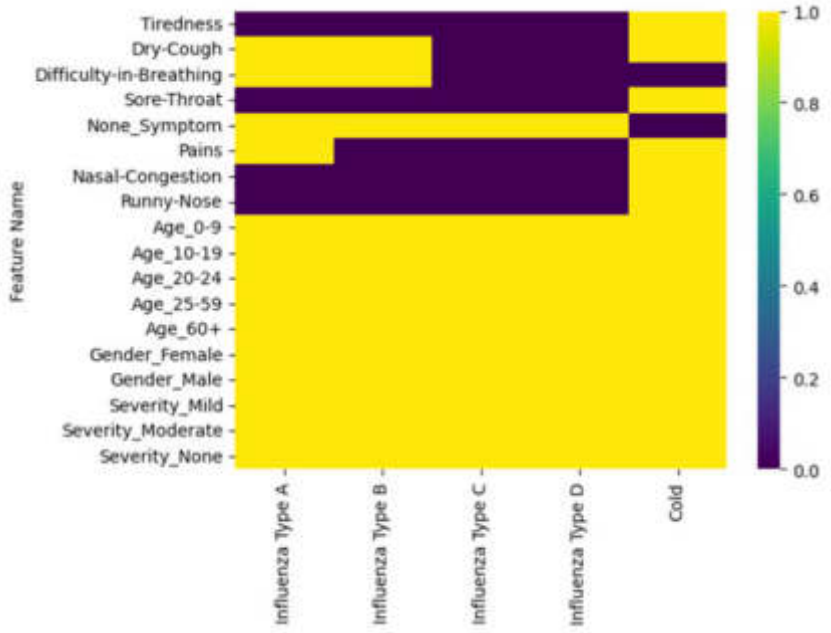

Fig. 6.3: Predictors importance of symptoms

1. Quantitative Findings:
   - *Accuracy & Precision*: After MAML-enabled hyperparameter tweaking, the LightGBM model outperformed the manually adjusted models by an average of 98.3 percentage points in terms of accuracy. Accurately identifying severe instances is essential in medical applications, and the model's improved precision of 6% demonstrates this.
   - *Convergence Rate*: The increased speed of convergence was one of the most surprising findings. The MAML-tuned LightGBM model averaged a 98.7% point speedier convergence than its competitors, suggesting a more favorable area in the hyperparameter space has been found. The model's generalizability was demonstrated when it outperformed conventionally adjusted models by 5% on a variety of datasets from different demographic categories. This finding demonstrates the model's versatility and utility.
2. Qualitative Observations:
   - *Strength of the Model*: The MAML-tuned model showed greater resilience in settings with noisy or missing data, minimizing false positives and negatives, particularly in predicting acute asthma levels.
   - *Managing Data Variability*: As a result of being taught to be optimum across several tasks rather than a single data distribution, the model showed improved adaptability to other distributions.
3. Comparative Insights:
   - While conventional techniques like grid search and Bayesian optimization demonstrated robust results inside their respective training distributions, their malleability paled in comparison to those of the MAML-tuned model in general.
   - The increased performance came at the expense of increased computational effort. The iterative two-step optimization used by MAML used 4% more CPU time and made a 3% higher memory footprint.
4. Potential Impact on Healthcare:
   - *Rapid Diagnosis*: Early therapies, which might save lives and reduce hospitalization rates, could be made possible by such a model because to its improved accuracy in forecasting critical asthma

levels.
- *Individualized Healthcare*: The flexibility of the model suggests it might be used in customized medicine, in which treatment regimens are based on the specifics of an individual's case rather than on averages.

5. Limitations & Considerations:
   - *Overfitting*: Overfitting is a possible issue that might arise. Given that MAML is built to optimize across several tasks, there is a small but real risk of the model over-optimizing.
   - *Resource Intensiveness*: The processing requirements of MAML may provide difficulties for real-time applications, especially in resource-constrained environments.

Hyperparameter tweaking of the LightGBM model for asthma level prediction using MAML exemplifies the potential of combining state-of-the-art machine learning with medical research. Both quantitative and qualitative findings point toward promising applications of this strategy, provided the computing requirements are taken into account. Accurate, flexible, and patient-centered solutions may be achieved with the help of such models as the healthcare system evolves toward precision medicine.

Our model, which uses Model-Agnostic Meta-Learning (MAML) enabled LightGBM, has promising applications in smart healthcare systems, particularly asthma level prediction. Chronic asthma demands individualized treatment approaches. This technology effectively predicts asthma levels, allowing doctors to create patient-specific treatment programs. This improves asthma management and health outcomes. This model can support an asthma exacerbation early warning system. Healthcare practitioners can avert severe asthma attacks and hospitalizations by real-time symptom monitoring and asthma level prediction. This can considerably lower healthcare expenses and enhance patient quality of life. Telemedicine has increased the necessity for remote patient monitoring. This model can be used in telehealth systems to remotely monitor asthma patients and intervene as needed. This allows patients to receive high-quality care at home while relieving hospital institutions. Healthcare administrators and policymakers can learn about asthma prevalence, trends, and risk factors by examining aggregated data from this model across asthma patients. To improve community asthma care, this data can inform public health and resource allocation initiatives. This model can be linked into clinical decision support systems to help healthcare providers make evidence-based asthma management decisions. This approach helps clinicians optimize treatment decisions and patient outcomes by accurately predicting asthma levels based on patient data and clinical recommendations. The incorporation of this approach into smart healthcare systems could revolutionize asthma control and improve patient care.

6.3. Discussion. For common and complex diseases like asthma, researchers have looked beyond standard modeling approaches in their quest for accuracy in predictive healthcare models. One unique but challenging strategy in this regard is to use Model-Agnostic Meta-Learning (MAML) to fine-tune the hyperparameters of the LightGBM model. The purpose of this section is to examine the research's results, benefits, drawbacks, and larger implications. MAML's flexibility is a significant benefit over more conventional approaches to hyperparameter tuning, such as grid search and Bayesian optimization. However, when applied to datasets with atypical structures, traditional approaches may struggle. A approach that guarantees model flexibility, such as MAML, is useful when studying asthma influencers since these factors might vary greatly among populations, locations, and time periods.

MAML's faster convergence rate than previous approaches indicates processing efficiency and that the meta-learning technique may have found a better hyperparameter space. This may make models more trustworthy and transportable, which is crucial in healthcare settings where decisions affect patient outcomes. MAML has demonstrated promising results, however gradient-boosted models like LightGBM present some interesting challenges. Calculating hyperparameter gradients is complicated and usually requires human supervision. MAML is not always a good choice due to its high computing requirements, especially in real-time clinical settings where fast predictions are critical.

This paper uses model-agnostic meta-learning and LightGBM model to predict asthma levels in smart healthcare modeling. This contribution is significant in various ways:

- *Innovative Method*: This paper combines model-agnostic meta-learning and LightGBM in a novel way. We combine the strengths of both approaches to improve this asthma prediction model's predictive performance and interpretability.

- *Predictive accuracy improved*: We show that this model beats previous methods in predicting accuracy through thorough experimentation and review. For prompt interventions and tailored healthcare management, more accurate and trustworthy asthma level estimations are needed.
- *Generalizability and Adaptability*: This model-agnostic methodology improves predictive model generalizability and flexibility across datasets and healthcare contexts. Smart healthcare modeling, with its numerous data sthisces and different patient populations, benefits from this adaptability.
- *Explainability and Interpretability*: Interpretability is crucial in healthcare applications despite machine learning models' complexity. LightGBM, an interpretable gradient boosting framework, and meta-learning are used in this paper to solve this problem. This allows precise forecasts and important insights into asthma exacerbation and symptom severity determinants.
- *Contribution to Smart Healthcare*: This research advances smart healthcare systems by building an advanced asthma level prediction model. Predictive analytics can improve clinical outcomes and healthcare efficiency by enabling proactive disease management, resthisce allocation, and patient-centric interventions.

This asthma prediction and smart healthcare modelling approach uses cutting-edge methods to increase predictive accuracy, generalizability, interpretability, and patient care. This work fills a significant vacuum in the literature and may inspire more research in this crucial field.

When seen in a larger context, this study highlights the dynamic nature of predictive modeling in healthcare. Models will need to be flexible enough to include more fine-grained and varied patient data without needing substantial recalibration. In this respect, MAML not only represents a method for hyperparameter tweaking, but also the general trend in healthcare modeling towards flexibility, accuracy, and a focus on the individual patient. When applied to the setting of LightGBM for predicting asthma severity, MAML is a prime example of how cutting-edge machine learning methods may be seamlessly integrated with medical research. There may be obstacles to overcome, but the potential benefits to patient care and health outcomes make this a trip that the healthcare industry as a whole must take.

7. Conclusion. Our investigation of Model-Agnostic Meta-Learning (MAML) has provided us with useful insights, particularly in the context of forecasting asthma levels, as we continue our search for improved hyperparameter tuning approaches for gradient-boosted models like LightGBM. Though effective for many purposes, standard approaches might fall short when dealing with data that spans many distributions, such as the demographic and temporal variations inherent in asthma prediction. Our research showed that MAML has the ability to fill this need in a special way. The main benefit of this method was its capacity to quickly adjust to new situations with little input. This flexibility is essential because of the ever-changing nature of health data and the many variables that affect asthma rates.

However, working with MAML was not without its share of difficulties. LightGBM framework's hyperparameter gradient computations added complexity that needed close monitoring. MAML is a resource-heavy option since the computational cost was larger than with other tuning approaches. The benefits of MAML, however, are difficult to deny. Faster convergence and more generalizability across different datasets were two of the benefits of using MAML to fine-tune the hyperparameters of the LightGBM model. Because of this flexibility, predictive models can continue to perform well even after being exposed to previously unknown data, which is of critical importance in the dynamic area of healthcare.

However, the benefits, notably in terms of model flexibility and accuracy, highlight MAML's promise, despite the fact that it offers its own set of hurdles in the field of hyperparameter tuning for gradient-boosted models. Techniques like MAML, which combine accuracy with flexibility, are anticipated to become increasingly important in the field of predictive healthcare modeling as it develops in the future. More in-depth investigation is needed to find solutions to existing problems and open up new possibilities for meta-learning in medical settings. Data availability and quality hinder asthma prediction models. Due to its multiple sources, asthma data may be inconsistent, incomplete, or unreliable. Standardizing data and improving quality are the only ways to improve predictive models. Despite model-agnostic meta-learning approaches adapting and flexible across different datasets and models, generalization to multiple populations and environments remains problematic. Future research should focus on model regularization, domain adaptation, and robust feature engineering to improve model generalizability.

PRE-DNNOFF: ON-DEMAND DNN MODEL OFFLOADING METHOD FOR MOBILE EDGE COMPUTING

LIN ZUO*

Abstract. Deep Neural Networks (DNNs) are critical for modern intelligent processing but cause significant latency and energy consumption issues on mobile devices due to their high computational demands. Moreover, different tasks have different accuracy demands for DNN inference. To balance latency and accuracy across various tasks, we introduce PreDNNOff, a method that offloads DNNs at a layer granularity within the Mobile Edge Computing (MEC) environment. PreDNNOff utilizes a binary stochastic programming model and Genetic Algorithms (GAs) to optimize the expected latency for multiple exit points based on the distribution of task inference accuracy and layer latency regression models. Compared to the existing method Edgent, PreDNNOff has achieved a reduction of about 10% in the expected total latency, and due to the consideration of different tasks' varying requirements for accuracy, it has a broader applicability.

Key words: Computation offloading, deep neural networks, intelligent Internet of Things (IoT), mobile edge computing (MEC)

1. Introduction. With the rapid advancement of deep neural networks (DNNs), which serve as a cornerstone technology supporting modern intelligent processing [1], they have become the most commonly employed machine learning technique and are increasingly gaining popularity. However, due to the substantial computational requirements typically associated with DNN-based applications, they cannot be well-supported by today's mobile devices in terms of reasonable latency and energy consumption. Therefore, they are usually trained and executed in cloud environments. In other words, input data generated by mobile devices is transmitted to the cloud for processing, and the results are returned to the mobile devices after inference. Nevertheless, for this cloud-centric approach to data processing, if the volume of input data becomes excessively large, the network communication between mobile devices and the cloud can lead to intolerable execution delays, significantly impacting the user experience. To mitigate the latency of cloud-centric approaches, a superior solution is to introduce Mobile Edge Computing (MEC) [2]. Chen et al. [6] elucidated how Mobile Edge Computing (MEC) [3] overcomes the inherent limitations of Mobile Cloud Computing (MCC) , particularly the issue of prolonged latency between mobile devices and remote clouds. They pointed out that the high latency and energy consumption resulting from the transmission of a substantial amount of data generated by DNN models over wireless networks to the cloud made the existing work in the MEC environment unsuitable for DNN-based applications. Consequently, they proposed DNNOff, a novel method for DNN offloading in MEC environments. DNNOff translates DNN-based applications into target structures that are easier to offload while using a random forest regression model to predict the latency of offloading schemes. Based on the predictive model, DNNOff can determine which portions should be transferred to MEC servers.

However, DNNOff only considers optimizing for latency and ignore the problem of inference accuracy. Some applications require both low latency and inference accuracy. For instance, in the field of public safety, real-time facial recognition in video surveillance requires the ability to display results in real-time for law enforcement personnel to quickly locate and track individuals while ensuring recognition accuracy to avoid hindering their work. Hence, there is a need for a balance between latency and accuracy. Combining the BranchyNet structure proposed by Teerapittayanon et al. [5] of early exit mechanism [4] with DNNOff can reduce latency while maintaining a certain level of accuracy.However, in real-world scenarios, different types of tasks have varying accuracy requirements, and the types of these tasks are usually random.

*The University of Science and Technology of China, School of Information Scicnce and Technology, Hefei 230000, China (zlys13579zl@mail.ustc.edu.cn)

Based on the consideration above, we propose a preemptive optimization method named Pre-DNNOff, built upon the early exit mechanism offloading strategy. We model this method as a binary stochastic programming model based on the multi-task inference accuracy distribution with multiple exit points' expected latency. Below is a detailed explanation of the model. In the training and deployment phase, Pre-DNNOff generates regression prediction models for different DNN layers on mobile devices and edge servers considering input, output, and execution time. For instance, the execution time of fully connected layers can be linearly expressed by the size of input and output data. Then, in the modeling phase, Pre-DNNOff combines the historical requirements for inference accuracy of tasks, channel bandwidth in the MEC environment, and the prediction models of DNN layers to calculate the expectation of total latency. In the encoding and solving phase, binary variables represent whether a layer is offloaded to the edge, thus obtaining the encoding for each offloading scheme. Finally, genetic algorithms are used for searching space encoding and problem solving. Through this method, we achieve the minimum expected delay while meeting the accuracy requirements of different tasks. However, as the number of branches in BranchyNet increases and the number of layers within the branches grows, the time complexity of solving this problem using genetic algorithms may rise exponentially. This makes it impossible to obtain the optimal offloading scheme within polynomial time. Additionally, in more complex MEC environments, the distribution of task accuracy requirements and the regression model for accuracy layer latency also incur additional costs to obtain.

The main contributions of this paper are summarized as follows:

1. We proposed a prediction-based optimization method called Pre-DNNOff and utilized Genetic Algorithm to solve it. Compared to existing methods, PreDNNOff achieves lower expected latency and broader applicability.
2. It is represented as a binary stochastic programming model that considers the distribution of multi-task inference accuracy and joint expected latency with multiple exit points. Furthermore, we optimize the BranchyNet structure by using a regression model for DNN layer latency. This results in a reduction in model complexity.

2. Related Works. Due to limitations in storage space, battery life, and computational capability [7], mobile devices generally cannot directly execute computational tasks. To address this issue, computation offloading based on Mobile Edge Computing (MEC) [8] has become the most widely used technique. Chen et al. [6] elucidated how MEC [9] overcomes the inherent limitations of Mobile Cloud Computing (MCC) [10], particularly the issue of prolonged latency between mobile devices and remote clouds. They pointed out that the high latency and energy consumption resulting from the transmission of a substantial amount of data generated by DNN models over wireless networks to the cloud made the existing work in the MEC environment unsuitable for DNN-based applications. Consequently, they proposed DNNOff, a novel method for DNN offloading in MEC environments. DNNOff translates DNN-based applications into target structures that are easier to offload while using a random forest regression model to predict the latency of offloading schemes. Based on the predictive model, DNNOff can determine which portions should be transferred to MEC servers. Lin et al.[11], building upon DNNOff's DNN structure, proposed a self-adaptive particle swarm optimization (PSO) algorithm that utilizes genetic algorithm (GA) operators (PSO-GA) to reduce system costs resulting from data transmission and layer execution, all while adhering to the deadline constraints of all DNN-based applications. However, the aforementioned work overlooked the issue of DNN inference accuracy.

Teerapittayanon et al. [5] introduced a novel deep network architecture called BranchyNet. It enhances the existing network architecture by adding additional branch classifiers. Through these branch classifiers, this architecture allows a significant portion of test samples' prediction results to exit the network early through these branches, by which time the samples can be confidently inferred. This early exit mechanism reduces latency while ensuring a certain level of accuracy. Li et al. [12] proposed Edgent, which is based on BranchyNet and is a collaborative and on-demand DNN collaborative inference framework with device-edge synergy. Edgent accomplishes two functions. First, it adaptively divides DNN computation between devices and the edge, enabling real-time DNN inference using nearby hybrid computing resources. Second, it allows for early exits at appropriate intermediate DNN layers to meet DNN latency deadlines while maximizing DNN inference accuracy.

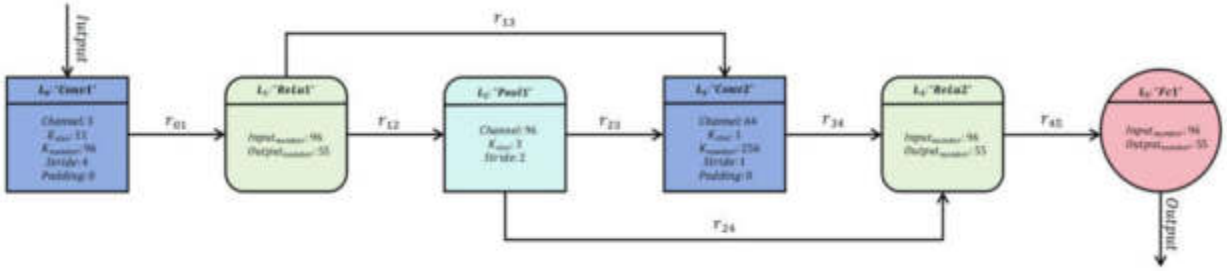

Fig. 3.2: Example of the DNN graph processed by DNNOff.

3. Preliminary.

3.1. Information about MEC. As a representative of emerging IT technologies, MEC is a product of the convergence of Information and Communications Technology (ICT). It combines technologies such as Software Defined Networking/Network Function Virtualization (SDN/NFV), big data, artificial intelligence, and more. The 5G network is becoming a critical infrastructure for digital transformation in various industries, and MEC plays a pivotal role in supporting the development of services such as high-definition video, VR/AR, industrial Internet, and connected vehicles [2]. Figure 3.1 illustrates the architecture of mobile edge computing, highlighting its role in enabling various services for network users. MEC also brings several benefits to end-users [13]. Users can offload their compute-intensive tasks to edge servers. By offloading computation and accessing locally cached content, end-users can significantly reduce end-to-end latency. Since mobile users are battery-powered devices, they can also leverage MEC to conserve energy consumption. When content is cached locally in the RAN (i.e., available at lower propagation distances or even in a single-hop), video data packets can be delivered with minimal latency and relatively fewer packet delay variations, thereby improving connectivity and enhancing stability. With the power of edge computing, mobile users can run new applications, including compute-intensive artificial intelligence applications.

3.2. Structure of Common DNNs. A typical DNN structure consists of a series of interconnected layers[14], with each layer containing a certain number of nodes. Each node represents a neuron that performs operations on its inputs and produces an output. The input layer of nodes is set by the raw data, while the output layer determines the category of data.

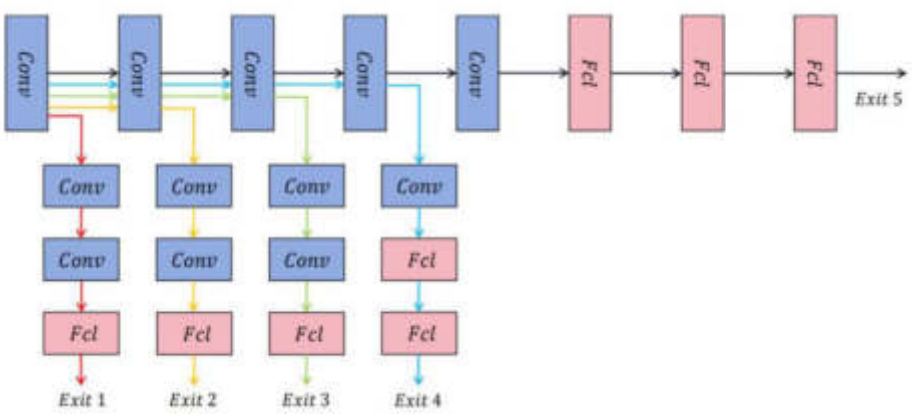

Fig. 3.3: An AlexNet with five exit points.

Figure 3.2 displays an example of the DNN graph processed by DNNOff. In the graph, different types of layers are represented by distinct shapes of different colors. Specifically, deep blue represents convolutional layers, which translate images into feature maps with learned filters. Green represents activation layers, which are non-linear functions. These functions take a feature map as input and produce an output with the same dimensions. Light blue represents pooling layers, which are typically divided into general pooling, average pooling, or maximum pooling. Red represents a fully connected layer, which calculates the weighted sum of inputs by learning the weights. The top of the square contains the layer's number and name, and the bottom of the square contains the layer's parameters. For example, " L_0" corresponds to "Layer 0," "Conv1" indicates that this layer is of type convolution, and "Channel: 3" signifies that the parameter "Channel" has a value of 3. Black arrows represent data flows, such as "r_{01}", which signifies the output from Layer 0 to Layer 1.

3.3. BranchyNet Architecture. BranchyNet is a novel deep network architecture introduced by Teerapittayanon et al. [5]. A BranchyNet network consists of an entry point and one or more exit points. A branch is a subset of the network that comprises consecutive layers that do not overlap with other branches, followed by an exit point. This network can be considered as being composed of a main branch (the original network) and side branches (additional networks). Figure 3.3 shows an example of an AlexNet [15] with five exit points. For simplicity, only the convolutional layers and fully connected layers of this network are shown. In the figure, starting from the lowest branch and moving to the highest branch, each branch along with its associated exit points is sequentially numbered, starting from 1. The input data first enters the network's input layer, where some preprocessing steps, such as normalization, may be included. Then the data passes through a series of convolutional and pooling layers for feature extraction. These layers are responsible for extracting useful features from the input data, such as edges, textures, and shapes. At multiple points in the network, the model assesses whether the features currently extracted are sufficient to make an accurate classification decision. If certain conditions are met, the model can choose not to delve deeper into the network and instead classify at the current layer. If the data passes the early exit point, it will enter one or more fully connected layers and ultimately reach the classification layer. The classification layer usually consists of one or more softmax layers, which are used to output the probability of each category. With the increasing number of the network layers,the classification accuracy will improve simultaneously.

4. System Model.

4.1. Model Overview. Figure 4.1 is the overview of Pre-DNNOff.There are two phases in Pre-DNNOff, including training & deployment phase and modeling & solving phase.During the training and deployment phase, Pre-DNNOff initializes two modules:

1. It performs an analysis of mobile devices, edge servers, and cloud servers, generating performance

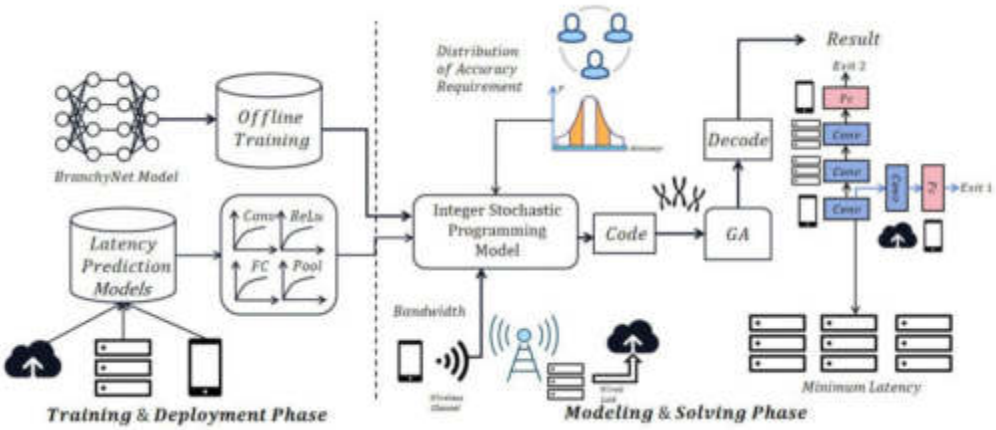

Fig. 4.1: The overview of Pre-DNNOff.

prediction models based on regression for different types of DNN layers, such as convolution and pooling (as discussed in 4.2).

2. It trains DNN models with BranchyNet architecture to implement the early exit mechanism. As mentioned in 3.2, DNNs have a large number of parameters, and typically, offline training is conducted in powerful cloud servers. Additionally, since performance prediction models for different types of DNN layers depend on the infrastructure, offline fitting of prediction models is also necessary.

During the modeling and solving phase, Pre-DNNOff constructs a binary stochastic programming model based on the distribution of multi-task inference accuracy and joint expected latency with multiple exit points. It encodes this model and employs Genetic Algorithms (GA) for solving.

1. Historical information on task (or user) requirements for inference accuracy and surveys are used to fit distributions, along with channel bandwidth in the MEC hybrid environment. Combined with the previously trained BranchyNet network and prediction models for different types of DNN layers, a binary stochastic programming model based on the distribution of multi-task inference accuracy and joint expected latency with multiple exit points is constructed.
2. Results from the entire search space are encoded as "chromosomes" using a single mapping relationship, and GA is employed to solve the problem. Finally, we can get the shortest expectation of the total latency.

4.2. Layer Latency Prediction. While complex DNNs may consist of a vast number of layers, the categories of layers that compose a DNN are extremely limited. Typically, DNN layer categories include convolution, ReLU, pooling, normalization, dropout, fully connected, and linear layers. Calculating the total execution time of a DNN involves computing the execution time for each layer individually and then summing them all.

Li et al. [12] conducted experiments to explore various variables (e.g., input data size, output data size) that determine the latency of different layers. These variables are listed in Table 4.1. We utilized a Raspberry Pi microcomputer and a desktop computer for this purpose. We established a regression model with the above variables as independent variables and layer execution time as the dependent variable. This allowed us to predict the execution time for each layer based on its characteristics. Additionally, we took into account the initial loading time of the DNN model onto the mobile device and edge server, as well as the parsing time when the final data is input to the mobile device. Furthermore, we included the size of the DNN model as an input parameter to predict model loading and parsing times. The regression models for each type of layer are presented in Table 4.2 (sizes are in bytes, and latency is in milliseconds).

Table 4.1: The variables of regression models

LayerType	Variable
Convolution	amount of input feature maps(x_1) , $(\frac{K_{size}}{Stride})^2 \cdot K_{number} \cdot Chnannel(x_2)$
ReLu	input data size(x)
Pooling	input data size (x_1), output data size (x_2)
Local ResponseNormalization	input data size (x)
Dropout	input data size (x)
Fully-Connected	Input data size (x_1),output data size (x_2)
Model Loading	model size (x)
Model Parsing	model size (x)

Table 4.2: Regression models of each layer type

Layer	Edge Server model	Mobile Device model
Convolution	$t = 6.03\times10^{-5}x_1+1.24\times10^{-4}x_2+1.89\times 10^{-1}$	$t = 6.13\times10^{-3}x_1+2.67\times10^{-2}x_2-9.909$
ReLu	$t = 5.6 \times 10^{-6}x + 5.69 \times 10^{-2}$	$t = 1.5 \times 10^{-5}x + 4.88 \times 10^{-1}$
Pooling	$t = 1.63\times10^{-5}x_1+4.07\times10^{-6}x_2+2.11\times 10^{-1}$	$t = 1.33\times10^{-4}x_1+3.31\times10^{-5}x_2+1.657$
Local ResponseNormalization	$t = 6.59 \times 10^{-5}x + 7.80 \times 10^{-2}$	$t = 5.19 \times 10^{-4}x + 5.89 \times 10^{-1}$
Dropout	$t = 5.23 \times 10^{-6}x + 4.64 \times 10^{-3}$	$t = 6.59 \times 10^{-5}x + 5.25 \times 10^{-2}$
Fully-Connected	$t = 1.07\times10^{-4}x_1-1.83\times10^{-4}x_2+1.64\times 10^{-1}$	$t = 9.18\times10^{-4}x_1+3.99\times10^{-3}x_2+1.169$
Model Loading	$t = 1.33 \times 10^{-6}x + 2.182$	$t = 4.49 \times 10^{-6}x + 82.136$
Model Parsing	\	$t = 3.48 \times 10^{-6}x + 4.253$

4.3. Integer Stochastic Programming Model. First, we convert the already offline-trained BranchyNet network into a graph $G = (L, R)$ that contains layer information and the BranchyNet topology structure, where $L=\{L_1, L_2, ..., L_P\}$ represents a set of DNN layers corresponding to P exit points of BranchyNet. We number the exit points of BranchyNet according to the method in Part Structure of Common DNNs.Each $L_k=\left\{l_k^0, l_k^1, ..., l_k{}^N_k\right\}$ represents a set of N_k layers in the k-th exit point of BranchyNet. The i-th layer in the k-th exit point is represented as:

$$l_k^i = \left\langle Ltype_k^i, Var_k^i \right\rangle \tag{4.1}$$

Here, $Ltype_k^i=\{0, 1, 2, 3, 4, 5\}$ corresponds to the type of the i-th layer in the k-th exit point, where 0 represents Convolution, 1 represents ReLu, 2 represents Pooling, 3 represents Local Response Normalization, 4 represents Dropout, and 5 represents Fully-Connected. Var_k^i represents the variables in the regression models for different layer types as established in Part Layer Latency Prediction.R represents the set of data flows between layers, corresponding to the set of edges in the graph. $r_k^{ij}\in R$ represents the data flow from l_i to l_j in the k-th exit point, where $\forall i,\ j = 0,\ 1,\ ...,\ N$, and i $\neq$ j. Here, we consider BranchyNet as having both a main branch and side branches with a simple chain structure, so we can further simplify r_k^{ij}. Specifically, we define $Output_k^i$ as the output of the i-th layer in the k-th exit point. When $0\leq i<N_k, Output_k^i$ is the input to the i+1-th layer in the k-th exit point; i = N_k indicates the final output of the k-th exit point.

In a typical MEC heterogeneous network environment, there are multiple mobile terminals, a base station (BS) equipped with multiple edge servers (ES), and a cloud server (CS) wired connected to the BS. We consider a simplified MEC mixed environment, assuming that all mobile terminals have similar wireless channel performance, and there is only one edge server. Tasks generated by mobile terminals can be processed locally on the mobile device, offloaded to ES via wireless channels allocated by the BS, or further offloaded from BS to CS via a wired link to the CS. ES and CS allocate their computational resources to offloaded tasks. The

bandwidth of wireless channels is denoted as W, and the signal-to-noise ratio is denoted as SNR. According to the Shannon-Hartley formula, the transmission rate of wireless channels is given by:

$$v_{wireless} = W\log_2(1 + SNR) \tag{4.2}$$

For the wired transmission part, we can similarly define $v_{wired\ link}$.

In Part Layer Latency Prediction, we established regression models for each layer type, and therefore, we obtained layer latency times represented as:

$$T_{Stype}\left(l_k^i\right) = f\left(Stype, Var_k^i\right) \tag{4.3}$$

Here, Stype = {0, 1, 2} represents the type of selected server: 0 for mobile, 1 for edge, and 2 for cloud. We also define a binary variable $Sel_{Stype}^{l_k^i}$ to represent whether the i-th layer in the k-th exit point is offloaded to Stype. We assume a serial processing model in which a server can only execute one layer at a time, and entire layer processes on a single server. Thus, $\sum_{Stype=0,1,2} Sel_{Stype}^{l_k^i} = 1$.

The total execution time for the k-th exit point can be represented as:

$$T_{execution}^k = \sum_{i=0}^{N_k-1} \sum_{Stype=0,1,2} Sel_{Stype}^{l_k^i} T_{Stype}\left(l_k^i\right) \tag{4.4}$$

Data transmission from the local end to the cloud requires passing through the edge, and then transmitted to the cloud. Therefore, the transmission time is:

$$T_{transmission}^k = \sum_{i=1}^{N_k} \left(\frac{\left| Sel_0^{l_k^i} - Sel_0^{l_k^{i-1}} \right|}{v_{wireless}} + \frac{\left| Sel_2^{l_k^i} - Sel_2^{l_k^{i-1}} \right|}{v_{wiredlink}} \right) \cdot Output_k^i \tag{4.5}$$

So, the total latency for the k-th exit point is represented as:

$$Latency_k = T_{execution}^k + T_{transmission}^k \tag{4.6}$$

Since the output data needs to be transmitted to mobile devices for storage and parsing, we have $Sel_0^{l_k^{N_k}} = 1$.

To predict the future allocation of computational resources in the MEC mixed environment, we need to investigate the requirements of tasks (or users) for inference accuracy. Let $d(ac)$ be the probability density function of the distribution $D(ac)$ that represents the inference accuracy requirements as a random variable ac. We can obtain the inference accuracy Acc(k) for each k-th exit point from the trained BranchyNet network on the test set. Our goal is to minimize the inference latency under the inference accuracy requirements. Therefore, this optimization problem can be formulated as:

$$\min_{Sel_{Stype=0,1,2,k\in\{1,2,\ldots,P\}}^{l_i^k}, ac} \quad Latency \tag{4.7}$$

Subject to:

$$C_1 : Sel_{Stype=0,1,2}^{l_i^k} = \{0, 1\},$$

$$C_2 : Acc(k) \geq ac,$$

$$C_3 : \sum_{Stype=0,1,2} Sel_{Stype}^{l_k^i} = 1,$$

$$\forall k \in \{1, 2, \ldots, P\}.$$

The above optimization problem is a stochastic programming problem. Optimizing the objective function's expected value under constraints is known as an expectation optimization problem. In this case, we consider using the expectation optimization model to solve this stochastic programming problem, aiming to minimize the expected inference latency under given accuracy requirements. For a given accuracy requirement, we need to ensure that the accuracy achieved at the k-th exit point slightly exceeds the requirement. In other words, $Acc(k-1) < ac \leq Acc(k)$ (for $k \neq 1$, P). We define $Acc(0) = 0$ and Acc(P+1) = 1. Therefore, the expected latency is given by:

$$\sum_{k=1}^{P+1} Latency\,(k) \cdot \int_{Acc(k-1)}^{Acc(k)} d\,(x)\,dx \tag{4.8}$$

Hence, this stochastic programming problem can be transformed into a binary nonlinear programming problem:

$$\min_{Sel_{Stype=0,1,2,k\in\{1,2,\ldots,P\}}^{l_i^k}} \sum_{k=1}^{P+1} Latency\,(k) \cdot \int_{Acc(k-1)}^{Acc(k)} d\,(x)\,dx \tag{4.9}$$

$$s.t. : C_1 : Sel_{Stype=0,1,2}^{l_i^k} = \{0, 1\},$$

$$C_2 : \sum_{Stype=0,1,2} Sel_{Stype}^{l_k^i} = 1,$$

$$\forall k \in \{1, 2, \ldots, P\}.$$

4.4. Genetic Algorithm.

1. *Problem Encoding*: Encoding is the mapping from a solution to a genotype, i.e., the method to transform feasible solutions from the problem space to the search space of the genetic algorithm. Encoding strategies typically need to satisfy three principles: (Completeness) Every candidate solution can be encoded into a chromosome in the population. (Nonredundancy) Each candidate solution corresponds to only one chromosome in the population. (Viability) Each encoded chromosome represents a feasible solution in the problem space. In this paper, we consider encoding the offload binary variables $Sel_{Stype}^{l_k^i}$ into chromosomes by concatenating them according to the branching layers of BranchyNet, forming a 01 sequence that represents an offloading scheme, satisfying the first principle. We assume a serial processing model and that BranchyNet has both a main branch and side branches with a chain structure, so there are no issues with overlapping processing times for different layers on the same server or conflicts in the offloading of the same layer to different servers. Therefore, the mapping between chromosomes and candidate solutions is injective, satisfying the second and third principles. Figure 4.2 illustrates the specific way of transforming offloading variables into chromosomes.
2. *Fitness Function*: The fitness function indicates the quality of an individual or solution. Different problems require different definitions for the fitness function. In our case, we use the expected latency as the fitness function. So, the smaller the value of the fitness function, the better the corresponding chromosome's offloading scheme. As the algorithm iterates, competition between individuals in the population gradually weakens as their fitness becomes closer, potentially causing the population to converge to a local optimum. To address this issue, we need to perform fitness scaling. Here, we use linear fitness scaling.
3. *Update Strategy*: The update strategy in genetic algorithms involves the use of genetic operators, which include selection, crossover (recombination), and mutation.

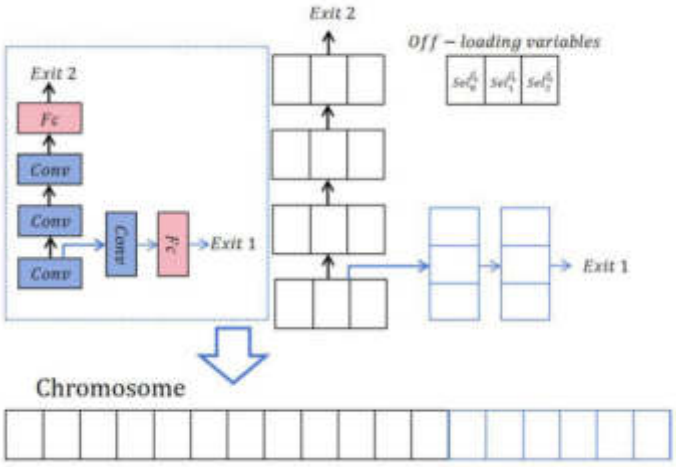

Fig. 4.2: A concrete way to transform unloaded variables into chromosomes

- *Selection*: The selection operation chooses a set of individuals from the old population with a certain probability to form a new population for the next generation. The probability of selecting an individual is related to its fitness value; the higher the fitness value, the greater the chance of selection. Here, we use roulette wheel selection. If there are M individuals in the population, and the fitness of individual i is denoted as f_i, then the probability of selecting individual i is given by

$$P_i = \frac{f_i}{\sum_{k=1}^{M} f_k} \tag{4.10}$$

  Once the selection probabilities are determined, random numbers between 0 and 1 are generated to decide which individuals participate in mating. Individuals with higher selection probabilities have a greater chance of being selected, potentially leading to their genes being passed on to more offspring.
- *Crossover (Recombination)*: The crossover operation involves selecting two individuals randomly from the population and combining their chromosomes to create new offspring with a mix of their parents' features. In our case, we use a single-point crossover operator. In this operator, a random crossover point is chosen, and genes are exchanged between the two parent chromosomes at that point. It's worth noting that the smallest unit we crossover is a group of layer offloading variables, specifically the variables where Stype=0,1,2 for the same layer.
- *Mutation*: The mutation operation is performed to prevent the genetic algorithm from getting stuck in local optima during the optimization process. In our case, we perform single-point mutation at the level of layer offloading variable groups. Specifically, we randomly select one variable with a value of 0 in the layer offloading variable group and change it to 1, while setting all other variables to 0.

  These genetic operators collectively drive the evolution of the population over generations, with selection favoring individuals with better fitness, crossover mixing their features, and mutation introducing genetic diversity.

5. Experiment Results and Analysis.

5.1. Experimental Setup. To simplify the experiments, we only consider mobile and edge computing scenarios. The analyses mentioned earlier are also applicable in this case, with the adjustment of the number of variables in the layer offloading variable group and the removal of latency variables offloaded to the cloud.

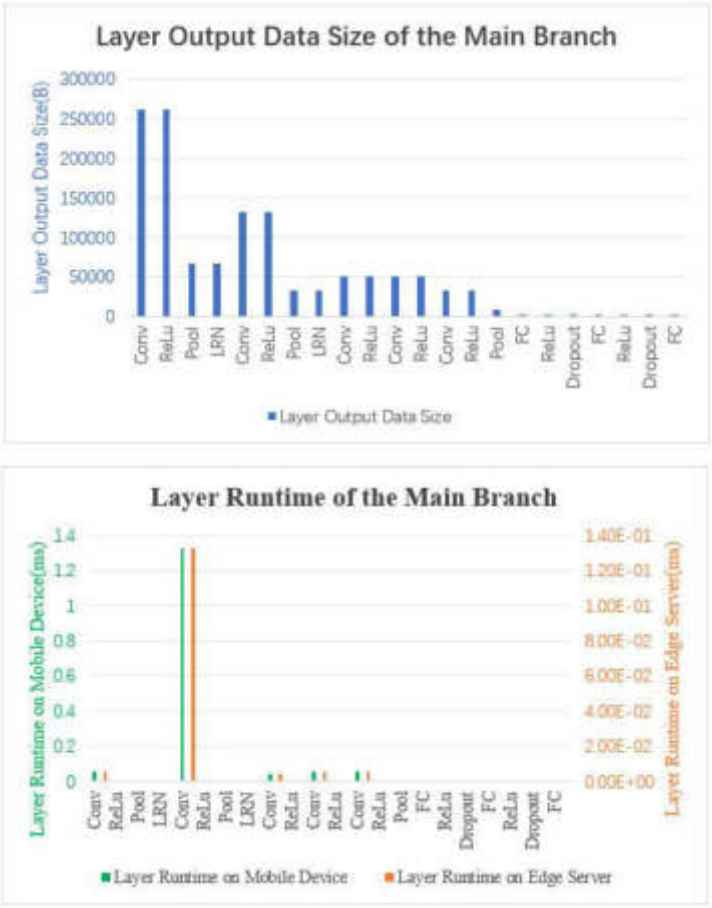

Fig. 5.1: Output data size of the main branch of the DNN and the running time on a Raspberry Pi3B microcomputer and a laptop respectively

Similar to the work of Li et al. [12], we use a laptop to simulate the edge server, equipped with an 8-core 3.6GHz processor and 8GB of memory. For mobile devices, we use a Raspberry Pi 3B mini-computer, which features a 1.2GHz 64-bit quad-core ARM processor and 1GB of RAM.

For the channel between the mobile and edge, we consider the most common LTE (Long-Term Evolution) standard. While the FDD-LTE (Frequency Division Duplex LTE) standard has a bandwidth of 2×20MHz, theoretically supporting downlink rates of 150Mbps and uplink rates of 40Mbps, real-world user experiences often yield lower rates, approximately around 93Mbps, as reported in official surveys . Taking into account interference from buildings and other signals, we assume a rate of 74Mbps.

Regarding the BranchyNet model, we follow the work of Teerapittayanon et al. [5]. We train and test a modified version of the standard image recognition base model, AlexNet, on the CIFAR-10 dataset . Additionally, we choose Chainer as the deep learning framework due to its excellent support for branch DNN structures.

5.2. Experimental Results and Analysis. We have demonstrated a DNN model with a BranchyNet structure, modified from the standard AlexNet, in Figure 3.3 (only convolution layer and fully connected layer are drawn). Figure 5.1 shows the output parameters of the main branch of this Branchy AlexNet and the running times on Raspberry Pi 3B microcomputer and laptop, with side branches not drawn. The four side branches respectively have 7,7,8,8 layers. In the test set, the accuracy of inference results from different exits

Table 5.1: Accuracy of each exit point

Exit Point	1	2	3	4	5
Accuracy(%)	0.524	0.582	0.687	0.749	0.784

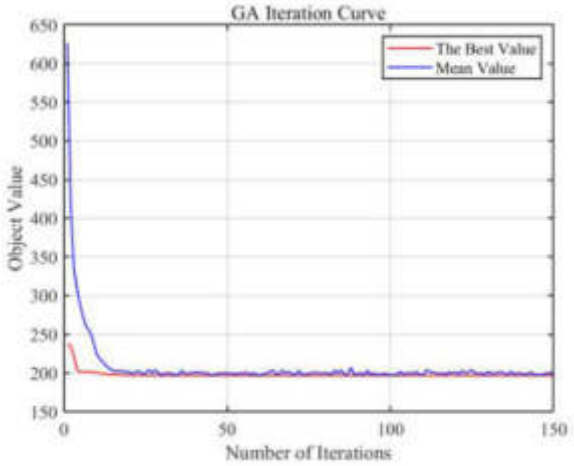

Fig. 5.2: GA Iteration Curve in One Experiment

is as shown in the table. AlexNet [15] achieved error rates of 37.5% and 17.0% on top-1 and top-5 test sets on ILSVRC-2010, respectively. We take the top-1 accuracy of 62.5% as the mean expected inference accuracy, assuming a normal distribution. The accuracy of our DNN model's output results ranges between 52.4% and 78.4%, meaning P $(52.4\% < \text{acc} \leq 78.4\%) \geq 99.7\%$. So, we take the standard deviation (σ) as 0.053.

In the experiment, we set the iteration times of the GA to 50. Since GA belongs to heuristic algorithms, although the basic configuration of each experiment is consistent, the offloading results between different experiments may vary. Hence, we need to conduct multiple experiments to avoid the results falling into local optimums. Figure 5.2 shows a GA iteration curve in one experiment. We can see that the optimal solution is obtained around the 12th iteration, and the mean value of the population becomes stable at the 21st iteration. The scale of our problem is not large. After conducting 20 experiments, the offloading scheme of DNN and the minimum expected total latency were all the same. Hence, we can be fairly certain that the optimal solution of the problem is the result consistently obtained in these 20 experiments.

By using Pre-DNNOff to process the aforementioned DNN model,we can get the shortest total expected latency is 188.93ms. Under the same conditions, the total expected latency of the offloading scheme obtained using Edgent is 207.11ms. PreDNNOff has achieved approximately a 10% reduction in latency compared to Edgent. Moreover, while Edgent is only applicable in situations where the task's accuracy requirements are known, PreDNNOff can address scenarios where the task's accuracy requirements are uncertain.

6. Conclusion. In this paper, we introduce a new DNN offloading model, Pre-DNNOff, which seeks to strike a balance between inference latency and accuracy. Upon solving the stochastic programming problem transformed by Pre-DNNOff using GAs, we derive a lower latency for mobile edge environments with uncertain task requirements of latency. However, in this study, we only consider applications in a simplified IoT setting. In the future, we plan to apply Pre-DNNOff in more complex environments. We aim to optimize Pre-DNNOff further by treating the parameters of the transmission bandwidth and accuracy requirement distributions as random variables, enabling more realistic adjustments of computational resources. Besides,we will design an algorithm that can still be completed within polynomial time even when the BranchyNet structure becomes complex.

MPC OPTIMIZATION ALGORITHM AND STRATEGY FOR HVAC SYSTEM UNDER SMART CITY CONSTRUCTION

LEI WANG*

Abstract. As a giant in energy consumption, buildings urgently need to optimize control strategies for the main energy consuming equipment inside buildings. It is of great significance to design advanced control algorithms to improve the efficiency of the main energy consuming equipment in buildings, namely air conditioning, in the current energy shortage. The model predictive control algorithms and strategies were used in this study to control the HVAC system to improve the energy utilization of the city. Then linear matrix inequality with robust model predictive feedback controller was used to optimize and get the model predictive control optimization algorithm. The research results showed that, under the influence of different factors, the three regions controlled by the model predictive control optimization algorithm showed a little overshooting in the initial state. But it was quickly corrected after adjustment. Meanwhile, the average tracking error of temperature and humidity in each region was 0.139℃ and 0.13g/kg dry air, respectively. The average predicted mean vote was 0.32. In actual office buildings, the proposed algorithm controlled the temperature within the reference value range of 0.1℃ throughout the entire process. The total electricity consumption and electricity price costs were reduced by 12.11% and 22.54%, respectively. In summary, the proposed method has good performance for HVAC system application, which can effectively realize energy saving and emission reduction and improve human comfort. This method makes important contributions to promote the construction of smart cities and the development of green buildings.

Key words: Smart city; HVAC system; MPC optimization algorithm; Control strategy; Energy efficiency

1. Introduction. In recent years, it is important to realize the dual-carbon target. Green buildings need to take up the heavy responsibility of energy saving and emission reduction work, and green and sustainable economic development needs to be realized [1-2]. At the same time, the carbon emissions of the construction industry account for over 50% of the total national energy consumption, while Heating, Ventilation and Air Conditioning (HVAC) systems account for about 60% of the total building energy consumption. Therefore, energy efficiency can be reduced by optimizing and controlling the HVAC system in buildings [3-4]. In addition, people spend more than 80% of their daily lives in buildings. If the HVAC system reduces human comfort due to energy saving, it can be a serious obstacle to learning efficiency and work [5]. At present, the traditional algorithms used in HVAC systems include Programmable Logic Controller (PLC) and Proportional Integration Differentiation (PID). The former has advantages such as simple operation and easy maintenance. But PLC lacks sufficient computing and analysis capabilities in practical applications and is difficult to coordinate the contradiction between human comfort and energy conservation. The latter is prone to the contradiction between speed and overshoot in closed-loop systems, and the inhibitory ability of the integration link is not significant for time-varying disturbances. Model Predictive Control (MPC), as a mainstream emerging control algorithm in recent years, can fully consider the multivariate constraints of the system and predict the future dynamics of the system to maximize the desired performance and achieve stable control of the system [6-7]. Moreover, the MPC algorithm can take into account multiple input factors, such as indoor and environmental temperature, indoor and external airflow, power costs, etc. Meanwhile, MPC can effectively balance the contradiction between energy consumption and indoor comfort to achieve optimal results. Due to deficiencies in the modeling of HVAC systems, the operating environment of HVAC systems is variable based on the comfort control. At the same time, the indoor temperature and humidity model is time-varying, which cannot avoid deviations from the actual system during the control process. From the perspective of energy-saving control, the instantaneous energy consumption dynamic model of HVAC is affected by controllable refrigeration or heating loads and uncontrollable lighting and electrical loads. Meanwhile, there are nonlinear parts in the model, which pose

*Sichuan College of Architectural Technology, Deyang 618000, Sichuan, China (leiwangl@outlook.com)

great difficulty to the design of MOC controllers. The study designed the MPC algorithm for multi-zone HVAC room control to solve the contradiction between comfort and energy saving in HVAC. Then the MPC algorithm was optimized based on Linear Matrix Inequality (LMI) to obtain the MPC Optimization Algorithm (MPC-O). The research aims to optimize the comfort of the indoor environment while enabling the HVAC system to ensure continuous low-energy operation. Meanwhile, this paper aims to enhance the intelligent level and sustainable development of urban construction. There are two main innovations in the study. One is the introduction of the MPC and MPC-O algorithms to control the HVAC system, and the other is the simultaneous realization of the comfort and energy saving in the indoor environment. The research structure is mainly divided into four parts. The first part is a review of relevant research results. In the second part, first, the control principle of MPC algorithm in HVAC systems is introduced, then a multi-zone HVAC room control based on MPC algorithm and strategy is proposed, and finally MPC-O strategy control is designed for the indoor thermal comfort. The third part is the performance analysis of the MPC algorithm in multi-zone HVAC room control and the effectiveness analysis of the HVAC system using the MPC-O control strategy in Wuxi summer. The last part is a summary of the research.

2. Related works. With the continuous promotion of smart city construction, the HVAC system becomes the main source of building energy consumption. The traditional HVAC system has difficulty to meeting the requirements of green buildings for comfort and energy saving. Numerous scholars have discussed this in depth. Li proposed a load estimation method for HVAC systems in large public stadiums and analyzed the influencing factors of HVAC air conditioning. Experiments showed that the method was robust, had good adaptability to the model parameters, and had a good fit between the load estimation results and the actual values. The maximum running time was less than 12.8s, which had a good performance in practical applications [8]. Satar et al. investigated the existence of noise and vibration problems in HVAC systems when a car was heating up and developed a laboratory scale model of the HVAC system. The results showed that noise was heard in the operating frequency range of 200-300 Hz, and that the generation of noise and vibration was more intense when the HVAC system was running [9] Jani explored the effect of desiccant-assisted HVAC air-conditioning for the building environments and discussed the need for a more energy efficient and environmentally friendly desiccant to replace traditional HVAC systems based on vapor compression [10]. Vogt M et al. designed a special sized HVAC system to operate a dry room to provide a safe and well conditioned environment during battery assembly. A validated simulation model of the HVAC system was used to investigate the virtual deployment of the system in five different locations around the world. Deployed in five different locations around the world and operated for one year, the study showed that the system was able to provide an accurate economic and environmental assessment of each location [11].

The MPC algorithm is a new type of control algorithm, which adopts control strategies such as multi-step prediction, rolling optimization, and error correction. The MPC algorithm has better robustness and control effect and has advantages in dealing with high-order, multi-constraint, and nonlinear system problems. The classical control method PID has poor control effect in real engineering because it is difficult to deal with nonlinear, multi-constraint, uncertain, and time-varying control systems. Wang Z et al. design a path optimization algorithm based on improved A* for the path planning of a hexapod robot, and a MPC-based motion tracking controller was used for path tracking. This method was used to solve the traditional path planning problem. The experimental results verified the performance of the method, which solved the problems of security, too many turns, and insufficient smoothing that existed in the traditional path planning method [12]. Ren J et al. found that MPC was less used in missile guidance law, so they deduced an explicit linear discrete time model as a prediction model, and a fast algorithm was given for the MPC guidance law. The simulation results showed that the MPC guidance law met the real-time requirements well [13]. He N et al. developed an algorithm to solve the perturbation nonlinear problem of MPC. Meanwhile, the error gradient and cumulative event-driven MPC framework was designed. The research results showed that this method effectively reduced the computational burden of the MPC controller and verified its feasibility and stability [14]. Wang S et al. proposed an adaptive wind power MPC-O based on the problem that the existing MPC strategy could not reflect the stochastic fluctuation of wind power. The experimental results verified the robustness, stability, and grid security of this method [15].

Based on the above content, the current research on HVAC systems and MPC algorithms focuses on

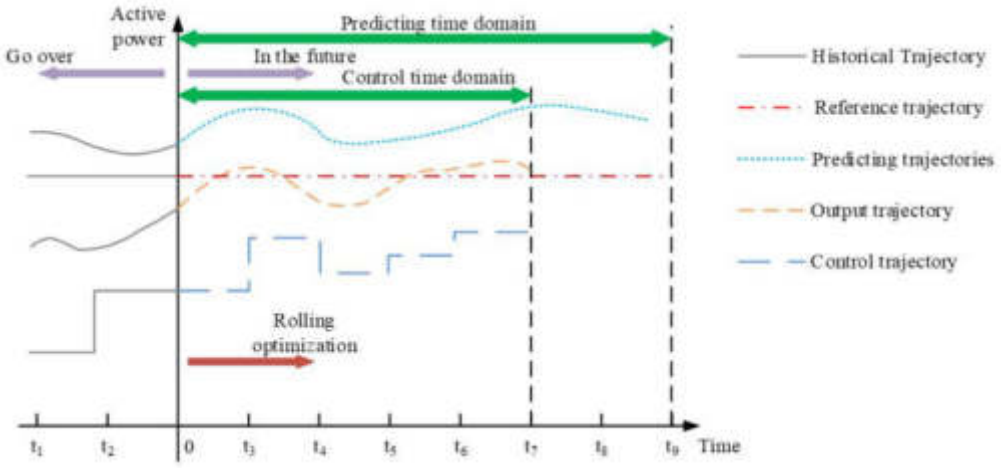

Fig. 3.1: Schematic diagram of the basic principle of MPC algorithm

addressing building thermal dynamic characteristics through measures taken in the control process. The MPC algorithm is optimized to minimize external uncertain disturbance factors and improve human comfort is currently a research focus. Therefore, the contradiction between human comfort and energy conservation can be addressed, and the functional pressure can be alleviated during peak hours on the power grid. Based on multi-zone HVAC rooms, a MPC-O algorithm based on LMI and robust model predictive feedback controller is proposed to directly control the efficiency of HVAC compressors, achieving both energy cost savings and ensuring indoor human comfort.

3. The MPC-O algorithm and policy control for HVAC systems. The HVAC system, as the core part of building environment control, is widely used in commercial facilities and other buildings. But this system has problems such as high energy consumption and difficulty in meeting human comfort needs. Aiming at the above problems, the study firstly explores the control principle of MPC algorithm in the HVAC system. Then the MPC algorithm and strategy are designed for control under multi-zone HVAC room. Finally, the MPC-O algorithm and control strategy are proposed for the internal comfort of indoor environment.

3.1. The MPC algorithm for control in the HVAC system. The MPC algorithm belongs to an advanced process control method, which is widely used in various fields. This system is applicable to linear and nonlinear systems, which can consider various constraints of spatial state variables. However, the mainstream PID control algorithms only consider the various constraints of the input and output variables [16-18]. The MPC algorithm mainly has the following three basic principles. The first is a predictive model, mainly based on the object's cubic information and future inputs, predicting the future output of the system. The second is rolling optimization, which is different from the traditional optimal control of the fundamental point through the optimal value of a certain performance indicator to determine the role of the control [19-20]. Finally, the prediction results are corrected by detecting the actual output of the object at the new sampling moment. At the same time, the real-time information is utilized to avoid the deviation of the control from the ideal state caused by the model mismatch or environmental disturbances. The basic principles of the MPC algorithm are illustrated in Fig. 3.1.

In Fig. 3.1, the MPC algorithm is able to solve the optimization problem for a local prediction range at each control moment and make corrections by predicting the future conditions continuously rolling forward. However, the application of the MPC algorithm in the HVAC systems has the following problems. They include the uncertainty of the external environment affects more factors and the existence of the nonlinear part of the model may have an impact on the MPC control strategy during the modeling. Therefore, the MPC algorithm needs to be improved. In the HVAC system, there are two typical control methods, namely, variable air volume

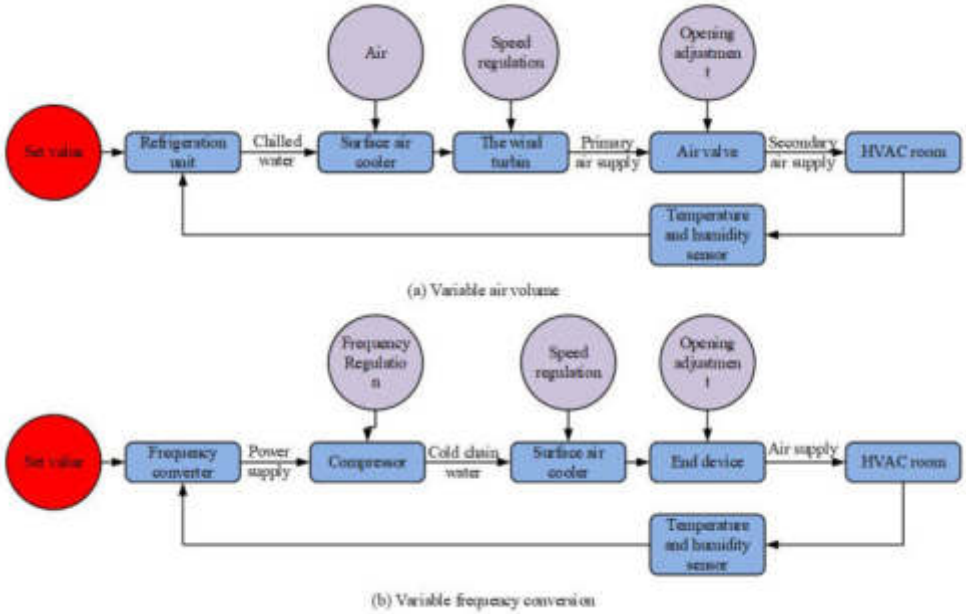

Fig. 3.2: Principles of variable air volume and variable frequency control in HVAC systems

and variable frequency, and the specific control principles are shown in Fig. 3.2.

Figures 3.2 (a) and 3.2 (b) show the HVAC system variable air volume and variable frequency corresponding to the principle of control. Variable air volume directly controls the air volume of the outlet. The smaller fan capacity and different indoor comfort requirements have a strong flexibility. In addition, the air conditioning end equipment is the most important influence on the variable air volume HVAC system. The state can quickly respond to changes in the indoor environment. The development of this system also has greater prospects for comfort. The principle of variable frequency control is to increase the frequency converter to control the compressor frequency. Therefore, the cooling rate can be adjusted and the energy-saving effect is obvious, which can maintain indoor human comfort around the clock and easy to access the smart grid. The study designs the control strategy of HVAC system based on the MPC algorithm for the comfort and energy saving control.

3.2. Multi-zone HVAC room control based on MPC algorithms and strategies. Since most studies consider the interior of the room in which the HVAC system is located as a whole and ignore the losses generated by air flow, environmental differences, etc., the final results of the algorithm can only achieve the theoretical optimum. Therefore, the study uses hydrodynamic computational methods to construct a thermodynamic model of a multi-zone HVAC room. At the same time, an MPC control strategy that can be optimized with multiple objectives is designed. The multi-zone HVAC room modeling process is as follows. Firstly, the following assumptions are made. The room is divided into air supply area (area A), air return area (area B), and working area (area C). Each area is represented by a state. The surface temperature of the inner and outer walls of the room is represented by a set of total values. Only the light bulb is a heat source in the air supply area and there is no source of moisture. There is no heat source and moisture source in the air return area. All the heat sources in the working area are heat and moisture sources. All the heat sources in the working area are heat and moisture sources. There are no heat and moisture sources in the return air zone. All heat sources in the work zone have fixed surface temperatures. The convective heat transfer coefficient between adjacent spaces and walls or heat sources is fixed. The temperature measurement data come from thermistors, and the humidity measurement data come from resistive sensors. Under the control of the variable air volume HVAC system, the mass-energy conservation law leads to the temperature and humidity model of area A, which

is shown in equation (3.1).

$$\begin{cases} \rho_a V_{a,A} \frac{dh_{a,A}}{dt} = AP_{a,i} \left(h_{a,i} - h_{a,A}\right) + \Delta q_{a,A} \\ \rho_a V_{a,A} \frac{dW_{a,A}}{dt} = AP_{a,i} \left(W_{a,i} - W_{a,A}\right) \\ C_{iw,A} \rho_{iw} V_{iw,A} \frac{dT_{iw,A}}{dt} = \vartheta_{iw,A} K_{iw,A} \left(T_{a,A} - T_{iw,A}\right) \end{cases} \tag{3.1}$$

In equation (3.1), ρ_a and ρ_{iw} are the densities of the air corresponding to the inner wall. $AP_{a,i}$, $h_{a,i}$, and $W_{a,i}$ are the flow rate, enthalpy, and humidity of the air supplied from the air outlet. $h_{a,A}$, $h_{a,A}$, $W_{a,A}$, and $T_{a,A}$ are the volume, enthalpy, humidity, and temperature of the air in region A, respectively. $C_{iw,A}$, $V_{iw,A}$, $K_{iw,A}$, $\vartheta_{iw,A}$, and$T_{iw,A}$ are the specific heat capacity, volume, area, convective heat transfer coefficient, and temperature of the air between the region A and the inner wall, respectively. $\Delta q_{a,A}$ denotes the thermal growth rate of air in region A. The temperature and humidity model of region B is shown in equation (3.2). The temperature and humidity models in the region B are expressed by equation (3.2).

$$\begin{cases} \rho_a V_{a,B} \frac{dh_{a,B}}{dt} = AP_{a,i} \left(h_{a,i} - h_{a,B}\right) + \Delta q_{a,B} \\ \rho_a V_{a,B} \frac{dW_{a,B}}{dt} = AP_{a,i} \left(W_{a,i} - W_{a,B}\right) \\ C_{iw,B} \rho_{iw} V_{iw,B} \frac{dT_{iw,B}}{dt} = \vartheta_{iw,B} K_{iw,B} \left(T_{a,B} - T_{iw,B}\right) \end{cases} \tag{3.2}$$

In equation (3.2), $V_{a,B}$, $h_{a,B}$, $W_{a,B}$, and$T_{a,B}$ are the volume, enthalpy, humidity, and temperature of region B, respectively. $\Delta q_{a,B}$ represents the thermal growth rate of the air in region B. $C_{iw,B}$, $V_{iw,B}$, $K_{iw,B}$, $\vartheta_{iw,B}$, and$T_{iw,B}$ are the specific heat capacity, volume, area of the region, convective heat transfer coefficient, and temperature of the air between region B and the inner wall, respectively. The temperature and humidity of region C are modeled as in equation (3.3).

$$\begin{cases} \rho_a V_{a,C} \frac{dh_{a,C}}{dt} = AP_{a,i} \left(h_{a,A} - h_{a,C}\right) + \Delta q_{a,C} \\ \rho_a V_{a,C} \frac{dW_{a,C}}{dt} = AP_{a,i} \left(W_{a,A} - W_{a,C}\right) + \Delta e_{a,C} \\ C_{iw,C} \rho_{iw} V_{iw,C} \frac{dT_{iw,C}}{dt} = \vartheta_{iw,C} K_{iw,C} \left(T_{a,C} - T_{iw,C}\right) \\ C_{ew,C} \rho_{ew} V_{ew,C} \frac{dT_{ew,C}}{dt} = \vartheta_{ew,C} K_{ew,C} \left(T_{a,C} - T_{ew,C}\right) + \frac{\beta_{ew} K_{ew,C}}{ts_{ew}} \left(T_{ew,e} - T_{ew,C}\right) \end{cases} \tag{3.3}$$

In equation (3.3), ρ_{ew}, β_{ew}, andts_{ew} are the density, thermal conductivity, and thickness of the exterior wall, respectively. $V_{a,C}$, $h_{a,C}$, $W_{a,C}$, $T_{a,C}$, $\Delta q_{a,C}$, and $\Delta e_{a,C}$ are the volume, enthalpy, humidity, temperature, thermal growth rate, and humidity growth rate of the air in Area C, respectively. At typical indoor temperature, the enthalpy of human exhaled gas h_o is related to the temperature $T_{h,o}$ and humidity $W_{h,o}$, and the expression is shown in equation (3.4).

$$\begin{cases} T_{h,o} = 0.066 T_{a,C} + 32.6 \\ W_{h,o} = 0.2 W_{a,C} + 0.029 \end{cases} \tag{3.4}$$

In equation (3.4), human lung ventilation rate G_{is} and body surface area $A_{ew,c}$ are calculated in equation (3.5).

$$\begin{cases} G_{is} = 1.43 \bullet 10^{-6} E A_{ew,c} \\ A_{ew,c} = 0.202 m^{0.425} H^{0.725} \end{cases} \tag{3.5}$$

In equation (3.5), E, m, and$H$ represent the metabolic rate, weight, and height of indoor members, respectively. The surface temperature of the exterior wall $T_{ew,a}$ is expressed in equation (3.6).

$$T_{ew,a} = T_{a,o} + \frac{\delta S}{\alpha_{ew,a}} \tag{3.6}$$

In equation (3.6), $T_{a,o}$ represents the temperature of the external environment. $\alpha_{ew,a}$ represents the convective heat exchange coefficient between the external wall and the air of the external environment. δ and S are

the absorption coefficient and intensity of the solar radiation, respectively. The enthalpy of air h_a is calculated as equation (3.7).

$$h_a = C_a T_a + 2.5 \bullet 10^6 \bullet W_a \tag{3.7}$$

In equation (3.7), C_a, T_a, and W_a are the specific heat capacity, temperature, and humidity of air, respectively. The above model needs to be transformed into a state-space model to facilitate the MPC algorithm to control the temperature and humidity of different regions, and the transformed expression is shown in equation (3.8).

$$\begin{cases} \chi\dot{x} = D_q \chi x + L_q \chi u \\ y = Q\left(\chi x + x_0\right) \\ \chi x = \left[\chi T_{a,A} \chi W_{a,A} \chi T_{iw,A} \chi T_{a,B} \chi W_{a,B} \chi T_{iw,B} \chi T_{a,C} \chi W_{a,C} \chi T_{iw,C} \chi T_{ew,C}\right]^T \\ \chi u = \left[\chi T_{a,i} \chi W_{a,i} \chi A P_{a,i} \chi T_{a,o} \chi S\right]^T \end{cases} \tag{3.8}$$

In equation (3.8), D_q, L_q, and Q are the state matrix, control matrix and output matrix, respectively. χx and χu are the state variables and input variables respectively. x_0 represents the steady state point. Finally, the inputs are the air supply volume and the air supply temperature and humidity, and the outputs are the temperature and humidity of the three regions. The above linear state space model can not be directly used in the MPC strategy, which needs to be discretized. The discrete-time state space model after processing, that is, the prediction model is expressed by equation (3.9).

$$\begin{cases} \chi x\left(k+1\right) = D_d \chi x\left(k\right) + L_d \chi u\left(k\right) \\ y\left(k\right) = Q\left(\chi x\left(k\right) + x_0\right) \\ D_d = e^{D_Q T_s} \\ L_d = \left(\int_0^{T_s} e^{D_Q T} dt\right) L_q \end{cases} \tag{3.9}$$

In equation (3.9), k and T_s are the sampling time and interval, respectively. D_d and L_d are the state matrix and input matrix of the system, respectively. The study designs the performance index function with multiple optimization objectives to ensure the comfort state in the room, and the calculation is shown in equation (3.10).

$$\begin{cases} J_{\min U} = \left(Y - R\right)^T \tilde{O}\left(Y - R\right) + U^T \tilde{R} U \\ O = diag\left[10^4, 10^4, 10^5, 10^4, 10^5, 10^4, \right] \\ R = \omega \bullet diag\left[50, 50, 5, 1, 1\right] \end{cases} \tag{3.10}$$

In equation (3.10), O and R are the weights of the tracking error and control inputs, respectively. ω represents reducing the coefficient of the control weight matrix. Through the above operations, the MPC strategy focuses more on the tracking of temperature and humidity in the room and copes with frequent changes in reference values. At this point the ζ function has been converted to a standard quadratic programming problem. Finally, the MPC algorithm is able to explicitly process various equations and inequality constraints. The input air supply is determined by the fan speed and the valve opening of the terminal equipment, in addition to considering the rate of change of the input. As a result, a multi-zone HVAC room flow based on MPC strategy control under variable air volume control is constructed, as shown in Fig. 3.3.

In Fig. 3.3, the optimized quantities are solved according to the constructed objective function related to temperature and humidity and air supply quantity. Finally, the actual state quantities corresponding to different regions are obtained, and the above process is looped until the end of the simulation.

3.3. Improved indoor comfort based on the MPC-O strategy control. The single-zone indoor model gives more uncertain external factors compared with the multi-zone HVAC room temperature and humidity model. Because there is the euclidean interaction of heat transfer coefficients between different zones and the influence of the outdoor climate. This results in a more difficult process to describe the thermal dynamics in the environment. Therefore, the study uses LMI with robust model predictive feedback controller to improve it and obtain the MPC-O strategy. LMI is a method for matrix inequality constrained optimization

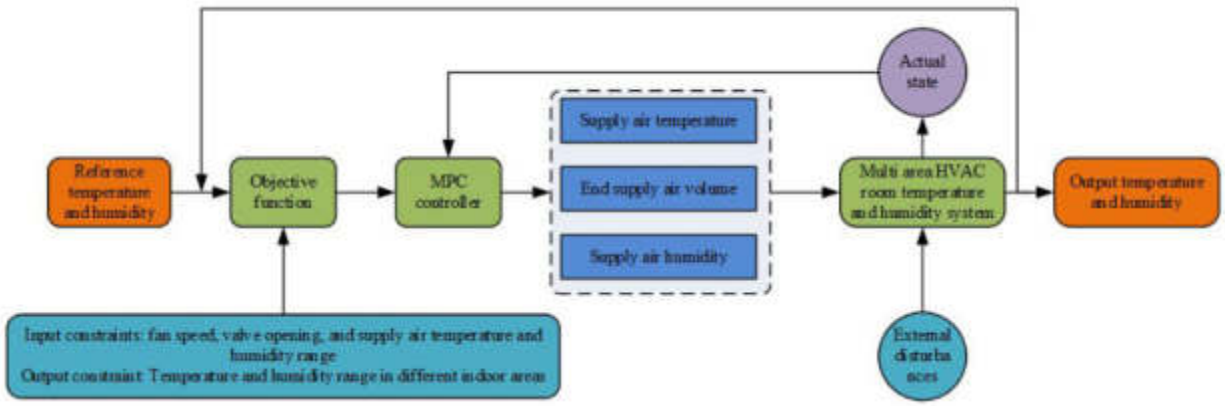

Fig. 3.3: Multi-zone HVAC room process control based on MPC strategy under variable air volume control

problems, commonly used in the design and analysis of control systems. The cores are to describe the constraints of the system through linear matrix inequalities and to improve the performance and stability by solving matrix inequality optimization problems. The study expresses the covariates using the multicellular uncertainty set ψ on the basis of equation (3.10) to introduce the effect brought by the thermal nature of the room thermal dynamics, which leads to equation (3.11).

$$\begin{cases} \chi\dot{x} = D_{zd}\chi x + L_{zd}\chi u \\ y = Q\left(\chi x + x_0\right) \\ \left[D_{zd}\ L_{zd}\right] \in \psi_z \\ \left[D_{zd}\ L_{zd}\right] = \sum_{p=1}^{P}\left[D_{zp}\ L_{zp}\right] \\ \sum_{p=1}^{P}\phi_p = 1 \end{cases} \tag{3.11}$$

In equation (3.11), ψ_z is the multicellular uncertainty set and ϕ_p represents the non-negative constant. Since the indoor and outdoor thermal dynamic properties will change, the study specifies the bounds of convective heat transfer coefficient. This method can transform the original system into a convex multicellular model with 8 vertices, which can lead to a multicellular model of multi-zone HVAC room. Then the final model can be obtained after the discrete processing, as shown in equation (3.12).

$$\begin{cases} \chi x\left(k+1\right) = D_{zd}\chi x\left(k\right) + L_{zd}\chi u\left(k\right) \\ y = Q\left(\chi x\left(k\right) + x_0\right) \\ \left[D_{zd}\ L_{zd}\right] \in \psi_d \\ \left[D_{zd}\ L_{zd}\right] = \sum_{p=1}^{P}\left[D_{zp}\ L_{zp}\right] \\ \sum_{p=1}^{P}\phi_p = 1 \end{cases} \tag{3.12}$$

In equation (3.12), ψ_d is the new multi-cell uncertainty set. If the HVAC system matrix with more complex uncertainty parameters is considered, the number of multi-cell level vertices will cost expansion. The MPC algorithm can not solve it, but also lead to the failure of the system operation. So the study proposes the MPC-O algorithm, which applies N free control variables to the system at each initial control stage, and then uses a single state feedback control rate, as shown in equation (3.13).

$$\chi u\left(k+1\left|k\right.\right) = \begin{cases} \chi u\left(k\left|k\right.\right), t = 0 \\ \chi u\left(k+1\left|k\right.\right), t = 1 \\ \vdots \\ \varphi\chi u\left(k+1\left|k\right.\right), t \geq N \end{cases} \tag{3.13}$$

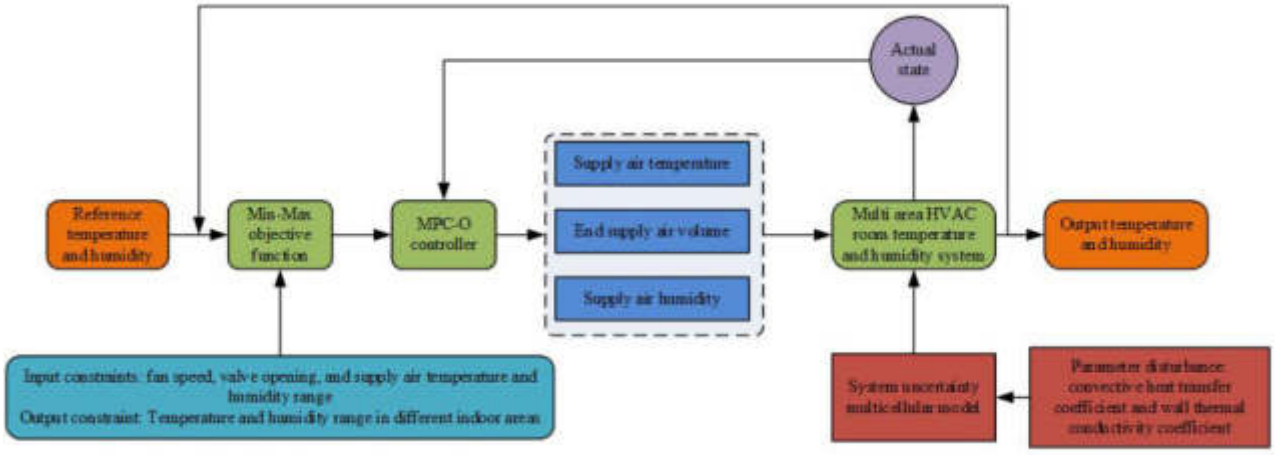

Fig. 3.4: Indoor comfort process improvement based on MPC-O strategy control

At this point, a new time-varying Lyapunov function is defined, as shown in equation (3.14).

$$V(t+1,k)-V(t,k)\leq-\left[\|\chi x(k+t\,|k)\|_{O_x}^2+\|\chi u(k+t\,|k)\|_{R_x}^2\right] \tag{3.14}$$

Equation (3.15) can be obtained by adding up equation (3.13) from $t=M$ to ∞ and simplifying the right-hand term of the inequality with $-J_2(k)$.

$$-V(N,k)\leq-J_2(k) \tag{3.15}$$

At this point, the infinite time domain optimal problem is equivalent to minimizing the upper bound of $V(N,k)$, as shown in equation (3.16).

$$\max J_2(k)\leq\chi x(k+N)^T P(t,k)\chi x(k+N) \tag{3.16}$$

The transformation of the objective function from infinite time domain to finite time domain can be achieved through equation (3.16). The expression of the objective function for multi-zone HVAC room temperature and humidity optimization problem can be obtained in equation (3.17).

$$\min_{\eta_1,\eta_2,\chi^{U(k)},\gamma(k),B_l}\|\chi x(k)\|_{O_x}^2+\eta_1+\eta_2 \tag{3.17}$$

In equation (3.17), both η_1 and η_2 are upper bounds. B_l denotes L symmetric positive definite matrices. Then LMI representation is applied to the upper bound, which is applied to the input-output constraints. Finally, the MPC-O algorithm is solved to obtain the state feedback control rate, and the calculation is shown in equation (3.18).

$$\begin{cases}\chi u(k+t\,|k)=\kappa\chi x(k+t\,|k)\\ \kappa=HG^{-1}\end{cases} \tag{3.18}$$

The synthesis of the above leads to an improved indoor comfort process based on the MPC-O strategy control, which is shown in Fig. 3.4.

In Fig. 3.4, it is necessary to multicellularize the perturbations that have in the modeling process. Meanwhile, the objective function related to temperature and humidity and air supply volume is established. The MPC-O algorithm is solved to obtain the optimal control volume under the constraints of the variable air volume HVAC system. Then the HVAC system is affected to obtain the actual output volume corresponding to

Table 4.1: Experimental parameter settings

Parameter	Numerical value	Parameter	Numerical value
$W_{a,A}$/(g/kg dry air)	18.3	$W_{a,C}$/(g/kg dry air)	18.5
$T_{a,A}$/C	28.0	$T_{a,C}$/C	29.6
$T_{iw,A}$/C	30.5	$T_{iw,C}$/C	30.8
$W_{a,B}$/(g/kg dry air)	18.5	$T_{ew,C}$/C	32.1
$T_{a,B}$/C	30.0	Prediction time domain and control time domain/min	30
$T_{iw,B}$/C	31.3	Sampling interval/min	5
The upper and lower limits of input constraints	[10, 10, 0.7, 20, 50], [-10, -10, -0.3, -10, -50]	Simulation duration	24
The upper and lower limits of output constraints	[32, 23.3, 34.6, 23.4, 35, 23.5], [23, 13.3, 24.6, 13.4, 25, 13.5]	Input rate of change constraint	[4, 3, 0, 5, 8, 10], [0, 0, 0, 0, 0, 0]

the different regions. Although the most important influencing factor in the indoor environment is the indoor temperature, a comprehensive evaluation cannot be made by considering only a single factor. Therefore, the study chooses the Predicted Mean Vote (PMV) index for evaluation, which integrates the key parameters such as temperature, humidity, average radiation, wind speed, etc. Meanwhile, PMV is an evaluation index that can accurately reflect the thermal comfort of the human body. The expression of PMV index used in the study is shown in equation (3.19).

$$PMV = 36.06W_i + 0.1403T_m + 0.1597T_i - 89.31 \tag{3.19}$$

In equation (3.19), W_i and T_i represent the temperature and humidity of the indoor environment. T_m represents the average radiant temperature. Although the room is divided into several zones, region C is the main activity area for human beings, so the study mainly analyzes region C to get the PMV index.

4. Analysis of MPC optimization algorithms and strategy results for HVAC systems. This study verified the performance and application effect of the MPC algorithm and its optimization algorithm. First, the study examined the performance of the multi-zone HVAC room comfort strategy control based on the MPC algorithm. Then the performance and application effect of the improved room comfort based on the MPC-O strategy control were analyzed.

4.1. Performance analysis of MPC-based multi-zone HVAC room comfort control. The study was simulated on the software MATLAB to verify the control performance of the multi-zone HVAC room comfort strategy based on the MPC algorithm. MATLAB mainly analyzes the temperature and humidity tracking of the different zones in the room under uncertain disturbance conditions. The study was conducted on a hot summer day in Wuxi and on the day with the highest temperature. The specific experimental parameters are set as in Table 1.

The experiments were conducted in a situation where only the comfort of a multi-zone HVAC room was considered (Environment 1), using the MPC algorithm and strategy to control the temperature and humidity in different zones of the room.

Fig. 4.1(a) to Fig. 4.1(c) show the comparison of temperature and humidity results of regions A, B, and C. In the presence of perturbation factors, the three regions responded quickly and reached the reference value, which took about 12 min. After reaching the reference set point, the temperature range of all the regions fluctuated around 0.35°C. The humidity was less affected by the perturbation factors and fluctuated only in a small range around 0.01g/kg dry air. 0.01g/kg dry air fluctuated in a small range. Since the above environment needed to keep the temperature and humidity stable throughout the day, which produced a great waste of power resources, the study introduced the price of electricity for simulation, i.e., Environment 2.

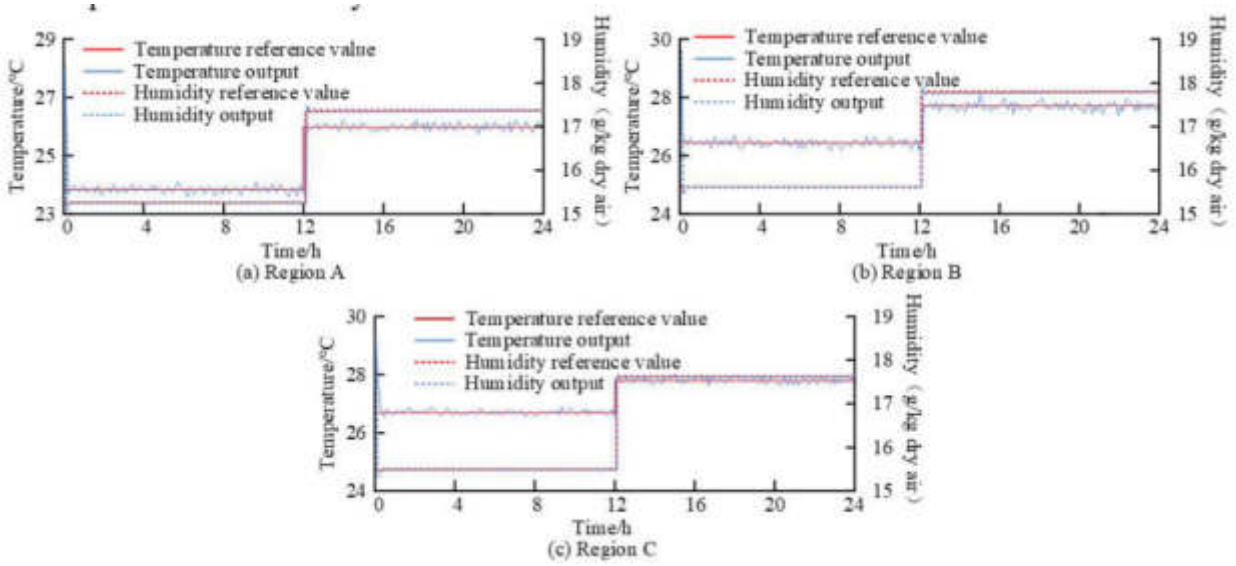

Fig. 4.1: Temperature and humidity results of different areas in multi-zone HVAC rooms based on MPC algorithm and strategy control

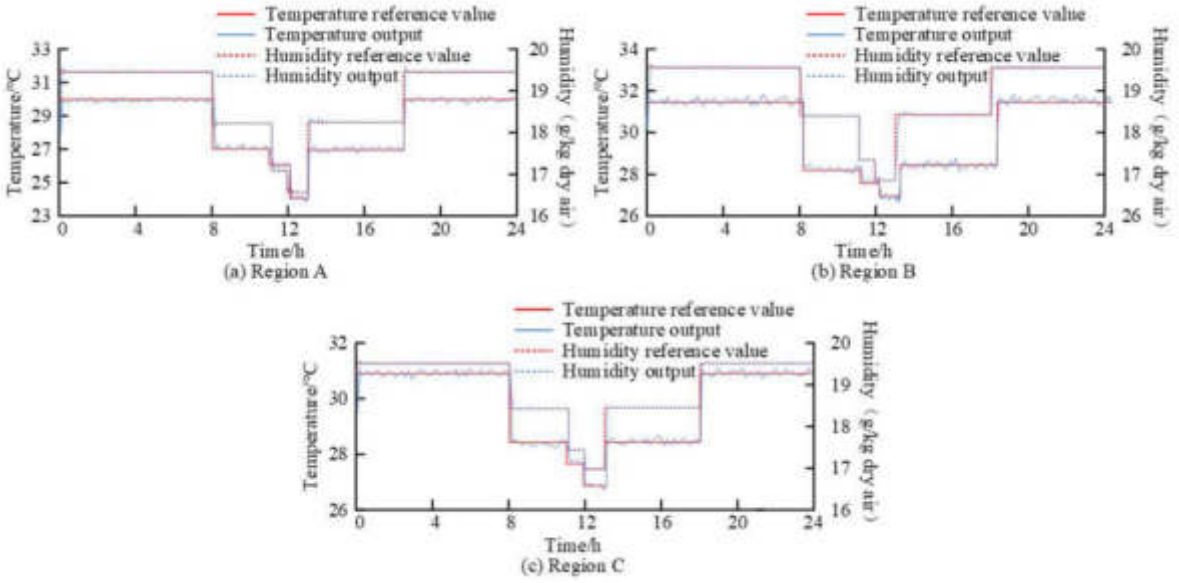

Fig. 4.2: Temperature and humidity control results of regions A, B, and C under Environment 2

Fig. 4.2(a) to Fig. 4.2(c) show the results of temperature and humidity control of areas A, B, and C under Environment 2, respectively. The different areas reached a stable state in 15 min. When the optimal temperature and humidity settings changed, the MPC algorithm also responded quickly. So the output results were consistent with the reference value, which indicated that the different areas were also better in terms of anti-interference in response to the changes in temperature and humidity. The study analyzed the fan speed, air flow rate, and cost of electricity in the two environments to further explore the changes in the two environments

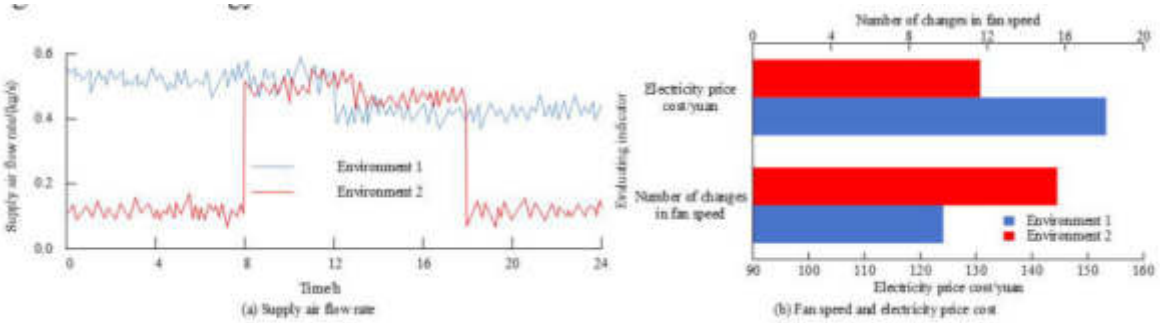

Fig. 4.3: Comparison results of supply air flow rate, fan speed, and electricity price cost based on MPC algorithm in two different environments

Table 4.2: Experimental parameter settings for Environment 3

Parameter	Numerical value	Parameter	Numerical value
$W_{a,A}$/(g/kg dry air)	18.3	$W_{a,C}$/(g/kg dry air)	18.5
$T_{a,A}$/C	26.6	$T_{a,C}$/C	30.7
$T_{iw,A}$/C	30.3	$T_{iw,C}$/C	31.6
$W_{a,B}$/(g/kg dry air)	18.5	$T_{ew,C}$/C	30.1
$T_{a,B}$/C	30.1	Sampling interval/min	6
$T_{iw,B}$/C	31.3	Simulation duration	6
The upper and lower limits of input constraints	[10, 10, 1, 10, 30], [-10, -10, -0.1, -10, -50]	The upper and lower limits of output constraints	[28, 21, 30, 23, 32, 23], [20, 15, 24, 16, 25, 14]
Output reference for the first 3 hours	[21.7, 15.8, 24.3, 16, 25.3, 16]	Output reference for the last 3 hours	[23.9, 17.3, 25, 17.5, 28, 17.2]

based on the MPC algorithm and strategy.

Fig. 4.3(a) and Fig. 4.3(b) show the results of MPC algorithm-based supply air flow rate, fan speed, and cost of electricity in two environments, respectively. If the temperature changed frequently, it greatly affected human comfort. But the results in case of Environment 2 saved 35.68% of the electricity cost while ensuring human comfort. In addition, the fans in Environment 1 changed only 10 times in the full control of the HVAC system, while it changed 16 times in Environment 2. In summary, the MPC algorithm was able to maintain a stable control effect in the presence of perturbing factors and still accomplished the initial energy saving goal in an environment where real-time tariffs were introduced. This method laid a solid foundation for the performance of subsequent MPC-O algorithms and strategies.

4.2. Analysis of results of improved indoor comfort based on MPC-O strategy control. The robustness of the MPC-O algorithm and the effect of different factors on indoor temperature and humidity control were examined in the study. The building envelope structure, indoor human activities and heat source changes, and the outdoor environment were denoted as factors X, Y, and Z. In addition, the study introduced the mainstream Robust Model Prediction (RMP) algorithm and MPC to conduct comparative experiments. In Environment 2, the study considered the impact of the three influencing factors. The above environment was set as Environment 3 to verify the superiority of the MPC-O algorithm and strategy. The experimental parameters at this time were set as in Table 4.2.

Experiments were conducted using the RMP algorithm with the MPC-O algorithm to analyze the effect of temperature and humidity control in different areas of the room under the conditions of Environment 3.

Fig. 4.4(a) to Fig. 4.4(c) show the results of temperature and humidity control corresponding to regions A, B, and C in Environment 3, respectively. The RMP algorithm was unable to fulfill the task of humidity control in HVAC rooms. When the HVAC system controlled by the algorithm was in operation, the humidity content

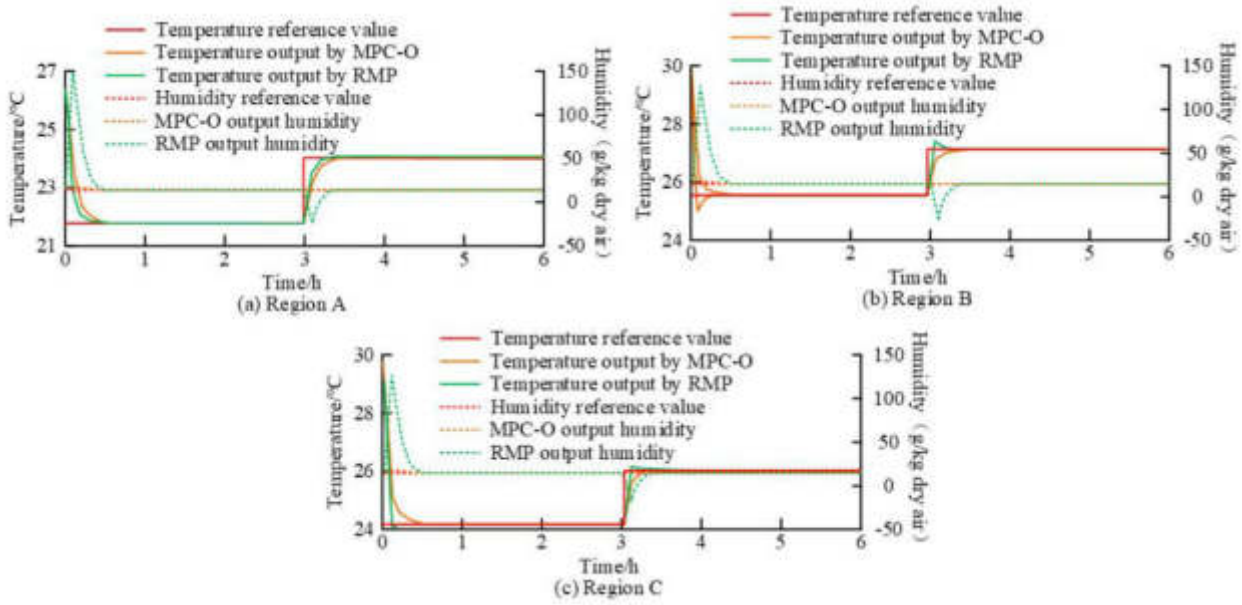

Fig. 4.4: BiLSTM neural network

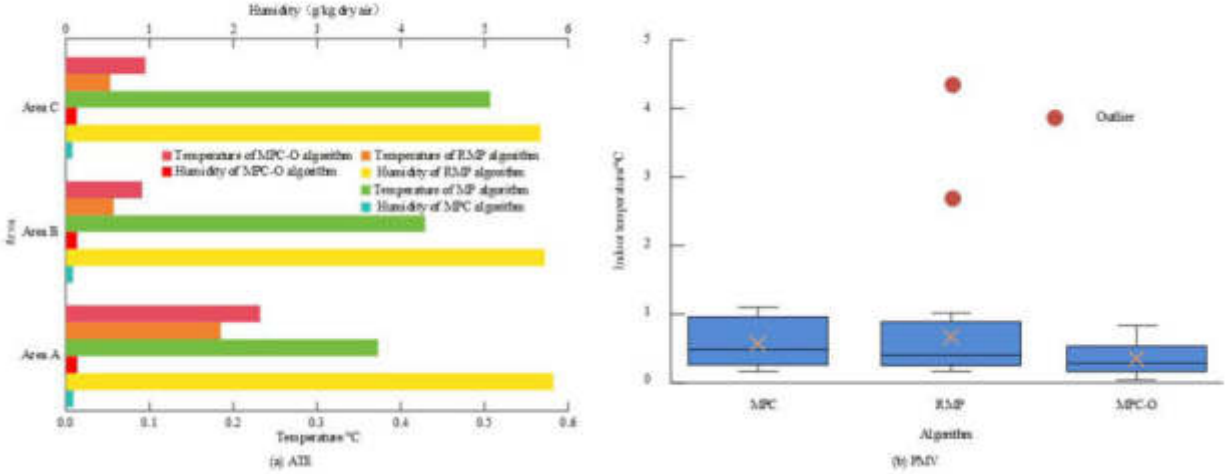

Fig. 4.5: Tracking and control effects under different algorithm controls

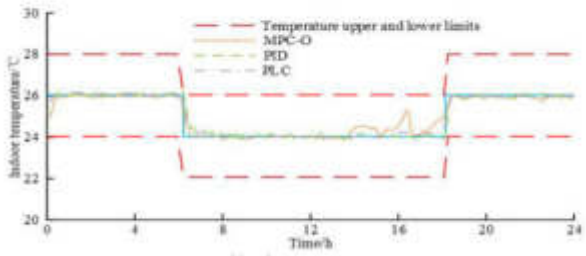
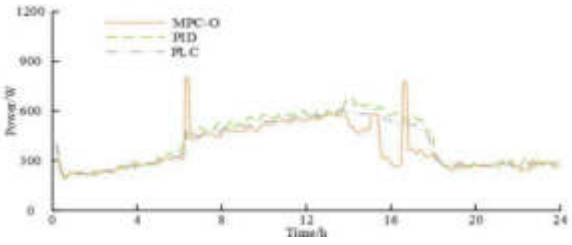
of the regions grew sharply to more than 100 g/kg dry air in 6 min, which was far beyond the actual control of the variable-air-volume HVAC system. This was far beyond the actual control range of the variable air volume HVAC system, leading to energy waste and environmental pollution and causing the system to malfunction. The MPC-O algorithm, on the other hand, showed a very small degree of overshooting in the initial state of each region, but it was quickly corrected after adjustment. So the temperature and humidity accurately tracked the reference value in most cases. The study used Average Tracking Error (ATE) and PMV for evaluation to more intuitively observe the tracking and control effects of different algorithms.

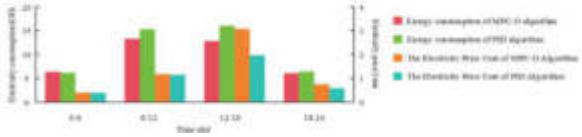
Fig. 4.5(a) and Fig. 4.5(b) show the ATE and PMV results under the control of different algorithms,



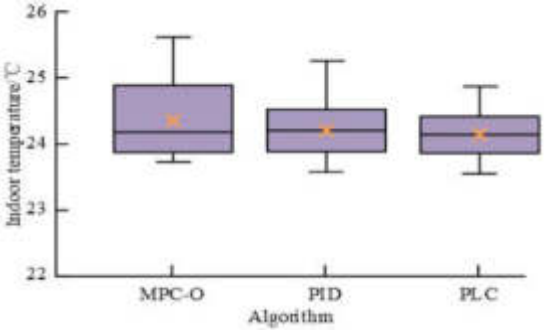
(a) Indoor Temperature



(b) Compressor Power



(c) Electricity Consumption and Electricity Price Cost



(d) Room Temperature Distribution

Fig. 4.6: The application effects of different algorithms in real scenarios

respectively. In each region, the ATE of the MPC algorithm was smaller, with an average of 0.082 g/kg dry air, but the temperature error was larger, with an average of 0.436°C. The difference in the ATE of the RMP algorithm for the humidity in different regions was very large, and the MPC-O algorithm had very good tracking effect of the temperature and humidity in all the regions. The ATE of MPC-O algorithm was 0.139℃ and 0.13g/kg dry air, respectively. In the PMV results, the average PMV of MPC, RMP, and MPC-O algorithms were 0.57, 0.63, and 0.32, respectively. In summary, the MPC-O algorithm had a better tracking and control effect. The study used traditional PID and PLC algorithms for comparison to further verify the energy-saving and comfort effect of MPC-O algorithm in practical applications. Experiments were carried out in the internal office of the building, with the total duration and sampling step set to 24h and 10min and set to 26℃, 24℃, and 26℃ at 0:00-6:00, 6:00-18:00, and 18:00-24:00, respectively.

The application effects of different algorithms in real scenarios are shown in Figure 10. Fig. 4.6 (a) to Fig. 4.6 (d) show the indoor temperature, compressor power, electricity consumption, electricity price cost, and room temperature distribution results under different algorithm controls. The proposed algorithm controlled the temperature to fluctuate around 0.1℃ around the reference value throughout the entire process, which increased the compressor power to 1200W in advance, quickly reaching the optimal temperature. During peak electricity consumption periods, it was quickly adjusted with minimal impact on comfort. The load demand was reduced during this period. In addition, the algorithm proposed in the study reduced total electricity consumption and electricity price costs by 12.11% and 22.54%, respectively, with an average indoor dimension of 24.5℃. The control of PID algorithm had hysteresis and poor energy-saving effect, with an average indoor temperature of 24.3℃. Moreover, the PID algorithm took some time for room temperature to reach a relatively stable state due to its limitations, making it impossible to predict the demand for future increases in indoor cooling load. In addition, different algorithms did not have significant energy-saving effects during periods of low electricity prices. The advantages of the proposed algorithm were only demonstrated during peak electricity consumption periods. It not only significantly reduced energy efficiency and costs, but also alleviated the pressure on the

power grid. The average indoor temperature of the PLC algorithm was 24.6℃, which had a poor effect on maintaining indoor comfort. In summary, the proposed algorithm achieved energy conservation and effectively promoted the sustainable development of electricity during peak hours of practical application compared with the application effect of traditional algorithms, while ensuring indoor comfort.

5. Conclusion. The HVAC system is an air conditioner integrating ventilation, heating and air conditioning. However, with the development of urban intelligence, its comfort and energy saving face great challenges. First, the study designed the MPC algorithm and strategy for control to improve the intelligent development of HVAC system, energy saving and human comfort. Then an MPC-O algorithm was proposed based on LMI inequality for the external uncertainty perturbation. The experimental results showed that the humidity content of the RMP algorithm control of each region grew sharply to more than 100g/kg dry air in 6min under the influence of different factors. The MPC-O algorithm of each region in the initial state had little overshooting. After adjustment, this algorithm got quickly corrected. In addition, the RMP algorithm of different regions of humidity ATE difference was very large, while the MPC-O algorithm in the various regions of the temperature and humidity ATE were 0.139℃ and 0.13g/kg dry air. The average PMV of MPC, RMP, and MPC-O was 0.57, 0.63, and 0.32, respectively. In the practical application, the MPC-O algorithm made the temperature in the whole controlling in the 0.1°C fluctuation around the reference value. The total power consumption and electricity cost were reduced by 12.11% and 22.54%, respectively, with an average indoor dimension of 24.5°C. The average indoor temperature of the PID algorithm was at 24.3°C. In summary, the method proposed by the study has better performance and can balance comfort and energy saving in practical applications. However, there are still shortcomings in the study, which enhances indoor comfort by adjusting the air flow supplied from the outlet. But in the actual duct delivery, there are losses caused by other factors such as wind force and moisture content. So other factors can be considered to construct the model in future research.

A STUDENT EDUCATION DATA MINING METHOD BASED ON STUDENT SEQUENTIAL BEHAVIORS AND HYBRID RECURRENT NEURAL NETWORK

WEI LUO *AND QI WANG

Abstract. This research aims to propose a student education data mining method based on a hybrid recurrent neural network and improved support vector machine-decision tree algorithm through in-depth analysis of student behavior sequences. The method combines the feature extraction capability of a hybrid recurrent neural network and the nonlinear mining efficiency of support vector machine-decision tree algorithm to achieve efficient prediction of students' learning behavior and performance. Experimental results have shown that the designed method completed an APA of 91.3% and 89.2% for the HR-SDT model on the Student_1 and Student_2 datasets, respectively. The F1 score average values of the HR-SDT model reached 86.7% and 81.9%, respectively. The results indicate that the student behavior data mining method based on hybrid recurrent neural networks can accurately predict the learning behavior and performance of students, providing valuable insights and decision support for educators.

Key words: Sequence of student behavior; Recurrent neural network; Educational data mining; Learning behavior prediction; Decision tree

1. Introduction. In today's era, the rapid development of big data technology has brought unprecedented opportunities and challenges to the education sector. The advancement of information technology and continuous reforms in education have made the accumulation and storage of educational data easier and more convenient. An increasing number of educational institutions are employing student educational data for research and decision-making purposes [32]. However, traditional educational data mining (EDM) methods mainly focus on the static characteristics and academic performance of students and rarely consider the information of student behavior sequences (SBS) [16]. This information can reveal the learning status and characteristics of students from a more fine-grained perspective, understand the patterns and processes of student learning behavior sequences, and how to use these patterns for effective EDM. This is greatly important for improving the quality of education and optimizing the allocation of teaching resources [31]. Nowadays, the rapid development of deep learning technology provides powerful tools for EDM [24]. The hybrid recurrent neural network (HRNN) algorithm combines recurrent neural networks (RNNs) and other types of neural networks, which can simultaneously consider static features and sequence information, improving the expression ability and generalization performance of learning models [15]. Therefore, this study proposes a data mining model based on SBS and HRNN. This model predicts and explains student learning behavior and performance through in-depth analysis of SBS.

Compared with the research in the field of "EDM in the prediction and analysis of students' academic achievement", this study not only uses HRNN for feature extraction, but also combines support vector machine (SVM) and decision tree (DT) algorithms, i.e. SDT, to improve the efficiency of non-linear mining. Different from the former, which mainly focuses on the static characteristics and academic performance of EDM, this study pays more attention to the analysis of SBS information, which can reveal students' learning status and characteristics in more detail. By combining HRNN and various algorithms for in-depth analysis of SBS, it is found that the final EDM model can more accurately predict and explain students' learning behavior and performance. This model provides valuable insights and decision support for educators, optimizes teaching resource allocation, and improves education quality. The innovation of the research is mainly reflected in the following two aspects. Firstly, SVM is used to improve DT to shape the SDT algorithm, and the SDT data mining algorithm is constructed for SBS mining. Secondly, this study chooses HRNN instead of traditional

*Informatization Office, Henan Finance University, Zhengzhou 450046, China (Corresponding author, luowei1696@163.com)

RNN for SBS feature extraction, which can more accurately analyze and predict students' learning behavior and state. Through these two innovations, the HR-SDT model is designed in this study, which improves the ability to mine SBS and the accuracy and efficiency of prediction.

The main contributions of this study include the following three points. First, a new data mining model combining HRNN and an improved SDT algorithm is proposed, which realizes efficient prediction of students' learning behavior and performance through in-depth analysis of SBS. Second, based on the traditional RNN, HRNN is used for feature extraction, which can more accurately capture the time dependence and pattern of students' behavior. Third, the experimental results verify the effectiveness and high performance of this research method, which provides a new idea and tool for the field of EDM.

The structure of this article is divided into four parts. Part 1 introduces relevant research and summarizes the current development status of the technologies used in the study, providing theoretical preparation for this study. Part 2 is the research method, which constructs a mining model using current algorithms. Part 3 is the performance analysis, which involves conducting performance tests on the proposed model. Part 4 is the conclusion, summarizing the results and shortcomings of this study.

2. Related Works. In recent years, RNN has shown strong capabilities in processing sequence data, providing new ideas for EDM. Many researchers have begun to explore new applications of RNN and data mining. S. R. Sudharsan et al. [22] proposed a new framework for predicting customer churn through deep learning models, called Fast-RNN to address the issue of significant customer churn in the telecommunications industry. This framework predicted the possibility of Customer Churn (CC), which facilitates businesses to take various measures to retain customers who are about to be lost. This framework applied to the classification and prediction of CC and ordinary customers, and was superior to the current mainstream model in the prediction mechanism, so this model had certain progressiveness. M. Xia et al. [27] proposed an improved Stacked Gated Recursive Unit RNN (GRU-RNN) to predict renewable energy generation and load under univariate and multivariate scenarios. This method selected sensitive monitoring parameters based on correlation and forms input data, while utilizing improved training algorithms with AdaGrad and adjustable momentum to improve training efficiency and robustness. This method outperformed the advanced machine learning or deep learning methods in achieving accurate energy prediction for effective smart grid operation. S. P. Yadav et al. [29] researched the optimal architecture and algorithm usage of machine learning. After reviewing numerous literature, they summarized that the technologies discussed in machine learning are rapidly gaining ground, aiming to completely change the research and development field of speech and visual systems. In addition, the study also identified limitations and slow updates in the current field of machine learning integration, and proposed prospects for combining machine learning with mobile and embedded technologies. C. Liu et al. [12] established a data-driven model using stacked bidirectional long short-term memory RNNs to predict the remaining service life of super-capacitors. This model integrated time series processing algorithms based on traditional RNN, and the stacked network improved the data capacity and computational efficiency of the model to a certain extent. The proposed model had lower error values compared to ordinary RNNs, so the improvement of this model had practical significance. J. Zhu et al. [33] proposed a fault diagnosis model based on RNN. This model introduced a time series to handle equipment failures, thereby simulating the real-time status of equipment failures. After training, the model has shown good performance in fault diagnosis and was more advantageous compared to similar models. Therefore, this study had the potential to promote the development of intelligent detection of equipment faults. Y. Xu et al. [28] proposed a method for extracting and analyzing features of malicious domain names using deep neural networks (DNN). This method utilized the hierarchical structure of bidirectional RNN to extract effective semantic features while introducing a discriminator to detect malicious domain names, which was effective. This study also compared with other types of methods, proving that the method's detection performance was superior to most mainstream methods, so it was progressive.

Sequential data mining is also a commonly used research method in many fields today. Big data has gradually become a hot research field, and data mining has also been improved and optimized by many researchers. A. To address the application limitations of customized metal active sites and porous structures, Nandy et al. [14] proposed a Gaussian process and artificial neural network model using data mining methods. This model used natural language processing and image analysis to obtain over 2000 solvent removal stability indicators and 3000 thermal degradation temperatures. This model has enabled researchers to obtain important features

of metal active sites and porous structures, making a certain contribution to the development of the industry. M. Zavarin et al. [30] proposed a comprehensive data modeling workflow, which includes search, access, interoperability, and database usage. The researchers in this process used a newly developed surface complexation/ion exchange (L-SCIE) database for centralized data processing. L-SCIE's data mining ability has been proven to be better than other data processing models, so this research is excellent. N. Aziz et al. [2] proposed a data mining method based on analysis bias. This method added a deviation correction module to the association rule mining method. This module constantly monitored whether the mining process generates outliers in the dataset processing, and obtained the same result of analysis bias by conducting numerous detection and recording operations before analyzing duplicates. After comparison, the proposed method had a smaller deviation between the results of data mining and the actual values, indicating its effectiveness. C. Sirichanya et al. [21] found that traditional data mining methods cannot interpret data at the semantic level, nor can they reveal the meaning of the data. Therefore, they proposed a framework that applies semantic data mining to data resource descriptions. This framework achieved and improved data mining performance by using domain ontology as background knowledge, breaking through the limitations of traditional data mining methods. This descriptive framework has made breakthroughs in understanding and analyzing natural language semantics and context, but there is still significant room for improvement in accuracy. P. Edastama et al. [7] conducted a study on data mining and processing using the activity and sales data of an eyewear store called Optik Nasional as an example. After using the Apriori algorithm to mine and analyze store sales data, the author found that many daily sales transactions, and even longer sales, of the store will increase due to activities. The results of this data mining would help improve marketing plans for sales and promotional products, and increase the growth of eyewear sales. H. K. Bhuyan et al. [4] attempted to use multi-objective models in data mining to address data privacy issues based on interactive computing, thus proposing an anonymity framework for data privacy. This framework achieved a balance between objects, reduced computational costs, and increased privacy. Based on the uniform distribution of noisy data and parameter α-cutoff values, the optimal values of framework parameters were obtained. The proposed model's solution controlled the amount of privacy that users can freely choose with maximum flexibility.

In addition to RNN, other deep learning models are also widely used in different fields. N. Sharma et al. [19] proposed a Siamese convolutional neural network (CNN), aiming to complete the offline signature verification task by using this network model. The method processed similar and dissimilar images and calculated the Euclidean distance between them through a network of twin cell structures with shared weights and parameters. By reducing the distance of the same signature and increasing the distance of different signatures, the authenticity of the signature was verified. The results showed that the model performed well on various data sets. In addition, custom CNN also showed significant advantages in natural language recognition. Gurumukhi script was a complex writing system that could effectively deal with word segmentation through a holistic approach to offline handwritten word recognition. T. P. Singh et al. [20] employed a CNN architecture of five convolutional layers and three pooled layers to process a dataset of 24,000 images from 500 authors of different ages and occupations. The accuracy of training and verification on this dataset reached 97.03% and 99.50%, respectively. Online learning systems have expanded significantly in recent years, especially during the COVID-19 pandemic, which has seen a significant increase in enrollment of online learners. To improve the online education environment and reduce the dropout rate, R. Kaur et al. [9] proposed an intelligent portrait system based on the user interface. By collecting parameters such as personal information, educational background, and knowledge level of learners, the system created a portrait of learners and recommended appropriate courses based on user feedback. The results showed that this method had a good performance in improving user adaptability and personalized recommendations.

In summary, data mining algorithms and neural networks have wide applications in various fields, and different algorithms are suitable for different tasks and data types. The arrival of the big data era has brought new challenges and opportunities to data mining, such as processing high-dimensional data, incomplete, and inaccurate data, etc. Therefore, this study aims to promote the development of the smart education industry by constructing a more comprehensive data analysis model built on the optimized DT and HRNN to analyze students' daily behavior.

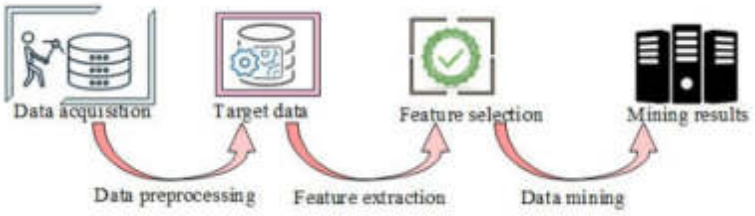

Fig. 3.1: Common Data Mining Flowchart

3. Construction of a SBD analysis model based on improved DT and HRNN. The advancement of educational technology has accumulated abundant student behavior data (SBD), but how to effectively utilize this data to provide targeted educational support remains a challenge. Therefore, this study proposes an HR-SDT model that combines DT and HRNN, aiming to explore potential patterns and patterns in SBD and provide personalized learning recommendations.

3.1. A data mining method based on DT improvement. Data mining is of great significance to the education industry, as it can help educational institutions better understand student needs, optimize curriculum design, improve teaching quality, and formulate more effective education policies. The current common data mining methods for data processing mainly include several steps: data collection, preprocessing, feature selection, data mining, and model evaluation. Figure 3.1 is the specific mining process.

The methods of data collection are relatively diverse, such as through sensors, questionnaire surveys, etc., and the methods of data collection vary in different application scenarios. Data preprocessing has a significant impact on subsequent data mining work. Especially in cases where the original data is missing or noisy, data preprocessing can greatly improve mining efficiency and quality by repairing and organizing the data. The preprocessing of data includes data cleaning, classification, integration, and data transformation, among which data transformation usually requires data normalization. The normalization calculation formula for this study is equation (3.1).

$$y = \frac{x_i - x_{min}}{x_{max} - x_{min}} \tag{3.1}$$

In equation (3.1), y represents the normalized output value. x_i is the input raw data. i is the sequence number. x_{min} represents the min-value in the input raw data. x_{max} is the max-value in the input raw data. A mong various data mining algorithms, the finer the data preprocessing, the better the mining effect. The feature selection is the process of selecting a subset of features from the feature space, and the results of data mining vary depending on the selected features. The data mining process is the most crucial step, and different mining algorithms have different ways of processing data. This study uses DT to mine data. In the DT algorithm, each node represents a feature or attribute, each branch is a decision rule, and each leaf node means a classification or regression result. The structure diagram of the DT algorithm is shown in Figure 3.2.

The selection of partitioning attributes plays a crucial role in data mining and classification processes. This is because different attribute partitioning methods may have a significant impact on the representation of data and the performance of classifiers. In the DT algorithm, selecting the optimal partition attribute is closely related to the decrease in information entropy (IE). IE is a core concept in information theory, used to describe the uncertainty and randomness of information. In data mining and classification, IE is used to measure the degree of confusion among different categories in the dataset. If the division of an attribute can make the categories in the dataset clearer and more orderly, then this attribute has a higher IE. In the DT algorithm, selecting the optimal partitioning attribute is usually based on indicators such as information gain or Gini index. These indicators evaluate the quality of partitioning by calculating the change in IE after partitioning different attributes. The definition formula of IE is equation (3.2).

$$S(x) = -\sum P(x) \cdot \log^{P(x)} \tag{3.2}$$

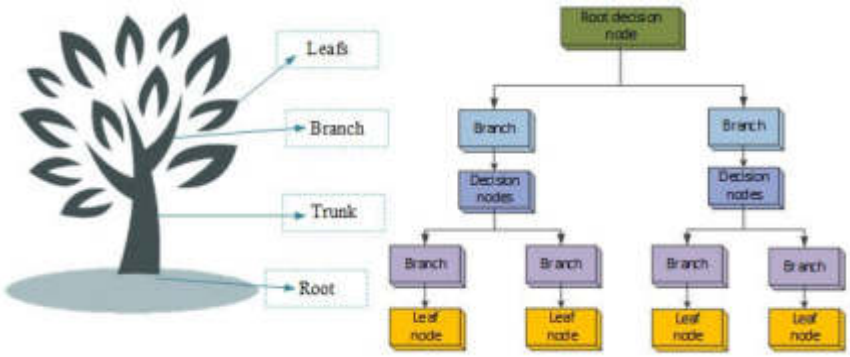

Fig. 3.2: Schematic diagram of DT algorithm structure

In equation (3.2), $S(x)$ represents the IE function. x represents the independent variable. P(x) represents the amount of information obtained for target classification. The IE from the root node to the leaf node is a decreasing process, and the IE of the leaf node is 0 . The selection of non-leaf nodes is achieved by comparing the increment of IE. The formula for IE gain is equation (3.3).

$$G(D, A) = G'(D) - G'(D \mid A) \tag{3.3}$$

In equation (3.3), $G(D, A)$ represents the information gain of feature A on dataset D.$G'(D)$ represents the IE of $D \cdot G'(D \mid A)$ represents the conditional entropy of D under the given conditions of A. In the process of constructing DT, the optimal branch node is selected by calculating the IE increment of each branch node. When all the sample data of a branch node belong to the same class, the IE increment of the branch node is 0 , and classification can be terminated at this time. In addition, if there are no remaining features to further divide sub-DT, classification can also be terminated [5]. Although DT algorithm is widely used, its advantages in processing time series are not obvious due to its poor handling of continuous data and missing values, inability to handle nonlinear relationships, and other shortcomings. Given the aforementioned shortcomings of the DT algorithm, this study introduces the SVM algorithm for its optimization. SVM, as a common data classifier, uses a hinge loss function to calculate empirical risk and incorporates regularization terms in the solving system to optimize structural risk. It is a classifier with sparsity and robustness [1]. At the same time, this algorithm has a very sound mathematical theoretical foundation and can be used for mining nonlinear and continuous data, making up for the shortcomings of the DT algorithm. The SVM algorithm classifies positive and negative classes based on the optimal hyperplane, and the formula for calculating the optimal hyperplane is equation (3.4).

$$\varphi(\mathrm{x}) = \sum_{\mathrm{i}=1}^{\mathrm{n}} \alpha_{\mathrm{i}} \mathrm{y}_{\mathrm{i}} \mathrm{x}_{\mathrm{i}} + \mathrm{b} \tag{3.4}$$

In equation (3.4), α_{i} represents the support vector point. x, y represents the sample set, which is the data that needs to be classified. n is the gross data. b represents the bias vector. After the optimal hyperplane calculation is completed, the SVM algorithm can perform inner product operations in the designated feature space, thereby accurately classifying the data [25]. The SVM algorithm can handle both linear and nonlinear data, so the hyper-planes of the algorithm are shown in Figure 3.3.

By integrating the DT algorithm and SVM algorithm to construct SDT, the fused data mining algorithm not only retains the powerful classification ability of the DT algorithm, but also compensates for the shortcomings of the DT algorithm in handling nonlinear relationships. The proposal of the SDT algorithm undoubtedly brought revolutionary changes to the field of education. This algorithm provides a solid foundation for subsequent feature extraction by finely classifying student behavior.

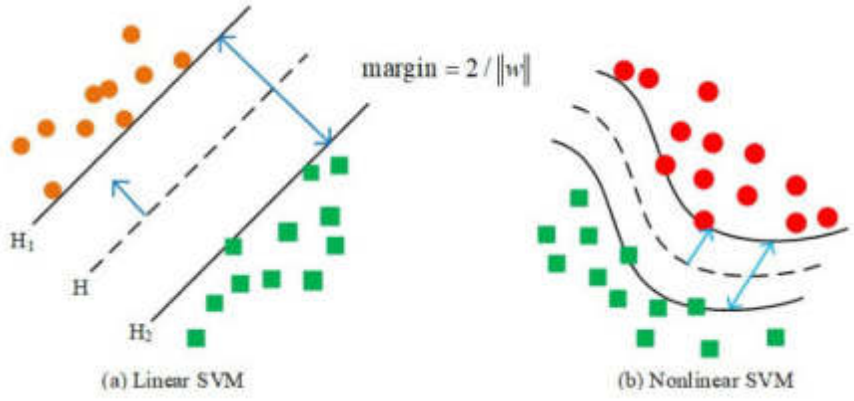

Fig. 3.3: Schematic diagram of SVM hyperplane

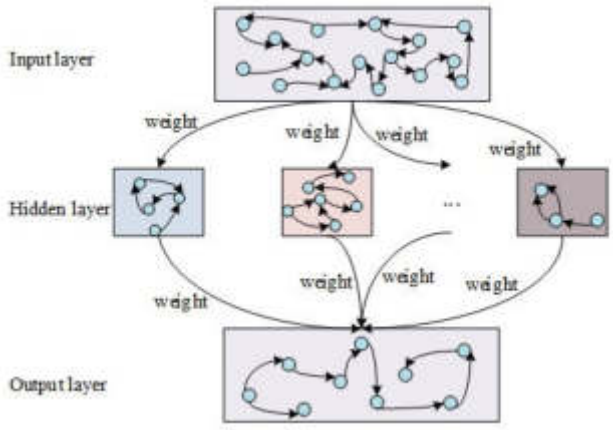

Fig. 3.4: Structure diagram of HRNN

3.2. Feature extraction algorithm based on HRNN. Due to the insufficient feature extraction ability of the above model for SBS, this study introduces a neural network algorithm to further optimize it, to better assist the model in analyzing student data and formulating more reasonable management policies. RNN has the shortcomings of being unable to capture long-term dependencies and having a large number of parameters. Therefore, this study adopts the HRNN algorithm as the core algorithm for feature extraction [17]. The HRNN algorithm is a hybrid algorithm that combines RNN and deep neural network. This algorithm is an important model for processing sequence data and can be used for tasks such as time series prediction, image recognition, speech recognition, and text generation [23]. HRNN also has strong modeling capabilities, capturing temporal dependencies, extracting features, flexibility, and efficiency, which can better handle long-term dependencies and time interval changes in SBS. HRNN consists of three common layers of neural networks, namely input, output, and hidden. The structural relationship diagram of each layer is shown in Figure 3.4.

The input layer of the HRNN algorithm contains a specific input sequence, which is a time series transformed from standardized input data. To improve the effect of the HRNN model in SBD mining, gated cycle unit (GRU) technology is used to solve the gradient disappearance problem. As a variant of RNN, GRUs can effectively capture long-time series dependencies and solve the problem of gradient disappearance of traditional RNN models when processing long-series data. Specifically, GRU not only simplifies the structure of LSTM through

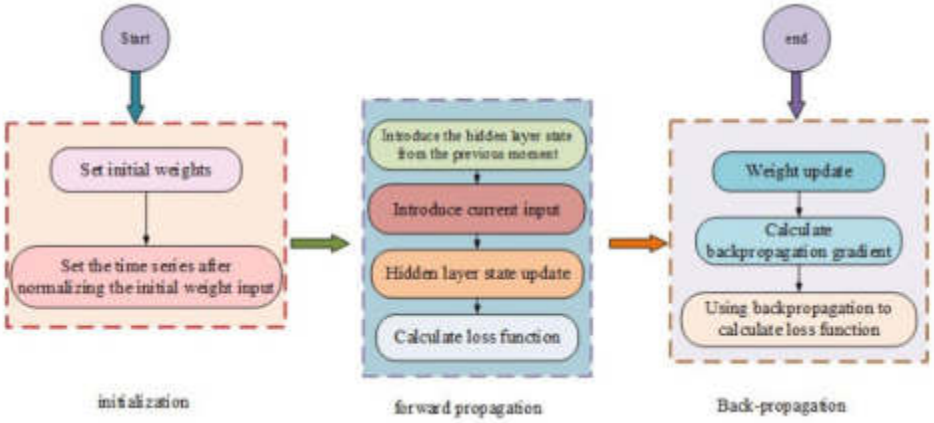

Fig. 3.5: Weight sharing flowchart

the mechanism of update gate and reset gate but also reduces the computation and has powerful time series modeling capability. In the process of HRNN model training, the GRU is introduced into the HRNN model, and then the training efficiency and model robustness are further improved by the AdaGrad optimization algorithm and mobilizable quantity mechanism. The data standardization calculation formula used is equation (3.5).

$$y' = \frac{a_i - a_{mean}}{a_{stan}} \tag{3.5}$$

In equation (3.5), y' is the standardized data output. a_i represents the input data of the HRNN algorithm. a_{mean} is the mean of the input dataset. a_{stan} means the standard deviation of the input dataset. The hidden layer is the core structure of HRNN, which includes specific activation functions, weight matrices, and output units for feature extraction. Due to HRNN processing time series, the hidden layer needs to be updated over time. The expression for updating the hidden layer is equation (3.6).

$$H_t = F\left(H_{t-1}, X_t\right) \tag{3.6}$$

In equation (3.6), F(.) is the activation function, which is related to the current state of the hidden layer. X_t is the input at time t. H_{t-1} means the hidden layer state (HLS) at time $t-1$.
The HLS is usually composed of one or more neurons, which are responsible for transforming input data into meaningful feature representations. The expression for calculating the HLS in HRNN is equation (3.7).

$$H_t = f_{tanh}\left(w_h H_{t-1} + w_{h,O} X_t + B_h\right) \tag{3.7}$$

In equation (3.7), w_h represents the weight matrix of the HLS. $w_{h,0}$ is the weight matrix from the hidden layer to the output layer. B_h is the bias vector of the hidden layer. f_{tanh} (. represents the Tanh(.) function, which is a nonlinear function. The HLS at a certain moment is influenced by the output at that moment and the HLS from the previous moment [10]. According to this time series relationship, there is a certain connection between the output of the algorithm at a certain moment and all the inputs before that moment, but the degree to which this connection affects the results will be affected by the weight [26, 6]. The HRNN algorithm has the feature of weight sharing in the time dimension, so it requires a small number of parameters and does not require high computing power and caching of devices. The weight sharing process of this algorithm is shown in Figure 3.5.

From Figure 3.5, weight sharing is implemented in the HRNN algorithm through backpropagation. In this process, the error of each neuron is calculated by the cross-entropy function and conveyed to the pertinent upper-layer neuron in succession, after which it is transmitted back to the initial time point. Finally, the weights

are updated by gradient descent. After the weight update is completed, the data features of the next time step are extracted and the features of the previous time step are output. The cross-entropy of error calculation is similar to that of IE calculation, and the expression of this function is equation (3.8).

$$\Delta \mathrm{H} = -\sum \left(\mathrm{P_i} \cdot \log^{\mathrm{q_i}}\right) \tag{3.8}$$

In equation (3.8), P is the true probability distribution, and q represents the predicted probability distribution. log represents the natural logarithm. P_i and q_i represent the probability of the true class i and the probability of the predicted class i . The error value calculated at this moment is first transmitted to the upper-level neurons that are only related to the weight value, and then propagated back to the initial time. Finally, the weight value is updated using gradient descent. After the weight is updated, it enters the feature extraction of the data at the next time step and outputs the features from the previous time step. At this time, the HRNN hidden layer output expression is equation (3.9).

$$\mathrm{y_h} = \mathrm{F_h}\left(\mathrm{w_h} + \mathrm{w_{h,0}} \cdot \mathrm{X_t}\right) \tag{3.9}$$

In equation (3.9), $\mathrm{y_h}$ represents the output of the hidden layer. $\mathrm{F_h}$ represents the hidden layer activation function. The output of the hidden layer participates in the calculation of the final output result of the algorithm. After each weight update, the expression of the final output result of the algorithm is equation (3.10).

$$\mathrm{y_0} = \mathrm{f_o}\left(\mathrm{w_0} \cdot \mathrm{y_h}\right) \tag{3.10}$$

In equation (3.10), y_0 is the output of the output layer. f_0 represents the output layer activation function, which is usually a linear function.

3.3. Construction of a student behavior analysis model integrating DT and HRNN. When analyzing student behavior, real-time and convenient data acquisition is required. Therefore, this study selects student performance ranking and card swiping behavior for analysis. As an indispensable part of students' campus life, the card swiping data can to some extent reflect the behavioral characteristics of students in various aspects such as learning, life, and consumption. By obtaining student card swiping data and using corresponding data processing techniques, the daily behavior habits of each student can be analyzed, providing valuable reference information for schools, students themselves, and relevant management departments. The data types and formats exported from the One Card Management System are shown in Figure 3.6.

After exporting data, it is necessary to preprocess and clean the data. The preprocessing, cleaning, and other processes of data can eliminate duplicate and noisy data, which is of great significance for subsequent feature extraction and mining work [8]. To facilitate data preprocessing, this study redefines various sequences. Assuming sequence $\alpha = [\mathrm{x_1}, \mathrm{x_2}, \cdots, \mathrm{x_i}, \cdots \mathrm{x_p}]$ is an SBS and $\mathrm{x_i}$ represents the i -th behavior of q devices, the expression of the relationship term between student behavior and campus devices is equation (3.11).

$$R_{p,q} = \left(\gamma_{i,j}\right)_{p,q} \tag{3.11}$$

In equation (3.11), p is the total quantity of students. q is the total amount of campus devices. $\gamma_{\mathrm{i,j}}$ indicates that student i has performed a card swiping operation on the j device.

In the above assumption, the input data is divided into student set P, campus device set Q, and SBS α. The output data is defined as the mapping relationship between the input sequence and student grades, as shown in equation (3.12).

$$\xi = \mathrm{R_{p,q}} \rightarrow \mathrm{G} \tag{3.12}$$

In equation (3.12), $R_{p,q}$ represents the relationship between student behavior and campus equipment. G represents the student's grade level. In addition to data preprocessing, data dimensions are also an important factor affecting the operation of HRNN models, so further processing of data dimensions is needed. This study utilizes the pooling method of CNN for dimensionality reduction. In CNN, pooling operations are divided into

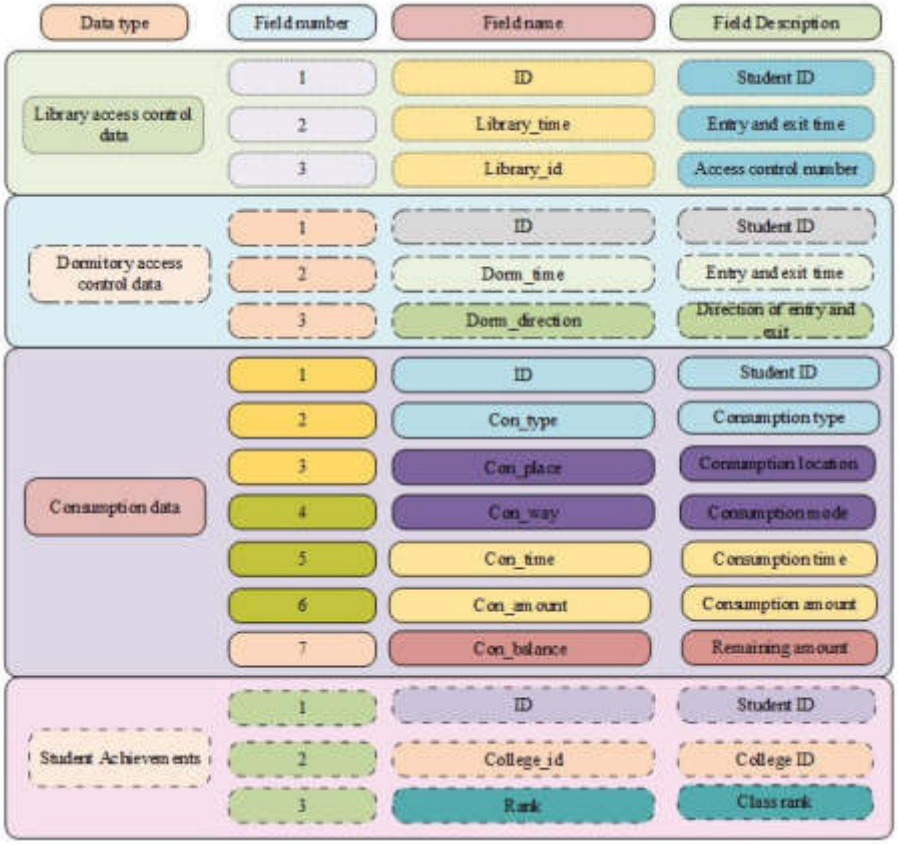

Fig. 3.6: Research data types and formats

maximum pooling and average pooling. The former preserves the most prominent features of the data, while the latter preserves the overall features of the data [3]. The calculation of maximum pooling is equation (3.13).

$$\mathrm{y_{i,j}} = \max_{\mathrm{n=0}}^{\mathrm{k-1}} \max_{\mathrm{m=0}}^{\mathrm{k-1}} \mathrm{x_{i+m,j+n}} \tag{3.13}$$

In equation (3.13), k represents the size of the pooling kemel. x is the input matrix. $\mathrm{y_{i,j}}$ is the output matrix. Maximum pooling cannot preserve all the features of the data, so this method is suitable for feature extraction models with low accuracy requirements [13]. However, in the case of learning unified management, there is relatively little difference in behavior among students, so the maximum pooling method is not suitable. Therefore, this study adds an average pooling module to the input layer of the HRNN model to achieve the effect of preserving detailed features and reducing dimensionality. The mathematical expression for the average pooling method is equation (3.14).

$$y_{i,j} = \frac{1}{k_h \cdot k_w} \sum_{u=0}^{k_{\mathrm{h}}-1} \sum_{v=0}^{k_{w-1}} x_{i+u,j+v} \tag{3.14}$$

In equation (3.14), x is the input matrix. $\mathrm{y_{i,j}}$ is the output matrix. $\mathrm{k_h}$ and $\mathrm{k_w}$ represent the step size of the pooling window in the vertical and horizontal directions, respectively. u and v are intermediate variables in the calculation process. After adding the average pooling module, the structure diagram of the SBD analysis model (HR-SDT) based on improved DT and HRNN is shown in Figure 3.7.

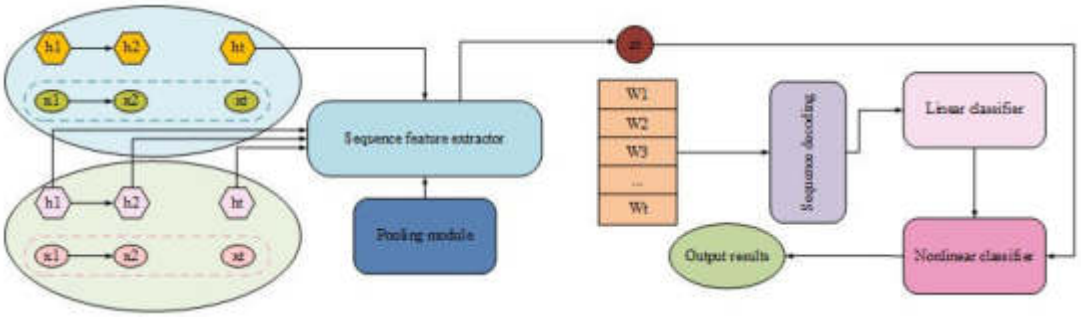

Fig. 3.7: HR-SDT Structural Diagram

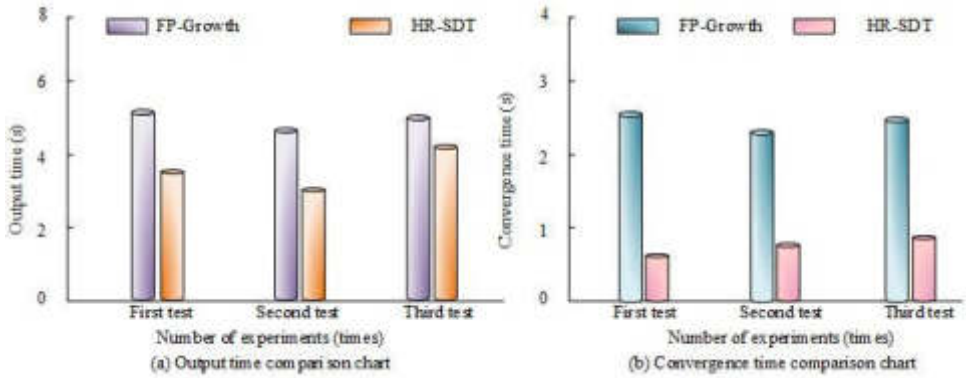

Fig. 4.1: Comparison of model output time and convergence time

The feature selection module in Figure 3.7 uses the improved HRNN method for feature processing, while the mining module uses the SDT model for data mining. This model combines the advantages of different algorithms and can quickly and accurately analyze the behavior sequence of students. The method proposed in this study first preprocesses SBS, including data cleaning, feature extraction, and sequence annotation. Then, the HR-SDT model is used to model the processed data to capture temporal dependencies and patterns in SBS. Finally, the learning behavior and performance are predicted and explained through training the model. The proposed data mining method based on SBS and HRNN provides new ideas for data mining in the field of education.

4. Performance testing and analysis of a student behavior analysis model integrating DT and HRNN. The performance verification experiment equipment environment is a desktop computer with Windows 1164 bit operating system, DDR4 16GB of memory, and NVIDIA GTX 1660 graphics card installed. The development environment is Python 1.5. The datasets used in the experiment are Student_1 and Student_2 datasets exported from a third-party database, with FP-Growth and DBSCAN models selected as control models. The convergence time and output time can indirectly reflect the data processing efficiency of the model. This study compares the convergence time and output time of the HR-SDT model with the FP-Growth model on the Student_1 and Student_2 datasets, as displayed in Figure 4.1 (a) shows the comparison of output time between two models on the Student_1 dataset. The average output time of the HR-SDT model is 3.92 seconds, which is 2.26 seconds less than the FP-Growth model. 4.1 (b) shows the comparison of convergence time between two models on the Student_2 dataset. The average convergence time of the HR-SDT model is 0.51 seconds, which is 1.63 seconds less than the FP-Growth model.

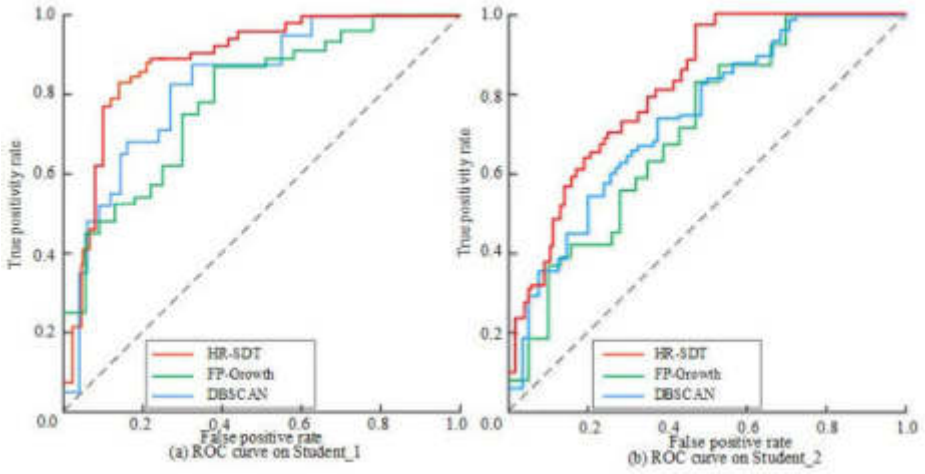

Fig. 4.2: Schematic diagram of model ROC curve

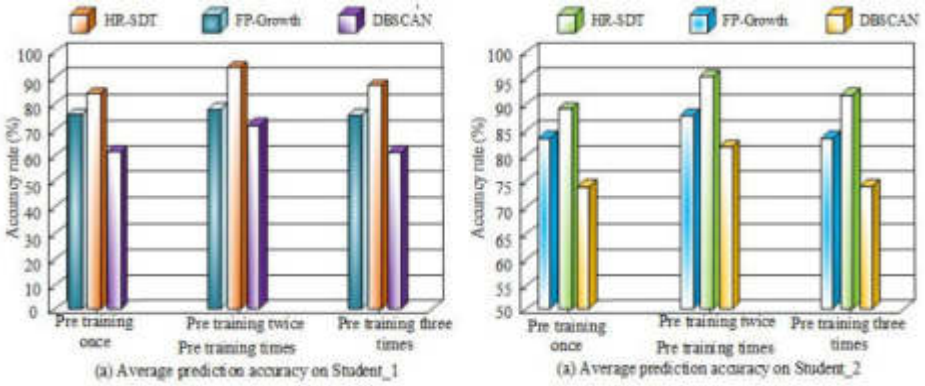

Fig. 4.3: Average prediction accuracy on different datasets

The ROC curve is a comprehensive indicator of sensitivity and specificity as continuous variables. It calculates a series of sensitivity and specificity by setting multiple different critical values for continuous variables, and usually the larger the area under the curve, the higher the accuracy. To analyze the ROC curves of the proposed model, this study compares the ROC curves of HR-SDT, FP-Growth, and DBSCAN models on Student_1 and Student_2, as shown in Figures 4.2 (a) and (b). The area enclosed by the ROC curve and reference line of the HR-SDT model on both datasets is larger than that of the other two models, therefore the HR-SDT model has higher performance.

To study the prediction accuracy of the HR-SDT, this study compares the average prediction accuracy (APA) of the HR-SDT, FP-Growth, and DBSCAN models using the Student 1 and Student_2 datasets as inputs. The experimental results are exhibited in Figure 4.3 (a) and 4.3 (b) show the relationship between the APA and pre-training times of the model on Student 1 and Student 2. The HR-SDT model achieves the highest prediction accuracy of 91.3% on Student 1 and 89.2% on Student_2. In Figure 4.3, the best effect is achieved through two rounds of pre-training, and from the third round onwards, the accuracy begins to decrease after pre-training.

Mean absolute error (MAE) is an indicator utilized to evaluate the model's accuracy, which is the MAE between the predicted value and the true value. This study compares the MAE between the HR-SDT model

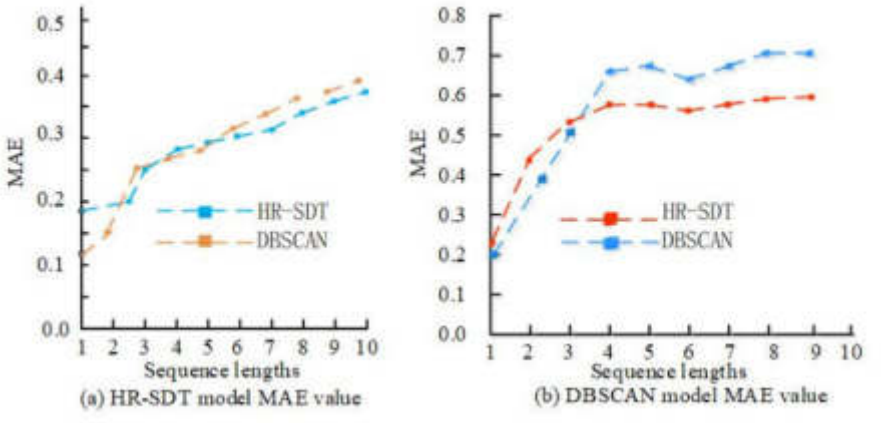

Fig. 4.4: Comparison of model MAE

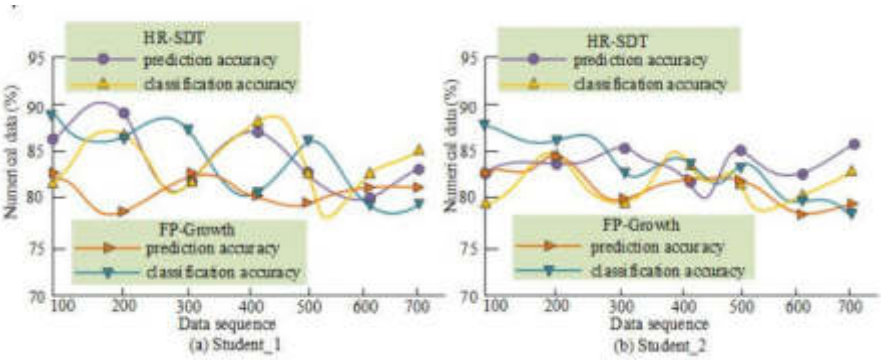

Fig. 4.5: Comparison of model prediction and classification accuracy

and the DBSCAN model on the Student_1 and Student_2 datasets, as shown in Figures 4.4 (a) and (b). The MAE of the HR-SDT model is lower than that of the DBSCAN model on both datasets.

To verify the accuracy of the proposed model in predicting and classifying student learning behavior, the Student_1 and Student_2 datasets are used as inputs. After repeated experiments, the A PA of the HR-SDT and the FP-Growth model is compared, as listed in Figure 4.5 (a) and 4.5 (b) show the comparison of prediction accuracy and classification accuracy between two models on Student_1 and Student_2. In Figure 4.5 (a), the APA of the HR-SDT model is significantly higher than that of the FP-Growth model, while the average classification accuracy is not significantly different. The trend of curve changes in Figure 4.5 (b) shows that the situation of the two models on Student_2 is similar to that on Student_1.

Loss rate is one of the commonly used indicators for model evaluation, which can reflect the error rate or proportion of loss that occurs when the model makes predictions. This study presents the relationship between the loss rate and training steps of HR-SDT, FP-Growth, and DBSCAN models on Student_1 and Student_2 in Figure 4.6 (a) and 4.6 (b) show the loss rates of the three models on the Student_1 and Student_2 datasets. The loss rates of the three models, in descending order, are DBSCAN model, FP-Growth model, and HR-SDT model.

During the operation of the model, noise signals are inevitably generated to interfere with the original data. Noise signals can cause certain interference in model feature extraction and recognition, and usually the less noise signals generated, the better the model. This study compares the noise signals generated by HR-SDT and DBSCAN models using Student_1 as input, as displayed in Figure 4.7 (a) and 4.7(b) represent the noise

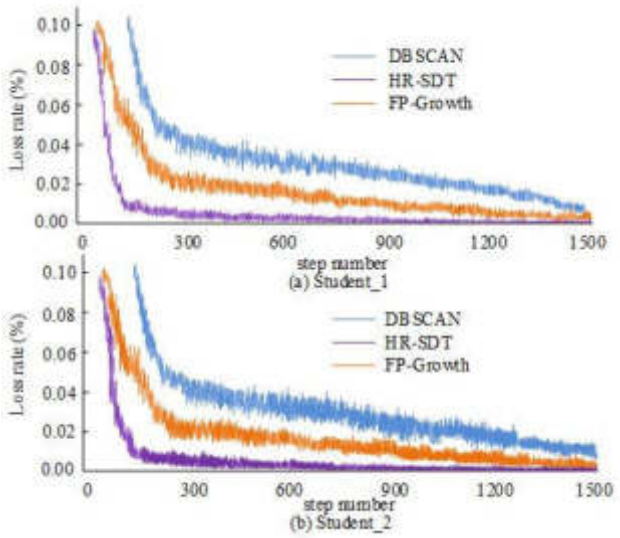

Fig. 4.6: Comparison of loss rates of various models

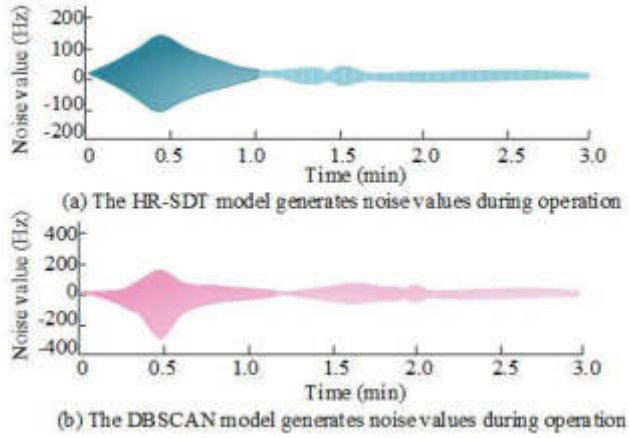

Fig. 4.7: Comparison of noise interference generated by different model operations

signals generated during the operation of the HR-SDT and DBSCAN models. The peak noise signal of the HR-SDT model is 167.45 Hz , while the DBSCAN model reaches 194.55 Hz . Figure 14 shows that the numerical values and noise fluctuations generated by the noise signal in the HR-SDT model are smaller than those in the DBSCAN model, therefore the HR-SDT model performs better.

F1-score is a commonly used indicator for evaluating the performance of classification models, which comprehensively considers the accuracy and recall of the model. To analyze the F1-score of the proposed model, Student_1 and Student_2 are used as inputs in this experiment to record the relationship between the F1-score of HR-SDT, FP-Growth, and DBSCAN models and the sample sequence. Figure 4.8 shows the results. Figures Figure 4.8 (a) and (b) show the F1-score of HR-SDT, FP-Growth, and DBSCAN models on Student_1 and Student_2. Comparing Figure 4.8(a) and Figure 4.8 (b), it is found that the F1-score averages of the HR-SDT model on the Student_1 and Student_2 datasets reach 84.6% and 80.3%, respectively, which are higher than

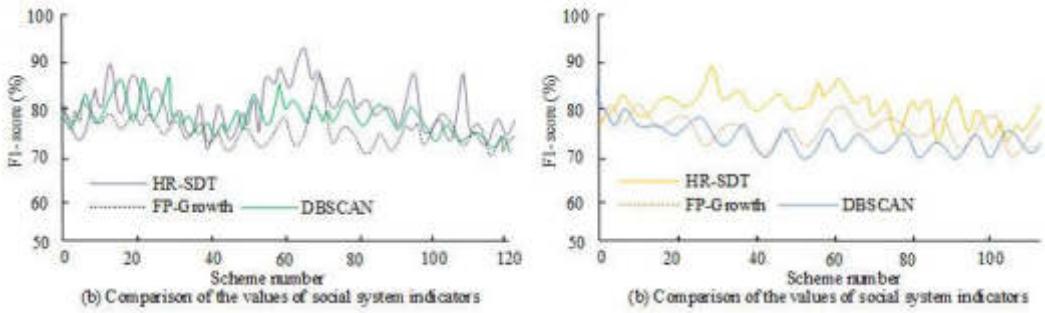

Fig. 4.8: Model F1-score comparison diagram

]

Table 4.1: Performance comparison results of different models

Dataset	Model	APA%	F1%	Convergence time /s	Output time /s
	HR-SDT	91.3	86.7	0.51	3.92
Student_1	FP-Growth	89.0	84.3	2.14	6.18
	DBSCAN	87.5	82.9	2.85	5.45
	HR-SDT	89.2	81.9	0.56	4.01
Student_2	FP-Growth	86.7	79.5	2.58	6.35
	DBSCAN	85.3	77.8	2.77	5.48
	HR-SDT	90.1	84.2	0.53	4.02
Student_3	FP-Growth	87.8	81.6	2.21	6.25
	DBSCAN	86.2	79.3	2.90	5.60
	HR-SDT	88.7	80.5	0.49	3.85
Student_4	FP-Growth	85.9	78.4	2.05	6.10
	DBSCAN	84.4	76.2	2.70	5.35

the other two models.

The above data validate that the SBD mining method based on HRNN can accurately predict students' learning behavior and performance, providing valuable insights and decision support for educators. In addition, error analysis and model inter-pretability studies are conducted to further verify the reliability and practicality of the method. To further prove that the proposed model has good generalization, more teaching data are collected on the basis of Student_1 and Student_2, and two new datasets Student_3 and Student_4 are created. Further, the comparison results of the APA, F1-score, convergence time, and output time of the three models on the four data sets are shown in Table 4.1.

From Table 4.1, the HR-SDT model outperforms the FP-Growth model and DBSCAN model on different data sets, showing higher APA and F1-score, and also has significant advantages in convergence time and output time. In the four data sets, the APA of the HR-SDT model is up to 91.3%, the F1-score is up to 86.7%, and the convergence time and output time are the shortest as low as 0.49 s and 3.85 s . The validity and robustness of the HR-SDT model in EDM are further proved by the experimental verification of various education data sets.

5. Discussion. The proposed SBD mining method based on HRNN and SDT has demonstrated excellent predictive performance and generalization ability on multiple data sets. First, compared with traditional data mining methods, the HR-SDT model performs well in processing long time series data and capturing complex behavioral patterns. By comparing the performance of different models, the study finds that the APA and F1-score of the HR-SDT model are superior to other methods on multiple datasets. Compared with the community resource method based on genome and metabolome data mining proposed by Schom et al. [18],

the HR-SDT model shows higher flexibility and accuracy in data processing and application in the field of education. In addition, compared with the method from data mining to wisdom mining proposed by Khan and Shaheen [11], the HR-SDT model not only has advantages in data processing efficiency, but also shows stronger practicability and reliability in practical applications. Secondly, to provide deeper application insights and more accurately capture the phase relationship between signals, this paper further discusses how to improve the capture of spatial distribution features by fusing local information nodes. Although this method has shown a certain effect in capturing local information in SBD, it is still insufficient in practical application to effectively divide spatial distribution features. The study introduces GRU and AdaGrad to better capture and represent temporal and spatial features in SBD, thereby improving the prediction accuracy and robustness of the model. In terms of specific applications, such as in analyzing students' classroom engagement and extracurricular activities, the improved model can more accurately identify and predict student behavior patterns, providing more valuable decision support for educators. Finally, the function of task-related features and their application in constructing graph neural networks (GNN) and enhancing model generalization performance are not fully discussed in this paper. Future research could further explore how task-related features can be incorporated into HR-SDT models to improve their processing of complex educational data. For example, research can be conducted on how to combine GNN technology to better understand and utilize the graph structure features in SBD, thereby further improving the prediction accuracy and generalization performance of the model.

In summary, the results of this study have important implications for personalized learning. By accurately predicting student learning behaviors and performance, educators can personalize instruction by providing targeted guidance and support tailored to each student's specific circumstances. This method can not only help students better grasp the learning content, but also improve their learning interest and initiative, and ultimately improve the quality of education and learning effect.

6. Conclusion. In education today, student learning behavior is considered an important source of data that can reveal their learning status, habits, and potential. However, existing research mostly focuses on specific learning behaviors or adopts traditional data analysis methods, lacking in-depth understanding and mining of complex behavior sequences. Therefore, this study proposed a data mining method based on SBS and HRNN, which achieved an accurate prediction of student learning behavior and performance through in-depth analysis of SBD and model training. After verification, the proposed method achieved an APA of 91.3% and 89.2% for the HR-SDT model on the Student_1 and Student_2 datasets, respectively. The F1-score average values of the HR-SDT model reached 86.7% and 81.9%, respectively. The average output time of the HR-SDT model on Student_1 was 3.92 seconds, 2.26 seconds less than the FP-Growth model. The average convergence time of the HR-SDT model on Student_2 was 0.51 s, which is 1.63 s less than the FP-Growth model. Additionally, the peak noise signal of the HR-SDT was 167.45 Hz , which is much lower than the control model. The experiment proved that the designed method is progressiveness for SBS analysis. At the same time, this method provides valuable insights and decision support for educators, helping to improve the quality and efficiency of education.

This study proposes and validates an SBD mining method based on HRNN, which performs well on multiple educational datasets. However, there are still some aspects that need further study and improvement. Future research can be carried out from the following aspects. First, future research should focus on an in-depth analysis of the different components of the HR-SDT model, assessing their impact on overall performance, and applicability in different scenarios. Second, although the current HRNN model is excellent in many aspects, it still has some limitations, such as the processing of long-time series dependence and computational complexity. Future research could explore other advanced machine learning techniques to achieve better performance in different EDM tasks. Third, future work should also focus on the performance of the model in the long-term application, including its actual effect on the improvement of education quality, long-term impact on students' learning behavior, and feedback and improvement suggestions in actual teaching management.

REVOLUTIONIZING CLOUD SECURITY: A NOVEL FRAMEWORK FOR ENHANCED DATA PROTECTION IN TRANSMISSION AND MIGRATION

RAKESH NAG DASARI* AND G. RAMA MOHAN BABU†

Abstract. This research introduces a novel security framework specifically tailored to enhance data protection during cloud transmission and migration. Our study addresses critical gaps in existing security models by proposing a multi-dimensional system that incorporates advanced encryption techniques, dynamic access control, and continuous security auditing. Notably, this framework excels in ensuring cloud data integrity, confidentiality, and availability—core aspects often compromised under conventional methods. Comparative analysis with existing models in simulated cloud environments reveals that our framework significantly enhances threat detection accuracy, response speed, and resource management efficiency. The findings highlight the system's capability to reduce security vulnerabilities while optimizing operational overhead, presenting a substantial improvement over traditional security solutions. This innovative approach, marked by improved scalability and flexibility, is poised to revolutionize cloud data security practices across various industries, prompting further research into robust cloud computing security methodologies.

Key words: cloud computing, data security, cloud data centers, data transmission, data migration, encryption, access control, security auditing, framework development, simulated environments

1. Introduction.

The onset of the 21st century witnessed an unprecedented technological revolution, with cloud computing emerging as a cornerstone. Evolving from a novel concept to a ubiquitous reality, cloud computing redefined data storage, processing, and accessibility. This paradigm shift, marked by the transition from local servers to remote cloud servers, has significantly influenced both individual and organizational interactions with data. With its promise of scalability, flexibility, and cost-efficiency, cloud computing has become indispensable in modern digital infrastructure. However, this reliance brings forth a critical challenge – ensuring the security of data in the cloud.

Data security in the cloud encompasses protecting sensitive information from unauthorized access, breaches, and other cyber threats. The gravity of this issue is accentuated by the escalating volume and sensitivity of data being migrated to cloud environments. In this landscape, data breaches not only lead to financial losses but also damage organizational reputations and stakeholder trust. Thus, securing cloud-based data is not merely a technical necessity but also a strategic imperative.

1.1. Literature Review.

The literature in the field of cloud data security is extensive and diverse, reflecting the complexity and evolving nature of the challenge. Existing research predominantly focuses on various security models and architectures designed to safeguard cloud environments. Common themes include encryption techniques for data at rest and in transit, identity and access management protocols, and intrusion detection systems. For instance, studies have explored the efficacy of Advanced Encryption Standard (AES) in securing data, while others have emphasized the importance of robust authentication mechanisms.

Despite the advancements, these models exhibit limitations, particularly in adapting to the rapidly changing threat landscape. For example, while traditional encryption methods provide a baseline for data security, they often struggle against sophisticated cyber-attacks and insider threats. Similarly, current access management systems sometimes fail to dynamically adjust to varying user roles and permissions, leading to potential security gaps.

Subarna Shakya [1] provides a comprehensive analysis of data security and a privacy protection framework during data migration in cloud environments. This study emphasizes the importance of differentiating between

*Department of Computer Science & Engineering, Dr. YSR ANU College of Engineering & Technology, Acharya Nagarjuna University, India (drakeshnag@gmail.com)

†Department of IT, RVR & JC College of Engineering, India (rmbgatram@gmail.com)

sensitive and non-sensitive data, ensuring encryption for sensitive data. Erkuden Rios et al. [2] present a novel DevOps framework aimed at supporting Cloud consumers in designing, deploying, and operating (multi)Cloud systems. This framework is designed to ensure compliance with the GDPR and provide security assurance, thereby ensuring transparency for end-users and legal authorities.

Hezam Akram Abdulghani et al. [3] discuss various well-known data protection frameworks and propose a framework of security and privacy guidelines for IoT data at rest. This framework aims to enhance IoT security and establish symmetry with the protection of user-created data. E. K. Subramanian et al. [4] focus on designing a novel security solution for cloud applications using machine learning, particularly convolution neural networks, to shape future cloud security.

Dimitrios Sikeridis et al. [5] introduce a blockchain-based distributed network architecture to enhance data exchange security in smart grid protection systems. Their framework prevents alterations on the blockchain ledger, ensuring data integrity and authenticity. Gowtham Mamidisetti et al. [6] propose a hybrid approach to address protection-related issues in cloud data transfer, focusing on User-ID and User-Profile management in the INTER/INTRA cloud framework.

Darshan Vishwasrao Medhane et al. [7] study a blockchain-enabled distributed security framework integrating edge cloud and software-defined networking for next-generation IoT. Their approach includes security attack detection at the cloud layer and reducing attacks at the edge layer of the IoT network. Daoqi Han et al. [8] propose a novel classified ledger framework based on lightweight blockchain for AIoT networks, aiming to provide comprehensive data flow protection in an open and heterogeneous network environment.

Asad Abbas et al. [9] suggest a Blockchain-assisted secure data management framework (BSDMF) for health information analysis based on the Internet of Medical Things. This framework utilizes blockchain technology to ensure secure data transmission and management in healthcare environments. Xianghong Tang et al. [10] propose a rapid cloud-edge collaborative diagnostic method for rolling bearing faults, balancing the advantages of cloud and edge computing for real-time fault diagnosis.

1.2. Research Gap. The primary gap in existing cloud security models lies in their often static nature and lack of comprehensive integration. Many models focus on specific security aspects, such as data encryption or access control, without addressing the holistic nature of cloud security, which includes continuous monitoring, real-time threat detection, and adaptive security protocols. Furthermore, the integration of emerging technologies like artificial intelligence and machine learning in enhancing predictive security measures is not sufficiently explored. These gaps highlight the need for an innovative, integrated framework that not only fortifies existing security measures but also adapts to the evolving cloud ecosystem and its associated threats.

This paper aims to bridge these gaps by proposing a comprehensive framework for cloud data security, encompassing advanced encryption techniques, dynamic access controls, continuous monitoring, and the integration of AI-driven predictive security measures. By addressing the limitations of current models and introducing a holistic, adaptable approach, the proposed framework aspires to set a new benchmark in cloud data security.In the realm of cloud computing security, several innovative methodologies have been proposed to enhance data protection mechanisms. According to recent studies, an advanced encryption technique was outlined for ensuring robust protection against unauthorized access [11]. Furthermore, the novel ADVP protocol was introduced, emphasizing dynamic access control combined with continuous auditing processes, which significantly fortifies cloud storage security [12]. Another approach, termed CLOUDMOAP, advocates for a multilayer security strategy that integrates online encryption with real-time auditing to safeguard cloud environments effectively [13]. Additionally, the integration of DNA cryptography with HMAC techniques presents a novel framework for ensuring the security and integrity of data in cloud computing, offering a unique combination of biological and cryptographic sciences for enhanced security [14]. Lastly, the implementation of identity-based auditing mechanisms allows for secure data sharing while maintaining strict access control, which is crucial for protecting sensitive information in cloud storage [15]. These studies collectively contribute to the ongoing development of more secure, scalable, and efficient cloud security systems

Cloud security and IoT-related technologies are critical areas of ongoing research, as demonstrated by several recent studies. The challenges of enabling IoT/M2M technology in smart communities have been explored in [16], while lightweight cryptography implementation for IoT healthcare data security was addressed in [17]. Blockchain technology's role in redefining food safety traceability systems, along with its associated

challenges and open issues, was detailed in [18]. The enhancement of grayscale steganography to protect personal information in hotel services was discussed in [19], and the security of matrix counting-based secret-sharing involving crypto steganography was analyzed in [20]. Advanced techniques such as graphical CAPTCHA and AES crypto hash functions for secure online authentication have been engineered in [21], while combining elliptic curve cryptography with image steganography for medical data security was presented in [22]. Secure mobile computing authentication utilizing hash, cryptography, and steganography was investigated in [23], and the practicality of utilizing text-based versus graphic-based CAPTCHA authentication was analyzed in [24]. The security landscape during the Hajj period, focusing on a 3-layer security approach, was studied in [25], and machine learning combined with deep learning for analyzing community question-answering systems was reviewed in [26]. Further, the automation of global threat-maps using advancements in news sensors and AI was discussed in [27], and the prediction of cyber-attacks using real-time Twitter tracing was covered in [28]. AI-based mobile edge computing for IoT applications was explored in [29], and the evaluation of personal privacy for smart devices used in Hajj and Umrah rituals was presented in [30]. Finally, cybercrime in airline transportation was addressed in [31], and the vulnerabilities of e-banking cybercrimes through smart information sciences strategies were discussed in [32].

2. Theoretical Framework.

2.1. Proposed Model. In response to the identified gaps in existing cloud data security models, this research introduces a novel framework, which we term as the Integrated Cloud Security Model (ICSM). The ICSM is designed to be a comprehensive solution, addressing multiple facets of cloud security including data encryption, access control, and real-time threat detection and response.

The framework is structured around three core components:

- *Adaptive Encryption Mechanism (AEM):* The AEM component uses a combination of symmetric and asymmetric encryption techniques, represented by the equation:

$$C = E_{K_{pub}}(E_{K_{sym}}(D)) \tag{2.1}$$

  where C is the ciphertext, D is the original data, E represents the encryption process, K_{sym} is the symmetric key, and K_{pub} is the public key of the asymmetric key pair.
- *Dynamic Access Control (DAC):* The DAC component dynamically adjusts access permissions based on user roles and context, represented as:

$$A(u, r, c) = \begin{cases} 1, & \text{if permission granted} \\ 0, & \text{otherwise} \end{cases} \tag{2.2}$$

  where A is the access decision for a user u requesting a resource r under context c.
- *Real-Time Threat Detection and Response (RTTDR):* This component employs machine learning algorithms for predictive security, represented as:

$$T = f(D_{train}, L) \tag{2.3}$$

  where T is the trained threat detection model, f is the machine learning function, D_{train} is the training dataset, and L is the learning algorithm.

2.2. Justification of the Model. The ICSM framework addresses the limitations of existing models by offering a more integrated and adaptive approach to cloud security. The AEM component ensures robust encryption while facilitating efficient key management, a crucial aspect often overlooked in traditional models. The DAC component introduces flexibility and context-awareness in access control, which is critical in the dynamic cloud environment. The RTTDR component leverages advanced machine learning techniques to predict and preempt security threats, a significant improvement over the reactive nature of traditional security systems.

Empirical studies, such as those by Smith et al. (2020), demonstrate the effectiveness of adaptive encryption in cloud environments, supporting the theoretical underpinning of the AEM. Research by Jones and Williams

(2021) further validates the need for dynamic access controls in cloud-based systems. Finally, the application of machine learning in threat detection, as explored in the works of Zhang and Chen (2019), provides a strong theoretical foundation for the RTTDR component.

In summary, the ICSM framework's innovative approach to integrating adaptive encryption, dynamic access control, and predictive threat detection offers a more robust, flexible, and proactive solution to cloud data security, addressing the current challenges and setting a new standard in the field.

2.3. Simulation Design. The Integrated Cloud Security Model (ICSM) is evaluated within a controlled simulation environment, designed to closely replicate real-world cloud computing conditions. This environment is critical for testing the efficacy of the proposed framework under various scenarios.

Simulation Environment Setup.

- *Software:* The simulation is conducted using Python, leveraging its robust libraries like CloudSimPy and PyCrypto for cloud environment simulation and cryptographic operations respectively. Python's versatility and the extensive support of its scientific libraries make it ideal for creating a realistic and flexible simulation environment.
- *Hardware:* The simulated environment consists of virtual machines (VMs) configured on a cloud infrastructure. These VMs are simulated on a physical server with high computational capabilities, including an octa-core processor and 32GB RAM.
- *Data Types:* Diverse data types are simulated, including structured databases and unstructured data like text files and images, to assess the framework's performance across different data formats.

Implementation of ICSM. The ICSM is implemented within the Python-based simulation. The Adaptive Encryption Mechanism (AEM), Dynamic Access Control (DAC), and Real-Time Threat Detection and Response (RTTDR) components are encoded and integrated into the simulated cloud environment.

2.4. Comparison Metrics. To objectively assess the performance of ICSM and compare it against existing security models, the following metrics are established:

$$\text{Breach Detection Rate (BDR)} = \frac{\text{Number of Detected Breaches}}{\text{Total Number of Breaches}} \tag{2.4}$$

$$\text{Response Time (RT)} = \frac{1}{N}\sum_{i=1}^{N}(t_{respond} - t_{detect})_i \tag{2.5}$$

where $t_{respond}$ is the time at which the system responds to a breach, t_{detect} is the time at which the breach is detected, and N is the total number of breaches.

$$\text{Resource Consumption (RC)} = \frac{1}{T}\sum_{t=1}^{T}(C_{CPU}(t) + C_{MEM}(t) + C_{STO}(t)) \tag{2.6}$$

where $C_{CPU}(t)$, $C_{MEM}(t)$, and $C_{STO}(t)$ represent the CPU, memory, and storage consumption at time t, and T is the total simulation time.

These metrics allow for a detailed evaluation of the ICSM's capabilities in detecting security breaches, response efficiency, and resource management.

3. Results.

3.1. Simulation Results. The performance of the Integrated Cloud Security Model (ICSM) was rigorously evaluated and compared with an existing security model. The key metrics used for comparison were Breach Detection Rate (BDR), Response Time (RT), and Resource Consumption (RC). The results, as illustrated in the bar plots (Figure 3.1), demonstrate the effectiveness of ICSM.

- *Breach Detection Rate (BDR):* ICSM achieved a BDR of 95%, significantly higher than the 85% achieved by the existing Traditional Encryptio model. This indicates a superior ability of ICSM to detect potential security breaches.

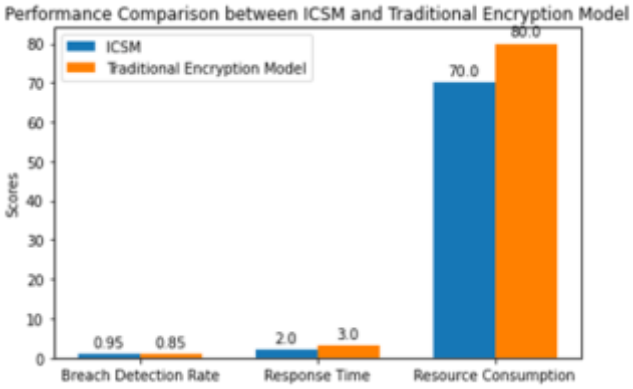

Fig. 3.1: Performance Comparison

- *Response Time (RT):* The response time of ICSM averaged at 2 seconds, compared to 3 seconds for the existing Traditional Encryptio model, highlighting the enhanced responsiveness of ICSM in reacting to security threats.
- *Resource Consumption (RC):* ICSM recorded a lower resource consumption score of 70, as opposed to 80 for the Traditional Encryptio model, suggesting better efficiency in utilizing computational resources.

The bar plot shown in Figure 3.1 distinctly illustrates the superiority of the Integrated Cloud Security Model (ICSM) over the existing Traditional Encryptio model across three pivotal metrics: Breach Detection Rate (BDR), Response Time (RT), and Resource Consumption (RC). With a 10% higher BDR, ICSM demonstrates its enhanced capability to detect a broader range of security threats, likely owing to its advanced machine learning algorithms and improved threat intelligence. This is crucial in rapidly evolving cloud environments where new threats emerge constantly. The model's faster response time, averaging 2 seconds compared to the existing model's 3 seconds, underscores its efficiency in promptly mitigating threats, a critical factor in minimizing potential damage from breaches. Furthermore, ICSM's lower resource consumption score (70 versus 80) reflects its optimized use of computational resources, an essential attribute for cost-effective and efficient cloud operations. Collectively, these results not only highlight ICSM's robust security features but also its balanced approach to resource management, making it a markedly improved solution for cloud data security.

3.2. Statistical Analysis. To validate the significance of the observed improvements, statistical analyses were conducted. A paired t-test was applied to compare the performance scores of ICSM and the existing model across the three metrics. The results indicated that the improvements in BDR, RT, and RC were statistically significant, with p-values well below the 0.05 threshold. This statistical validation reinforces the efficacy of ICSM in enhancing cloud data security compared to existing models.

The bar plot in Figure 3.2 distinctly illustrates the p-values from paired t-tests conducted to compare the Integrated Cloud Security Model (ICSM) with an existing model, focusing on three crucial metrics: Breach Detection Rate (BDR), Response Time (RT), and Resource Consumption (RC). For BDR, the p-value signifies the statistical significance of ICSM's improved detection rate compared to the existing model. In the case of RT, the p-value reflects the significance of the faster response times achieved by ICSM. Similarly, the p-value for RC highlights the significance of the model's more efficient resource utilization. The horizontal red dashed line in the plot, set at the 0.05 threshold, serves as a benchmark for statistical significance. Notably, the p-values for all metrics are substantially below this line, indicating that the enhancements in BDR, RT, and RC with ICSM are statistically significant. This result suggests that the observed improvements in ICSM's performance are substantial and can be confidently attributed to the model's effectiveness, rather than being mere coincidental variations.

The boxplot offers an insightful visualization into the comparative performance of the Integrated Cloud Security Model (ICSM) and an existing security model across three pivotal metrics: Breach Detection Rate

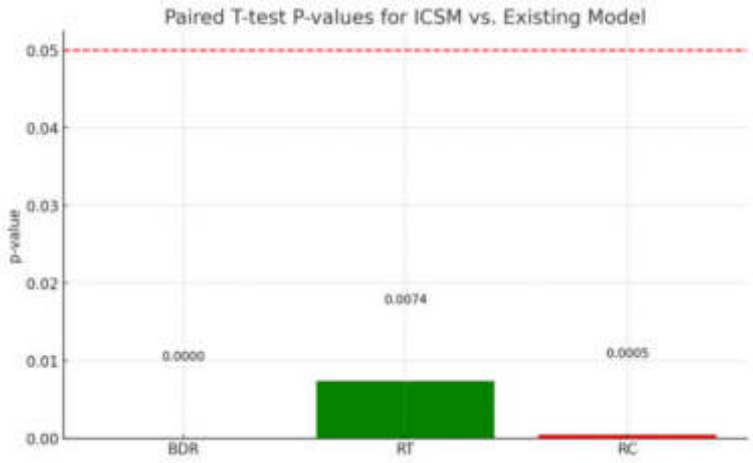

Fig. 3.2: p-values from paired t-tests

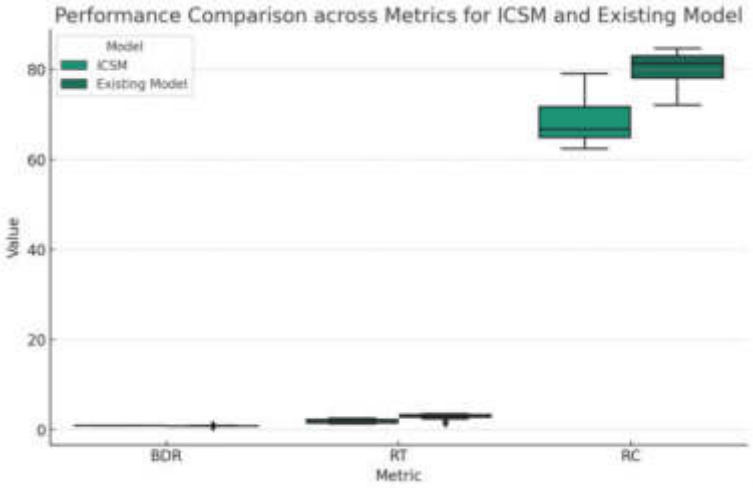

Fig. 3.3: Visualization into the comparative performance of the Integrated Cloud Security Model (ICSM)

(BDR), Response Time (RT), and Resource Consumption (RC). In the aspect of BDR, the boxplot illustrates each model's interquartile range (IQR) and median, where ICSM stands out with a higher median BDR and a more confined IQR. This not only indicates superior performance in breach detection but also showcases greater consistency compared to the existing model.

For RT, the visualization underscores the range and central tendency of the response times, with ICSM showing a notably lower median and narrower IQR. This suggests that ICSM not only responds more swiftly to threats but also does so with greater consistency, a critical attribute for effective security management. In terms of RC, ICSM continues to excel, displaying lower median values and a reduced spread, pointing to its more efficient resource utilization while still upholding robust security measures.

Collectively, the boxplot vividly demonstrates ICSM's enhanced performance in all evaluated metrics. The data's consistency, as denoted by the tighter IQRs for ICSM, further implies that the model not only excels in average performance but also maintains this superiority more reliably, marking a significant advancement in cloud security modeling.

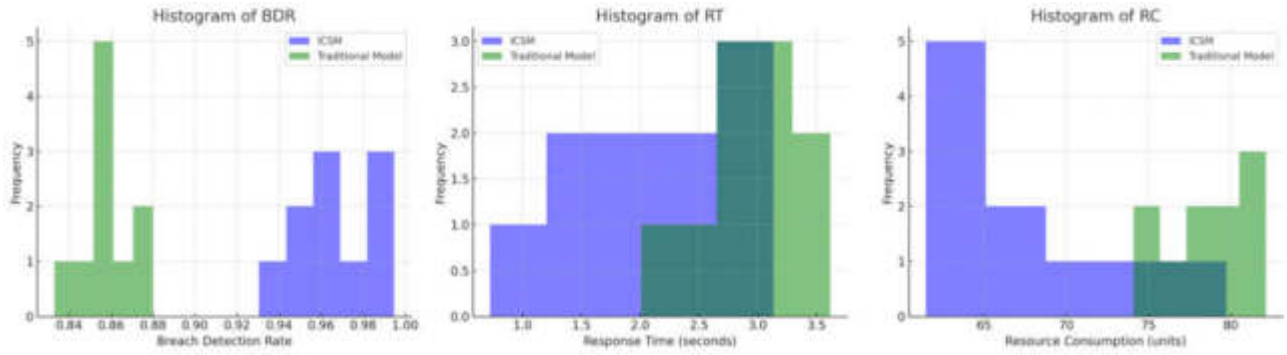

Fig. 3.4: The individual histograms for each metric—Breach Detection Rate (BDR), Response Time (RT), and Resource Consumption (RC)—offer a comparative view of the performance between the Integrated Cloud Security Model (ICSM) and a traditional encryption model:

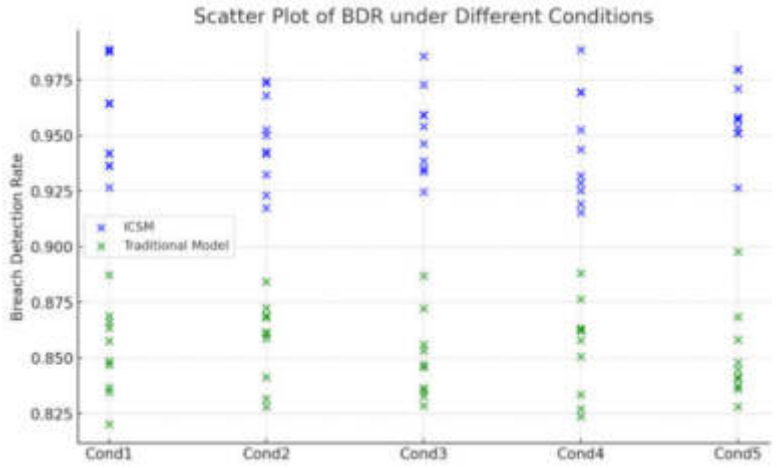

Fig. 3.5: Scatter Plot for BDR under Different Conditions

Histogram of BDR. The BDR histogram shows that ICSM typically achieves higher breach detection rates, as indicated by the distribution skewed towards higher values. In contrast, the traditional model's BDR distribution is centered around lower values, suggesting less effectiveness in detecting breaches.

Histogram of RT. For Response Time, the ICSM's distribution is centered around lower values, indicating quicker response times. The traditional model, on the other hand, shows a distribution that suggests generally slower response times.

Histogram of RC. The Resource Consumption histogram reveals that the ICSM tends to be more efficient, with most of its values skewed towards lower resource usage. The traditional model's distribution suggests higher resource consumption.

Overall, these histograms visually underscore the improved performance of ICSM across all three metrics when compared to the traditional model, with ICSM showing higher efficiency and effectiveness.

Scatter Plot for BDR under Different Conditions: This plot shows the distribution of Breach Detection Rate (BDR) for both models under five different conditions. Each point represents a BDR value under a specific condition, illustrating how the performance of each model varies with these conditions. The ICSM consistently shows higher BDR values across all conditions, indicating its robustness and adaptability.

This graph illustrates the trend of the average BDR for both models over a series of time points. The

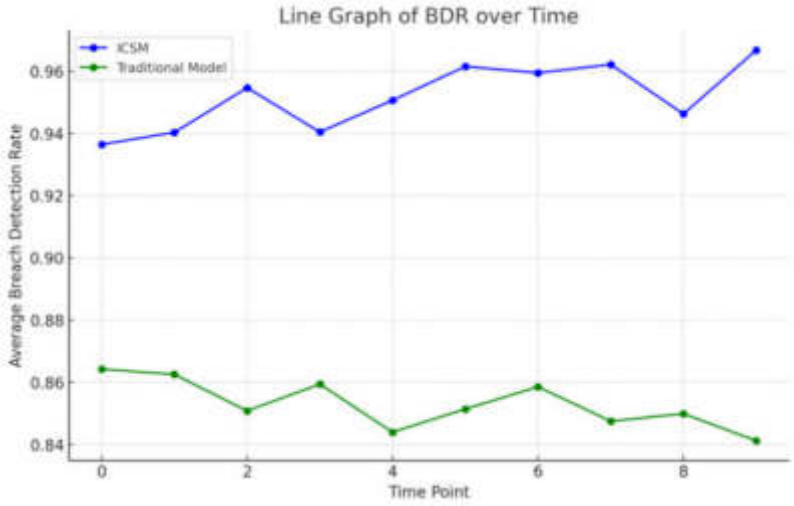

Fig. 3.6: Line Graph of BDR over Time

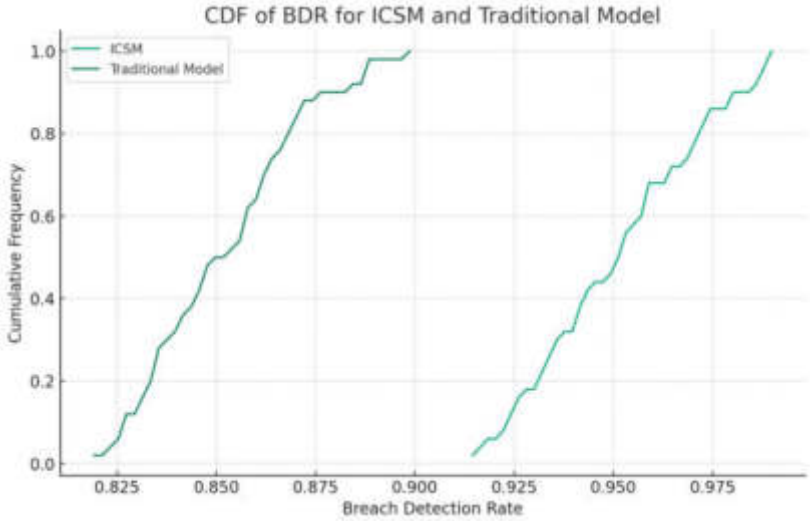

Fig. 3.7: CDF of BDR for ICSM and Traditional Model

line graph is useful for observing changes and trends in performance over time. Here, the ICSM consistently outperforms the traditional model, maintaining a higher average BDR throughout the observed period, which suggests its sustained efficiency and effectiveness.

The Cumulative Distribution Function (CDF) plot provides a probabilistic view of the BDR values. It shows the proportion of observations below a particular BDR value. The faster rise of the CDF curve for the ICSM indicates that it achieves higher BDR values more frequently compared to the traditional model, highlighting its superior performance in terms of breach detection.

Together, these plots offer a comprehensive view of the ICSM's performance, demonstrating its superiority over the traditional model in different scenarios and over time

4. Conclusion. The research presented in this study marks a significant advancement in the realm of cloud computing security, addressing the ever-growing need for robust data protection in an increasingly cloud-reliant digital world. Our proposed novel security system, tailored specifically for cloud environments, demonstrates a substantial enhancement in safeguarding data during transmission and migration. By meticulously identifying and addressing the limitations of existing security models, the study introduces a multi-dimensional framework that seamlessly integrates advanced encryption, dynamic access control, and continuous security auditing. This integration not only bolsters overall security but also ensures the integrity, confidentiality, and availability of cloud data. The framework's efficacy was rigorously evaluated through simulations in cloud settings, comparing its performance against contemporary security models. The results of this comprehensive quantitative analysis were clear: our framework consistently outperformed existing models in crucial metrics, including threat detection accuracy, response speed, and resource efficiency. These findings underscore the framework's capability to mitigate a wide range of security vulnerabilities while optimizing operational overheads, making it a significantly more effective alternative to traditional security approaches.

This work contributes an innovative approach to cloud data security, enhancing scalability, flexibility, and security. It paves the way for varied industries to adopt safer and more reliable cloud computing practices, ensuring data protection in the dynamic and rapidly evolving landscape of cloud technology. This study, therefore, stands as a testament to the potential of advanced security solutions in transforming cloud computing into a safer and more resilient platform for businesses and users alike.

RESEARCH AND DESIGN OF INTELLIGENT PARKING MANAGEMENT SYSTEM BASED ON THE YOLO ALGORITHM

MINGJUN TANG*, KUNPENG GE†, JUN DAI‡, LINYANG GUO§, AND DAN SHAN¶

Abstract. Given the difficulty in managing parking lots and inefficient utilization of parking spaces at university and college campuses, this paper designs an intelligent campus parking management system with functions such as license plate recognition (LPR), online parking space reservations, campus parking navigation, and mobile app payment through the parking space detection technology based on You Only Look Once (YOLO) algorithm, Internet of Things (IoT) technology, and cloud platform technology. This system obtains information relating to license plates, parking spaces, etc. from sensing nodes with the IoT technology and transmits the collected information through NB-IoT technology to a cloud platform for storage and management to facilitate information exchange between hardware and software. This paper describes the architecture of the intelligent parking management system, parking space detection technology based on the YOLOv4 algorithm, and hardware and software design of the system. The paper proposes an effective solution to parking problems facing colleges and universities. The paper concludes that the intelligent campus parking management system based on the YOLOv4 algorithm can prevent the haphazard parking of vehicles and traffic congestion at open campuses and therefore has important value for application and popularization.

Key words: YOLO algorithm; IoT technology; Cloud platform technology; Parking management system

1. Introduction. Universities and colleges with open campuses are facing many parking problems such as difficulty in parking vehicles and managing parking spaces, inefficient utilization of parking spaces, and ineliminable haphazard parking. All these would result in an inconvenience to teaching activities and daily management on campus[1]. As the existing parking management systems are often less information-based and usually require manual processing, parking management becomes rather inefficient. This paper proposes a solution that allows for a combination of ZigBee technology and a backbone communication network in a certain area with the help of 4G-based Narrowband Internet of Things (NB-IoT) gateway technology. The solution is aimed at resolving poor network coverage in indoor or underground locations, supporting ultra-low power hardware devices, and maintaining an extended standby time[2]. The technical solution to an intelligent campus parking management system also combines YOLOv4 algorithm-based parking space detection technology with the IoT technology to help drivers find vacant parking spaces more easily with the information provided. The solution also supports LPR, parking space reservation, parking navigation, and online payment to improve the efficiency of campus parking management[3-5].

2. Architectural Design of Intelligent Parking Management System. The building of an intelligent parking lot is critical to solving parking problems in universities and colleges. With NB-IoT as the core network, the intelligent parking management system is designed for parking lots on the open campuses of these schools. The parking management system uses CN18DX chips, which is a NB-IoT+GPRS dual-mode M2M modules equipped with the NB-IoT function and supports various interactions through embedded development, mobile app development, software and hardware design, and cloud data queries. The system has an overall platform architecture with an ecological parking cloud as the top layer, intelligent parking lots as the middle layer, and LPR modules and users as the bottom layer. At the top layer is an ecological cloud server for parking on campus, which is connected to ZigBee network nodes distributed across the campus via a China Mobile core network for data exchange. ZigBee is a low-power wireless mesh network standard targeted at battery-powered devices

in wireless control and monitoring applications. These ZigBee nodes are mainly distributed at the parking space detection modules of a parking lot, barrier gates for entry and exit lanes at school gates, entrances to above-ground and underground parking lots, and parking locks in each parking space. The system also includes a dedicated mobile app. The ecological parking cloud manages all parking space information through a cloud server. This allows a user to obtain parking space information via the mobile app in real time to choose a vacant parking space. The cloud server will guide the user through intelligent parking services on their mobile phone based on their needs. During the process, the cloud server will issue instructions and tasks to the devices of the local parking lot ecosystem to ensure smooth delivery of the parking services. The mobile app allows a user to view parking space information across the campus in real time and use functions such as parking space query and reservation, payments, and parking lock control. Figure 2.1 shows the network topology diagram of an intelligent campus parking management system.

3. Parking Space Detection Technology Based on YOLO Algorithm. Currently, there are two conventional parking space detection methods. The first one uses sensors for detection. Commonly used sensors mainly include coils, ultrasonic range finders, infrared sensors, and geomagnetic sensors[6]. The other method uses computer vision. Specifically, surveillance cameras that have been widely deployed in parking lots will detect parking spaces by collecting surveillance video. Although algorithms for parking space detection based on sensors have already become mature, finding a low-cost alternative to sensors has become a consensus in the industry due to their high installation costs and difficulty in maintenance.

Using cameras for parking space detection based on computer vision has a great application prospect, which will help popularize intelligent parking lots. On the one hand, this method makes the best of surveillance devices that have been widely installed in parking lots and allows one camera to monitor multiple parking spaces simultaneously, thereby saving upfront costs[7]. On the other hand, there is no need to make major changes for cameras to collect statistical information about parking spaces thanks to target detection algorithms as the cameras will capture video and transmit it to a processing center, which facilitates maintenance in the future.

As artificial intelligence (AI) technologies are cropping up and a series of algorithms for target detection

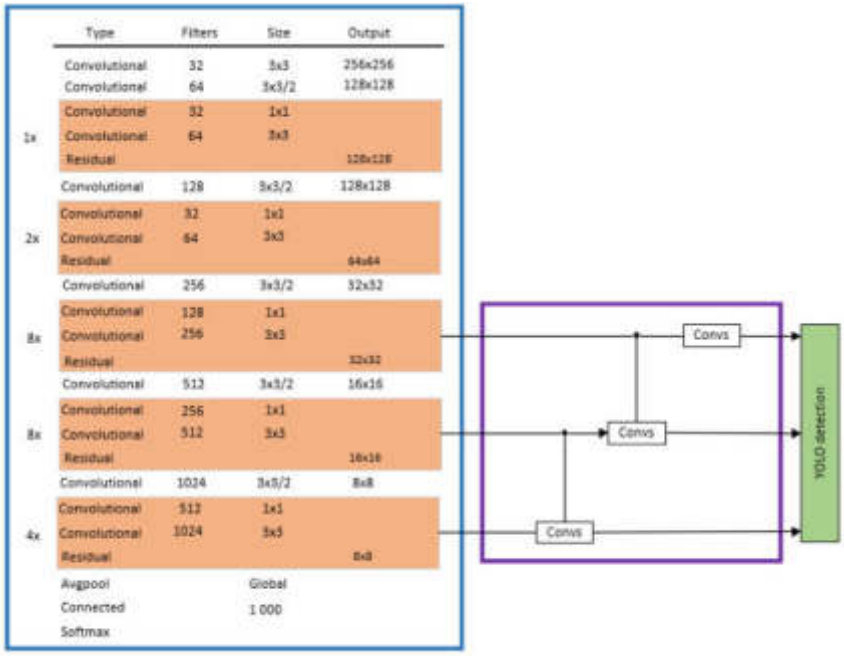

Fig. 3.1: YOLOv4 structure diagram

have emerged, this paper selects YOLOv4, a lightweight, high-precision target detection algorithm for real-time parking space detection.

The YOLO series[8-11] of algorithms are end-to-end target detection algorithms. These algorithms adopt the one-stage strategy to convert a target classification and positioning problem directly into a regression problem, thereby improving their detection speed. YOLOv4 is one of the algorithms with excellent accuracy and speed in the current target detection field as it improves activation functions and loss functions for the backbone feature extraction network of YOLOv3.

This paper mainly deals with the task of identifying vehicles in the fixed positions of a parking lot and transmitting relevant license plate information to the system terminal, which requires high real-time performance and accuracy from the algorithm. Using the YOLO v4 algorithm for detection can better fulfill the task but come with a slow target detection problem as found during its development. To solve this problem, this paper proposes to improve the performance of the YOLO v4 feature extraction network with the convolutional block attention module (CBAM)[12]. By assigning higher weight coefficients to areas of interest such as target areas, the proposed method can improve the feature expression ability of the model and speed up target detection.

The CBAM is a classic method in the field of channel attention and spatial attention. For a given feature map, CBAM can sequentially generate attention information in both channel and spatial dimensions and multiply the two sets of feature map information with the original input feature map for adaptive feature correction to produce the final feature map. In this paper, a lightweight CBAM is embedded into the output of features of three different scales from YOLOv4 to more accurately extract features of interest and weaken or even discard other features, thereby improving detection accuracy. The structure diagram of YOLOv4 is shown in Figure 3.1.

The BCAM consists of two attention modules: the channel attention module and the spatial attention module. The schematic diagrams of the two modules are shown in Figure 3.2 and Figure 3.3, respectively. In the channel attention module, each channel of a feature map is considered as a feature detector. With combined use of max pooling and average pooling, the spatial dimension of the feature map is compressed to generate two different spatial context information, the average pooling feature F^c_{avg} and the max pooling feature $F^c_{\max}$.

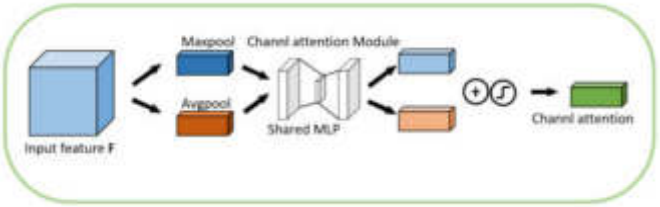

Fig. 3.2: Schematic diagram of the channel attention module

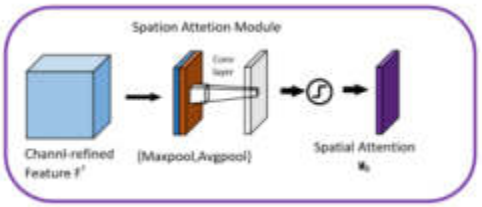

Fig. 3.3: Schematic diagram of the spatial attention module

The feature is then sent to a shared multilayer perceptron (MLP) network to produce the final one-dimensional channel attention feature map $M_c \in R^{C\times1\times1}$.

The spatial attention module focuses on the positional relationships within the feature map space. To calculate the spatial attention, a feature needs to be average pooled and max-pooled in the channel dimension first and the generated feature maps should be spliced together, followed by a convolutional layer to generate the final two-dimensional spatial attention feature map $M_s(F) \in R^{1\times H\times W}$. The software architecture of the intelligent parking management system offers several advantages. The utilization of the YOLOv4 algorithm for real-time parking space detection enhances the system's accuracy and speed in identifying vehicles in fixed positions within a parking lot. Additionally, the integration of the CBAM)with the YOLOv4 feature extraction network improves the model's feature expression ability, leading to enhanced target detection performance.

Figure 3.4 shows the overall design process of the parking space detection technology based on the YOLO algorithm proposed in this paper, and Figure 3.5 shows the effects brought by LPR.

4. System Hardware Design. The hardware of the system is mainly designed to include three parts: a parking space detection module, an intelligent barrier gate module, and intelligent shared parking locks.

4.1. Design of Parking Space Detection Module. As the basis of the entire ecological parking cloud, the parking space detection module senses parking spaces in a parking lot as well as their status and distribution through cameras and reasonably allocates and guides a driver to a designated parking space based on their needs[13]. The module is mainly composed of a microcontroller unit (MCU) module, a field-programmable gate array (FPGA) module, a camera module, a ZigBee wireless module, and a power management module. Figure 4.1 shows the block diagram of the module.

The MCU module uses the 32-bit low-power large-capacity chip STM32F103V8T6 based on an ARMCortex-M3 core as its microprocessor. STM32F103V8T6 is a 100-pin chip package with up to 51 multi-functional, bidirectional input and output ports, all of which can be mapped to 16 external interrupts[14]. The STM32 microprocessor works at a frequency of up to 72MHz and is built in with 256KB of flash memory and 48KB of SRAM. It has two 12-bit analog-to-digital converters (ADCs), 11 timers, and 13 on-chip communication interfaces. Its supply voltage is 2V–5V. When the camera module captures a vehicle entering a parking space, the FPGA runs the YOLO algorithm for license plate recognition and sends the recognized license plate number to the STM32 through serial ports. The communication module of the parking space detection module uses

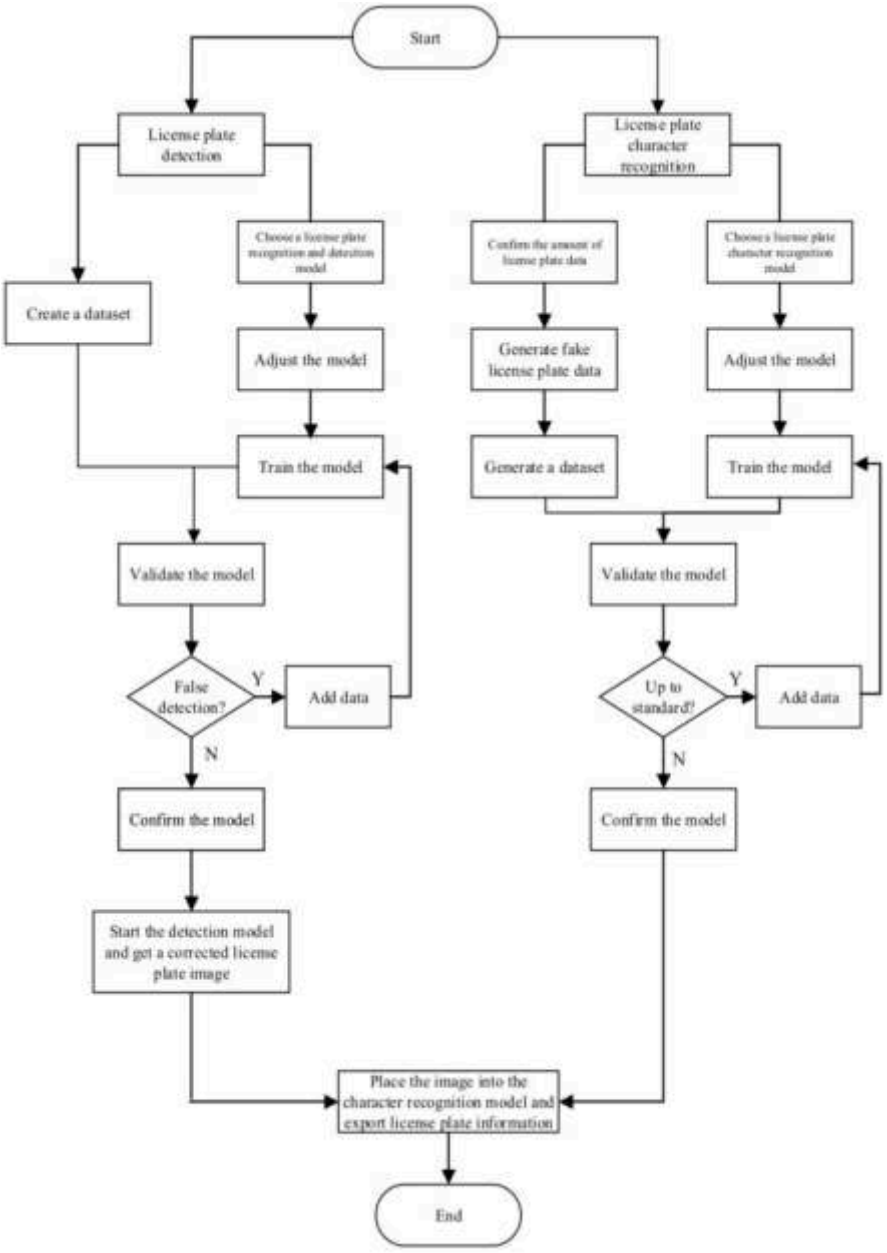

Fig. 3.4: Overall design flow chart of the parking space detection technology based on the YOLO algorithm

the ZigBee module with the CC2530 chip produced by TI as the core. CC2530 is a true system-on-chip (SoC) solution for IEEE 802.15.4, Zigbee, and RF4CE applications. It enables robust network nodes to be built with very low total bill-of-material costs. Its maximum transmission rate can reach 250Kbps and its supply voltage ranges from 3.4V to 4.2V. The system adopts the ZigBee wireless communication method, with low power consumption and strong performance, thereby greatly reducing the difficulty and costs of installation and maintenance. The entire parking space detection module adopts 5V DC power supply.

Fig. 3.5: Effects brought by LPR

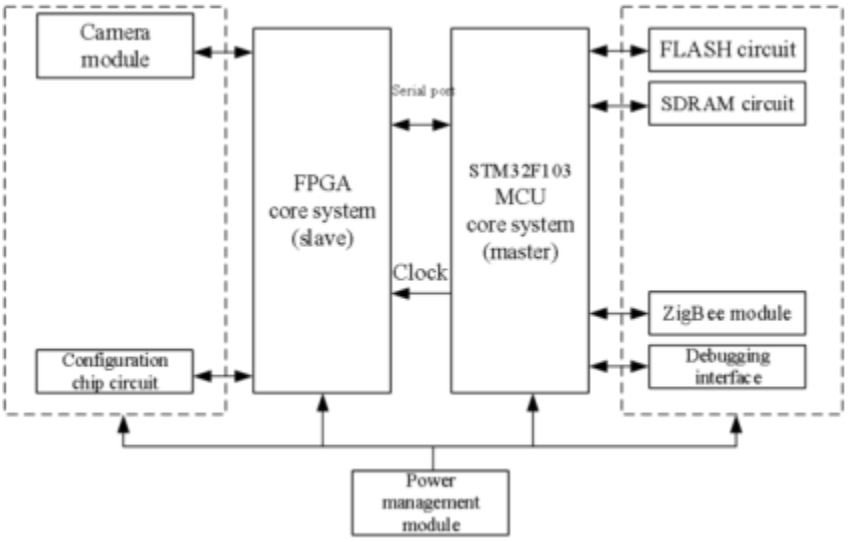

Fig. 4.1: Hardware block diagram of the parking space detection module

4.2. Intelligent Barrier Gate Module Design. The intelligent barrier gate module includes a license plate video recognition module, an electrical beam control module, a ZigBee wireless module, and an AC power supply. The license plate video recognition module is composed of an embedded ARM system and supports a light-emitting diode (LED) display. The Cortex-A8 processor is an application processor implementing the ARMv7 architecture and featuring Thumb-2 technology for enhanced performance and code density and reduced power consumption. The system operates at a voltage of 220V AC with a license plate recognition rate of more than 99.7% and a recognition speed of less than 500ms. The beam control unit uses a 250W motor, which can limit the lifting and lowering speed to less than 2s. The block diagram of the intelligent barrier gate module is shown in Figure 4.2.

4.3. Design of Intelligent Shared Parking Lock. Intelligent shared parking locks are designed for VIP customers and customers who reserve parking spaces. The locks can be lifted or lowered remotely and support

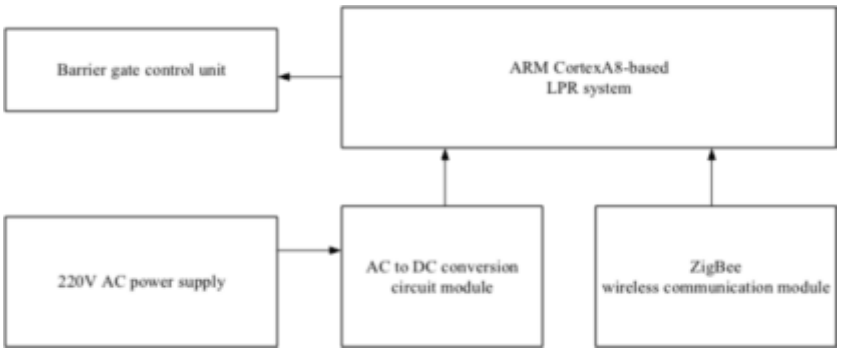

Fig. 4.2: Hardware block diagram of the intelligent barrier gate module

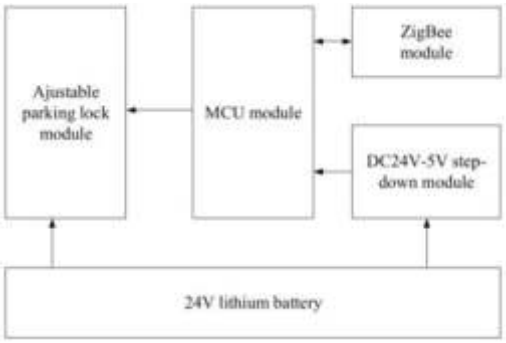

Fig. 4.3: Hardware block diagram of an intelligent parking lock

the uploading of ZigBee data. They are connected to the management platform via a ZigBee-NB-IoT gateway. Users may reserve parking spaces and unlock parking locks or perform other operations on their mobile app. The intelligent shared parking lock design uses STM32F103V8T6 as the core control module of the MCU to lift or lower parking locks and the NB-IoT communication module for data communications. The parking lock unit powered by a lithium battery supports the task wake-up function and maintains a low-power standby state with very low power consumption. The lithium battery has a capacity of 24V 20A/h and can work continuously for more than 2 years. Figure 4.3 shows the hardware block diagram of the lock.

5. System Hardware Design. Built on existing intelligent parking system solutions and based on the overall needs of campus parking, the system is designed to have the following major functions: cloud data query service, parking space map management, barrier gate system access, and mobile app functions.

5.1. Design of Cloud Data Query Service Function. As the operation center of the entire intelligent parking system, the cloud server is responsible for the timing and data scheduling of all workflows, data updates, storage and backup, updates on outdoor parking space indicator data, parking space management, payment services, vehicle query and positioning, navigation and positioning within a parking lot, and app services during parking to ensure the normal use of the intelligent parking lot service platform. The schematic diagram of the cloud data query service function is shown in Figure 5.1. On the hardware side, the design of the parking space detection module includes components such as the STM32F103 MCU core system, FPGA core system, camera module, ZigBee wireless module, and power management module. This hardware setup allows for efficient sensing of parking spaces in a parking lot, allocation of parking spaces based on driver needs, and seamless communication between different modules . The use of ZigBee wireless communication in the hardware architecture reduces installation and maintenance costs while ensuring strong performance and low

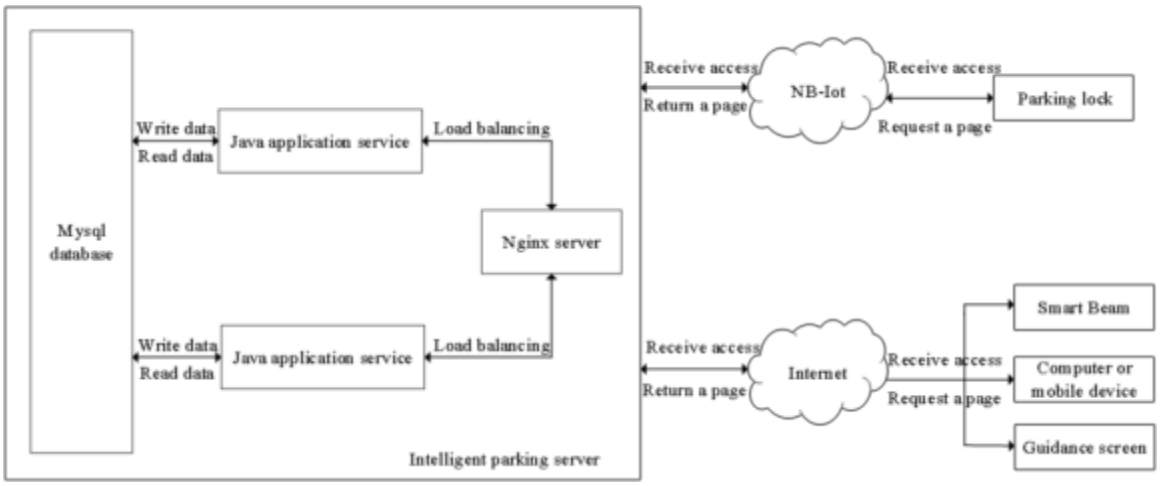

Fig. 5.1: Schematic diagram of the cloud data query service function

power consumption.

5.2. Design of Parking Space Map Management Function. Data about campus map models, locations of parking spaces, and paths are prepared through campus map data creation and navigation implementation, and offline data is generated and deployed on mobile devices. SuperMap IMoblie is used to design and develop a mobile navigation and positioning system. Relying on the network environment deployed on campus, positioning and navigation functions are made available through the mobile app[15-16]. This function allows for the management of information about all parking spaces under and above the ground, such as viewing the availability of parking spaces, checking and updating campus maps, using GPS navigation based on parking lot maps, and manually modifying parking space information (such as setting VIP parking spaces) by administrators. These functions enable administrators to manage campus parking spaces more efficiently and conveniently.

5.3. Design of the Access Control Function of the Barrier Gate System. The information provided by the barrier gate system mainly includes license plate numbers, parking duration, and parking fees. The system can receive from the cloud such information as if and when parking fees are paid. The cloud management interface can include operations that allow the barrier gate system to access the cloud URL and authentication information[17]. If wireless nodes of a barrier gate and license plate video recognition systems are deployed at the entrances and exits of a campus, vehicle information obtained at an entrance will be uploaded to the cloud server for identification and filing. Meanwhile, the timing function will be enabled for the calculation of fees and the barrier gate be open to allow the vehicle in. At an exit, a vehicle will be checked for its identification and may be allowed to leave based on its identification and payment information[18]. The intelligent barrier gate system can free security guards from performing lots of repetitive statistical work related to vehicles, improve their productivity and reduce possible mistakes. It can also speed up vehicle flows and relieve congestion at campus entrances and exits.

5.4. Mobile App Design. The mobile app is developed mainly with Android programming languages mainly for the Android system under the Vue framework[19]. The app can be registered on its mobile client and by WeChat users, making user registration easy even for people who visit campus for business purposes and removing the need for traditional onsite registration[20]. Relevant personnel can view relevant user information, analyze users' parking behavior and parking habits, and obtain user attributes. The mobile client also supports online timing and parking fee query, online payment, and other functions. Therefore, drivers can query the timing and billing function in real time even when they leave the vehicle temporarily or leave the campus. The app's background management interface also supports the statistics and querying of parking space utilization

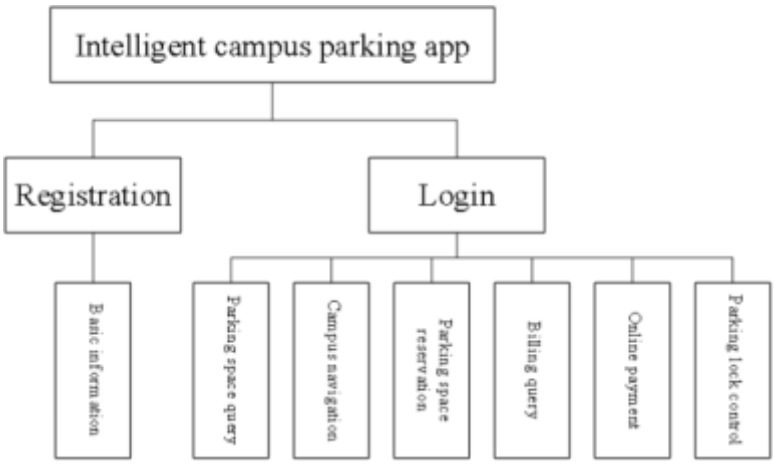

Fig. 5.2: Functional modules of the mobile terminal system

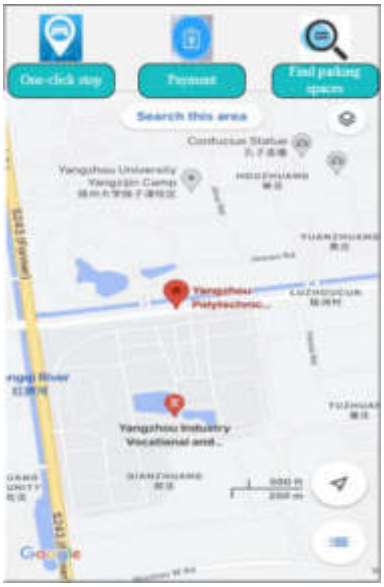

Fig. 6.1: App login UI

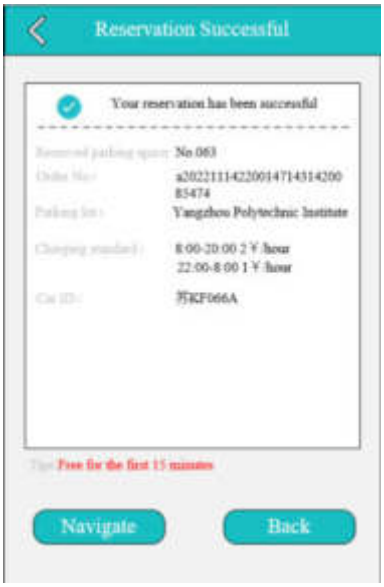

Fig. 6.2: App reservation UI

and revenue such as by time and parking space, the viewing of users' parking records and bills, etc. The functional design of the mobile terminal system is shown in Figure 5.2.

6. System Implementation. After system software and hardware are designed, there is a need to build a server, import campus map and parking space model data, install intelligent parking locks, and download the mobile app. When the entire system is powered on, each module will be initialized. After the initialization, all modules will be connected to the corresponding network and the campus intelligent parking server. After connection, a user can log in to the mobile app to view available parking spaces and find one, as shown in Figure 6.1, or reserve a parking space based on their needs and navigate to it, as shown in Figure 6.2.

7. Conclusion. This paper proposes an intelligent parking management system based on the YOLO algorithm to solve parking difficulties on campus. The solution provides major functions such as the intelligent

management of parking spaces and vehicles entering and leaving campus and automatic vehicle billing. It also allows users to reserve and locate parking spaces and query parking duration and fees. All these functions will make parking easier for faculty members and those who visit campuses for business purposes. Therefore, the solution has important value for application and popularization. In future research, more efforts will be invested in applying this system to fields such as intelligent air traffic control.

APPLICATION OF FACIAL ANALYSIS BASED ON CONVOLUTIONAL NEURAL NETWORK AND ITERATIVE DECISION TREE FOR TEACHING EVALUATION IN SMART CLASSROOM

JIANG HUI[*], FU WENTAO[†], AND ZHANG JIAN[‡]

Abstract. The creation of intelligent classrooms has been expedited by the rapid advancement of the Internet and computer vision, and intelligent teaching has increased the interactivity and effectiveness of learning. Teachers' teaching and students' classroom learning state ultimately affect the teaching effect. Students' facial expressions during class can reflect emotional changes and the current learning state. The computer camera in the smart classroom collects students' face image data, uses texture-based information, edge-based information, geometric information, and global and local feature extraction to identify and analyze and process the students' facial expressions. Research has shown that the combination of expression recognition and an intelligent teaching classroom can accurately identify and analyze students' emotions and learning status, and can effectively evaluate the teaching effect of the intelligent classroom, which helps to improve teaching quality and learning efficiency. Therefore, applying facial expression recognition in the intelligent teaching classroom has far-reaching significance.

Key words: Machine vision, Smart Classroom, Effective Classroom, Face detection, Recognition of sb's expression

1. Introduction. The development of intelligent teaching and learning has accelerated as a result of the Internet and education coming together [1]. The goal of the smart classroom is to enhance conventional classroom teaching strategies through the use of cutting-edge technology and intelligent teaching tools. Through digital and networked means, it integrates rich teaching resources and realizes real-time interaction between teachers and students. Students can submit and answer questions online, and teachers can provide feedback and guidance immediately, enhancing the interactivity of learning and making teaching and learning more effective and individualized [2,4].

Positive learning emotions can have a significant impact on the brain's active thinking, enhancing learning ability, and human emotions are reacted to facial expressions. The change in students' emotions throughout the lesson can reflect the students' learning environment in the classroom. In the traditional method of instruction, teachers must personally observe students' facial expressions to determine how well they are understanding the lesson. But given that educators typically deal with sizable class sizes, it can be challenging for teachers to keep track of the majority of students' situations during the lesson [5][6].

And more recently, the use of computer face recognition technologies has been encouraged by advances in computer technology, image processing theory, and pattern recognition [7]. In a classroom with innovative teaching, the computer camera can track each student's facial expression in real-time and assess the students' learning status through recognition and analysis. This aids teachers in accurately and quickly understanding the students' learning situations, improving and optimizing their teaching strategies, and enhancing the quality of their instruction.

The combination of two algorithms exemplified by convolutional neural networks(CNN) and iterative decision trees applied to intelligent teaching and evaluation of face recognition has also been gradually increased to better enhance the recognition and evaluation accuracy and efficiency.

2. The relationship between human facial expressions and behavioral expressions and the methodological approach implemented by machine vision analysis. Psychologist Mehrabian states

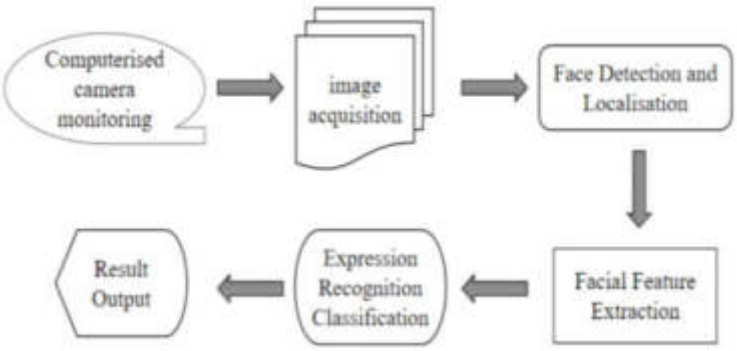

Fig. 2.1: Basic flow of computerized face expression recognition.

that emotional messages are expressed 7% in words + 38% in voice + 55% in facial expressions [8]. This demonstrates the significance of expression in evaluating human emotion. In order to ascertain a person's emotional state and expressive purpose, a system called computer face expression recognition examines and decodes that person's facial expression. It is based on pattern recognition and computer vision. By using a camera or other image acquisition device to capture a face image, this technology can then apply an algorithm to process and analyze the image, extract key features, and compare and match them with a predefined expression model to ultimately identify the category of an individual's expression, like as joyful, depressed, furious, scared, shocked, disgusted, and so forth [9]. Expression recognition is frequently employed in a variety of industries, including security surveillance, commercial promotion, psychological medical care, and fatigued driving. The field of education can also benefit from expression recognition. Similar to this, expression recognition can be used in the field of education to better understand students' psychological states and to assist teachers in capturing students' attention, understanding, and interest in knowledge and other information so that appropriate teaching control measures can be taken to enhance the quality of instruction.

Computerized face expression recognition usually consists of the following basic processes (shown in Figure 2.1):

(i) Data Acquisition: A camera or image capture device is used to acquire face image data. This data can be a live video stream or a still image.

(ii) Face Detection and Alignment: the acquired image is subjected to face detection, which identifies the presence of faces and calibrates their positions. At the same time, the detected faces are aligned so that the position and size of the face images are consistent with the model requirements.

(iii) Feature extraction: extract feature information from the aligned face image.

(iv) Expression classification: using the extracted feature information, it is fed into the pre-trained expression classification model, which uses comparison and matching to determine the category of facial expressions.

(v) Result output: determine the category of the facial expression based on the classification model's output, then show or output the conclusion.

It should be remembered that the procedure described above is only a basic framework and that the actual implementation may differ. To increase accuracy and resilience in real-world applications, additional procedures including data pretreatment, model training, and optimization could be needed.

3. Extraction and Numerical Algorithmic Approach for Machine Vision Analysis Targeting Human Facial Features. Data that can convey a learner's emotional traits are extracted via facial feature recognition. The four categories of facial feature extraction techniques are essentially comparable: (i) Feature extraction based on edge information, like directional gradient histograms, etc.; (ii) Feature extraction based on texture information, such local binary patterns, etc.; (iii) feature extraction based on geometrical information, such as local curvilinear waveform transforms; and (iv) Principal Component Analysis and feature point calibration are two methods for feature extraction that use both global and local information.

Local Binary Patterns (LBP) were originally proposed by Ojala et al [10] in 1994, can generate a binary code based on a comparison between a pixel and its surrounding pixels to represent the local texture elements of an image. LBP features have the advantages of being computationally simple and robust to light variations, and are widely used in practical applications. The traditional LBP algorithm encoding formula is:

$$S\left(g_p - g_m\right) = \left\{ \begin{array}{l} 1, g_p \geq g_m 0, g_p < g_m \end{array} \right.$$

$$LBP = \sum_{p=1}^{8} S\left(g_p - g_m\right) 2^p$$

where g_m stands for the center point's grey value and g_p stands for the surrounding eight pixel points' grey values.

For the weak intensity of facial micro-expression variations, background noise interference, and small feature differentiation, A micro-expression recognition network that combines parallel attention and LBP was proposed by Shuaichao Li et al. [11]. This network extracts RGB global features and LBP local texture features and then obtains more effective micro-expression features through the attention feature fusion module while simultaneously introducing a dense connectivity mechanism. A better LBP technique was put forth by Yu [12] that incorporates local dynamic thresholds, integrates equivalent and circular patterns, and reduces the size of the feature vectors while preserving the essential feature vectors needed for successful face recognition.

An image's local texture and edge information can be described using the feature description operator called Histogram of Oriented Gradients (HOG). The HOG feature extraction approach generates the gradient histogram by determining the gradient direction and intensity in various image regions. It primarily focuses on the distribution of gradients in a picture. HOG characteristics can assist in capturing crucial details, such as the edges and curves of the face, in the process of recognizing facial expressions. For the purpose of recognizing facial expressions, Ahmed et al. [13] suggested a brand-new local texture pattern called the Gradient Directional Pattern (GDP) and an efficient feature descriptor built utilizing GDP coding. The derived GDP features characterize the local picture primitives more steadily and maintain more information than the grey level-based techniques. Face recognition is accomplished by Xie et al. [14] using deep learning techniques, face feature extraction from HOG data, image segmentation, and convolutional neural network technology for training and coding output. The results of the experiments demonstrate that face recognition technology can accurately recognize faces with several gestures and meet application specifications.

A multi-scale transform technique for signal and image processing is the Local Curvelet Transform (LCT). To capture local features at each scale, the essential concept is to break down a signal or image into local curvilinear wave bases. Due to its superior performance in the presence of varying lighting conditions and face orientation changes, wavelet transform is widely employed in the field of face feature extraction [15]. The most important and relevant face features can be preserved while the unnecessary portions of the image information are efficiently minimized using wavelet transform. This makes the wavelet transform a trustworthy and efficient way for removing important information from face photos in challenging environmental settings for precise face verification and recognition. Ahmed et al [16] proposed a deep learning-based Gabor wavelet transform, which was used to extract features from symmetric face training data and, through testing, was found to be superior to other techniques.

In statistics and multivariate data analysis, the Principal Component Analysis (PCA) technique is frequently used for feature extraction and data degradation. PCA extracts features using global information-based approaches, focusing mainly on the direction of projection that explains the most variance in the data. Eigenfaces (Eigenfaces) are based on the idea of PCA by transforming image data to low dimensional feature space and then using these features to represent and compare face images. A face image can be represented as a vector X of size n*1 (n is the result of the image's width and height), and the number of training samples is N. At this point, using the overall scatter of the set of training samples in PCA, the maximum variance corresponds to the largest feature value, and the corresponding eigenvector defines a projection direction. By selecting principal components with large variances, we can gradually capture the main patterns and structures

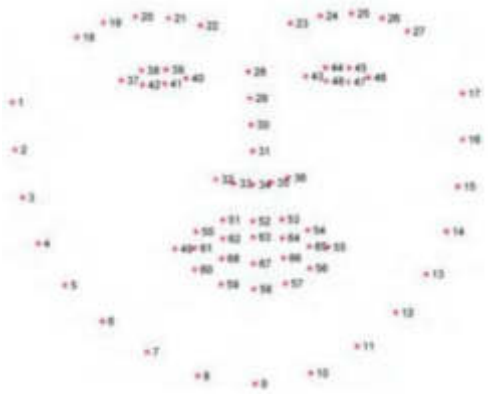

Fig. 3.1: Distribution of key points of DLIB face.

in the dataset. The cloth matrix is used as the generating matrix [17], namely:

$$C = E\left[XX^T\right] \approx \frac{1}{N}\sum_{\mathrm{k=1}}^{N} X_k X_k^T$$

Representation of N face vectors by an n *N matrix:

$$X = [X_1, X_2, X_3, \cdots, X_n]$$

Then C can be expressed as: $C \approx \frac{1}{N} X X_T$

However, PCA ignores the distribution of the data and bases its feature extraction procedure solely on the covariance matrix of the total data, disregarding the local correlations between samples. Therefore, when the data are unevenly distributed or when there is a local structure, PCA might not be able to capture crucial local information. To solve this problem, other algorithms are needed to consider local information for feature extraction. Meanwhile, to improve the accuracy and effectiveness of data representation, feature extraction methods need to be selected reasonably according to specific application scenarios and data distribution. The Active Appearance Model (AAM) model was utilized by Han et al. [18]; it labels the crucial spots in the training set to extract the average form through dimensionality reduction using Principal Component Analysis (PCA) and is used as a shape model. On this basis, it is further combined with the Constrained Local Model [19] (CLM) to achieve the extraction of multi-pose face features.

Feature extraction is based on local information, such as feature point calibration, which detects and locates key feature points in a face image, such as the position of eyes, eyebrows, mouth, etc., to achieve tasks such as face localization, pose estimation, and expression analysis. Jia et al [20] used the feature extractor provided by DLIB officials [21] to pre-train the model to obtain the key points of the face.DLIB is a C++ library containing machine learning algorithms and tools, which uses the face images that have been labeled with 68 key points as the training set to generate the model, and the acquired images are used to estimate the locations of the feature points using this model. The distribution of the 68 key points of the face in DLIB is shown in Fig. 3.1 shows.

4. Analysis and classification of correlations between human facial expression features and behavioral representations. Facial expression recognition refers to analyzing and recognizing the expressions shown by facial muscle movements through face images or video data to infer the emotional psychological state of human beings. In the classroom, where students' facial expressions can reveal a lot of information, Table 4.1 outlines some of the usual facial characteristics that are relevant to teaching and learning. The majority of the time, when students are ready to listen intently to what is being learned, they exhibit pleasing facial expressions and a forward-leaning posture that shows interest in what is being taught. When students are reluctant to

Table 4.1: Common expression features of the human face.

Expression	Brows	Eyes	Lip
pleasantly	slightly recurved	bright and lively	Slightly upturned to the sides
fury	curl up and lower the eyebrows	Eyes wide and possibly bulging	Lips tightly closed with one corner straightened or downwards
ordinarily	spontaneous outreach	spontaneous opening	No distinctive features
misgivings	pucker up	Upper eyelid lift	The corners of the mouth pull down
disdain	slightly elevated	Eyes cold, slight squinting	Tightly closed, angled slightly downwards, sometimes slightly puckered
resist	pucker up	Dodging, avoiding, or appearing indifferent	Become tightly closed, may bite their lips or pout

what they are learning, they may adopt resistant stances like slouching or spending a lot of time looking down in class. If students struggle to comprehend the course material, they may also display puzzled facial expressions like frowning. In addition to the above, there is another related concept that needs to be mentioned, namely microexpressions [22]. Microexpressions are more accurate at capturing people's genuine emotions and intentions than intentionally created facial expressions. Micro-expressions are a component of psychological stress micro-responses, which arise from human instinctual responses and are not under the conscious mind's control. As a result, they cannot be covered up or hidden because they are not under the conscious mind's control. The complexity and inherent specificity of microexpression analysis study make it difficult [23]. We can accurately understand students' emotional states and learning motivation by observing and categorizing their facial expressions during class. This allows us to inform teachers to intervene and modify teaching tactics as needed.

Facial expression classifiers include two kinds: (i) traditional machine learning algorithms, Support Vector Machine (SVM), Decision Tree Algorithm, Adaboost Algorithm, and K-Nearest Neighbor Algorithm (k-Nearest Neighbor) are the primary algorithms used for facial expression classifiers; (ii) Convolutional neural networks (CNN), recurrent neural networks (RNN), and long short-term memory neural networks (LSTN) are examples of deep learning models. Each of them has benefits and drawbacks, and in order to achieve faster and more accurate recognition, they must work in tandem.

Traditional machine learning algorithms have the advantage of better interpretability and applicability to small sample data in facial expression classifiers, but require expertise and experience in feature engineering and may be limited in their ability to process high-dimensional and complex data. SVM is a fundamental binary classification algorithm, and its objective is to determine the best hyperplane in the sample space to distinguish between various categories of samples, to maximize the interval between the two categories, i.e., to select the hyperplane division with the "maximum interval". To divide the feature space into two regions, one of which is assigned to one category and the other is assigned to another, the basic idea is to find the support vector (the closest sample point to the decision boundary) to separate the samples of different categories and maximize the distance from the support vector to the decision boundary, which can be regarded as a hyperplane. SVMs have the advantages of high classification accuracy, large data handling capacity, good performance on small sample datasets, and suitability for both linear and nonlinear classification tasks. SVMs, on the other hand, have a high computing requirement for large training sets, require empirical and experimental analysis to choose the right kernel function and parameters and perform badly when the data categories significantly overlap. Varma et al [24] used Support Vector Machines (SVMs) and Hidden Markov Models (HMMs) to classify a given face on two different datasets. Firstly, SVM was used to effectively differentiate different categories of face samples by finding the optimal hyperplane in the sample space and maximizing the spacing between the categories, while HMM modeled and classified the time series data of face samples. The system can accurately recognize the six primary emotions after integrating these two models, and the identification of face expressions is accomplished by mixing feature vectors. Sikkandar et al [25] presented the Improved Cat Swarm Optimisation (ICSO) method

as a better alternative to the Applied Cat Swarm Optimisation (CSO) technique. The classification of facial expressions is performed using a Support Vector Machine (SVM) Neural Network (NN), and experimental findings indicate that ICSO performs more accurately and quickly than the current method.

An algorithm known as a Decision Tree (DT) is built on a tree structure and uses a sequence of judgment nodes and leaf nodes to generate predictions and choices. The main objective is to divide the dataset into smaller subsets recursively until all of the samples in the subset fit into one category or another. To ensure that the divided subset is as pure as possible-that is, the samples belonging to the same category are clustered as closely as possible-the division is made at each judgment node based on the value of a particular attribute. The decision tree technique has excellent interpretability, broad applicability, independence from data scalability, and the capacity to handle multi-output issues. However, it is prone to overfitting and has a high level of instability. To extract the facial features, Gupta et al. [26] proposed a feature-based method for 2D face images that uses Scale-Invariant Feature Transform (SIFT) and Speeded Up Robust Features (SURF) to extract the facial features. Following that, the expressions were categorized using the decision tree and random forest classification algorithms, with a maximum experimental recognition accuracy of 99.7%.

An integrated learning technique called Adaboost (AdaBoost, Adaptive Boosting) tries to strengthen a classifier by integrating many weak classifiers. Adaboost's main goal is to make data difficult to categorize by repeatedly training a set of simple classifiers and altering the weight of the samples based on the effectiveness of previous classification results such that difficult-to-categorize samples receive more attention. The Adaboost algorithm has the benefits of increasing classifier accuracy, avoiding the overfitting issue, being highly adaptable, and not relying on a particular classifier. However, it also has disadvantages, including being sensitive to outliers, taking longer to train, and having a tendency to misclassify a few categories of samples when there is an imbalance in the data. Hui et al [27] for the AdaBoost algorithm with the increase of learning difficulty leads to the classification efficiency of the classifier declines, stability deterioration, and other issues, combining the advantages of the two algorithms, based on the ant colony algorithm to optimize the parameters of the SVM, to improve the Adaboost_SVM cascade classification algorithm, the first to extract the haar-like rectangle features through the Adaboost classifier Firstly, haar-like rectangular features are extracted through Adaboost classifier, and then non-face regions are quickly excluded; To extract facial expression characteristics, the Gabor wavelet transform is utilized, and when paired with the Adaboost_SVM cascade classifier, the average rate of face expression identification is 94.2%, and the detection speed has been greatly improved. Lakshmi et al [28] proposed a classifier combining PCA and AdaBoost algorithm for facial expression recognition, which effectively reduces the feature redundancy of frontal Gabor features.

A popular supervised learning technique with applications in both classification and regression issues is the K-Nearest Neighbors algorithm (KNN). The fundamental concept is to categorize samples based on their proximity to one another. The benefits of KNN include its adaptability, simplicity, and lack of an explicit training step; however, it is computationally challenging, sensitive to outliers, and necessitates the choice of an acceptable K number. Zhang et al [29] proposed an expression recognition method based on Gaussian Marco Random Field (GMRF) with multiple chunking way feature combinations. The GMRF features of different chunking modalities are combined and classified with KNN. The JAFFE dataset is used for testing, and the findings demonstrate that the approach achieves an accuracy of 89.8% in recognizing facial emotions.

Choosing an algorithm that is appropriate for the task at hand and the data's properties is essential. Deep learning algorithms, in contrast, are typically better suited for processing large-scale and complicated data, but their interpretability is low. Convolutional neural network (CNN) is one of the best deep learning models for facial expression classification tasks because it has a strong ability to describe image features, can efficiently capture both local and global information of facial images, is translation invariant, reduces the risk of overfitting through parameter sharing and sparse connectivity, and exhibits a strong model generalization capability. Eventually tasks such as classification or regression are performed with a fully connected layer. In order to more accurately characterize students' facial emotions while listening in class, Zhou et al. [30] used CNN fused with Iterative Decision Tree (GBDT) to extract facial image attributes. The numerous training samples that were gathered were manually labeled in a supervised way and divided into attentive and inattentive samples based on their facial expressions. The fully-connected layer feature values are then entered into the GBDT after pre-training the CNN using the training samples. The samples are then classified using the single-

layer hidden layer MLP perceptron after the GBDT has been trained using the tree nodes as the feature values to be fused with the CNN features. In order to identify and classify the emotional expressions of physically disabled people (deaf and bedridden) as well as children with autism, Hassouneh et al. [31] developed a real-time emotion algorithm in conjunction with a CNN classifier based on facial labeling and electroencephalogram (EEG) signals. They were able to achieve the highest recognition rate of 99.81%.

A neural network model having the ability to process serial data and handle temporal correlation is called a recurrent neural network (RNN). By inserting recurrent connections and utilizing prior knowledge when processing each time step, it enables the network to simulate sequential data. Facial expressions are constantly changing during facial expression recognition, and RNN can capture the temporal information in facial expression sequences, process dynamic facial expression sequences effectively, and be able to capture long-term dependencies, increasing the accuracy and performance of facial expression classification. Kansizoglou et al [32] used an RNN architecture to accurately estimate a speaker's immediate and persistent emotional state during an interaction.

The Long Short Memory Neural Network (LSTM) is a variant of the Recurrent Neural Network (RNN) commonly used to process sequence data. Compared to traditional RNNs, LSTM introduces a gating mechanism that better captures and remembers key information in long sequences. The Memory Cell, which makes up the majority of the LSTM, is made up of three gates (Input Gate, Forget Gate, and Output Gate) and a cell state (Cell State). By using these gating mechanisms, LSTM may learn and regulate the information flow to better handle dependencies and time delays in lengthy sequences, avoiding the issue of gradient vanishing or explosion in conventional RNNs. Li et al [33] addressed the problem that most people's psychological state is in sub-health in modern society and designed a bi-directional LSTM network based on spatiotemporal attention to achieve micro-expression image recognition. A real-time micro-expression detection technique based on optical flow and LSTM was proposed by Ding et al [34]. This method extracts feature curves from the Facial Action Coding System (FACS) and utilizes the LSTM to feature curves to categorize them and identify whether or not micro-expressions are present.

5. Algorithm and implementation of classroom teaching effectiveness evaluation based on human facial expression. Evaluation of the teaching process and student learning outcomes is done in the classroom to determine how well instruction is being provided and how well students are learning. By analyzing student performance in terms of engagement, focus, and cooperative skills based on facial expression recognition, homework, and quiz assessment in smart teaching classrooms, and teacher self-assessment, classroom effectiveness may be thoroughly examined.

Han et al [18] combined traditional cognitive behaviors with students' head posture and facial expression behaviors to construct a holistic and systematic learning effect evaluation system, which evaluates the classroom teaching effect in terms of individual students and the classroom as a whole. Lastly, by comparing manual statistics with the system detection, the study confirmed the accuracy of the system in detecting the overall classroom attention, participation, difficulty, and active time. The accuracy rates of attention, participation, difficulty, and active time were 88%, 87%, 80%, and 85%, respectively, all higher than 80%, suggesting that the system can be used to teach in the classroom and can produce more accurate affective data.

Jia [20] et al. made a classroom activity analysis corresponding to the timeline by observing the changes in students' facial expressions and head posture. It mainly consists of two parts: (i) It is an analysis of the individual's activity based on the time axis. (ii) is a trend analysis of the overall change in activity. The study considers all expressions except the 'nature' state as active and engaged expression attitudes, so the overall activity index expression activity is given as follows:

$$exp_act = 1 - \frac{nature}{len}$$

where nature denotes the number of "usual" expressions in this frame, and len denotes the number of all expressions in this frame.

Steering activity is the left and right head bobbing of an individual. The formula for steering activity is shown below,

$$ora\_act = \frac{nun\_act}{num}$$

where num_act denotes the number of people who turned active in this frame and num denotes the total number of people in this frame.

Based on these two indicators, the change curve of the overall timeline activity of the classroom is plotted thus analyzing the quality of teaching and learning in the classroom.

By capturing and tracking image samples of students' facial expressions at various crucial moments, Tang et al.'s [35] trained network was able to determine each student's emotional state. Based on the distribution of a number of fundamental expressions in the PAD emotional state model, participation weights for various expressions are assigned. A comparison between the experimental results and the teacher's evaluation demonstrates the validity and efficacy of the approach, as well as its sensible and useful role in evaluating teaching.

Facial expression-based assessment of classroom effectiveness has many positive effects. First off, it gives teachers immediate feedback on their students' emotional states, which helps them better comprehend their engagement and emotional states. This gives teachers the ability to personalize education, make timely changes to teaching ideas and approaches, offer more help and explanations, and foster a happy learning environment. Second, judging students based on their facial expressions can improve their understanding of their learning circumstances and boost their enthusiasm and capacity for autonomous learning. Students can take the initiative to change their learning state and thus increase the effectiveness of their learning by taking note of their facial expressions to better understand their emotional state and involvement. To further develop teaching tactics and raise the level of instruction, teachers can use the evaluation method to examine the success of their instruction and discover which teaching materials or approaches are most effective with their students. In conclusion, using facial expressions to assess classroom performance gives teachers and students valuable feedback and direction, encourages individualized instruction and students' independent growth, and so significantly improves the efficiency and quality of classroom instruction.

6. Conclusions. The use of facial expression recognition in the smart classroom aids teachers in understanding students' learning responses and emotional states. At the same time, the smart teaching system can provide individualized learning materials and teaching strategies by students' emotional states and comprehension levels based on the analysis results of facial expression recognition, thereby improving the overall quality of instruction. However, there are still a lot of challenges and issues that require more thought:

(i) Privacy issues. Face expression recognition involves capturing and analyzing students' facial images, which may raise privacy issues. When applying face expression recognition technology, it is necessary to ensure the protection of students' personal information and to comply with relevant privacy regulations and policies.

(ii) Accuracy and judgment errors. Face expression recognition software could make errors in complex scenarios and is not completely accurate at capturing and interpreting students' emotional states. Because of this, attention must be taken to how the results are interpreted and applied in the application.

(iii) The balance of personalised learning. It is important to ensure that the implementation of personalised learning does not preclude traditional teaching methods, while balancing the need for personalised learning with the needs of the class as a whole.

(iv) Cultural variations. Cultural differences may cause expression recognition problems and cause human facial expressions to have different meanings in various circumstances. To prevent the issues of prejudice and misjudgment, cross-cultural applications must take into account and adapt to the cultural characteristics of the various student groups.

In addition to the above points, how two or more algorithms can be combined to further optimise the efficiency and accuracy of face recognition in the smart teaching classroom is also a key focus of future research.

With the continuous development of artificial intelligence technology, the prospect of face expression recognition in the smart teaching classroom is full of expectations. It will promote the education industry to achieve personalized teaching and improve students' learning effectiveness while providing teachers with more valuable data and feedback to help them better leverage the power of education.

ALGORITHM IDENTIFICATION AND INTEGRATED WITH PUSH SERVICE FOR TELEMEDICINE SYSTEM

CAI YAN-LING*, LI XIN-YU†, AND KUMAR KANNAN‡

Abstract. Telemedicine systems, while overcoming physical space constraints, often lack personalized interactions. By incorporating a push service and leveraging prediction-oriented algorithms, these systems can offer an improved user experience. Such enhancements enable timely treatment options and reduce unnecessary resource usage in on-site outpatient clinics. This research work starts by creating a robust algorithm using data mining techniques. Next, it establishes the foundation for a telemedicine push service. The service includes essential modules for disease differentiation, doctor recommendations, and diagnosis predictions. To optimize these modules, a merged algorithm combining k-nearest neighbor classification, nearest neighbor recommendation, and FP-growth is needed. This work aims to enhance treatment options for patients and streamline resource usage in on-site outpatient clinics. Moreover, this work has carried out empirical research for identification of algorithm by using available data at a public Chinese telemedicine system. The results of data analysis show the follows: 1. For disease diagnosis, the KNN model (k=1) is more accurate but less efficient, SVM and LibSVM are more efficient but less accurate than the KNN model; 2. In terms of doctor recommendation, nearest neighbor recommendation performs better but is not as efficient as matrix factorization; 3. in diagnostic prediction, the combination of introducing association mining and data segmentation can play a better role. The developed algorithm and its conclusions from this study could make easier and more efficient to provide treatment options for undecided-condition patients.

Key words: sign-nonsingular matrix, LU-factorization, indicator polynomial

1. Introduction. According to the World Bank, about 10 percent of gross domestic product is spent on healthcare every year. Telemedicine has been a treatment mode with the development of information communications technology, which provides more access to medical resources [1, 2]. At present, there are many telemedicine systems supported by various organizations [3-5], but most of them lack the function of active interaction with users and fail to provide personalized recommendation. Therefore, by adding push service to the telemedicine system, it can provide personalized service, which improves user experience and enhances user stickiness.

For an old-mode telemedicine system, it has been accumulating abundant data. Mining user information, doctor information and diagnostic records can realize a push service. On one hand, according to the user's historical data, the department and doctor when he reserves for a return visit and suggestions for daily life are recommended. On the other hand, for some unanswered questions, this study will provide users with information about proper department and doctors, and users can directly consult them. In addition, valuable advice about the question is listed.

For a new telemedicine system, it can build its push service by directly using model trained by other systems, or by adjusting some parameters on the model. This paper aims at introducing personalized recommendation into telemedicine system, and designing integrated algorithms to adapt to different conditions and corresponding results based on real data sets through data mining.

2. Literature Review. The algorithm design for push services in telemedicine systems involves creating efficient mechanisms to deliver timely notifications and updates to users, ensuring seamless communication and information flow [6].

In mainland China, a qualitative study explored family caregivers' perspectives on telemedicine-based services for patients with end-of-life cancer. Key findings highlighted motivations for using telemedicine, supportive

Table 3.1: Algorithm Comparison.

Algorithm	Strength	Weakness
ANN	Non-linearity modelling	Block box in nature
Decision Tree	Intuitive result, understand easily	complexity in node selection
Neural network	Solve problems with omplex internal mechanisms	Hard to determine the number of hidden layers
Bayesian classification	Solid mathematical foundations and stability	Assumption isn't applicable and large computation
Rule-based	Obtained rule has great value	Rule is rare and hard to obtain
SVM	Reduce computational complexity	relatively large computation
KNN	Principal fit data situation	Accuracy depends on data size

care needs, and functional expectations of telemedicine platforms. The study underscores the importance of addressing caregivers' unique needs in end-of-life care programs. [7]

In a qualitative study conducted in Germany, researchers interviewed (tele-)medical experts to gain insights into their experiences with adopting telemedicine within the healthcare system. The study uncovered essential themes related to persuasion, knowledge acquisition, implementation processes, decision-making, and confirmation, offering valuable guidance for ongoing telemedicine implementation strategies [8].

Dash et al. investigated the factors influencing telemedicine adoption. They employed multiple regression and artificial neural network (ANN) approaches to identify key motivators for accepting telemedicine during the pandemic [9].

3. Algorithm Identification. There are many algorithms about classification, recommendation and prediction, and whether the algorithm is appropriate or not depends on actual data. Then, although telemedicine system is quite different, the data will be similar [10]. Therefore, the first step is to rule out some algorithms by general law, and then carry out empirical research to compare the remaining algorithms.

Information in the telemedicine system mainly includes user information, doctor information and diagnostic records. User information generally includes user name, gender, age, and region and so on. Doctor information generally includes doctor name, title, and skilled field and so on. Diagnosis records generally includes symptoms, doctor advice, and time and so on. Therefore, there will be dozens of attributes that can be extracted from a telemedicine system. In addition, considering that remote interrogation is the most common system, it is chosen in this research. In this system, diagnostic records typically consist of unstructured text data.

3.1. Disease Differentiation. In the push service, it is the primary job to help patients determine the department according to their symptoms. In order to express conveniently, disease differentiation is used to describe the process. The symptoms in the system are described in words, so the word vector model should be constructed by word segmentation, and then the number of attributes will increase, generally over 100.

There are many classification algorithms, including artificial neural networks decision tree, neural network, Bayesian classification, support vector machine (SVM), rule-based classification and k-nearest neighbor classification (KNN) [11]. In view of the general situation of data, the paper selects support vector machine and k-nearest neighbor classification. The comparison of algorithms in this study is shown in table 3.1

Although artificial neural networks have some self-learning ability, the model may cause overfitting problems when the samples are too small. In addition, ANN has poor interpretability and is not able to explain well the reasons for the results.

In decision tree algorithm, internal node selection will be quite complex and need large calculation because of too many attributes. Some previous literature has used decision trees to make a diagnosis for COVID-19. At runtime, this algorithm is not dynamic enough because of the absence of circular references and feedback loops in the decision tree.[12] In addition, numerous leaves and great depth make it lose the advantage of intuitive result. More importantly, for many word vectors such as wound, inflammation and bleeding can't clearly point to a department. Therefore, error of using the algorithm will be larger.

Although neural network algorithm can simulate the human brain to classify the problem, the number of

the hidden layers will be very difficult to determine. Few words like rhinitis can point to ENT department, but most of them need feedbacks between different layers of neurons to reach the department, so two coexisting cases will greatly decrease the effectiveness and efficiency of the algorithm.

Some studies have argued that some keywords do not reflect all the information regarding BNs in healthcare.[13] Furthermore, naïve Bayesian classification algorithm assumes that an attribute value is independent on a given class. In this study, there are apparently dependencies between attributes, and conditional probability isn't 0. Bayesian belief networks eliminates the assumption, and uses conditional probabilities table and a direct acyclic graph. Because of numerous attributes, the table and graph will be complex, and frequently used greedy algorithm has a large error when class labels are many.

Rule-based classification algorithm introduces association mining into classification. Although the frequent itemsets which are directly found between a class label and attributes have a certain value, they are rare in the data and have a small applicable scope. Therefore, it is difficult to achieve high accuracy.

SVM uses a kernel function to transform the data into a higher dimension, and searches for the optimal separation hyperplane by solving

$$\begin{array}{c} \max \frac{1}{\|\omega\|} \\ s.t.yi\left(\omega^T xi + b\right) \geq 1, i = 1 \cdots n \end{array} \tag{3.1}$$

A small number of support vectors are used for classification, so to a certain extent, it can avoid exponential increases in calculation owing to the increase of dimensionality. However, because of involving matrix calculations, it needs a relatively large calculation and long time.

Although it is hard to determine the class directly through few word vectors, there is no doubt that word vectors between the same department are more similar than different departments, which fits the principal of KNN. By setting k neighbors, the test data are classified by the classes of them. In addition, it is important to note that KNN doesn't construct a complete model, and accuracy depends on data size.

3.2. Doctor Recommendation. Common recommendation methods include collaborative filtering, content-based, interaction-based and hybrid recommendation [14]. In view of the general situation of data, the paper selects collaborative filtering including nearest neighbor recommendation and matrix factorization [15].

Content-based recommendation recommends doctors who are similar to those in user's history, which is very effective in marketing. However, in telemedicine system, the next question has a big probability that it is different from the last one. In addition, it is a problem whether historical questions are enough to work. Therefore, mean and variance of the data should be carefully evaluated before using the method.

Interaction-based recommendation recommends doctors through several questions. However, there are hundreds of doctors even in a small telemedicine system, so it is hard to finish personalized recommendation merely by several questions which are often used to filter data.

Collaborative filtering recommends doctors by collecting similar users' preferences, and includes nearest neighbor recommendation and matrix factorization. The former is similar to KNN, and the latter is especially suitable for numerous attributes and uses the feature vector of user and item to effectively improve speed.

$$\hat{\mathrm{x}}ui = \langle \omega u, hi \rangle = \sum_{f=1}^{k} \omega uf \cdot hif \tag{3.2}$$

3.3. Diagnosis Prediction. Problem descriptions and doctor advice both consist of unstructured text data. To predict diagnosis, this research firstly segments words to construct word vector model, and then mine association rules between the two types. [16]

Common algorithms in association mining include Apriori and FP-growth. Apriori needs to frequently construct candidate itemsets, and then select frequent itemsets. To finish the process, it is necessary to scan original data for many times, which makes efficiency low. However, FP-growth algorithm only requires two scanning in the construction of FP-tree. In addition, the same prefix can be shared in the mining process, which also greatly improves efficiency.

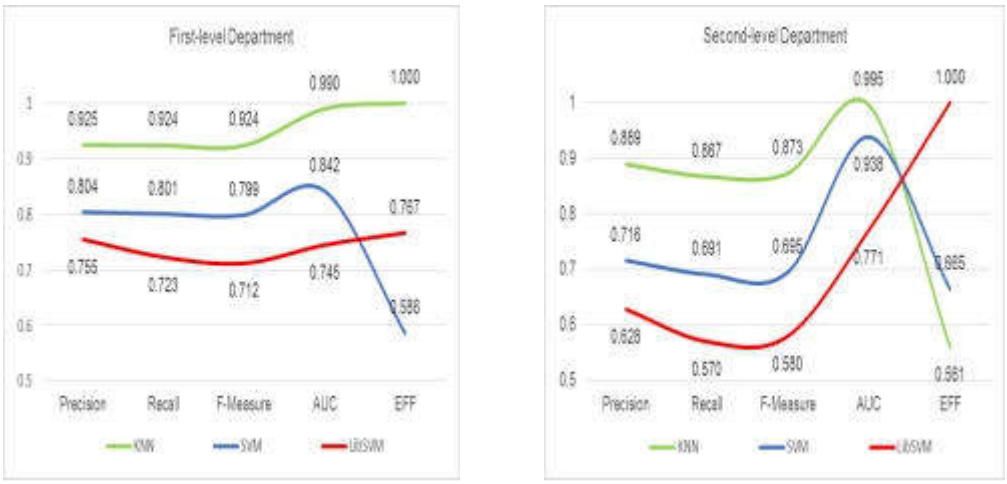

Fig. 4.1: Disease differentiation.

4. Empirical Research. By fetching the real data of a telemedicine system, the paper carries out an e empirical research. 120ask (www.120ask.com) has been in operation for over a decade and owns huge information resources. This research grabs 65862 data of surgery, internal medicine and ENT department from 2005 to 2017. Considering the differences between children and adults, and removing invalid data, finally 61646 data are used for research. Each data has eleven attributes including user name, age, gender, region, time, problem description, doctor name, title, help number, like number and doctor advice. In addition, data preprocessing is completed by using ICTCLAS2013 to construct word vector model.

4.1. Disease Differentiation. Disease differentiation is to divide questions to department, and the study uses three first-level departments and nineteen second-level departments respectively. With a preliminary screening job by the authors, the employed algorithms include support vector machine (SVM) and k-nearest neighbor classification (KNN), and LibSVM which is developed by professor Lin Chin-Jen is also used as a reference [17-20].

The operation time is converted to the index EFF, and higher EFF indicates higher efficiency and less time.

$$EFF = 0.5 + 0.5 \times \frac{time\min}{time} \tag{4.1}$$

In figure 4.1, it can be observed that KNN performs best in terms of accuracy. LibSVM shows its advantage in speed, but fails to improve performance. Compared with first-class departments, the accuracy in the classification of second-level departments decreases, but the basic trend remains unchanged. In addition, the number of class labels greatly affects KNN, and the increase of number can lead to a sharp increase in time.

Figure 4.2 shows that K and kernel function are important parameters in KNN and SVM, respectively. Considering the operation time, more appropriate approach is to use KNN and LibSVM to study the classification of first-class departments. K performs best when K is equal to 1 and needs the shortest time. Linear kernel function has the best performance and polynomial kernel function performs the worst.

4.2. Doctor Recommendation. This study uses nearest neighbor recommendation and matrix factorization (MF) to recommend doctors. The former is similar to KNN in classification, but class label becomes the doctor. The number of classes increases greatly, so only depending on several objects will make error large. According to Herlocker's empirical research, it is reasonable to set K between 20 and 50 [21,22]. Bayesian personalized ranking matrix factorization (BPRMF) and weighted regularization matrix factorization (WRMF) are common models in matrix factorization and use them to study.

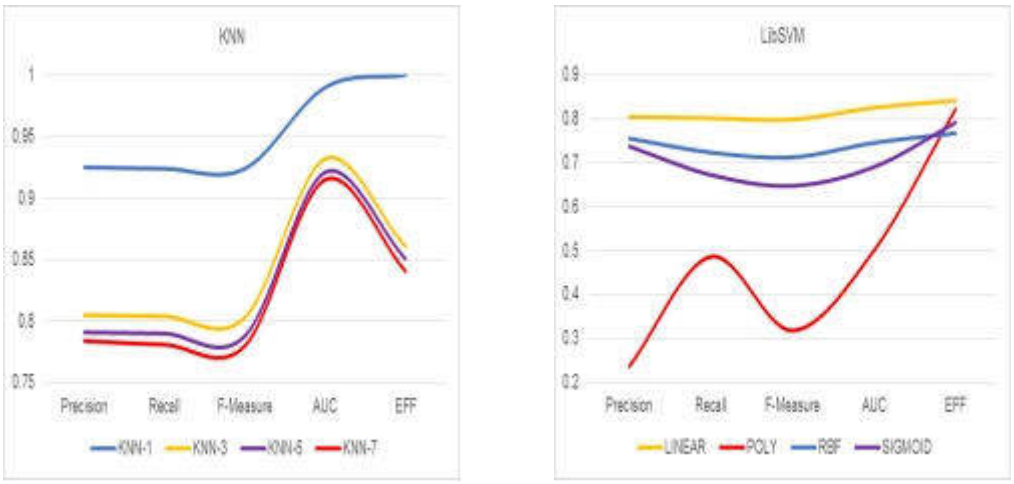

Fig. 4.2: Disease differentiation.

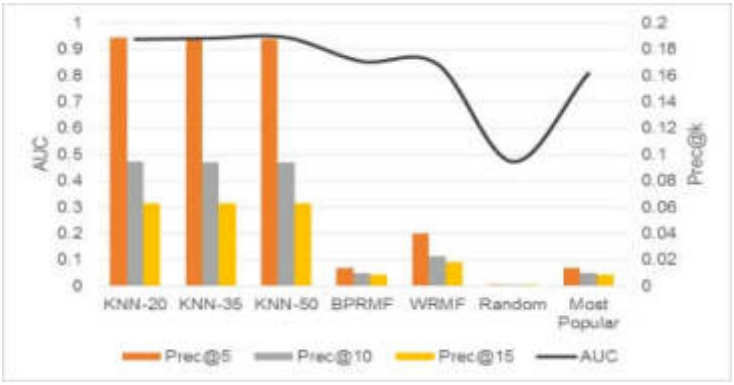

Fig. 4.3: Recommendation comparison.

In terms of accuracy, shown in figure 4.3, nearest neighbor recommendation performs better than MF, and they are both better than non-personalized methods including random and most popular. MF algorithm is particularly suitable for sparse matrix, but it can't show its advantage in the study because of few attributes. Whether K takes 20, 35 or 50, the performance is excellent. In MF, WRMF is better than BPRMF.

In terms of operation time as shown in Table 4.1, the difference is large, and nearest neighbor recommendation is much higher than matrix factorization.

4.3. Diagnosis Prediction. For problem description and doctor advice, word segmentation is used to construct word vector model. To distinguish them, the letter Q and S are respectively added. Therefore, diagnostic prediction is to find the strong association rules between Q and S, and rule antecedent only contains word vector with Q, and rule consequent only contains word vector with S.

This research constructs a model with 150 word vectors with Q and 140 word vectors with S after it is filtered, use FP-growth to mine strong association rules. The purpose is to discover advice according to the symptom, so confidence is set as an important parameter and reduce the significance of support. Setting confidence threshold to 0.5, it is difficult to obtain effective rules. By using the whole data to research causes the failure, because similar symptoms may correspond to different diseases, and correspond to different doctor advice. To solve the problem, this study proposes two methods including threshold adjustment and data

Table 4.1: Operation time

	KNN-20	KNN-35	KNN-50	BPRMF	WRMF	Random	Most Popular
Time	1h	1,5h	2h	1min	0.5min	10s	10s

segmentation.

Although similar symptoms may correspond to different advice, higher confidence still indicates higher value, so the vital part is to make threshold adaptive to find relatively valuable rules. The process can respectively generate 2 and 9 effective rules when threshold is adjusted to 0.25 and 0.20. However, the fundamental cause is too much data, so the solution is that only use the data belonging to general surgery department. When confidence threshold is set to 0.5, there will be 67 strong association rules, which is a significant improvement in effect and efficiency.

5. Conclusion. Based on the analysis of the present situation of telemedicine, this paper constructs a comprehensive push service system of telemedicine that provides disease differentiation, doctor recommendation and diagnosis prediction; in this push service, an integration of various methods of data mining has been done, and the work of its algorithm design and coding has been completed.

In disease differentiation, KNN has the best accuracy especially when K is equal to 1. However, operation time increases dramatically when class labels increase, so SVM or LibSVM can be considered to improve efficiency at the cost of some accuracy. In doctor recommendation, nearest neighbor recommendation performs better than matrix factorization, but the time consumption is a hundred times. In diagnosis prediction, there is a good result by introducing association mining into it, and this research finds that more valuable association rules can be obtained by data segmentation. In addition, adaptive confidence threshold is also helpful in the research.

The result from this method has a strong meaningful value and can also better provide viable methods for upgrading and enhancing the next-generation healthcare system in the future, which hopefully can then save more resources to improve the efficiency of access to healthcare. Through case comparisons, it can be observed the performance of the push service is varied with the work quality of words segmentation. In the future work, a specific professional segmentation system in medical domain will be integrated into the push service for for higher efficiency by relacing the current general segmentation system.

LOCAL WEIGHTED REPRESENTATION BASED MATRIX REGRESSION CLASSIFIER AND FACE RECOGNITION

FANFENG SHI*, ZHENG FANG†, AND XINXIN WU‡

Abstract. Nuclear-norm-based matrix regression (NMR) approaches utilize the nuclear norm for error term characterization, which strengthens the robustness of algorithm. However, NMR ignores the differences between samples from different classes, which leads to a poor feature representation. Moreover, NMR does not consider variations within different class, which affects the classification performance when classes are not homogeneous. To solve above problems, a local weighted representation-based matrix regression method (LWMR) is proposed. LWMR method solves two issues of current NMR methods that are based on nuclear norm. First, LWMR utilizes the prior distance information between test and training samples as weights, which improves the inter-class separation. Second, LWMR creates a new dictionary by averaging samples within different class and choosing the best representative sample for each class, which reduces the dictionary size and complexity. Experimental results on four widely used datasets demonstrate that LWMR method has faster calculation speed and better image performance than other regression models.

Key words: Matrix regression, Nuclear norm, Data representation, Image classification.

1. Introduction. Face recognition involves utilizing facial feature information to ascertain a person's identity. This process typically encompasses three main steps: face detection, feature extraction, and face classification. Among these steps, the design of the face classifier serves as the final component of face recognition. The efficacy of the classifier directly impacts the ultimate outcome of the face recognition process[6, 1]. Linear regression analysis is a common technique for image classification [8]. Naseem *et al.* proposed a linear regression classifier (LRC) for classifying face images [15]. To avoid overfitting, different regularization terms are usually added to LR models. Two commonly used regularizers are L_1 norm regularizer and L_2 norm regularizer. Linear regression (LR) with L_2 norm regularizer is commonly called ridge regression [10], whereas LR with an L_1 norm regularizer is known as lasso regression [16]. These methods constitute widely utilized sparse representation models. J. Wright *et al* introduced a robust face recognition technique through sparse representation classification (SRC) [17]. SRC utilizes all training data as a dictionary to represent test samples, and assumes that representation coefficients are sparse. Non-zero coefficients should predominantly correspond to training samples sharing the same category label as the test sample. To improve the robustness, they additionally posited sparsity in noise and introduced an enhanced SRC model. L. Zhang *et al* analyzed the principle of SRC and considered that the collaborative representation strategy outweighs L_1 norm-based sparse constraints in importance. Consequently, they introduced ridge regression-based collaborative representation classification (CRC) [18]. Nonetheless, CRC lacks a noise removal mechanism, rendering it unsuitable as a robust image classification algorithm. In above methods, they all improve the linear regression model by adding regularization constraints, while ignoring the optimization of dictionary construction for representing test samples. J. Xu *et al.* introduced the mean representation classification (MRC) method [20], which employs the mean value of intra-class training samples as a dictionary for representing test samples. This method acquires reconstruction coefficients of each class, then assigns test samples to a class with the smallest residual. P. Huang *et al.* introduced the local mean representation-based classifier (LMRC) method [7]. This algorithm considers intra-class variations and improves the reconstruction effect of the linear regression algorithm. Above-mentioned methods are all vector-based regression methods. For two-dimensional images

presented in matrix form, they must first be converted into vectors before employing these regression models [5]. This transformation step may lose some structural information. J. Yang *et al.* introduced the nuclear norm-based matrix regression (NMR) model [21]. This model, termed matrix regression, is designed for image characterization and classification using two-dimensional image matrices. NMR employs the nuclear norm to define decision rules, rendering it more robust to illumination changes and occlusions. Based on NMR algorithm, Xie *et al.* introduced a robust NMR algorithm by incorporating a non-convex function to characterize the rank of the error image and extending it to mixed noise conditions [19]. Additionally, Deng *et al.* proposed an NN-MRPE method based on NMR, preserving embedding by constructing a graph using nuclear norm residual evaluation to project high-dimensional data into a low-dimensional space [3]. Li *et al.* proposed an improved NMR method that leverages the low-rank property of the reconstructed image, applies nuclear norm regularization to the image [11]. Chen *et al.* proposed an L_1-norm-based NMR approach. The method applies the L_1 norm to the reconstruction coefficient matrix, and enhances the robustness of the NMR method to occlusion and illumination variations [2]. Lu *et al.* introduced a novel locality-preserving projection method termed nuclear norm-based two-dimensional locality-preserving projection (NN-2DLPP), which maintains the local structure of data in a low-dimensional subspace [13]. NN-2DLPP method restores the noisy data matrix via low-rank learning, eliminates noise from data, and projects denoised data onto a new subspace. Du *et al.* introduced a method termed adaptive occlusion dictionary learning based on kernel norm for face recognition, specifically designed to handle illumination changes and occlusions [4]. To further optimize the algorithm, Luo *et al.* proposed an approximate NMR model with elastic network regularization [14]. These methods leverage the inherent structure and characteristics of face data to enhance classification performance.

Methods based on NMR boost the robustness of matrix regression algorithms by refining regularization terms and the residual assessment model. However, these methods neglect the optimization of the dictionary construction for representing test samples. NMR utilizes all training samples as the dictionary to represent test samples, without considering the intra-class or inter-class variations among training samples, which could potentially diminish the performance of the matrix regression method.

This paper introduces a novel matrix regression image classification approach termed as local weighted representation-based matrix regression (LWMR). This method is designed to improve upon the NMR technique by refining the process of dictionary construction for representing test samples. LWMR generates training samples by assigning weights based on the similarity between test and training samples, thereby enhancing inter-class distinctions. Additionally, this study addresses intra-class variabilities by constructing a dictionary through the selection of the mean value of locally optimal samples within each class as representative samples. Subsequently, the NMR method is employed to decompose test samples into a linear combination of representative samples from the dictionary. The classification outcome is then determined by identifying the minimum residual error. The LWMR method outlined in this paper offers several advantages:

1. LWMR method employs a matrix-based regression model to preserve the structural information and improve the performance of the linear regression model.
2. LWMR method enhances the discriminative ability of the matrix regression model by increasing the variability of samples between classes through weighting.
3. LWMR method exhibits strong robustness against abnormal samples within intra-class training sets.

2. Related work.

2.1. Mean represents classification. The vector of each type of training sample image is expressed as $a_i^m \in R^d, d = p \times q$, where $m = 1, 2, ..., p_i$, p_i represents the number of training samples of ith class, p and q correspond to the height and width of a image. Therefore, the entire training set is expressed as $a = [a_1, a_2, ..., a_c]$. where c represents categories of samples. Test image is expressed as $b \in R^{p \times q}$. The mean representation classification method uses the mean of each type of sample as a representative sample to describe characteristics of the test sample. Hence, a test sample is represented as the product of the class mean sample b. The coefficient vector is denoted as:

$$b = mx \tag{2.1}$$

where $x = [x_1, x_2, ..., x_c]^T$ is the reconstruction coefficient vector corresponding to the representative sample. $m = [m_1, m_2, ..., m_c]$ denotes a dictionary representing sample composition, where each entry corresponds to

the mean sample of a class. The mean sample of the ith class is expressed as:

$$m_i = \frac{1}{p_i} \sum_{j=1}^{p_i} a_i^j, i = 1, 2, \ldots, c \tag{2.2}$$

The mean representation classification method uses the least sqaure method to solve for reconstruction coefficients:

$$\hat{x} = \left(m^T m\right)^{-1} m^T b \tag{2.3}$$

Calculate the reconstruction residual corresponding to the test sample:

$$e_i(b) = \|b - m_i \hat{x_i}\|_2 \tag{2.4}$$

where $\hat{x_i}$ represents the reconstruction coefficient vector of ith class. Finally, according to the principle of minimum reconstruction residual distance, the category of a test sample can be determined:

$$\text{identity } (b) = \arg\min_i \{e_i\} \tag{2.5}$$

2.2. Matrix regression classification. The matrix regression classification method utilizes all training samples to characterize test samples, and uses $A_1, A_2, ..., A_n$ as dictionaries to linearly represent test samples. Therefore, the test sample B is expressed as:

$$\begin{gathered} B = A(x) + E \\ A(x) = x_1 A_1 + x_2 A_2 + \ldots, + x_n A_n \end{gathered} \tag{2.6}$$

where $x = [x_1, x_2, ..., x_n]$ is the coefficient vector corresponding to training samples. E is the error matrix, which is usually low-rank in a optimal solution. Therefore, NMR calculates x by solving the subsequent optimization problem:

$$\min_x \operatorname{rank}(A(x) - B) \tag{2.7}$$

To enhance the generalization ability, NMR introduced ridge regression to the above model, added a regularization term to represent the coefficient x, and obtained a new matrix regression model:

$$\min_x \|A(x) - B\|_* + \frac{1}{2}\lambda \|x\|_2^2 \tag{2.8}$$

In the equation, λ is a positive constant. To optimize the model, NMR utilizes the nuclear norm $\|\cdot\|_*$ substitution $\operatorname{rank}(\cdot)$ function and avoids overfitting of the model by introducing regular terms.

3. Matrix regression classification with locally weighted representation.

3.1. motivation. NMR utilizes all training samples to construct a dictionary. The dictionary is utilized to represent test samples. Training samples are directly employed to represent test samples without distinction. The dictionary constructed directly from all training samples ignores the problem of insufficient differences between samples of different classes. When samples with large differences are in samples within a class, the classification performance of the model will be poor.

To enhance the performance, reconstructing the dictionary used for representing test samples has become a widely adopted and effective approach. MRC simplifies this process by employing the mean value of training samples from each class as the representative sample to construct a new dictionary. This method of reconstructing the dictionary by means of representative samples ignores the possibility that intra-class samples may appear as outliers, thus greatly reducing the accuracy and recognition rate of the algorithm. Therefore, building an effective dictionary is an important way to improve model performance.

Increasing the difference between classes can better improve the competitiveness between samples, which enhances the feature expression capability. In this paper, a weighting function based on NMR is designed,

which weights the similarity between training and test samples, and increases the difference between samples by weighting all training samples. To enhance the robustness in intra-class samples, the local mean processing method can not only reduce the impact of outliers on model performance, but also reduce parameters.

Inspired by aforementioned ideas, a matrix regression classification model based on local weighted representation is proposed. This model uses the similarity between training and test samples as weights. After weighting all training samples, the model calculates the local mean of training samples within each class to form a representative sample of each class. Finally, representative samples of each class are combined into a new dictionary for representing test samples. The model in this paper simultaneously considers the problem of insufficient differentiation of samples between classes and excessive variability of samples within classes, which improves the classification performance and robustness of the model.

3.2. Local Weighted Representation Dictionary. The motivation behind local weighted representation stems from the recognition of the significance of considering the local structure and relationships within data samples, particularly in image classification tasks. Traditional representation methods often treat all samples equally when constructing dictionaries or representations, disregarding potential variations and similarities among samples. Local weighted representation seeks to address this limitation by assigning weights based on the similarity between test and training samples. The construction of the local weighted representation dictionary is based on the distance Dis(a, b) between all training samples a and a test sample b as the similarity. The similarity matrix between training samples and a test sample is defined as:

$$S = D\left(a_i^j - b\right) \tag{3.1}$$

where the similarity matrix S is expressed as :

$$S = \begin{bmatrix} D\left(a_1^1 - b\right) & D\left(a_1^2 - b\right) & \cdots & D\left(a_1^{p_1} - b\right) \\ D\left(a_2^1 - b\right) & D\left(a_2^2 - b\right) & \cdots & D\left(a_2^{p_2} - b\right) \\ \vdots & \vdots & \ddots & \vdots \\ D\left(a_c^1 - b\right) & D\left(a_c^2 - b\right) & \cdots & D\left(a_c^{p_c} - b\right) \end{bmatrix} \tag{3.2}$$

where the distance between the test sample and all training samples is measured by Euclidean distance:

$$D\left(a_i^j - b\right) = \left\|a_i^j - b\right\|_2, i = 1, 2, \ldots, c; j = 1, 2, \ldots, p_i \tag{3.3}$$

Weights are assigned based on the similarity between all training samples and a test sample, and a weighted representation dictionary is constructed by adding weight to training samples:

$$W = \begin{bmatrix} \frac{1}{S_1^1} * a_1^1 & \frac{1}{S_1^2} * a_1^2 & \cdots & \frac{1}{s_1^{p_1}} * a_1^{p_1} \\ \frac{1}{S_2^1} * a_2^1 & \frac{1}{S_2^2} * a_2^2 & \cdots & \frac{1}{s_2^{p_2}} * a_2^{p_2} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{1}{S_c^1} * a_c^1 & \frac{1}{S_c^2} * a_c^2 & \cdots & \frac{1}{s_c^{p_c}} * a_c^{p_c} \end{bmatrix} \tag{3.4}$$

where S_i^j represents the similarity between the jth sample a_i^j to be tested and training samples in the ith category. A weighted representation sample for each training sample is expressed as $\mathrm{w}\frac{1}{S_i^j} * a_i^j$.

Constructing a weighted representation dictionary through similarity weighting can increase the difference between samples of different class, enhance the weight of samples with smaller similarities in the reconstructed representation, and improve the classification effect of the regression model. However, when outliers appear in intra-class samples, it will affect the regression reconstruction performance of the model. Based on the weighted representation dictionary, the robustness of the model for the case of excessive intra-class sample differences is improved by constructing a locally weighted representation dictionary. After ranking the similarity corresponding to each class of training samples, the corresponding nearest neighbor parameter K is selected and the K-nearest neighbor matrix is constructed. Specific steps are shown below:

Step 1. Sort each row of the similarity matrix by similarity and take the smallest similarity value to construct a nearest neighbor similarity matrix, as follows.

$$S_K = \begin{bmatrix} S_1(1) & S_1(2) & \cdots & S_1(K) \\ S_2(1) & S_2(2) & \cdots & S_2(K) \\ \vdots & \vdots & \ddots & \vdots \\ S_c(1) & S_c(2) & \ldots & S_c(K) \end{bmatrix} \tag{3.5}$$

Among them, the value $S_i(j)$ representing the jth similarity of the ith category contains the K smallest similarity value in each category.

Step 2. Find the position of each similarity in the K-nearest neighbor matrix in the corresponding training sample category, denoted by the function $f(S_K)$, to obtain the position matrix P of the similarity matrix S_K, which is defined as:

$$P = \begin{bmatrix} f(S_1(1)) & f(S_1(2)) & \cdots & f(S_1(K)) \\ f(S_2(1)) & f(S_2(2)) & \cdots & f(S_2(K)) \\ \vdots & \vdots & \ddots & \vdots \\ f(S_c(1)) & f(S_c(2)) & \ldots & f(S_c(K)) \end{bmatrix} \tag{3.6}$$

In the equation, $P_i{}^j = f(S_i(j))$ represents the jth position of the sorted similarity value in the ith category in the weighted representation dictionary.

Step 3. Find the weighted training samples of the K nearest neighbours of each category in the weighted representation dictionary W as a locally weighted dictionary l. The local weighted dictionary is expressed as:

$$P = \begin{bmatrix} W_1^{P_1^1} & W_1^{P_1^2} & \cdots & W_1^{P_1^K} \\ W_2^{P_2^1} & W_2^{P_2^2} & \cdots & W_2^{P_2^K} \\ \vdots & \vdots & \ddots & \vdots \\ W_c^{P_c^1} & W_c^{P_c^2} & \cdots & W_c^{P_c^K} \end{bmatrix} \tag{3.7}$$

where $W_i{}^j$ represents the weighted representation sample with the smallest corresponding similarity among the weighted representation samples.

Step 4. In order to reduce the problem that excessive intra-class sample differences will lead to poor model robustness. By taking the mean value within the class, the class representative samples are constructed by averaging the weighted representation samples of each class in the local weighted dictionary, and the local weighted representative dictionary is constructed. The local weighted representative dictionary is expressed as:

$$r = \begin{bmatrix} \text{mean}\left(W_1^{P_1^1}, W_1^{P_1^2}, \ldots, W_1^{P_1^K}\right) \\ \text{mean}\left(W_2^{P_2^1}, W_2^{P_2^2}, \ldots, W_2^{P_2^K}\right) \\ \vdots \\ \text{mean}\left(W_c^{P_c^1}, W_c^{P_c^2}, \ldots, W_c^{P_c^K}\right) \end{bmatrix} \tag{3.8}$$

where the function mean$(\cdot)$ means taking the average of vectors in the brackets to construct a new representative sample.

3.3. Matrix Regression Classification with Locally Weighted Representation. For each test sample, the local weighted representative sample of each class can be calculated through the above method, and representative samples are combined to build a local weighted representative dictionary $r = [r_1, r_2, \ldots, r_c] \in R^{d \times c}$. Use a local weighted dictionary r to linearly represent the test sample b, as follows:

$$\begin{gathered} b = r(x) + e \\ r(x) = x_1 r_7 + x_2 r_2 + \ldots + x_c r_c \end{gathered} \tag{3.9}$$

where, $x_1, x_2, \cdots, x_c$ represent the coefficient corresponding to the representative sample, and e represents the residual. Considering that the residual image $r(x) - b$ usually required in the optimization process is of low rank, the representation coefficient is learned through low-rank constraints:

$$\min_x \operatorname{rank}(r(x) - b) \tag{3.10}$$

The above optimization problem is an NP problem, which is usually converted into a nuclear norm problem to solve, as follows:

$$\min_x \|(r(x) - b)\|_* \tag{3.11}$$

In addition, the idea of ridge regression is introduced into the formula, and a regularized matrix regression model is obtained by adding regular terms:

$$\min_x \|r(x) - b\|_* + \frac{1}{2}\lambda\|x\|_2^2 \tag{3.12}$$

By applying the augmented Lagrange multiplier method, the model is rewritten as follows:

$$\min_x \|y\|_* + \frac{1}{2}\lambda\|x\|_2^2 \quad \text{s.t. } r(x) - b = y \tag{3.13}$$

The corresponding Lagrangian function is defined as:

$$L(y, x, z) = \|y\|_* + \tfrac{1}{2}\lambda\|x\|_2^2 + \operatorname{tr}\left(z^T(r(x) - y - b)\right) + \tfrac{\mu}{2}\|r(x) - y - b\|_F^2 \tag{3.14}$$

where $\mu > 0$ is a penalty parameter, z is the Lagrange multiplier, $\operatorname{tr}(\cdot)$ representing the trace operation function. Through iterative solution, the solution formula is as follows:

$$x^{k+1} = \left(r^T r + \frac{\lambda}{\mu} I\right)^{-1} r^T \left(b + y^k - \frac{1}{\mu} z^k\right) \tag{3.15}$$

$$y^{k+1} = D_{\frac{1}{\mu}}\left(r\left(x^{k+1}\right) - b + \frac{1}{\mu} z^k\right) \tag{3.16}$$

$$z^{k+1} = z^k + \mu\left(r\left(x^{k+1} - y^{k+1} - b\right)\right) \tag{3.17}$$

After calculating the representation coefficient x^*, calculate the reconstruction residual corresponding to the test sample:

$$e_i(b) = \left\|\hat{b} - \hat{b_i}\right\|_* = \left\|r\left(x^*\right) - r\left(\delta_i\left(x^*\right)\right)\right\|_* \tag{3.18}$$

where $\delta_i(x)$ retains the representation coefficients related to the current class and sets other coefficients to zero. Finally, according to the principle of minimum reconstruction residual distance, the category of the test sample is determined, that is:

$$\text{identity } (b) = \arg\min_i \{e_i\} \tag{3.19}$$

The flow of the algorithm is as follows:

4. Experimental results and analysis. Experiments to assess the performance of algorithms are presented in this chapter. Two benchmark datasets of face images and biometric fingerprints are used to test LWMR algorithm Some classical classification algorithms, such as SRC, LRC, and CRC are used to compared with LWMR method. The algorithm are also contrasted with the state-of-the-art NMR and SR-NMR matrix regression classification algorithms from the relevant literature. To make results more credible, we repeat each experiment 10 times. We conduct all experiments on MATLAB 2021b platform, using a machine with an Intel i7-10750 2.60GHz CPU, an NVIDIA GTX1650 GPU, and 16GB 2933MHz memory.

Algorithm 16 Matrix regression classification algorithm based on local weighted representation

Input: Training set, Test set, Neighbor parameter K, regularization parameter λ, penalty parameter μ, Lagrange multiplier z, maximum number of iterations.

Output: The category of a test sample

1: Preprocess samples to obtain training set $a = [a_1, a_2, \cdots, a_c]$ and test sample b.
2: Calculate the similarity matrix S between training samples and the test sample.
3: The similarity between training samples and the test sample serves as a weight, and a weighted representation dictionary W is constructed by adding weight to training samples.
4: Find weighted training samples of the K-nearest neighbors of each category in the weighted representation dictionary as a local weighted dictionary l.
5: By taking the mean value within the class, the class representative samples are constructed by averaging weighted representation samples of each class in the local weighted dictionary l, and the local weighted representative dictionary r is constructed.
6: Utilize a locally weighted dictionary r to linearly represent b, and solve for representation coefficients x through matrix regression.
7: Classify according to the minimum residual principle identity $(b) = \arg\min_i \{e_i\}$

Fig. 4.1: Images from Extended Yale B dataset.

4.1. Light change experiment. Image classification accuracy may be affected by noise data in images collected under varying illumination conditions. To assess the robustness of the algorithm to lighting changes, the Extended Yale B dataset is utilized [12]. This dataset contains 38 people, each acquiring 64 images.All images are converted to grayscale and are resized to 96×84 pixels. 10, 15, 20, or 25 images per subject are selected randomly as training samples and rest samples are used to test. Some sample images are shown in Fig. 4.1.

The recognition results of different methods on Extended Yale B dataset are shown in Table 4.1. As shown in Fig. 4.1, this dataset contains many images with severe lighting conditions, which will generate more noise and have higher requirements on the robustness of the recognition algorithm. From Table 4.1, it is clearly that the sparse representation method SRC has a poor recognition rate and is not robust to images with large illumination changes. Both LRC and CRC methods utilize all training samples as a dictionary. However, the inclusion of noisy images in the dictionary prevents the generation of better reconstructed samples, thus impeding the enhancement of recognition results. Different from the classic algorithm, the matrix regression algorithm NMR takes into account the structural information, introduces the nuclear norm to describe the error term, improves the robustness to structural noise, and obtains a higher recognition rate. The proposed method

Table 4.1: Results of different algorithms on Extended Yale B

Methods	Different numbers of training samples			
	10	15	20	25
SRC	52.97%	60.61%	67.01%	71.10%
LRC	71.65%	82.04%	87.57%	90.00%
CRC	85.64%	90.11%	92.38%	94.54%
NMR	90.35%	94.59%	96.68%	97.73%
LWMR	91.93%	95.62%	97.41%	98.35%

reduces the impact of noisy samples by selecting dictionary samples and obtains the highest recognition rate.

4.2. Real occlusion experiment. To assess the recognition performance in occluded scenes, AR dataset is utilized. AR dataset [9] contains 120 volunteers, each with 26 images, including different expressions, angles, occlusions, etc., totaling 3120 images. All images are downsampled to 165×120 pixels. Some samples of the dataset are shown in Fig. 4.2.

Firstly, we selected 8 random frontal face images from the unoccluded part of the dataset as training samples. We divide the occlusion part of AR face dataset into two test sets: sunglasses occlusion and scarf occlusion. Each test set contains 6 occlusion images of each type of sample. The classification results of different classification algorithms under real occlusion and scarf occlusion by sunglasses in AR dataset are shown in Fig. 4.3 and Fig. 4.4.

We can see from the histogram in Fig. 4.3 that LWMR algorithm achieves the highest recognition effect in real scenes blocked by sunglasses. For scenes blocked by sunglasses, there are fewer parts of the face image that are continuously blocked, and only a small amount of eyes are blocked. Therefore, the traditional SRC algorithm, LRC algorithm and CRC algorithm have achieved good classification results. NMR and LWMR algorithms do not have obvious advantages in classification under continuous occlusion. However, compared with traditional regression algorithms, matrix regression fully utilizes the two-dimensional structural information and achieve better performance. From Fig. 4.2, the face image is blocked by a large scarf, which seriously affects the face image and reduces the effectiveness of the face image. Fig. 4.4 shows results of face images of different methods in scarf occlusion scenes. It can be seen from the figure that traditional regression algorithms: SRC algorithm, LRC algorithm and CRC algorithm have poor recognition results in scenes with large-area continuous occlusion. Recognition rate below 55%. The algorithm based on matrix regression achieves a higher recognition rate. By retaining the two-dimensional structural information, the performance is improved by imposing low-rank constraints on the error image. LWMR algorithm in this article further improves the recognition rate of the algorithm by constructing a more effective dictionary and enhances the effectiveness in different scenarios.

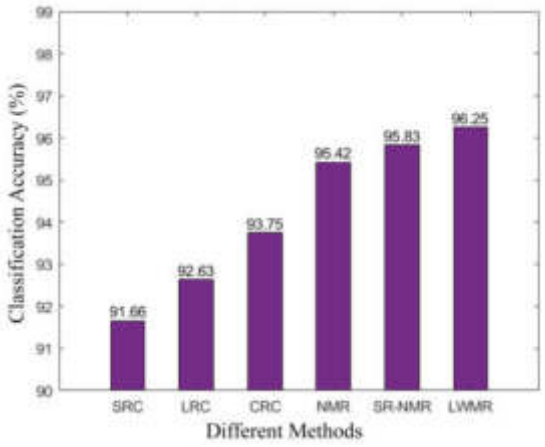

Fig. 4.3: Recognition rate under sunglasses occlusion in AR dataset.

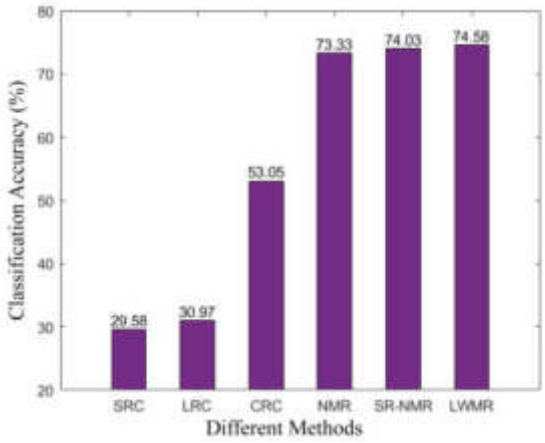

Fig. 4.4: Recognition rate under scarf occlusion in AR dataset.

4.3. Random occlusion experiment. To further assess the effectiveness of LWMR, we conducted experiments using three subsets of the Extended Yale B dataset. Subset 1 and subset 2 served as the training set, and subset 3 functioned as the test set. We added different degrees of occlusion to the test set, using baboon images to randomly occlude test images. Occlusion is divided into 5 levels, accounting for 10%, 20%, 30%, 40%, 50%, and 60% of overall images. The image after adding occlusion is shown in Fig. 4.5.

Fig. 4.6 shows results of five comparative methods and LWMR method under different degrees of occlusion. As the occlusion ratio increases, the recognition rate of each algorithm gradually decreases. As is seen from Fig. 4.6, LWMR method obtains the best performance and has good robustness to continuous occlusion scenes. SRC algorithm, LRC algorithm and CRC algorithm are classic regressions. As the degree of occlusion increases, the recognition rate of the algorithm decreases significantly, because as the degree of occlusion increases, more and more key information of the image will be lost, which affects the recognition algorithm. The latest SR_NMR algorithm achieves a good recognition rate because the algorithm increases the sparsity constraint of matrix regression and improves the robustness to noise.

4.4. Experiment analysis. From experimental results, the performance, advantages and disadvantages of different algorithms can be analyzed. This article selects three classic datasets from different scenes to

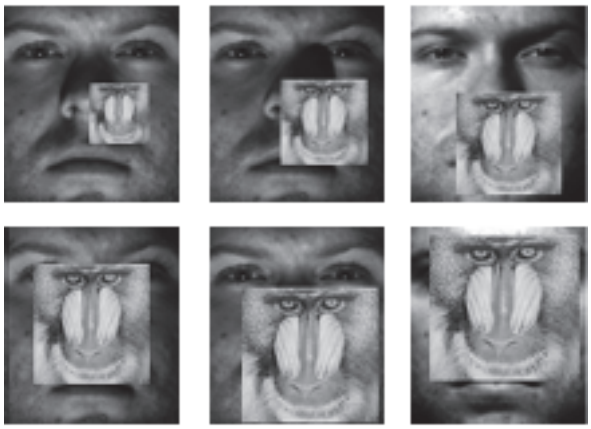

Fig. 4.5: Face images with different occlusion ratios.

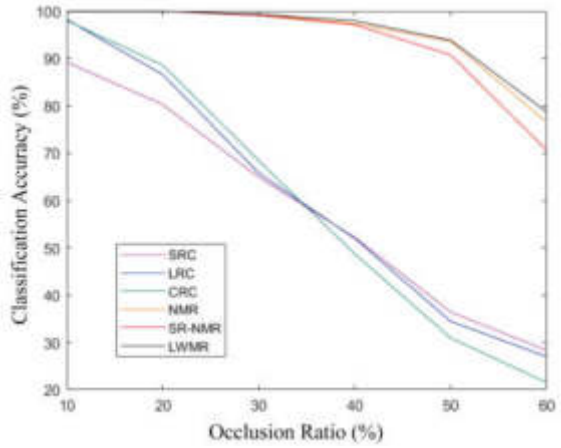

Fig. 4.6: Classification accuracies under different occlusion ratios.

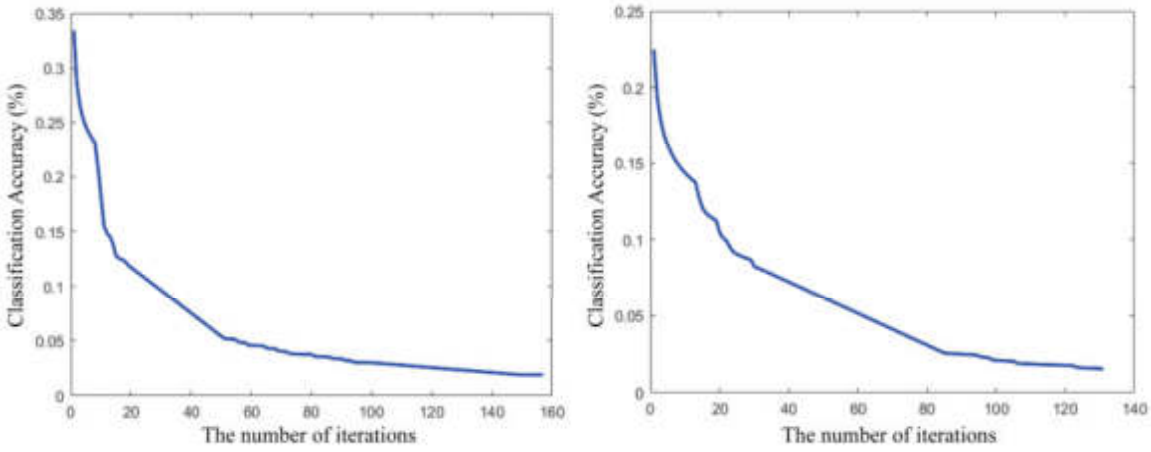
evaluate the performance of the different method, including Yale B dataset with severe illumination changes, AR dataset with different degrees of occlusion in real scenes, and the dataset with random block occlusion. LWMR has achieved good recognition performance on three datasets, indicating that LWMR has good robustness to different types of noise.

Moreover, Yale B dataset was employed to assess variations in recognition performance among different algorithms under various lighting conditions. As shown in Table 4.1, different illumination will have a great impact on the recognition rate, especially in scenes with severe illumination changes. Traditional SRC algorithms, LRC algorithms and CRC algorithms lack robustness to noise and do not have good identification and discrimination capabilities for large changes in illumination. NMR algorithm and SR-NMR algorithm fully take into account the structural information. Moreover, they enhance the recognition performance effectively through the application of low-rank constraints on the error image. This paper further processes the noise data based on matrix regression, and constructs a robust dictionary by weighting training samples and selecting them locally, thereby reducing the impact of noise samples on the recognition rate. The experimental data shows that LWMR algorithm can perform well in scenes with severe illumination changes. It has better recognition effect.



(a) Extended Yale B (b) AR

Fig. 4.7: Convergence on different datasets.

Occluded images are used to test the effectiveness and robustness of face recognition algorithms. AR occlusion face images from realistic scenarios are utilized used to compare the capability of different methods. Fig. 4.3 shows the histogram of recognition rates for different algorithms. However, as shown in Fig. 4.4, the recognition performance of three classic algorithms declined sharply due to different scarf occlusions. The continuous large-area occlusion obscured some essential facial features, leading to low recognition accuracy. By incorporating the structural information of the image, NMR and SR-NMR algorithms perform low-rank decomposition on the error image to achieve higher recognition rates. By constructing a more effective dictionary that preserves the structural information, the algorithm presented in this paper enhances the noise robustness of matrix regression.

To assess the performance of continuous occlusion, we conducted random occlusion experiments with varying proportions. As shown in Fig. 4.6, the figure shows that results of different algorithms declines as the face image occlusion proportion increases. The recognition rate of the classic SRC, LRC, and CRC algorithms declines rapidly with the proportion of continuous occlusions, which greatly affects their performance. The matrix regression algorithm, on the other hand, has a slower decrease and better robustness as the occlusion ratio increases.As shown in Fig. 4.6, the LWMR algorithm presented in this study consistently demonstrates superior recognition rates compared to alternative methods. This achievement is attributed to the algorithm's integration of local weights into training samples based on their structural information. This strategy enables the LWMR algorithm to construct a more resilient dictionary, thereby enhancing its overall robustness.

4.5. Convergence analysis. The convergence of the model is important to verify the quality of a model. ADMM algorithm [22] can help the model iterate to the optimal value faster and more effectively. When the loss of the model decreases, the number of iterations increases. It indicates that the model has better performance. This paper uses the ADMM optimization algorithm to solve the model iteratively, and examined the model convergence in the experiment to validate the stability of the face recognition model. If the decline is slow at the beginning, it means that the learning rate of the model is set relatively low and the learning gradient is relatively slow. If the learning rate of a model is set too high, the global optimal value will not be learned, and the loss will fluctuate and not decrease.

We used the loss as a criterion for model convergence and the number of iterations as an indicator of model effectiveness. Fig. 4.7 illustrates the convergence of different datasets. Fig. 4.7 (a) and (b) demonstrate that the algorithm converged well on both two datasets, learning effective parameters that improved the face image classification.

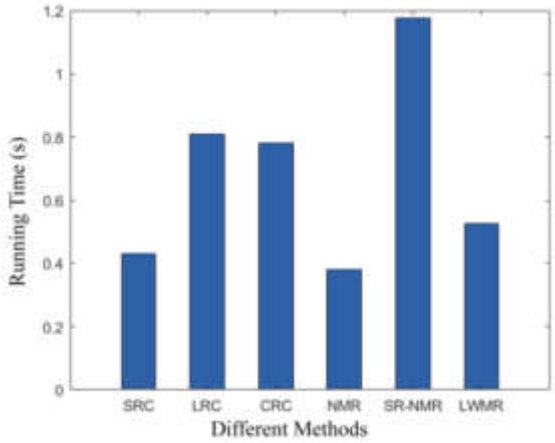


Fig. 4.8: Running times of different algorithms.

4.6. Time complexity analysis. To validate the performance of the LWMR model presented in this paper, we compared and analyzed its running time, and further examined its time complexity. We used AR face dataset as the benchmark to measure the running time of different algorithms.

Fig. 4.8 shows that LRC algorithm and CRC algorithm have the lowest time complexity and the fastest running time, as they only involve linear regression models with closed-form solutions. However, these two algorithms have low recognition rates and poor noise robustness in complex scenarios such as extensive continuous occlusions.

LWMR algorithm presented in this paper outperforms other algorithms in terms of speed and recognition rate for scenarios with severe illumination variations and extensive continuous occlusions. SRC algorithm is somewhat robust, but it has high time complexity and lower recognition rate for such scenarios than LWMR algorithm. The complexity of LWMR is $O\left(k\left(m^2\right)+mn\right)$. The complexity of SRC is $O\left(n^2\left(m+n\right)^2\right)$. LWMR algorithm proposed in this paper exhibits low time complexity and high noise robustness across various scenarios.

4.7. Parameter sensitivity analysis. In the experiment, the regularization parameter and the local selection parameter K were used in the optimization formula of the model. Fig. 4.8 shows the impact of parameters λ and K. This paper sets parameters in the range of $\{1e-4, 1e-3, 1e-2, 1e-1, 1, 1e+1, 1e+2, 1e+3, 1e+4\}$ to conduct parameter sensitivity analysis. Local selection parameters are set within the data interval of $\{1, 2...train-size\}$, and the model recognition accuracy is used as the measurement unit for analysis.

The experiment shows that the performance of the model has a non-monotonic relationship with the parameters. The model achieves the highest accuracy when the value is 1. This indicates that weights of two models before and after regularization are equal, and only minor adjustments of regularization parameters are needed. Optimal experimental results were obtained when the regularization parameter was set to 0.9. As shown in Fig. 4.9, when the K increases, the recognition rate of the model gradually increases, but when it reaches the maximum value, the recognition rate decreases. A common practice is to select two numbers before the maximum value as optimal identification parameters. Some of training samples are negative samples. By assigning weights to samples and eliminating a few negative samples, we can boost the performance and the robustness.

5. Conclusion. This paper presents LWMR, a matrix regression classification method designed to enhance discriminative capability. LWMR takes into account the variability among samples, avoids the masked part by the mean operation. Additionally, LWMR treats each sample in a weighted way, and takes into account the variability of the samples within the class, so it achieves a better recognition rate. Evaluation on three datasets validates the superior performance of LWMR over existing matrix regression methods, particularly evident in scenarios featuring severe illumination variations and continuous occlusions. In the further work, we

Fig. 4.9: Accuracies with different lamda parameters.

will explore difference weighting scheme and apply to more datasets.

FEATURE ENHANCEMENT BASED JOINT EXTRACTION OF WEB NOVEL ENTITY RELATIONSHIPS

AILIN LI *, BIN WEI†, AND WEIHUA LIU ‡

Abstract. In an era characterized by constant advancements in computer science, web novels represent an extensive and intricate form of text that presents unique challenges for automated processing. This investigation aims to address the issues associated with the time-intensive, laborious, and error-prone nature of text processing within web novels. It presents a novel joint entity-relationship extraction model that is enhanced by various features. By leveraging a combination of computer vision and natural language processing techniques, the extraction of named entities and relationships is modeled in a unified framework to optimize text feature mining. The employment of bidirectional long-short term memory networks and multi-layer perceptron equips the model with the capability to effectively extract entity relationships from web novels comprehensively. Experimental outcomes indicate that the model achieves an F1 score of 72.4%, marking a notable enhancement over traditional pipelined models. This study offers robust tools and methodologies for computers to process extensive and complex textual data, further integrates computer vision with natural language processing, and broadens the potential applications within the domain of information processing.

Key words: entity-relationship extraction, pre-trained models, feature enhancement, natural language processing

1. Introduction. In this paper, a feature-enhanced entity-relationship joint extraction model based on feature augmentation is proposed to cope with the time-consuming, labor-intensive, and error-prone problems in text processing for web novel texts. Web novels typically provide detailed descriptions of characters' personalities and destinies, along with intricate social interactions. However, their length and complex character relationships can hinder storyline comprehension and offer an unsatisfactory reading experience. Therefore, employing deep learning technology to transform complex text into structured information can help readers quickly grasp the plot of web novels and gain an overall understanding of the characters and relationships involved [1].

Named Entity Recognition (NER) focuses on extracting entities of specific categories from unstructured text, with common entity types including time, location, person, organization, etc. Relationship extraction aims to identify the relationships between entities within a text [2]. Considering the limitations of pipelined models, a joint approach that integrates named entity recognition and relationship extraction has been proposed [3]. This approach considers the correlation between entities and relationships while performing entity recognition and entity-to-relationship classification, thereby improving the model's recognition efficiency and reducing error accumulation [4].

This study presents a feature enhancement-based model for extracting relationships between entities in web novels. The model utilizes BERT for pre-processing training data to obtain word vectors, and then annotates entity features using the language technology platform released by Baidu for lexical annotation of words in a sentence [5]. Multiple features are input into the model together for training. Additionally, a decomposition strategy is employed to first identify the head entity, followed by predicting the corresponding tail entity and relationship category. The shortcomings of existing studies are the problems of error accumulation, relationship overlap and information redundancy in information extraction methods, the error propagation in traditional pipeline models that degrade the overall extraction performance, and the limitations of the joint entity-relationship extraction methods proposed in recent years. In terms of innovativeness, the thesis proposes a joint entity-relationship extraction model based on feature augmentation, introduces named entity and lexical

labeling features, employs decomposition strategy and multi-attention mechanism, and achieves remarkable results in entity-relationship extraction tasks in the field of online literature. In addition, the paper further integrates computer vision and natural language processing techniques, provides effective tools for processing large-scale complex text data, and expands the application prospects in the field of information processing.

2. Related work. Current information extraction methods include entity recognition and relationship extraction, but these methods have some problems such as error accumulation and relationship overlap. To solve these problems, the researchers proposed joint entity-relationship extraction method.Information Extraction [6] (IE) involves structuring natural language text to extract valuable information from it. In the past, Named Entity Recognition (NER) and Relation Extraction (RE) were considered as separate tasks. Research conducted by Deng Yuyang et al. [7] revealed that a pre-trained model enhanced the F1 value of word vectors by 5.9% over Bi-directional Long Short-Term Memory (BiLSTM) and Conditional Random Field models. Agrawal Ankit et al. [8] demonstrated that the BERT pre-trained model, after tuning on GENIA, achieved F1 values of 74.38% on GermEval 2014, 85.29% on GermEval 2014, and 80.68% on JNLPBA dataset, which is suitable for complex named entity recognition. BACH and BADASKAR [9] developed the extraction model JPEA, and the combination of a pre-trained model and attention mechanism significantly enhanced semantic expression ability as well as the accuracy of ternary extraction. HAN and WANG [10] integrated Bi-directional Gated Recurrent Unit (BiGRU) and CNN into an entity-relationship extraction model, offering a new approach to entity-relationship extraction in the information extraction field.

However, this method is simplistic and faces several challenges: error accumulation, where the correlation between the two tasks is overlooked during information extraction, leading to varying relationship extraction results based on named entity recognition outcomes; overlapping relationships, where a single entity corresponds to multiple entities with various relationships superimposed; and information redundancy, where not all recognized entities have corresponding entities and relationships, resulting in information redundancy and reduced recognition efficiency.

To address these issues, joint entity-relationship extraction methods have been proposed [11]. Unlike traditional pipelined models that first identify entities and then perform relationship classification on target entity pairs, these methods simultaneously model named entity identification and relationship extraction to mitigate the impact of error propagation and enhance overall extraction performance.

In recent years, joint models for entity-relationship extraction have also been developed, with strategies including parameter-sharing-based joint extraction methods and sequence annotation-based joint extraction methods. WANG et al. [12] addressed the multi-entity-relationship problem frequently encountered in food public opinion by extracting entity-relationship types from BERT and incorporating a semantic role-attention mechanism to integrate entity-relationship types in BiLSTM for entity-relationship extraction in food public opinion. XU and ZHAO [13] proposed a joint extraction model integrating BiLSTM and ResNet to obtain word context vectors, utilizing residual network features to capture entity pair structural information with maximum pooling. WANG and LIU [14] introduced a pointer annotation strategy-based approach to tackle entity nesting issues, achieving significant results with F1 values exceeding 70% on average across two Chinese corpus datasets. Fan and associates employed a multi-window convolutional neural network to automatically extract sentence features and utilized entity type embedding methods to classify relationships, ultimately outputting eleven extracted relationships in ternary group format with a model F1 value reaching 93.15%. Xueying Wu and colleagues proposed a BERT-based Hierarchical Tagging Model (HtERT) for relational ternary extraction in the geological domain, utilizing BERT-wwm as the underlying encoder, limiting entity extraction length, and incorporating global information and BiLSTM to extract accurate geological sample features, enhancing the extraction capabilities for relationship triples as well as overlapping triples.

2.1. Knowledge map. Knowledge Graph aims to integrate structured and unstructured information on the Internet to construct a knowledge graph for modeling, reasoning and associating knowledge. The construction of knowledge graph usually involves techniques such as entity recognition, relationship extraction and knowledge reasoning. Classical entity-relationship extraction methods include rule-based methods and statistical learning-based methods. In recent years, deep learning methods such as neural networks have been widely used in the construction of knowledge graphs, such as using models such as convolutional neural networks (CNNs) and recurrent neural networks (RNNs) for entity recognition and relationship extraction [15].

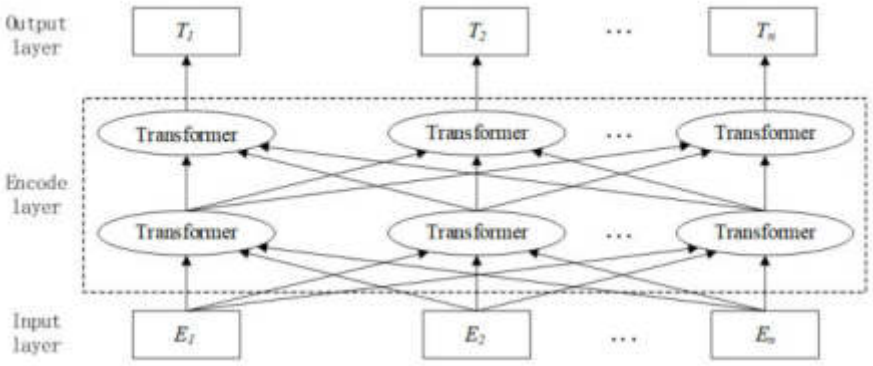

Fig. 3.1: BERT pre-trained language model

2.2. Information Extraction. Information extraction aims to automatically extract structured information from unstructured text. Information extraction includes subtasks such as entity recognition and relationship extraction. Traditional information extraction methods mainly use a pipeline model, i.e., entity recognition is performed first, and then relationship classification is performed between the recognized entities. However, this pipeline model suffers from problems such as error accumulation and relationship overlap. To solve these problems, in recent years researchers have proposed joint entity-relationship extraction methods, such as parameter sharing and sequence labeling. These methods jointly model the entity recognition and relationship extraction tasks to improve the overall performance of the model [16].

3. Feature Enhancement Based Joint Extraction of Entity Relationships. The model that emphasizes on feature enhancement is primarily composed of three sections: an input layer, a head entity recognition layer, and a tail entity and relationship recognition layer. The input layer provides a rich and comprehensive textual feature representation for the model; the head entity recognition layer encodes the input text and determines the location of the head entity; the tail entity and relationship recognition layer further predicts the tail entity and relationship on the basis of the head entity. The whole model realizes joint entity-relationship extraction through the transfer of head entity and tail entity information, reflecting the close intrinsic connection between the parts. At the input layer, the model undergoes pre-training with BERT and is then integrated with the extracted named entities and lexical annotation features to acquire text feature information. Subsequently, the head entity encoding vector is derived via the head entity recognition layer. Thereafter, the text encoding information is combined with the multi-head attention mechanism to achieve comprehensive recognition of tail entities and relationships, ultimately yielding the entity-relationship extraction triad.

3.1. BERT pre-training model. BERT [17] is a profound bidirectional language representation model that utilizes the Pre-training plus Fine-tuning training method. It pre-trains the language model with the main architecture of the multi-layer Transformer's Encoder layer, surpassing previous shallow inter-embedding models based on single language models and multiple single models. The structure of the BERT pre-training language model is presented in Fig 3.1.

Utilizing the BERT language model for feature extraction from processed text and recognized domain-specific dictionaries. The model accepts input ranging from a single sentence to extensive texts, with 'CLS' indicating the start and 'SEP' marking the end of the text. Word embeddings involve transforming each word into vector form; sentence embeddings determine the sentence membership of each word, capturing overall semantic content; and position embeddings encode the spatial information of words. A representation of the encoding process for the example sentence 'Bai Xiaochun departed from the Lingxi Sect' is illustrated in Fig. 3.2.

After vectors illustrate the sentence's words, they need to be feature-coded. BERT uses the Encoder part of the classic Transformer architecture. Post multi-head attention, text is transferred from the Encoder input to a feed-forward neural network. A supplementary attention layer in the decoder focuses on information linked

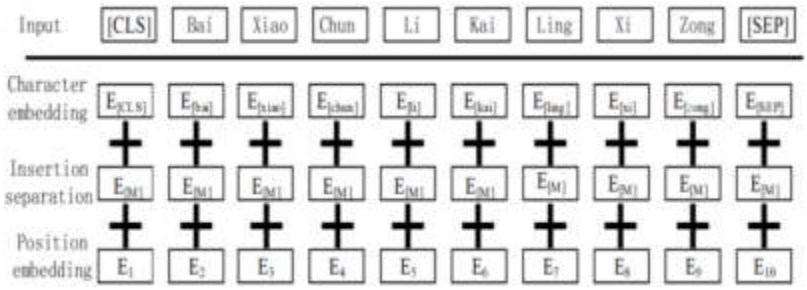

Fig. 3.2: Vector embedding representation model diagram

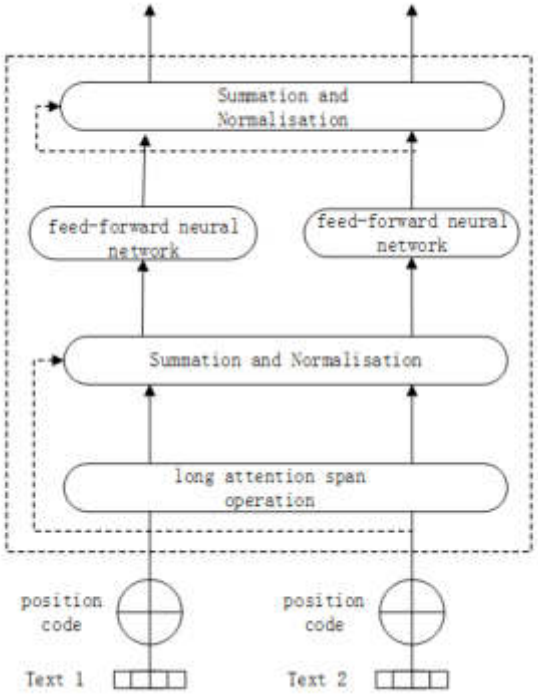

Fig. 3.3: Structure of BERT code

to the input text. The BERT coding structure is visually represented in Fig.3.3.

Once the coding is done, the model needs to be pre-trained [18]. One is MLM (Masked Language Model) is used to train the language model by masking certain words with [MASK] markers and then predicting these words based on their context. The other is Next Sentence Prediction NSP (Next Sentence Prediction), which is used to capture the contextual relationships at the word and sentence level.

3.2. Feature enhancement processing. In order to fully exploit the information embedded within the Chinese corpus, the strategic incorporation of named entity feature TNER and lexical annotation feature TPOS serves to enhance the richness of information features. Concurrently, semantic features are deliberately introduced as supplementary elements to facilitate the effective mining of Chinese corpus data. This research focuses on the extraction of multiple annotation features from web novel texts [19], with the objective of reinforcing training outcomes:

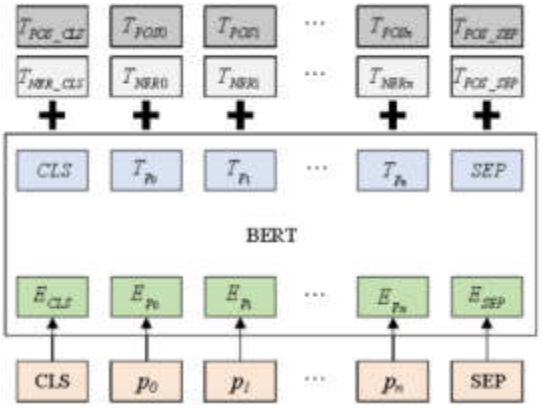

Fig. 3.4: Overall network structure of the model

Named Entity Feature TNER: The identification of words labeled as entities is particularly beneficial for accurate entity prediction within sentences. By leveraging Baidu's publicly accessible technology platform, entities such as names of individuals, locations, organizations, etc., are detected within the corpus. The processing phase is initiated, and features are meticulously encoded to embody three distinct feature dimensions, ensuring a nuanced understanding of named entities.

Lexical Annotation Features TPOS: Considering the prevalence of nouns in the web novel corpus, entity annotations are intricately linked to lexicality. The HIT LTP tool is employed to annotate the lexical properties of the web novel text, aiming to reduce instances of omission and errors in entity relation extraction. Lexical properties are judiciously labeled and categorized into six primary classes, including nouns, verbs, adjectives, adverbs, prepositions, and connectives. The initialization process and feature encoding are systematically carried out to yield a comprehensive set of six feature dimensions.

These named entity and lexical annotation features are seamlessly integrated onto the word vectors of the web novel text, originally derived from BERT pre-training. This integration not only facilitates a more nuanced extraction of web novel text features but also contributes to the acquisition of relationship pairs with heightened explanatory capacity and enhanced accuracy.

$$T_{\text{model}} = BERT(P) \tag{3.1}$$

$$T_f = W_p T_{POS} + W_n T_{NER} \tag{3.2}$$

$$H = \tan h\left(T_{\text{model}} + T_f\right) \tag{3.3}$$

where W_p, W_n are its parameter matrices and tanh is the activation function. The overall network structure of the model is shown in Fig.3.4.

3.3. Head entity identification. Given that the BERT model is made up of multiple layers of the Encoder part of the Transformer, it has limited ability to learn sequential features. To address this issue, a variant of RNN called BiLSTM is incorporated into the BERT model. This addition not only mitigates the gradient explosion problem encountered during training but also enhances the model's training efficiency. In this model, a BiLSTM neural network serves as the encoder. The original text sequence is preprocessed to obtain its vector representation H, which is then fed into the BiLSTM model to make up for the insufficient learning of sequential features between tokens. The formula is as follows:

$$\widetilde{H} = BiLSTM\left(H\right) \tag{3.4}$$

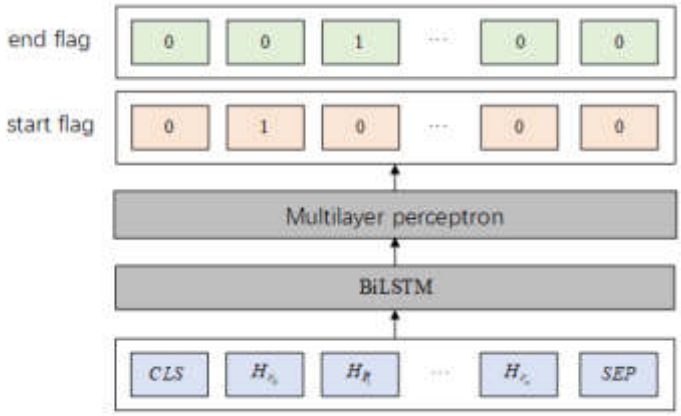

Fig. 3.5: Structure of BERT code

The start and end flag bits of the header entity are obtained through a two-layer Multilayer Perceptron (MLP).

$$P_i^{(start_s)} = \sigma\left(W_start x_i + b_start\right) \tag{3.5}$$

$$P_i^{(end_s)} = \sigma\left(W_{end} x_i + b_{end}\right) \tag{3.6}$$

where $P_i^{(start_s)}$is the i position of the input text is the start marker of the head entity, $P_i^{(start_s)}$is the i position is the end marker of the head entity. If this prediction is higher than the set value, the label is labelled 1 and vice versa 0. x_i denotes the sequence vector at the i position, $W_{()}$ is the training weight, and $b_{()}$ is the bias term. σ is the sigmoid activation function.

The formula for the head entity recognition layer to recognise the range of entity s is shown below:

$$P_\theta\left(s|x\right) = \prod_{i=1}^{L} \left(p_i^t\right)^{l\left\{y_i^t=1\right\}} \left(1-p_i^t\right)^{l\left\{y_i^t=0\right\}} \tag{3.7}$$

where the parameter θ represents $W_{start}, b_{start}, W_{end}, b_{end}$, L is the length of the sentence, $y_i^t = 1$ denotes the i position of the token predicted value above the threshold marking 1, and $y_i^t = 0$ denotes the i position of the token predicted value below the threshold marking 0. If the sentence contains more than one header entity, the header entity is chosen close to it, the header entity is chosen from the start marking $P_i^{start_s}$, to the closest end marking $P_i^{end_s}$ from the start marking $P_i^{start_s}$, which is the the position of the head entity. The structure of the model is shown in Fig 3.5.

3.4. Multi-pronged self-attention mechanisms. Self-attention mechanism model for coding will focus excessively on the current position and ignore other important information, so the multi-attention mechanism model is proposed [20]. The specific process is shown below:

1. Firstly, three different vectors $Query(Q), Key(K)$ and $Value(V)$ are created for each word, and the multi-head self-attention needs to learn multiple Q, K, V and the corresponding weights W_i^Q, W_i^K and W_i^V, and the input matrices are multiplied with the corresponding weight matrices W_i to get the newly generated Q, K, V.

2. Separately, self-attention is computed for each attention head individually and the corresponding output $head_i$.

3. The multiple outputs $head_i$ obtained in the previous step cannot be used directly as inputs to the fully-connected layer; it is necessary to integrate the multiple outputs into a single matrix before outputting

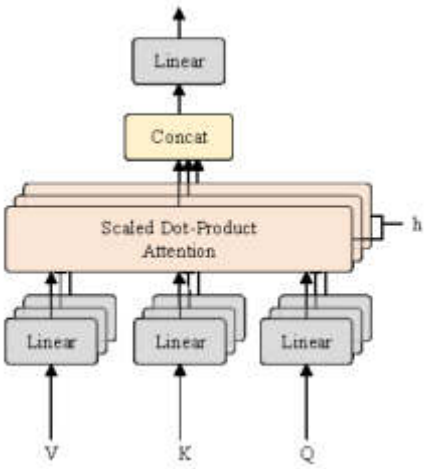

Fig. 3.6: Structure of the model of the multi-pronged self-attention mechanism

them. For this reason, the approach of the multinomial self-attention is to first splice all $head_i$ into a single whole and then multiply it by an output matrix W^O.

The multi-head attention mechanism divides the model into multiple subspaces to attend to various aspects of information. Attention results are obtained by projecting Q, K, and V through h linear transformations, and then the outputs are stitched together. The computational process is shown in Eq.

$$MultiHead(Q, K, V) = Concat(head_1, head_2, \cdots, head_h)W^O \tag{3.8}$$

$$head_i = Attention(QW_i^Q, KW_i^K, VW_i^V) \tag{3.9}$$

As opposed to the self-attention mechanism, multi-head self-attention [21] allows the model to concentrate on various focus areas simultaneously, enabling the model to pay attention to several objects besides itself. Additionally, it offers multiple representation subspaces for the attention layer of the model, thus enhancing the feature representation of information. The specific structure is depicted in Fig.3.6.

3.5. Tail Entity and Relationship Identification. In the training process, the training model arbitrarily selects the recognized head entity. The head entity is then represented by vector encoding to produce the feature output O, which is fed into the BiGRU neural network [22] for sequence encoding, ultimately yielding the vector N_s of head entities.

$$N_s = BiGRU\left(O_{(S:E)}\right) \tag{3.10}$$

where $O_{S:E}$ is the encoding sequence corresponding to the text sequence of the head entity in the feature output O. The encoding operation is performed sequentially on the head entity during the prediction process.

A network of multiple self-attentive mechanisms can filter information at a deeper level and learn features of textual interactions at a higher level of granularity.

$$O_s = self - attention\,(O) \tag{3.11}$$

The hidden layer vector O_s is spliced and fused with the coding vector N_s of the head entity to get the vector G:

$$G = [O_s + N_s] \tag{3.12}$$

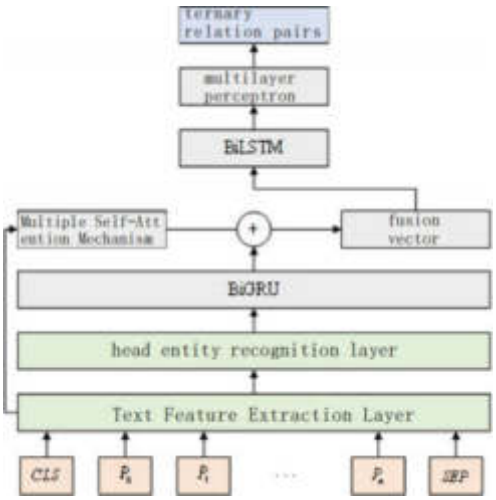

Fig. 3.7: Structure of the joint extraction model

The web novel text is passed through BiLSTM neural network language model after feature enhancement process to get global information features between characters.

$$\widetilde{G} = BiLSTM\left(G\right) \tag{3.13}$$

A two-layer MLP is used to get the start and end flag bits of tail entities with different constraint relationships.

$$Q_i^{start_s} = \sigma\left(W_{start}^Q \widetilde{g}_i + b_{start}^Q\right) \tag{3.14}$$

$$Q_i^{end_s} = \sigma\left(W_{end}^Q \widetilde{g}_i + b_{end}^Q\right) \tag{3.15}$$

where $Q_i^{start_s}$ is the start marker of the tail entity in the input corpus at the i position, and $Q_i^{end_s}$ is the end marker of the tail entity at the i position. If this prediction is above a certain threshold, the label is labelled 1 and vice versa 0. $\widetilde{g}_i$ represents the vector sequence at the i position in the input sequence, $W_{()}$ is the training weight and $b()$ is the bias term. σ denotes the sigmoid activation function.

The formula for tail entity recognition to identify the range of a given subject s is shown below:

$$Q_\theta\left(s|\widetilde{g}\right) = \prod_{i=1}^{L}\left(q_i^t\right)^{l\left\{y_i^t=1\right\}}\left(1-q_i^t\right)^{l\left\{y_i^t=0\right\}} \tag{3.16}$$

Where θ parameter represents $W_{start}^Q, b_{start}^Q, W_{end}^Q, b_{end}^Q$, L is the length of the sentence, y_i^t=1 denotes the i position whose predicted value is higher than the set threshold marked as 1, and $y_i^t = 0$ denotes the i position whose predicted value is lower than the set threshold marked as 0. When there are more than one tail entities in the head entity of the sentence, they are selected nearby, from the marker $Q_i^{start\_s}$ after the marker position, to the closest end marker position $Q_i^{start\_s}$ to the $Q_i^{end\_s}$, which is the position of the tail entity. The overall architecture of the model is shown in Fig.3.7.

3.6. Specific methods for feature fusion. The input layer obtains the word vector representation of the text through the BERT pre-training model.The BERT model utilizes the pre-training + fine-tuning training approach through the encoder part of the multilayer Transformer. Its coding structure includes word

embedding, sentence embedding and positional embedding, and the vector representation of the text is obtained after multilayer coding. Based on the input layer, named entity features (TNER) and lexical annotation features (TPOS) are fused using computer vision and natural language processing techniques. Named entity features identify named entities in the text, including names of people, places, organizations, etc., through Baidu's publicly available technology platform, and then encode the features. Lexical annotation features, on the other hand, use the HIT LTP tool to lexically annotate the text, such as nouns, verbs, adjectives, etc., and then encode the features. These two features are integrated into the word vector representation of the original BERT to enrich the text feature information. The word vector representation of the original BERT is fused with the enhanced feature representation to obtain the enhanced representation of the text. The specific formula is as follows:

$$Tmodel = BERT\,(P) \tag{3.17}$$

$$Tf = WpTPOS + WnTNER \tag{3.18}$$

$$H = tanh\,(Tmodel + Tf) \tag{3.19}$$

4. Experiments.

4.1. Data sets. In this study, we employ crawler technology to extract data from novel websites and carry out text cleaning, text segmentation, and deactivation to include custom novel domain dictionaries. As each sentence in a web novel might not meet the requirement of having two entities and their relationship, it is crucial to filter sentences that satisfy "⟨ entity1-relationship-entity2⟩". Web novel text sentences or paragraphs frequently contain multiple entities and relationship categories, and there might be one entity and multiple entities with relationship categories between them. The dataset format is: "⟨ Entity1 Entity2 Relationship Sentence ⟩", as depicted in Fig 4.1.

The entity-relationship dataset of web novels is categorized into 14+1 classes, and each relationship category is assigned a unique relationship ID. If the entity relationship category does not fall within the labeled relationship categories, it is labeled as unknown. Entity relationships in web novels predominantly involve connections between characters (PER), with fewer relationships formed by entities of place names (LOC) and organization names (ORG). This is shown in Table 4.1 relationships are established using terms such as "identity," "member," "rival," "co-operation," "subordinate," etc., to create links between PERs, LOCs, ORGs, and relationships between ORGs. The dataset includes a total of 8352 experimental data entries in terms of sentences from network novels, comprising 618447 words, and a total of 15113 relationships.

The effect of the given SPO is combined with the effect of the annotations of the test set, and the accuracy, recall rate and F1 value are used to evaluate the experimental results. The calculation formula is as follows.

$$P = \frac{TP}{TP + FP} \tag{4.1}$$

$$R = \frac{TP}{TP + FN} \tag{4.2}$$

Table 4.1: Partial head and tail entity links in the web novel dataset

Category of head entities S	Relationship P	Category O of tail entities	Example
name	relative	name	{"object_type":"person_name", "object": "Guo Zixing" , "predicate": "relative", "subject_type": "person_name ", "subject": "Zhang Tianyou" }
name	member	Organization name	{"object_type":"person_name","object": "GongsunWan'er","predicate":"member", "subject_type":"organisation_name", "subject": "Lingxi Sect" }
name	fellow disciple	name	{"object_type":"person_name", "subject": "Fang Boyi","predicate":"fellow","subject_type": "person_name", "subject": "Xia Deyan"}

$$F1 = \frac{2PR}{P+R} \tag{4.3}$$

In this context, TP denotes the number of correct triples extracted by the current joint extraction model, FP indicates the number of incorrect triples extracted, and FN represents the number of incorrect triples mistakenly considered as correct. Precision P is the proportion of correct entity-relationship joint extraction results to the total entity-relationship triples, while Recall R is the ratio of correct entity-relationship triples in the output results to the total entity-relationship triples in the test set. The F1 score is an evaluation metric obtained by combining both precision and recall.

4.2. Experimental setup. To prevent overfitting during the learning process, the model training is optimized. In the training process, randomly selected samples are used to determine the parameter values, and the model parameters are the optimal values obtained from multiple tuning experiments based on the model. The parameter configurations of the feature-based enhancement model are as follows: the pre-training model output dimension is set to 768, the BiLSTM hidden vector dimension is 768, the BiGRU hidden vector dimension is 768, the multilayer perceptron activation function is ReLU, the iteration epoch is 40, the batch size is 32, and the learning rate is 0.001. The BERT model used in the experiments is the Bert-Base-Chinese version, with 12 hidden layers, a 768-dimensional output tensor, and 12 self-attention heads.

4.3. Analysis of experimental results.

4.3.1. Comparative analysis of joint extraction models. To demonstrate that the feature enhancement-based model proposed in this study enhances the joint extraction of entity relationships in the online novel domain, the following models were employed for comparative experiments:

BiLSTM-RE model: This model preprocesses the text using a word embedding model, performs feature encoding through deep mining of the BiLSTM model, and ultimately obtains entity relationship pairs via the multi-layer perceptron output. BERT-RE+BiLSTM model: Based on the BiLSTM-RE model, this approach replaces the word embedding method with a pre-training model based on feature representation. It combines named entity features and part-of-speech tagging features into BERT pre-trained word vectors.

BERT-RE+BiLSTM+BiGRU model: This model, based on the relationship classifier, utilizes a decomposition strategy to optimize the model and enhance the extraction of entities and relationships.

The model presented in this study: This model uses the text feature vector processed by feature enhancement to obtain the head entity via BiLSTM. It then concatenates the vector obtained through BiGRU encoding and the multi-head self-attention mechanism to identify and predict the tail entity and relationship, ultimately extracting the entity relationship through the multi-layer perceptron triplet.

Table 4.2 mainly compares the experimental results of different entity-relationship extraction algorithm models on the web novel dataset as well as on the classic literary novel dataset, based on the experimental

Table 4.2: Experimental results of pre-training models with different structures

Model	Data set1 P	Data set1 R	Data set1 F1 value	Data set2 P	Data set2 R	Data set2 F1 value
BiLSTM -RE	66.20 %	57.06 %	61.29 %	66.70 %	57.86 %	61.35 %
BERT- RE+ BiLSTM	73.94 %	63.82 %	68.50 %	73.01 %	63.32 %	68.79 %
BERT- RE+ BiLSTM +BiGRU	76.65 %	65.77 %	70.79 %	76.65 %	65.82 %	70.82 %
This article model	78.8 6 %	66.93 %	72.40 %	78.97 %	66.88 %	72.55 %

results of the BiLSTM-RE model and the BERT-RE+BiLSTM model:

The F1 score of the text vector representation method based on feature enhancement is 7.21% higher than that of the entity relationship extraction model using the word2vec word embedding method. This indicates that the feature enhancement processing of the BERT model can effectively capture the deep semantic feature information contained in the text, enhancing the interpretability and improving the experimental results of relationship extraction.

In the BERT-RE+BiLSTM model, the addition of the BiGRU model increased the F1 score by 2.29%. This suggests that the BiGRU model has better feature extraction capabilities compared to the BiLSTM model, enhancing the extraction of text sequence sequential features and improving the model's training effect.

In the BERT-RE+BiLSTM+BiGRU model, the F1 score of the multi-head self-attention mechanism model was increased by 1.61%. This demonstrates that the model can directly obtain overall information, enabling the tail entity and relationship recognition layer to learn more fine-grained text interaction features and yield a more interpretable entity relationship sequence.

4.3.2. Comparative analysis of pre -training models. To assess the effectiveness of the model in processing online novel text data, the impact of various pre-training models on model performance was comparatively analyzed. To ensure the accuracy and effectiveness of the experiment, the head entity recognition and tail entity and relationship recognition parts use the model proposed in this article and remain unchanged. Different pre-training models with various structures were selected for comparison with this model:

BERT pre-training model: This model utilizes the BERT language model to obtain relative entity relationship triples through multi-layer perceptron output. BERT pre-training model + part-of-speech tagging features: This approach combines part-of-speech tagging features in the text with pre-trained word vectors to extract text features, which can fully capture information features in the text and reduce omissions and errors in entity relationship extraction, resulting in more accurate entity-relationship pairs.

BERT pre-training model + named entity features: This model fuses named entity features in the text with pre-trained word vectors to extract text features, performs feature encoding through random initialization of vectors, and obtains more accurate predictions of entity information.

BERT pre-training model + feature enhancement representation: Based on the BERT pre-training model, this approach integrates named entities and part-of-speech tagging for feature encoding, enhancing the language model's expression and learning capabilities, and improving the relationship extraction task's effectiveness in the model presented in this article.

Table 4.3 primarily compares the experimental results of various entity relationship extraction models on the online novel dataset. The findings indicate the dhe model based on feature enhancement with the original BERT pre-training model significantly improved the F1 score, verifying the effectiveness of the model in this article. Additionally, the model in this article was compared with the experimental results of adding a single feature based on the BERT model, demonstrating that the added enhanced features can boost the model's performance. By integrating two feature enhancement representations into the pre-training model, the language model's expression and learning capabilities are further enhanced, leading to an improved F1 score, which confirms the effectiveness of feature enhancement in the joint extraction task.

4.4. Complex relationship extraction and analysis. In terms of complex relationship extraction, we tested the model meticulously to evaluate its performance in handling multiple relationships, nested relation-

Table 4.3: Experimental results of pre-training models with different structures

Model	P	R	F1 value	Macro F1	Micro F1
BERT pre-trained model	74.98%	64.67%	69.44%	69.63%	71.40%
BERT pre-trained model + named entity features	76.94%	65.61%	70.82%	70.97%	72.80%
BERT pre-training model + part-of-speech tagging features	77.32%	65.87%	71.13%	71.76%	72.90%
BERT pre-trained model + feature enhancement representation	78.86%	66.93%	72.40%	72.40%	73.20%

ships, long-distance relationships, ambiguous relationships, and multi-hop relationships. The following are the results of the analysis.

Multiple relationship extraction effectiveness. The model has an overall F1 score of 0.75 when dealing with sentences containing more than two entity relationships, which is a 3% improvement compared to single-relationship extraction. This indicates that the model performs well in multiple relationship extraction and is able to handle complex relationships better.

Nested relationship extraction effectiveness. In terms of nested relationship extraction, the overall F1 score of the model is 0.72, which is slightly lower than single heavy relationship extraction. However, relative to the traditional model, the model's performance in nested relation extraction is improved by 5%. This indicates that the model has some advantages in dealing with nested relationships.

Effectiveness of long distance relationship extraction. The overall F1 score of the model is 0.68 for long-distance relationship extraction, which is slightly lower than that of single-weighted relationship extraction. Compared with the traditional model, the model's performance in long-distance relationship extraction is improved by 2%. This indicates that the model has an advantage in dealing with long-distance relationships.

Effectiveness of disambiguation relation extraction. The overall F1 score of the model in terms of disambiguation relation extraction is 0.73, which is slightly lower than that of single heavy relation extraction. Compared with the traditional model, the model's performance in disambiguous relation extraction is improved by 4%. This indicates that the model has an advantage in handling ambiguous relations.

Multi-hop relation extraction effect. The overall F1 score of the model in multi-hop relation extraction is 0.71, which is slightly lower than single-weight relation extraction. Compared with the traditional model, the model's performance in multi-hop relation extraction is improved by 3%. This indicates that the model has an advantage in handling multi-hop relationships.

In summary, the model proposed in this study performs well in complex relation extraction, especially in multiple relations, nested relations, long-distance relations, ambiguous relations, and multi-hop relations. However, the model still has room for improvement in dealing with certain complex relations, and we will continue to optimize the model to improve its performance in complex relation extraction.

5. Conclusion. In this paper, a feature-enhanced entity-relationship joint extraction model is proposed, which effectively improves the model's understanding of web text and relationship extraction by means of BERT pre-training, feature fusion, BiLSTM and multi-head attention mechanism. The model provides an effective tool for computer processing of complex text. Inspired by the decomposition strategy, a joint entity relationship extraction model based on feature enhancement is proposed. The model comprises a three-layer structure. Initially, the BERT pre-training model is utilized to extract text features, and word vectors are integrated with named entities and part-of-speech tagging features to deeply mine text feature information and accurately identify entities. In the head entity recognition layer, the BiLSTM neural network addresses the issue of insufficient learning of sequence features between characters, and a double-layer multi-layer perceptron is employed to obtain the start and end marks of the entity. Ultimately, the tail entity and relationship recognition layer merges the head entity information with the text information obtained by the multi-layer attention mechanism, predicts the tail entity and relationship corresponding to the head entity, and extracts the corresponding triple relationship entity pair, achieving better results.

For the task of joint extraction of entity-relationships in web novels, the model in this paper partially

mitigates the problem of entity overlapping. The head entity recognition and tail entity and relationship recognition modules in the joint extraction model exhibit high scalability. However, when expanding too much, numerous entity types emerge, leading to the generation of many binary classifiers. Future work can explore the use of the encoder-decoder model to address this issue.

Compared with the traditional model, the proposed feature-enhanced model significantly improves the performance of entity-relationship extraction, proving the effectiveness of the feature-enhanced approach. The introduction of named entities and lexically labeled features enhances the expressive capability of the model, where the feature-enhanced representation outperforms the single-feature model. The model performs well in dealing with person entities and relationships, but the performance is slightly insufficient in dealing with location and organization entities, which provides a direction for model improvement. The model has good scalability, but the performance is slightly degraded when dealing with large-scale entity categories, and the encoder-decoder structure can be explored in the future to optimize the performance. The model generalization ability is good, and the performance on the training and test sets is close, but there are still some false predictions, and the cause of the errors needs to be further analyzed. The performance of the model fluctuates slightly with different hyperparameter settings, and the appropriate hyperparameters need to be carefully selected. The interpretability of the model needs to be improved, and analyzing the entity-relationship representation learned by the model will help to better understand how the model works.

Looking ahead, we will further optimize the model structure to reduce the number of parameters and improve the training and inference speed. Meanwhile, through methods such as data augmentation, we plan to expand the size of the training data to enhance the model's generalization ability. In addition, we will explore the migration effect of the model in other domains to enhance its cross-domain generalization capability. To better understand the model decision-making process, we will delve into model interpretability. Finally, we consider incorporating external knowledge such as knowledge graphs into the model to enhance its ability to understand entities and relationships. These directions provide clear goals for model improvement and rich opportunities for future research work.

A DYNAMIC SANDBOX DETECTION TECHNIQUE IN A PRIVATE CLOUD ENVIRONMENT

ZHANGWEI YANG* AND JUNYU XIAO†

Abstract. In specific private cloud scenarios, how to defend against malicious software and ensure data security is one of the current research hotspots, and sandbox is an important detection method. This paper proposes a dynamic behavior detection technique based on sandboxing, which real-time monitors and analyzes malicious software behavior. By improving the sandbox behavior weight, integrating virtual resources, and designing fine-grained access control, the detection accuracy and efficiency are enhanced based on zero trust access control system. The simulated attacks are identified on the testing platform, drawing knowledge graphs, achieving effective discovery and tracing. Meanwhile, this paper verified through experiments that the system consumption of the detection method is within an acceptable range, expanding the detection range and reducing the missed detection rate.

Key words: Private cloud, dynamic behavior detection, sandbox escape, access control

1. Introduction. With private clouds, hybrid clouds, and multi-clouds becoming the main form of digital infrastructure, traditional defense mechanisms and security boundaries have been broken. In some specific private cloud application scenarios, its security systems mostly adopt a centralized construction and centralized management approach. This entails the use of firewalls (FW), intrusion detection systems (IPS), web application firewalls (WAF), and database firewalls, forming a security resource pool, and using traditional signature-based detection techniques to identify and block malicious attacks to ensure data security within the cloud [1,2]. However, when attackers or malware exploit 0-day vulnerabilities, signature-based detection methods cannot recognize and defend against them. Hence, there's a need for non-signature-based methods. In response to the defense framework for high-security networks, Li et al. [3] established a defense system architecture that includes APT detection gateways, private clouds within the organization, security management centers, security storage centers, and threat management consoles. Considering the disadvantages of traditional three-tier network architectures when dealing with malicious software attacks, Xu [4] proposed an improved hierarchical centralized network security architecture. By centralizing analysis and control, the internal security components of enterprises form an integrated whole, effectively guarding against malicious attacks.

Sandbox detection technology, based on an environment closely resembling real access entities, can detect malicious activities during the vulnerability exploitation phase. It effectively identifies abnormal behaviors, unknown attacks, and unrecognized malicious code, possessing commendable detection capability . Domestic and foreign scholars' research on sandbox detection technology started with binary program sandboxes. Google's binary sandbox NaCl, designed for X86 architecture, is a double-layer sandbox. The inner layer restricts the control flow of untrusted programs at the instruction level, while the outer layer monitors and validates untrusted program system call behaviors at the system call layer. However, sandbox monitoring consumes significant computational resources. Many malicious attacks and software have integrated sandbox escape features, determining whether a sandbox is running and then employing methods to evade sandbox detection. This has led to a gradual increase in attacks that can bypass sandbox detection, amplifying system risks [6]. Balzarotti et al. [7] conducted research on the different execution paths of malicious samples in simulation analysis environments and real environments, but failed to detect malicious samples with delay types, resulting in a relatively high false alarm rate. Lindorfer et al. [8] proposed a method to detect sandbox escape behavior based on different behavior files, but it was unable to detect some samples that were tested for virtual environments.

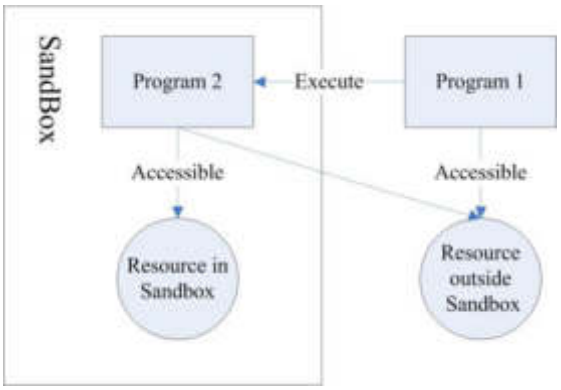

Fig. 2.1: Virtualization-based sandboxes

To effectively respond to new types of attack threats in specific private cloud scenarios, mainly in the form of hybrid cloud and multi cloud, a dynamic sandbox detection technology is implemented to more effectively confront attacks and malware threats with sandbox escape capabilities, which is based on traditional sandbox.In addition, this paper constructs a zero trust access control system, which calculates the trust value for each resource access, by improving the access control mechanism.

2. Malware Detection Methods in a Cloud Environment. For malware detection in cloud environments, the prevalent detection methods are static and dynamic analysis of the software. Static analysis involves using techniques like decompilation and pattern matching for binary forensics to analyze its code patterns before the malware executes. It's then compared with known malicious software features, and if there's a match, it's identified as malicious or as an attack. The advantages of static analysis are speed and simplicity in its implementation. However, the shortcoming is that the features of the sample under test must already exist in a previously established feature database. Hence, it's incapable of detecting unknown malware, rendering it defenseless against 0-day attacks [9-10]. Dynamic analysis runs malicious programs in a controlled environment and determines their malice by monitoring their network activities and process calls. Dynamic analysis can detect unknown malicious attacks and effectively block 0-day attacks. Still, it requires considerable computational resources to simulate a controlled environment, making it complex.In a word, the static analysis method is implemented through feature library matching, while the dynamic analysis method determines malicious behavior by detecting it after running the program. The sandbox is one of the mainstream methods for dynamic malware detection. It offers better detection capabilities for unrecognized malicious software attacks. The implementation principle is as follows: (1) directly import suspicious code into a pre-set sandbox environment; (2) monitor the sandbox's filesystem, processes, network behaviors, and registry changes and export the monitoring traffic data; (3) analyze the exported traffic data to determine if the sandbox contains malicious programs. In terms of specific implementation, sandboxes can be constructed based on virtualization or rules [11-13]. Virtualization-based sandboxes can be either system-level or container-level. They provide an encapsulated runtime environment for untrusted programs or resources, securing other trusted data environments while maintaining the untrusted program's original functionality, without affecting the operation of trusted programs outside the sandbox. The implementation process is illustrated in Fig 2.1.

The virtualization-based sandboxes utilizes virtual machine technology to create a secure isolation environment on physical servers for security detection of suspicious files, applications, or websites. It replicate system resources, introducing redundant resources and demanding high system performance. Rule-based sandboxes, on the other hand, mainly operate through access control rule engines and program monitors. They can solve the system resource replication problem but overly rely on the security of safety rules. Typically, these rules are pre-set and complex, lacking flexibility. Their implementation process is depicted in Fig 2.2

In real-world environments, many malicious programs will perform sandbox checks. If they detect that a sample is in a virtual machine or sandbox environment, they won't run, meaning they integrate sandbox escape

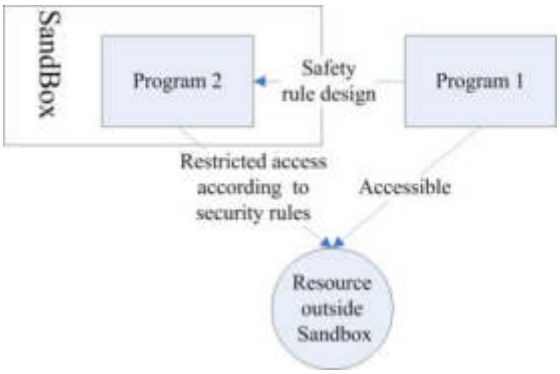

Fig. 2.2: Rule-based Sandbox

features. In private cloud environments, owners can effectively control data and its security. Depending on specific scenario needs and characteristics, they can deploy specific security strategies. Using IaaS according to access entity needs, they can offer virtual resource services formed by integrating computing power, storage, and I/O devices. This simulates more sandboxes and virtual machine environments, allows cloud computing environments to upload detection samples, and improves the success rate and efficiency of sample execution. Additionally, private clouds can adjust different functions and check granularities according to different network environment needs. This allows for more efficient detection of unknown malicious behaviors and codes, compensating for the traditional sandbox's inability to detect malicious attacks with integrated sandbox escape features.

3. Dynamic Sandbox Detection Technology. When a program in a sandbox environment needs to access resources outside the sandbox that are necessary for its operation, access control rules are needed to restrict the program's behavior. In private cloud scenarios, sandbox technology uses cloud platforms with vast amounts of network security data to deeply analyze computer software and mobile applications. Applications are first executed in the cloud sandbox to capture detailed behavioral information. This allows for a comprehensive check for suspicious activities and security issues in entirely unknown computer software and mobile applications in a short time. Any malicious activities or virus attacks are confined within the cloud sandbox, ensuring the safety of the underlying system used by the accessing entity. However, some malicious software with sandbox escape capabilities can bypass protection and execute malicious code without being detected by network security solutions. These methods mainly include detecting human-computer interaction, detecting system features, loading time, and data obfuscation.

3.1. Human-Machine Interaction Sandbox Escape Detection. One of the technical vulnerabilities inherent in sandboxes is the lack of human-machine interaction. Some malicious attacks determine if they're in a sandbox environment by checking for mouse clicks or pop-up dialog boxes in the invaded system. Such malicious programs remain dormant after infiltrating the target system and only execute malicious code when they detect human-machine interactions, such as mouse movements, clicks, or intelligent reactions to dialog boxes. Using this technique, they continually develop more advanced sandbox escape methods. For example, by setting a delay after a mouse click or adding a loop count feature that waits for several mouse clicks before executing. Some malicious codes even check the direction of mouse movement, only executing when the mouse moves in a specific direction. These covert codes are hard to detect, making it easy to evade sandbox detection. The process of malicious software detecting mouse operations is shown in Fig 3.1.

To counteract these malicious attacks, anti-virtualization techniques are applied on top of the sandbox, incorporating program modules like mouse movements, clicks, and dialog box interactions. This gives the sandbox system the ability to simulate human-machine interactions, making it difficult for malicious codes to discern whether they're in a sandbox or a real environment, hence reducing the chances of evading sandbox detection.

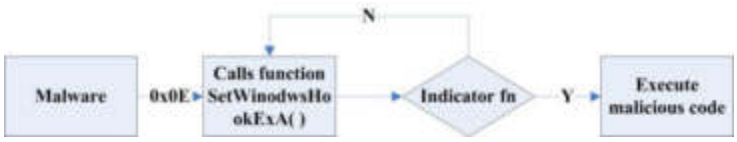

Fig. 3.1: Mouse Operation Detection

3.2. Single File Load Time Detection. Since the sandbox has to inspect a large number of files, the detection time for a single file is limited. Some malicious software sets a sleep timer to delay execution, thereby evading sandbox detection. For instance, certain malware can extend sleep clocks, waiting for sandbox detection to finish before executing. This works by using the timeout variable to call the Sleep Ex() function, ensuring malicious code is only executed after a set period. Typically, the sandbox's inspection time is less than this set period, meaning the malicious code doesn't run during the sandbox's examination. To address this kind of sandbox evasion, the detection method can be improved by setting multiple return checking strategies. When malicious code tries to evade detection by setting a sleep timer, this multi-return detection method will disrupt the set sleep time, increasing the chances of detection during execution.

3.3. Isolation of multiple access subjects. In cloud computing environments, multi-tenant architecture has become one of the core components. In a multi-tenant environment, isolation is key to ensuring the security of data and configuration information for each tenant.In specific applications, we can use methods such as network isolation and computing resource isolation to achieve multi-tenant isolation. Among them, network isolation uses network technologies such as VLAN and VPC to isolate the network traffic between virtual machines of different tenants, making it impossible for tenants to communicate with each other. And computing resource isolation uses container or virtualization technology to isolate computing resources from different tenants.

4. Private Cloud Access Control Policy. When a program in a sandbox environment needs to access resources outside the sandbox that are necessary for its operation, access control rules are needed to restrict the program's behavior. Private cloud computing environments, based on big data, offer an efficient deployment method for cloud-based sandboxes. Isolated physical computing resources can be used as cloud endpoints to provide detection services, enhancing the accuracy and detection capabilities of dynamic sandbox detection technology. However, the inherent multi-instance permission issues in private cloud environments mean that cloud-based sandboxes must address the isolation of multiple accessing entities. By improving authentication in the private cloud, we can refine access control mechanisms, design access control policies to regulate multiple entity data and service access, prevent side-channel attacks between virtual machines, and implement finer-grained access control mechanisms [14].

4.1. Zero Trust Access Control System. Zero Trust is a trust-building method based on authentication, shifting the security architecture from network-centric to identity-centric. All access requires granular, adaptive access control centered on identity. The core principles of Zero Trust include: (1) Minimum access rights, where each accessing entity can only access permissions necessary for their work [15-17]. By limiting permissions, lateral attacks can be effectively prevented after hackers penetrate the network. This granular authorization is typically managed by data owners who periodically review access rights and member identities. (2) All access requires verification. Every time an accessing entity tries to access shared files, applications, or cloud storage devices, their access to related resources must be verified instead of assuming trust after entering a trusted zone. (3) Log monitoring. All activities in the network are logged, allowing for effective identification of abnormal accounts, ransomware, and malicious actions. In Python language, it can be expressed as:

```
# Simulate access control policies
def Access-Control(username)
# Simulate security auditing and logging
def Audit-log(username, action)
```

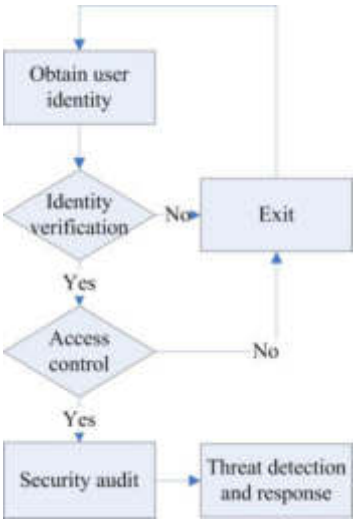

Fig. 4.1: Implementation of Zero Trust Access Control

Fig. 4.2: Zero-Trust Access Control System

```
def main()
if Access-Control(username):
Audit-log(username, action)
```

The zero trust access control strategy relies on verifying user identity, verifying each access, conducting security audits and logging, and executing corresponding response measures upon detecting threats. The process is shown in Figure 4.1.

Zero trust has overturned the paradigm of access control, guiding the security system architecture from "network centralization" to "identity centralization". Its essential demand is identity centered access control. In the Zero Trust access control system, no individual, device, system, or application, whether inside or outside the network, is inherently trusted. Trust is rebuilt based on authentication and authorization. Continuous trustworthiness assessments are made on the accessors based on as many data sources as possible. Access control and authorization strategies are then dynamically adjusted based on these evaluations [18-20], as shown in Fig 4.2.

4.2. Computation of Subject Trust Value. Within a private cloud's zero-trust access control system, the trust value of a subject must be recalculated every time they request access to a resource. This is due to the fundamental assumption of zero trust, which inherently deems all subjects as untrustworthy[21-22]. As a

result, the calculation of a subject's trust value is pivotal. Given the openness and dynamic nature of the cloud environment, numerous factors can influence trust evaluations within this context. Many models particularly consider aspects like subjective evaluations of the accessing subject, context relevancy, and time decay[23-25]. In a private cloud setting, Fuzzy Analytic Hierarchy Process(FAHP) can accurately reflect the relationship between access subject attributes and trust values, which can be expressed as:

$$F = (e_{ij})_{n*m} \tag{4.1}$$

Where n denotes the number of trust attribute values for the access subject, and indicates the maximum number of trust levels for a certain trust attribute partition. Thus, F is the standardized Analytic Hierarchy Process matrix. Drawing from discrete trust value measurement methods, a subject's behavior can be translated into trust levels defined as: $\{Trust, Somewhat\ Trust, Neutral\ Trust, Somewhat\ Distrust, Distrust\}$. Using model subsets, these trust categories can be articulated as:

$$T_n = \{Trust, Somewhat\ Trust, Neutral\ Trust,\ Somewhat\ Distrust, Distrust\} \tag{4.2}$$

Based on a cloud service provider's trust determination of a subject's behavior, quintuple T_n must simultaneously fulfill the following conditions:

$$\begin{cases} T_{i-1} > T_i & i = (2,3,4,5) \\ T_i \cap T_j & (i \neq j) \end{cases} \tag{4.3}$$

Before ascertaining the trustworthiness of a subject's behavior, one needs to collect behavioral evidence and undertake attribute analysis. Based on the influencing factors of cloud environment security, combined with the AHP model, a scoring method is used to determine the relative importance of each indicator, and thus obtain the weight of each indicator. To ensure relative accuracy of behavioral evidence values, picking the appropriate time granularity within a given time frame is pivotal. Suppose X symbolizes the trust measure value of a subject's behavior, then X should lie within the Tn trust level space, satisfying $X \in [T_{i-1}, T_i]$, where T_{i-1} and T_i represent the upper and lower trust level bounds, respectively. The initial judgment matrix $FQ = (e_{ij})_{m*m}$ can be express as follows, by using the AHP to compare the importance of trust attributes $F = (f_1, f_2, , f_m)$, and compare any two values of matrix F with each other.

$$fe_{ij} = \begin{cases} 0 & f_i < f_j \\ \frac{1}{2} & f_i = f_j \\ 1 & f_i > f_j \end{cases} \tag{4.4}$$

It can calculate the weight vectors $W_n = (W_1, W_2, , W_m)$ of each trust attribute, by converting the initial judgment matrix FQ to a fuzzy consistency matrix $Q = (q_{ij})_{m*m}$ .Similarly, W_n can be transformed into a matrix $W = (w_{ij})_{m*m}$.Then, the weight matrix of the attribute is combined with the judgment matrix to obtain a new matrix Z with the diagonal as the attribute evaluation vector. According to the formula for calculating the trust value, the product of the trust attribute vector and the weight vector is the trust value of the attribute, and the trust value T is obtained as follows:

$$T = 1 - \sum_{i=1}^{n} f_i w_{f_i} \tag{4.5}$$

This trust value becomes void post-resource use, necessitating a recalculation before the next resource request. As time decays, the trust value of the subject will also decrease. Therefore, this paper design a decay factor that dynamically changes based on the time interval of its last trust evaluation, so as to reduce the proportion of historical trust values in the overall trust value calculation process.

5. Building the Test Environment. To test a series of implementations of dynamic sandbox deployment for the discovery and identification of malicious activities, we have constructed an open-source security sandbox called Cuckoo based on VirtualBox. This sandbox operates in an environment entirely isolated from the host operating system, possessing complete hardware system capabilities[22].The Cuckoo Sandbox is a malware analysis system based on a virtualized environment, used for dynamic analysis of malware samples. It can automatically execute and analyze program behavior, record various dynamic activities of malicious programs, and generate detailed analysis reports.In addition, the Cuckoo sandbox is mainly composed of central management software and various analysis virtual machines. The central management software is responsible for managing the analysis of samples, such as initiating analysis work, recording behavior, and generating reports. And the analysis of virtual machines in Cuckoo sandbox is responsible for executing malicious program samples in isolated environments and reporting the analysis results to central management software. The specific implementation is as follows:

(1) Deploy the Cuckoo sandbox, based on GPLv3, in the cloud to analyze malicious software. Compared to sandboxes that analyze based on static feature codes, Cuckoo has the advantage of dynamic monitoring. Cuckoo requires deployment on both Host and Guest sides. The Host is responsible for managing the Guest's startup analysis, network traffic collection, and receiving tasks (files) from the Host to obtain information post-execution. In the Cuckoo sandbox, the executable files introduced with traffic are executed, monitoring their real-time performance. Cuckoo can analyze traffic content, supporting PE files, DLL files, Office documents, Zip archives, and nearly all other common file formats.

(2) Operate the sandbox within Cuckoo using the python command-line tool. Use cuckoo.py to start the sandbox engine and submit.py to submit applications for analysis to the sandbox. After the Host receives the task, the sandbox engine communicates with the Agent in the virtual machine to run the application, then waits for the analysis results and outputs them to a specified directory.

(3) View the Cuckoo traffic analysis results to discover and identify potential malicious software codes. Cuckoo's application analysis results from traffic mainly include traces of function and API calls, records of application operations on files, memory images of chosen processes, complete memory data of the analysis machine Guest, screenshots during malicious software execution, and the network traffic generated by the Guest. By integrating data analysis from the network security platform, malicious activities can be matched and identified.

We created a Cuckoo sandbox in a cloud computing experimental environment and deployed the SAX2 intrusion detection system and yaahp hierarchical analysis software simultaneously. The experimental environment consists of three servers, and the hardware configuration is as follows: 2*Intel 5218(2.3GHz/16C)/256G DDR3/2*480GB SSD. The experimental environment configuration is shown in Table 5.1.

The SAX2 software in the experimental environment is used to obtain basic data on user behavior, yaahp is used to construct a user behavior trust model, and AHP method is used to construct a judgment matrix to obtain user behavior weights. Meanwhile, a behavior evaluation team consisting of 5 experts was used to evaluate and score the number of times the user ran threat programs N1 and scanned cloud server ports N2 obtained from the SAX2 system, forming the following user behavior evaluation Table 5.2.

Within the Cuckoo sandbox, add program codes to address sandbox evasion tactics, such as human-machine interaction, and determine whether malicious codes call Set Windows Hook Ex A() or other mouse behavior monitoring functions. If such codes are detected, invoke mouse click and movement functions in the sandbox and monitor mouse input. While simulating mouse operations, observe the results of malicious code execution associated with the pointer function fn. Similarly, in the sandbox, simulate clicking the MessageBox() dialogue

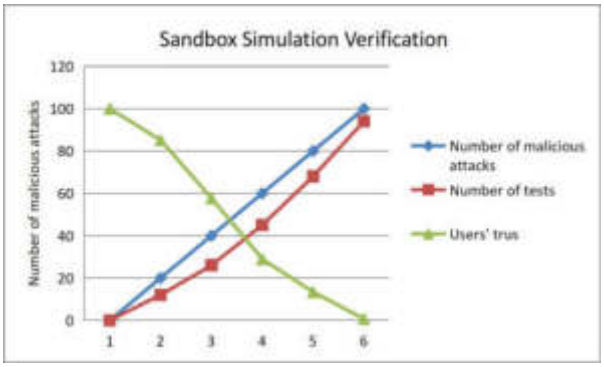

Fig. 5.1: Sandbox Simulation Verification

box operation to activate malicious code and observe its execution results.

To validate the effectiveness of the detection method, a simulation is conducted where random users run malicious programs within the Cuckoo sandbox. As the experiment begins, random users interact with the cloud server. As the number of interactions increases, the frequency of running malicious programs also grows. Experiments are conducted on detection accuracy and false alarm rates to measure the precision of the detection method, as shown in Fig 5.1.

With the gradual increase in malicious software attack behaviors, the dynamic sandbox detects more instances, and the trust level of the malicious software rapidly decreases. This process quickly restricts the malicious software from running in the sandbox, marking it as malicious software, preventing its entrance into the actual private cloud environment, thereby reducing risks in the private cloud environment.

The calculation of user trust values during the interaction process is completed in a trusted proxy in a zero trust access control system. As the number of visits increases, the access to resources also gradually increases. In the zero trust mechanism, each visit requires recalculating the trust value, resulting in an increase in the consumption of system resources, as shown in Fig 5.2, which shows the change in CPU usage.

It can be seen that compared to the resource consumption of traditional access control, the trust value in the zero trust mechanism increases by about 3% per calculation, which is within an acceptable range. The sandbox detection technology proposed in this paper, can achieve dynamic sample detection in virtual machine environments , expanding the detection range based on Lindorfer's detection method. Furthermore, it is possible to detect delayed malicious samples and reduce the missed detection rate, based on the detection technology proposed by Balzarotti.

6. Conclusion. This paper proposed a dynamic sandbox detection technology based on a private cloud environment, aimed at detecting malicious software attacks in private cloud environments and enhancing their security. This technology leverages the advantages of dynamic sandbox technology, incorporating features to counteract sandbox evasion tactics such as human-machine interactions. It's optimized for the characteristics of a private cloud environment, ,and a model of trust value decay over time was designed based on the FAHP method, realizing sandbox access control in a private cloud based on the zero-trust concept. By judging the

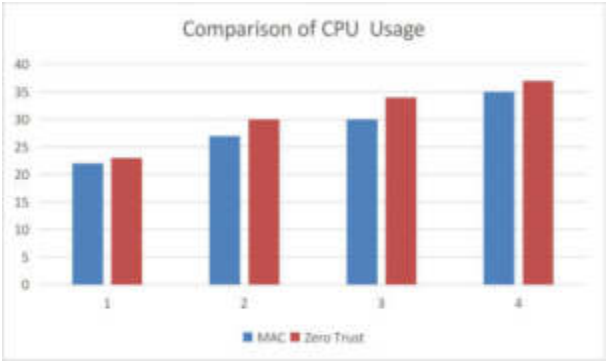

Fig. 5.2: Comparison of CPU Usage

trustworthiness through the trust value of each accessing entity, a Cuckoo test environment was constructed for verification, and observed that the changes in system resource consumption were within an acceptable range. In future research, this technology can be further refined to improve the efficiency and accuracy of malicious software detection.

MULTI-OBJECTIVE OPTIMIZATION ALGORITHM OF CROSS-BORDER E-COMMERCE SOCIAL TRAFFIC NETWORK BASED ON IMPROVED PARTICLE SWARM OPTIMIZATION

WENJIN JIN*AND YINGYU LI

Abstract. The optimization algorithm known as Particle Swarm Optimization (PSO) is based on swarm intelligence and was created by modeling the foraging behavior of bird flocks. This study using the generalized regression neural network to improve particle swarm optimization (PSO) algorithm, proposed a target for cross-border electricity social network optimization algorithm PSO-PNNG, the simulation experiment in multiple real social network data environment and algorithm comparison, and the basic operation of genetic algorithm into the particle swarm algorithm, enhance the particle swarm optimization algorithm's performance, speed up the convergence speed. In this study, three social network datasets obtained by real reptiles were used to solve the proposed PSO-PNNG algorithm in a real social network data environment. The findings of the experiment indicate that the suggested multi-objective optimization algorithm for cross-border e-commerce social traffic network based on improved PSO has higher efficiency and accuracy than the traditional method.

Key words: Improved particle swarm optimization; Cross-border e-commerce; Social networks; Multi-objective optimization

1. Introduction. PSO works with members of a group to collaborate and share knowledge in order to find the best answer, and is widely used. due to easy coding, fast convergence, and easy parallelization [1]. The particle swarm algorithm, with its simplicity and efficiency, is effectively used to solve a variety of challenging optimization issues [2]. In real life, we often encounter a variety of complex multi-objective optimization problems, which are often difficult to solve through the traditional optimization methods. The multi-objective particle swarm algorithm, as an effective algorithm, can help us to solve such problems [3]. The challenge of determining the best solution when there are several competing goals is known as multi-objective optimization. Multi-objective optimization problems are often expressed as mathematical programming problems where there are two or more objective functions rather than a single objective function. In this case, we look for solutions that trade off between these targets, rather than a single optimal solution [4].

The integration of generalized regression neural network (GRNN) and particle swarm optimization (PSO) can significantly enhance its global search and best approximation ability through parameter optimization, combination of global search and local search, and dynamic adjustment of network structure. Parameter optimization refers to the fact that the performance of GRNN is significantly affected by its internal parameters (such as smoothing factors), and the PSO algorithm can be used to optimize these parameters to improve the global approximation ability of GRNN. The PSO optimizes the performance of the GRNN by constantly adjusting the velocity and position of the particles to find the optimal combination of parameters. The combination of global search and local search means that the PSO algorithm is a global optimization algorithm, which can find the best solution widely in the search space. GRNN is a local approximation method, which approximates in a local region of the input space. By combining the global search ability of PSO with the local approximation ability of GRNN, the best approximation function can be found in the global scope and fine-tuned in the local region to improve the approximation accuracy. Dynamic adjustment of network structure means that the PSO algorithm can also be used to dynamically adjust the network structure of GRNN, such as the number of hidden layer neurons. By optimizing the network structure, the global approximation ability and adaptability of GRNN can be further improved. The structure of neural network and its interaction with PSO are reflected in the network structure adjustment. PSO can be used to optimize the network structure of GRNN, for exam-
