ple, the optimal number of hidden layer neurons can be determined by PSO, or the most suitable radial basis function can be selected. PSO searches different network configurations to find the network structure with the best performance.

As an important form of trade digitalization, the rapid development of new generation digital technologies like big data, cloud computing, and other technologies such as internet, blockchain, and 5G has provided cross-border e-commerce with a strong [5, 6, 7] technological base for its growth. At present, cross-border e-commerce has entered a new stage of industrial digitalization. Based on the new generation of digital technology, cross-border e-commerce uses a variety of business models to digitally transform commodity information flow, logistics and capital flow, thereby effectively improving the logistics efficiency, payment security, marketing conversion rate and the quality of production and operation decision-making of cross-border e-commerce, and promoting the digital development of cross-border e-commerce industry. Improve the operational efficiency of the cross-border e-commerce ecosystem. In the context of the rapid development of the global digital economy, cross-border e-commerce enterprises should focus on digitalization, give full play to the potential of digital elements, and accelerate their development and transformation [8].

The rise of social networks has changed People's Daily life style. People can easily express their opinions and emotions with the help of social media, and establish a wide range of social relationships [9] through social platforms. Related research on social networks can not only excavate the structural characteristics of the crowd in social networks, but also analyze and predict the flow direction of information transmission on the network and the possible consequences of information transmission. Therefore, research on social networks has important theoretical research significance and practical application value. For viral marketing of social networks, Influence Maximization (IM) aims to find and activate the influence of several user nodes with high influence from social networks, and make use of the word-of-mouth characteristics of social users to trigger the chain transmission of influence among users, so as to maximize the spread of influence [10]. Thanks to the advancements in 5G and Internet of Things technology in recent years, location-based advertising marketing has shown great commercial potential. Influence maximization in social networks has become an important research branch in the field of influence maximization. In contrast to the conventional influence maximization issue, which maximizes propagation in the whole picture of social network, influence maximization problem considers various characteristics and attributes of users in the physical world, so that influence [11] can achieve the best propagation effect among some location-related user groups.

In the fierce competition of e-commerce, it is very important to assist users to explore their needs. Many enterprises use efficient personalized recommendation technology to turn the potential demand of visitors into the real consumption of purchasers, and then improve business profits. Known as the "king of recommendation system", at least one fifth of the items sold in Amazon Mall come from the recommendation system [12]. Netflix claims that about 60% of movies and videos are discovered through its recommendation system; YouTube designed an experiment to compare click-through rates between recommended lists and popular lists, and found that personalized items were twice as likely to be viewed as popular items. Social networks have the characteristics of instant consultation and sharing, open media, realistic user interaction and wide coverage. They are the key hubs linking real life, virtual environment and physical communication. They penetrate into all aspects of human life in an all-round way and promote the transformation and upgrading of business models in the e-commerce industry. It is also hailed by the Internet industry as the next "treasure" after the invention of search engine.

The study uses a particle swarm optimization algorithm and improves by introducing a generalized regression neural network. This improvement may improve the performance and adaptability of the algorithm. At the same time, integrating the basic operation of the genetic algorithm into the particle swarm algorithm can further enhance its performance and convergence speed. These methods are all feasible and are widely used in the optimization field. Furthermore, this paper is also introduces the research significance and practical application value of social network. Through the relevant research on social network, we can not only mine the structural characteristics of people in social network, but also analyze and predict the direction of information transmission on the network and the possible consequences of information transmission. The improved PSO-PNNG multi-objective recommendation optimization technique for cross-border e-commerce social traffic networks is proposed in this research based on the improved particle swarm algorithm (PSO), and conducts

simulation experiments and algorithm comparison in multiple real social network data environments. The experimental results show that the proposed multi-objective optimization algorithm for cross-border e-commerce social traffic network based on improved PSO has higher efficiency and accuracy than the traditional method.

2. Literature Review. The optimization algorithm is a method for finding the optimal solution, which aims to find the optimal solution to solve the given problem while satisfying specific constraints. The optimization algorithm has been well studied in the literature, and there are a large number of methods. The original PSO was specially developed to solve the problem of continuous value optimization. Although the original PSO algorithm has been widely used in various optimization problems, the PSO algorithm cannot directly solve discrete optimization problems [13]. However, the update strategy of the traditional PSO algorithm is to update the position and speed of particles by learning global optimal particles, which can easily lead to a decrease in population diversity, making it easy to fall into local optimal solutions or premature convergence [14]. The performance of the PSO algorithm is sensitive to the control parameter values used, and it is difficult to adjust the parameters. The calculation amount of adjusting the control parameters for the current problem is very high [15]. In addition, PSO algorithms may need more iterations when looking for high-quality solutions, resulting in slower convergence. When dealing with some complex problems such as nonlinear and non-stationary, the performance of the PSO algorithm may be affected to a certain extent. Therefore, to improve the traditional PSO algorithm, the generalized neural network has strong pattern recognition and local search ability, and can effectively find the local optimal solution to the problem. Genetic algorithms have global search capabilities and can find high-quality solutions on a large scale. Combining the two can give full play to their respective advantages, accelerate the convergence speed of the particle swarm algorithm, and improve the overall search efficiency of the algorithm. Therefore, an improved PSO-PNNG optimization algorithm is very important to improve the efficiency and performance of the particle swarm optimization algorithm.

In comparison with other algorithms, ten particle swarm optimization and ten differential evolution variants were selected for comparison on numerous single-objective numerical benchmarks and 22 realistic problems. On average, the differential evolution algorithm is significantly better than the PSO algorithm and is used at two to three times the frequency of the differential evolution algorithm [16]. Particle swarm optimization (PSO) is a simple and effective optimization method, which has been applied in many fields. However, the particle swarm algorithm has defects such as early convergence and poor population diversity [17], so the improved particle swarm optimization algorithm is proposed. For example, combine the particle swarm algorithm and the genetic algorithm (GA), set the dynamic inertia weight, increase the sigmoid function to improve the crossover and mutation probability of the genetic algorithm, and change the selection method. The results show that the improved particle swarm algorithm solves the better routing results, with faster speed and higher stability [18]. In order to overcome these shortcomings of PSO, a multi-based learning PSO algorithm (MLPSO) is also proposed. In MLPSO, the multi-sample selection strategy (MSS) and the adaptive sample crossover strategy (ASC) are used to select the appropriate learning sample for the whole. Experimental results show that MLPSO outperforms MLPSO over 7 competitive PSO variants and 19 metaheuristics in most functions [19]. In addition, in order to solve the improved particle swarm algorithm (PSO) limited by the robot topology, strange position and back solution accuracy, some scholars are proposed to solve the inverse problem of the robot. The algorithm initializes the particle population based on the joint angle limit. The results show that the improved PSO has higher convergence accuracy and faster convergence rate than the other algorithms, and the proposed has is generality [20].

As a new trade model, cross-border e-commerce has been emerging for a short time, but it is developing rapidly. The research on it is booming all over the world, and it is fully recognized that its development brings positive impetus [16] to promote the development of the world market. Previous studies have highlighted the positive impact that cross-border e-commerce has already had on the economy and its potential growth. These impacts include challenges and opportunities for supply and demand, increased price competition, the positive impact of improving efficiency in the retail sector and production in other sectors, and promoting the benefits of individual and household consumers and Labour productivity and GDP growth [17]. Some studies have suggested that the development of cross-border e-commerce brings many benefits, Such as access to a diverse range of sellers and products from all over the world, reduced information asymmetry, reduced search costs, adequate comparison in the selection of goods, open and transparent competition among sellers, greater

time savings, and most importantly, it enables individual consumers to share their comments and experiences through shopping platforms and social media [18].

China can form a brand theory with global influence in the reconstruction research of brand theory in the digital age. In the era of digital economy, the traditional classic brand theory cannot explain the brand practice under the environment of digital media, and it is urgent to reconstruct, and the global business community urgently needs new brand theory guidance. Some scholars believe that the essence of communication for brands in the digital era has not changed, and traditional creative experiences are still valid. In the digital platform, a series of new communication methods have emerged, and consumers have to be placed in the center position, and word-of-mouth has become more important [19].

While accuracy is indeed critical to a recommendation system, a good "user-centric" recommendation system should not be limited to accuracy. Many users' consumption preferences are habitual (stereotyped: they often consume a certain type of item or consume it in a certain way) and the items they buy are mostly popular items [20]. In order to make predictions more accurate, the system tends to recommend similar items that better fit the user's history. Or popular items that are more likely to be purchased. The reason for this dilemma: In improving the accuracy of the system, it reduces the variety and novelty. It can be seen that when designing a social network recommendation system, multiple goals should be considered: not only to ensure satisfactory accuracy, but also to maximize the variety and novelty. Multiple recommendation of long-tail items is a necessary condition [21] to increase the diversity and novelty of the system. At present, the optimization routing algorithms in other fields have been quite perfect, and related technologies have been widely used, but these optimization routing algorithms can not be directly applied to social networks [22]. The specific form of the multi-objective optimization problem in the recommended algorithm is to find an optimal collection of items under the condition of meeting the constraints of user satisfaction and diversity. The goal of optimizing the cross-border e-commerce social traffic network is to increase user engagement, user retention, and conversion rates of cross-border e-commerce platforms, thereby increasing sales and profits. The variables that need to be optimized mainly include content quality, interactive activities, social functions, personalized recommendations, and user experience, etc. This paper solves the multi-objective optimization problem of cross-border e-commerce social traffic networks through improved particle swarm optimization algorithms. The purpose is to enable the recommendation system of cross-border e-commerce platforms not only achieve the accuracy of recommendations, but also take into account the novelty and diversity of recommendations at the same time, so that the recommendation algorithm is not limited to stereotypical data such as users' historical purchases, but also needs to accurately mine users' preferences and recommend more diverse results to users, so as to promote the development of cross-border e-commerce platform social networks.

3. Model Construction. A complex network diagram can be represented as $G(V, E)$, where, $V = \{v_i \mid i = 0, \ldots, n\}$, $E = \{e_{ji} = \{v_i, v_j\} \mid v_i, v_j \in V\}$, N is the number of nodes in $|V| = N$, and e_{ij} is the connections between v_i, v_j edges. In most literature, graphs use an adjacency matrix $A = [a_{ij}]_{V \times V} \cdot a_{ij} = 1$ to represent the v_i, v_j where an edge exists between nodes, otherwise $a_{ij} = 0$. This study considers a social network represented by a directed random graph $G = (V, E, \omega)$ with $|V| = n$ nodes and $|(u, \nu) \in E| = m$ weighted edges. Each edge is associated with the right of infection $\omega \in [0, 1]$, indicating the likelihood of infecting u node once it is infected ν. Suppose a group of suspicious nodes V_I in a social network is observed that may be infected by information, but it is not clear which specific nodes are infected. Instead, the probability of a node ν can be given by probability $p(\nu)$. In a normal social network, this probability can be determined by analyzing the text content to determine the likelihood that the information will be transmitted. Finding a collection of nodes or edges whose removal will result in the biggest impact of the infected node aborting is the aim of a social network multi-objective optimization problem. It is also assumed that the candidate nodes or edges of a subset C can be removed from the graph, so the subset C can be determined according to the current situation. If you want to include the multi-target information of the social network more quickly, the subset C can include nodes from highly suspicious or even external nodes V_I. If you want to maximize the influence of the subset, then the subset C can contain edges associated with suspicious nodes in V_I or C.

Given $G = (V, E)$ and a seed set S, the influence propagation of the set S can be expressed as $I(\cdot)$, the expected number of infected nodes at the end of the propagation process, where the expected value represents the randomness of all thresholds θ_v. One of the existing classical problems is the influence maximization

problem, which requires the degree of maximization $I(\cdot)$ of a seed set containing a number of k nodes. In the actual context of social networks, the infection weight $w(u, v)$ between nodes u and nodes v can be estimated by the interaction frequency between nodes u and nodes v. The probability distribution of possible seed sets is defined using $V_I = (V_I, p)$ representing the suspicious node set V_I and its probability as the source node. And the probability of a particular seed set $X \subset V_I$ can be given by equation (3.1).

$$P(X) = \prod_{u,v \in X, V_I/X} p(u) * (1 - p(v)) \tag{3.1}$$

The expected propagation influence of V_I can be defined by considering the seed set X as shown in Equation (3.2). $I(\cdot)$ Representing the influence spread of the seed set, this formula can fully represent the expected spread impact. Because the goal of the algorithm is to remove k nodes or edges from the social network to minimize the transmission influence of infected nodes V in the remaining network G' and maximize the influence of $I(G) - I(G')$. When it is a group of nodes S, all edges adjacent to it are also removed from the graph. Therefore, two social network multi-objective optimization problems can be formulated as follows.

$$I(V) = \sum I(\cdot) * P(X) \tag{3.2}$$

Edge-based transmission control, that is, the probability of a given $G = (V, E, w)$, suspicious node being infected is $V_I = (V_I, p)$, candidate subset C and budget $k \in [1, C]$, edge-based transmission control problem requires the edge set $T^*(\cdot)$ shown in equation (3.3) to maximize the blocking influence $I(G) - I(G')$. The purpose of formula (3.3) is to describe the goal of the edge-based propagation control problem, that is, to maximize the propagation impact of blocking the network by selecting the set of some edges.

$$T^*(\cdot) = \underset{T_k \subseteq C, |T_k| = k}{\arg\max} \{I(G) - I(G')\}. \tag{3.3}$$

For node-based propagation control, given a random graph $G = (V, E, w)$, the probability of suspicious nodes and their infection is V_I, a candidate set C and budget $k \in [1, C]$, and node-based propagation control problems require that the knode-set S^* can maximize the influence $I(S_k, V_I)$, while the multi-objective optimization problems of social networks based on edges and nodes are NP-hard problems. The economic scheduling of the social network model takes the lowest operating cost of the whole network as the objective function, schedules according to the coordination equation method and the equal incremental rate method, comprehensively considers the cost of multi-objective optimization and the loss generated, and maximizes the overall benefit of the whole network by sacrificing local benefits, which reflects the optimization of the entire social network cost. The loss of the $EC(P_G)$ multi-objective optimization model of the social network can be defined as formula (3.4). where, EC represents multi-objective economic cost, P_G represents the possibility of partial benefit loss. The purpose of formula (3.4) is to define the loss of the multi-objective optimization model of social networks, that is, $EC(P_G)$, which is used to measure costs and losses in the network. The purpose is to comprehensively consider costs and losses in the process of economic scheduling, so as to achieve the goal of the lowest operating cost of the whole network.

$$EC(P_1, \ldots, P_D) = \sum_{d=1}^{D} 10^{-2}(\alpha_d + \beta_d P_{Gd} + \gamma_d P_{Gd}^2) + \xi_d \exp(\lambda_d P_{Gd}) \tag{3.4}$$

Considering that the multi-objective optimization of social networks is a multi-objective problem, this paper will convert the multi-objective optimization problem proposed in this paper into a single objective problem, as shown in Formula (3.5). By converting into a single-objective problem, a single-objective optimization algorithm can be used to solve and simplify the complexity of the problem. The purpose is to optimize the scheduling of social networks more conveniently to achieve the best balance of multiple goals.

$$\begin{aligned} TC(\cdot) = {} & u * \sum_{d=1}^{D} FC_d(P_{Gd}) + h * (1 - u) * \sum_{d=1}^{D} EC_d(P_{Gd}) + P_L \\ & + abs\left(\sum_{d=1}^{D} P_{Gi} - P_D - P_L\right) \end{aligned} \tag{3.5}$$

This study assumes that there are Nindividual users n in a group of users who can be connected through a social network. Users i have a positive scalar value of public opinion, modeled as a state $x_i(t) \in R$ of t time,

and users interact with their neighbors through the social network and evolve their public opinion over time. The weighted edges E of the network graph Gare used to model the social interactions, and the edge sets are used to model the interactions between users. This study assumes that the graph G is strongly connected, and in the absence of external control inputs, the dynamics of public opinion (state) at each node i in the network are controlled by changes in the following Friedkin-Johnsen model as shown in Equation (3.6).

$$x_i(t+1) = q_i + \sum_{j:(i,j)\in E} a_{ij}(x_j(t) - q_j) + a_{ii}(x_i(t) - q_i) \tag{3.6}$$

where, $q_i \geqslant 0$ denotes the static cognition of the user i, $0 \leqslant a_{ij} < 1$ simulates the intensity of the influence of the userj's opinions on the user, and a_{ii} simulates the stabilityi of the user i. This istudy assumes that $\sum_{j=1}^{n} a_{ij} < 1$ for all i, that is, the weight matrix $A = [[a_{ij}]]$ is subrandom. Under this assumption, at any given time, each user's opinion can be divided into two components: a fixed ontology view and an additional disturbance resulting from interactions with neighboring nodes. In the absence of external input, all users revert to their own opinions. In the incentive scenario of this study, it is considered to be the better model, so the vector form can be written as shown in equation (3.7).

$$x(t+1) = Ax(t) + (I_n - A)q \tag{3.7}$$

Where, here $x(t)$ is the column vector with the first componenti, the $x_i(t)$ column vector representing the static view, and the identity matrix q. I_n Can be checked $x(t) \to q$ to satisfy without input. There are several mtarget sources, each of which can precisely inject control inputs into the node. This indicates that the control input is sent to the node by the target source. Each target source is able to map the control inputs to the node, meaning that the control input is oriented. When the target source j is connected to the node i and $\sum_i b_{ij} = 1$, the matrix $B \in R^{n\times m}$ maps the target source to the target node with $b_{ij} = 1$. And this study considers that it can be any real number, making it accept the values in the interval can provide additional $\{0, 1\}$ results. Moreover, the weighted minimum of the penalty function of social network loss, node fluctuation and each node exceeding the limit is defined as the objective function, P_{loss}^{new} represents the likelihood of new social network losses, while P_{loss}^{old} represents the likelihood of previous social network losses, as shown in equation (3.8).

The purpose is to provide an indicator to comprehensively evaluate social network optimization to guide the search process of the optimization algorithm.

$$\min F = \beta_1 \sum_{j\in\Omega^N} \frac{P_{loss}^{new}}{P_{loss}^{old}} + \beta_2 AU + \beta_3 \sum_{j\in\Omega^V} CF\left(\frac{\Delta V_j}{V_{j,\max} - V_{j,\min}}\right)^2 \tag{3.8}$$

In the continuous iterative optimization process of standard particle swarm optimization algorithm, the inertia weight needs to change with the change of particle fitness value, so as to better balance the particle search speed and improve the overall optimization ability of particles. Therefore, the value of inertia weight ω as a fixed constant is not conducive to the optimization of the algorithm, and real-time adaptive inertia weight ω is more helpful to solve the reactive power optimization problem. For the inertia weight coefficient, this study proposed the adaptive inertia weight, as shown in equation (3.9).

$$\omega = \omega_{\min} + (\omega_{\max} - \omega_{\min}) \exp\left(\frac{f_{\min}^n - f^n}{f_{average}^n - f_{\min}^n}\right) \tag{3.9}$$

In social networks, the connection between users is generally represented by constructing the relationship diagram, in which each user can be represented by the node $\nu_i \in V$, and the interaction class between users is represented by the edge $(\nu_i, \nu_j) \in E$. The community structure in social networks usually means that user nodes can be divided into subsets $C = \{C_1, C_2, \ldots, C_k\}$, so that nodes C_j in the same subset are closely linked and the connections between subgroups relatively sparse. Existing research focuses on disjoint community structures and makes each node belong to only one community. In social networks, users' forwarding, collection and comment can be identified as positive responses. Therefore, the set of social network users can be defined as $U = (a_1, a_2, a_3, \ldots, a_n)$, and the set of social network information is $I = (i_1, i_2, i_3, \ldots, i_k)$. Order $I(\cdot)$ represents the degree of interest $\frac{\overline{Luj}}{\overline{Lu}}$ of the user u to the user in the item attribute set A, $\overline{Luj}$ is the average of all scores

of the user u subattribute j, $\overline{Luj}$ is the average of all scoring items of the user u, so there are several set item sub-attributes, and the similarity of the user's preference for the item sub-attributes is shown in Eq. (3.10).

$$sim_P(u,v) = \frac{\sum_{j=1}^{n}(Puj-\overline{Pu})(Pvj-\overline{Pv})}{\sqrt{\sum_{j=1}^{n}(Puj-\overline{pu})^2}\sqrt{\sum_{j=1}^{n}(Pvj-\overline{Pv})^2}} \tag{3.10}$$

4. Algorithm design.

4.1. Algorithm framework. Particle swarm optimization algorithm (PSO) is an intelligent optimization algorithm inspired by bird foraging behavior, which is commonly used to solve various optimization problems. The fitness function determines the fitness value of the particle, and the fitness value of the particle is the standard used to judge the quality of the particle. There are interactions between the particles in the particle swarm optimization algorithm. Particles update their speed and position by sharing information to find the globally optimal solution. Each particle remembers the best position in its trajectory, and uses it to update its speed and direction. Each particle in the particle swarm can determine its next search track according to its current position and the information sharing mechanism between particles, and judge the merits of particles by the fitness value of particles, so as to iteratively find the optimal solution and finally find the optimal solution. The optimal solution is usually the extremum solution with the maximum or minimum fitness function value.

Determining the global optimal location within the PSO framework is critical because it represents the most ideal solution to the current optimization problem. To achieve this, the algorithm iteratively updates the position of the particle based on its speed, which is adjusted for both the personal best and the global best position. Over time, if the parameters of the algorithm are set properly, the particle swarm will converge to a global optimal solution. Convergence conditions are a set of criteria that determine when an algorithm finds a satisfactory solution and can be terminated. These conditions can be based on the number of iterations, changes in the global optimal position in successive iterations, or predetermined thresholds for the value of the objective function.

The particle adjusts its motion direction and speed in real time through the trajectory. The current position of the particle, the best position of the particle history and the best position of the population particle history are important factors affecting the trajectory of the particle. Initialize a population of particles in a multi-dimensional search space, the number of particles is set to n, the position information of the particles in the population is expressed as $X = (X_1, X_2, X_3, \ldots, X_n)$, the position information of the i th particle can be expressed as X_i, and the velocity information of the i th particle d dimensional space is also a d dimensional vector $V_i = (V_{i1}, V_{i2}, \ldots, V_{ij}, \ldots, V_{id})$. Due to the ability of memory, the particles can remember the best position in their running trajectory and obtain the global optimal solution P_{best} at the current moment with P_{opt}. The velocity and position of the basic particle swarm algorithm can be expressed as shown in Eq. (4.1) and Eq. (4.2).

$$V_{id}(t+1) = V_{id}(t) + c_1 r_1[P_{bestd}(t) - X_{id}(t)] + c_2 r_2[P_{optd}(t) - X_{id}(t)] \tag{4.1}$$

$$X_{id}(t+1) = X_{id}(t) + V_{id}(t) + c_1 r_1[P_{bestd}(t) - X_{id}(t)] + c_2 r_2[P_{optd}(t) - X_{id}(t)] \tag{4.2}$$

where t represents the moment; V_{id} and X_{id} represent the speed and position of particle i on dimension d, respectively; c_1 and c_2 represent individual and social learning factors, respectively; P_{bestd} and P_{optd} represent the individual historical best position and the global optimal solution of the particle i on dimension d; r_1 and r_2 are the random number between $[0, 1]$.

The steps of the classical PSO are as follows. First, parameters such as the population size, maximum number of iterations are initialized and the individual optima and global optima are determined by calculating the particle fitness values. Secondly, the velocity and position of the particles are updated, and the fitness value of the updated particles is calculated, and their fitness value is compared to the individual optimal value P_{best}, If better, P_{best} is updated to the current value and the current value is updated to the individual optimal value. Otherwise continue iterate and continue comparing. The updated individual optima are compared to the global optimum P_{opt}, and if better, P_{opt} is updated to the current value and the particle current value is

updated to the global optimum. Otherwise continue iterate and continue comparing. Finally, the fitness value of the updated particle is terminated if the maximum number of iterations is satisfied.

In addition, the known particle fitness value will affect the trend of inertia weight ω, commonly used particle group algorithm is in the process of constant iterative optimization, inertial weight ω need as the particle fitness value changes, so as to better balance the particle search speed and improve the particle overall optimal ability.Therefore, the value of inertial weight ω as fixed constant is not conducive for the algorithm, and the real-time adaptive inertial weight ω is more helpful to solve the reactive power optimization problem. For the inertial weight coefficient, in this paper, the adaptive inertial weight $\omega(\cdot)$ is proposed as shown in Eq. (4.3).

$$\omega(\cdot) = \omega_{\min} + (\omega_{\max} - \omega_{\min}) \exp\left(\frac{f^n_{\min} - f^n}{f^n_{average} - f^n_{\min}}\right) \tag{4.3}$$

where $\omega_{\min}$ and $\omega_{\max}$ are the minimum and maximum values of the inertial weight, respectively; $f^n_{average}$ is the average fitness of all particles in the n iteration; f^n is the fitness of the particles at the n iteration; and $f^n_{\min}$ is the minimum fitness of all particles at the n iteration. By comparing the adaptive inertial weight $\omega(\cdot)$ with the original inertial weight ω, it can be seen that the adaptive inertial weight $\omega(\cdot)$ is more sensitive to the changes in particle fitness value compared to the original inertial weight ω. This means that the proposed algorithm can better balance the particle search speed and improve the particle overall optimal ability, making it more suitable for solving the reactive power optimization problem.

4.2. Algorithm Improvement. In order to improve the performance of the algorithm, the author improved the PSO algorithm and introduced genetic algorithm and neural network. Genetic algorithm is a kind of optimization algorithm based on natural selection and genetic principle, which can be used to solve various complex optimization problems. A neural network is a computational model that simulates the human brain's nervous system and can be used for learning and prediction. By introducing genetic algorithm and neural network into PSO algorithm, PSO-PNNG optimization algorithm is proposed. The crossover and mutation operation of genetic algorithm and the learning and adaptation ability of neural network are introduced in the process of particle swarm optimization, which improves the search efficiency and convergence speed of the algorithm. The effect of algorithm selection and adjustment on algorithm performance is that algorithm selection and adjustment have an important effect on algorithm performance. Selecting the appropriate algorithm can improve the efficiency and accuracy of solving the problem, and adjusting the parameters of the algorithm can further optimize the performance of the algorithm. In this study, by improving the PSO algorithm, the author introduced genetic algorithm and neural network to improve the search efficiency and convergence speed of the algorithm, so that the algorithm can better adapt to the multi-objective optimization problem of cross-border e-commerce social networks.

In this study, generalized regression neural network is used to improve the particle swarm optimization algorithm. Integration of generalized regression networks into particle swarm optimization algorithms requires initialization of a population of particles, each particle representing a candidate solution. For each particle, its fitness value is calculated according to the generalized regression neural network algorithm, which can be a function of the prediction error. The global optimal solution is updated according to the fitness values of all the particles. According to the current position, velocity and global optimal solution of the particle, using the formula of the particle swarm optimization algorithm, the updated position and velocity will affect the parameters of the generalized regression neural network. Then repeat the calculated fitness step to update the particle position and speed step until the stop condition is reached. By combining the generalized regression neural network algorithm with the particle swarm optimization algorithm, the global search capability of the PSO can be used to optimize the parameters and thus improve the prediction performance. Define a new particle representation and represent each particle as a parameter of a generalized neural network. In the optimization process of the particle swarm algorithm, the generalized neural network parameters of each particle are updated. Use a generalized neural network to predict or classify to evaluate the adaptability of each particle. Its principle is based on the local response of neurons to the outside world, and it has the advantages of global approximation and best approximation. Similar to the BP neural network, it consists of a three-layer forward network of input, hidden and output layers. Where the input layer transmits the input signal to the hidden layer, and the number of nodes in the hidden layer is equal to the input vector dimension of the sample. The node functions of the

hidden layer use radial Gaussian functions, and the nodes of the output layer are combined using specific linear functions.The basic principle is described below.

Let the j-dimensional vector, $x = [x_1, x_2, \ldots, x_j]^T$ be the input vector of the process, the corresponding output vector be y, and the joint probability density function of random variables x and y be $f(x, y)$. Since the theoretical basis of GRNN is a non-linear regression analysis, the regression is performed by calculating the conditional mathematical expectation of the corresponding y, given the value of x. GRNN estimates the sum of the joint probability density function, to build an estimated probability model. By training the input-output set, the probability density function estimator is constructed using the non-parametric density estimation method. For a given input vector x, assuming that the estimated function is continuous and smooth, the expected value family of the estimated y is expressed as shown in Eq. (4.4), and the continuous probability density function can be defined as shown in Eq. (4.5).

$$E[y|x] = \frac{\int_{-\infty}^{\infty} v f(x,v)\mathrm{d}v}{\int_{-\infty}^{+\infty} f(x,y)\mathrm{d}y} \tag{4.4}$$

$$f(x,y) = \frac{\sum_{i=1}^{k} \exp\left[\frac{(x-x_i)^T(x-x_i)}{2\sigma^2} * \frac{(y-y_i)^2}{2\sigma^2}\right]}{(2\pi)^{\frac{p+1}{2}} \sigma^{(p+1)} k} \tag{4.5}$$

where x_i, y_i is the i th sample value of the random variables x and y, respectively, σ is the smoothing parameter, p is the dimension of the random variable x, and k is the number of samples. First, the sample is input to the input layer, the number of nodes in the input layer is equal to the dimension p of the input vector, and then the elements of the input vector are transmitted to the mode layer, and its transfer function can be defined as shown in Eq. (4.6).

$$t_i = \exp\left(-\frac{D_i^2}{2\sigma^2}\right) \tag{4.6}$$

The sum layer has two types of nodes. The first type contains only one neuron, which arithmetic sums the output of all neurons in the pattern layer. The connection weight of each neuron between the neurons in the pattern layer and the neuron is 1, and its transfer function is $s_D = \sum_{i=1}^{n} P_i$; The second type contains remaining nodes that weighted sum the output of neurons in all pattern layers, the transfer function of the summing neuron j is $s_j = \sum_{i=1}^{n} y_{ij} P_i$. Where, y_{ij} is the connection weight between the i th neuron in the pattern layer and the j th summation neuron in the summation layer is the j th element in the i th output sample Y_i.

And use the basic operation of the genetic algorithm to improve the performance of the particle swarm algorithm to accelerate the convergence rate. In the process of optimizing the particle swarm algorithm, the operation of the genetic algorithm is introduced, and the genetic algorithm is used to evolve the particles in the particle swarm algorithm to generate new particles. Add the generated new particles to the particle swarm algorithm to update the state of the particle swarm. First randomly initiate N subgroups and remember them as GA_i, $i = 1, 2, \ldots, N$. Each subgroup runs its own genetic algorithm independently. After a certain number of generations, the optimal individual is taken out of the elite group in the upper layer and denoted as the particle group. The particle group algorithm is used to evolve the elite group. After a certain algebra, the stopping criterion is satisfied. If so, the output result and the algorithm stops. Otherwise, each genetic subgroup randomly obtains the individual extremums of k particles from the upper elite group, randomly replacing its own k individuals. N subgroup resumes the genetic algorithm operation and cycles until the stopping criterion is met. Classical genetic algorithms can converge to the global optimal solution as long as they contain the historical optimal solution in each generation of the population, whether before or after the operator, which is called the optimal retention strategy. In this paper, the genetic algorithm of evolving the underlying subgroup adopts the optimal retention strategy, finds the historical optimal solution before selecting the operator, and randomly replaces anyone in the current population if it is not in the current population. Thus the genetic algorithm used by the underlying subgroup has a global convergence. In particle swarm optimization, assuming that $p_{ib}(t)$ and $p_{gb}(t)$ remain unchanged in evolution, the $x_i(t)$ of the particle swarm algorithm converges to

$p_{ib}(t)$, φ represents the velocity of the particles and the weighted center of $p_{gb}(t)$ is shown in Eq. (4.7).

$$x_i(t) \to \frac{\varphi_1 p_{ib}(t)+\varphi_2 p_{gb}(t)}{\varphi} \tag{4.7}$$

Consider that the global optimal position is p_{gbest}, because the genetic algorithm of the underlying subgroup has global convergence. When the underlying subgroup converges to the global optimal solution, all the particles in the upper elite group will be in the global optimal position, and the individual extreme values are the same and remain unchanged in the evolutionary process, both are p_{gbest}. Therefore, when the underlying subgroup evolves with a genetic algorithm with optimal retention strategy, the upper particle group optimization has global convergence as long as ω, c_1 and c_2 satisfying Eq. (3.3) select the algorithm.

Algorithm 17 Improved particle swarm optimization (PSO) which fuses genetic algorithm and neural network

Input: s, $T(t)$, $D(t)$, $I(t)$
Output: $p_{ib}(t)$, p_{gbest}, F_{best}

Remember individual as $x_i(i = 0, 1, \ldots, n-1)$
Use the unbiased league selection method to select n individuals in the middle generation
if $f_i \leqslant f_k \to x_i' = x_i$ **then**
    Complete crossover of intermediate generation individuals (with 100% probability of crossover) to generate new generation individuals
    $x_i = rand1 * x_i' + (1 - rand2) * x_{i+1}'$
end if
Using non-consistent variation, each one-dimensional component of all individuals is mutated by probability P_m
if $rand \leqslant 5 \to x_j = x_i + \Delta(t, U_{\max}^j - x_j)$ **then**
    Calculate the fitness value of the individual
    Find the best individual in the current generation, update the historical best individual and its fitness value $I_{best}F_{best}$
end if
Return $p_{ib}(t)$, p_{gbest}, F_{best}

The steps of this algorithm are: initialize the particle swarm and calculate the adaptability value of each particle; select particles according to the adaptability value to form the intermediate generation; use inconsistent variation to mutate each particle of the intermediate generation, completely cross the particles of the intermediate generation, and generate a new generation of particles; then calculate the adaptation of the new generation of particles. Degree value, and update the best particle and adaptability value in history. Repeat the above steps until the stop condition is reached. The algorithm combines particle swarm optimization, genetic algorithm and neural network, and continuously optimizes the particle swarm through selection, crossover, mutation and other operations to find the optimal solution.

This study assumes that all individuals adopt the same information search strategy $s = S$, combined with Algorithm 17, considering the presence of smaller scale individual ε will transform the overall search strategy $S = S + \delta S$. In order to ensure that the GPU parallel get global optimal evolution algorithm in algorithm 18, by expanding the participant strategy space, improve the traditional evolution game, the computing complexity, in the rough set attribute evolution game each evolutionary population should adopt the population evolution law and behavior pattern of real game problem collaborative mechanism, enhance the global information exchange and local depth search balance, and how to determine the cooperative evolution strategy to make their utility can achieve their optimal solution set, so as to stabilize the global optimal solution set.

The input of the algorithm includes the problems to be optimized and related parameters, and the output is the optimized solution. The steps of the algorithm are: initialize the policy set and randomly select nodes with the policy set; use the policy set to select the edge according to the active edge LT model; if the edge is selected, the parallel probability is obtained according to the policy set; if the node is searched for by loop, it will be defined. The algorithm uses GPU for parallel computing, optimizes problems by selecting nodes and edges, and obtaining parallel probability according to the policy set.

Algorithm 18 GPU parallel optimal evolution algorithm

Input: s, $T(t)$, $D(t)$, $I(t)$
Output: $E^E(v)$, $E^o(v)$
Initializes the policy sets $\leftarrow \varnothing$
Select nodes uniformly at random using the policy setsv
Select edges according to live-edge LT model using policy set $s(u, v) \in E$
if select edge $(u, v) \in E$ **then**
    if edge $u \in V$ **then**
        Parallel probability obtained using the policy set $sE^E(v)$, $E^o(v)$
        else if loop search node then u, v
        Define $v = u$
    end if
end if
$E^E(v)$, $E^o(v)$

In addition, since the proposed algorithm is obtained by the GPU technology integrated evolutionary search and the optimal search strategy in parallel, the two strategies can complement each other in the control of information in the directed graph and the undirected graph, effectively improving the adaptability of the algorithm. Finally, the improved Particle Swarm Optimization Parallel of Neural Network and Genetic algorithm (PSO-PNNG) is formed, which integrates neural network and genetic algorithm.

5. Numerical examples.

5.1. Experimental design and data description. For reference [24, 25], Python software was used in this study, and nearly 30 user nodes of "opinion leaders" were taken as the initial node. User data sets of Facebook, Instagram and Twitter were captured as the basic data of the experimental simulation. Specifically, the capture time is from May 2, 2023 to October 24, 2023, and the data sample is shown in Table 1. These data sets contain a large amount of user information, such as user ID, user name, gender, age, geographic location, friend list, post content, etc. The research team uses the Tensorflow 1.5.1 framework to implement the proposed PSO-PNNG algorithm in this paper and compare the related algorithms. Before the experiment, all data were saved in CSV format in MySQL database for pre-processing, including removing noise data, processing missing values and outliers. For each social network dataset, the Rapidminer data mining tool is used to randomly extract 10% of user rating data as a test set, and the remaining 90% of user data as a training set. The experimental process was carried out in a grouping way, and the data was divided into 10 groups, and the cross-validation method was adopted, that is, the data set was divided into 10 equal parts, and one group of data was selected as the test set each time, and the other groups were selected as the training set. Finally, take the average value. In this study, 30 users with strong influence and their friends list are selected as the initial nodes of the social network to generate a complex social network. In order to verify the effectiveness and robustness of the proposed PSO-PNG algorithm, a comprehensive experiment was carried out in this study, and Numpy, Scipy, Pandas, Matplotlib and Theano packages were used to implement the proposed PSO-PNNG cross-border e-commerce multi-objective optimization algorithm. The algorithm aims to increase the traffic and conversion rate of cross-border e-commerce by optimizing the interaction and information dissemination between users. All experiments were conducted on Windows 10 servers with Intel Xeon processors (3.4 GHz) and 32 GB of RAM. The experimental results show that the PSO-PNG algorithm proposed in this paper has a good effect and application prospect in the AC network of cross-border e-commerce companies. The algorithm can effectively predict the interaction and information transmission between users, and provide more accurate marketing strategies and advertising programs for cross-border e-commerce. Since the results of the social network multiobjective optimization approach may vary from run to run, the evaluation results of the algorithm presented here are based on the average of Monte Carlo simulations over 1000 iterations with an operating standard deviation of 1.839.

In this study, the Closeness Centrality, Degree Centrality (DC), Intermediate Centrality (IC) and closeness

Table 5.1: Social network data set

Network serial number	Social network name	Type	Number of nodes	Number of node boundaries	Average degree	Average path of nodes	Clustering coefficient
1	Instagram	Directed	43571	824058	55.13	5.46	0.569
2	Facebook	Directed	55758	614516	63.37	6.47	0.615
3	Twitter	Directed	54537	675961	56.84	5.30	0.536

centrality of the proposed multi-objective optimization algorithm of cross-border e-commerce social transportation network based on PSO-PNNG are studied. CNC, Ant Colony Optimization (ACO), Swarm Optimization (SWO), K-Shell Centrality (K-Shell Centrality, ACO) KSC) and benchmarked algorithms such as Weighted K-Shell Degree Neighborhood (WKS-DN). Recommendation problems in social networks are often viewed as binary classification tasks, whereas In the binary classification task of evaluating the confusion matrix, there are two categories. For both categories, True Positives (TP) represent the number of correctly predicted links, and True Negatives (TN) indicate the number of correctly predicted unlinks. While False Positives (FP) represent the number of mispredicted links, and False Negatives (FN) indicate the number of mispredicted unlinks. Based on this, the evaluation indicators such as accuracy, accuracy rate, recall rate and F-measure used in this study can be expressed as shown in equations (5.1) – (5.4) respectively. In addition, combined with the literature, two precision functions are used: Mean Absolute Error (MAE) and Root Mean Square Error (RMSE). Equations (5.5) and (5.6) illustrate the particular computation techniques respectively.

$$Precision = \frac{TP}{TP+FP} \tag{5.1}$$

$$Accuracy = \frac{TP+TN}{P+N} \tag{5.2}$$

$$Recall = \frac{TP}{TP+FN} \tag{5.3}$$

$$F - measure = \frac{2*precision*recall}{precision+recall} \tag{5.4}$$

$$MAE = \frac{1}{N}\sum_{i=1}^{N}|f_i - y_i| \tag{5.5}$$

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(observed_t - predicted_i)^2} \tag{5.6}$$

Since the PSO-PNNG cross-border e-commerce social network multi-objective optimization algorithm defined in this paper is usually used in large-scale social network graphs. Therefore, the coloring finger of G paints each vertex with one color so that the color of any adjacent vertex is different, if the vertex of G can be colored with k colors, i. e., G is k point colorable; If G is k point coloring, but not $k-1$ point coloring, G is called k color map, k is the number of G colors, recorded as $x(G)$, which is the minimum value of k that colors G. Based on this, the greedy ant colony graph coloring solution technique (GAC-GC) uses the color allocation among the vertices of the network graph.

The introduction of graph shading in the optimization algorithm can help the algorithm better deal with constraints and optimize goals. By assigning nodes to different colors, constraints or optimization targets can be converted into node color restrictions. In this way, the algorithm can better handle constraints and optimize targets, thus improving the efficiency and accuracy of the algorithm. This method is essentially a

Algorithm 19 The concrete steps of the social network graph coloring algorithm used

Input: Graph $G = (V, E)$, S, A, P, τ, k
Output: Upper and lower bounds $B(+)/B(-)$
1: Settings $B(\cdot) \leftarrow \varnothing$
2: Calculate the upper and lower bounds with the improved Greedy algorithm $B(+)/B(-)$
3: **while** $G(\cdot) = \sum x_{ik} * x_{jk} = 0$, x_{ik}, $x_{jk} \in \{0, 1\}$ **do**
4: **if** there is no solution then make a lower bound $B(-) = B(-) + 1$ **then**
5: Calculate the upper bound $B(+)$
6: **end if**
7: $B(-)! = B(+)$
8: **end while**

linear decomposition of the graph for color. To make the proposed solution algorithm suitable for large-scale graphs, a hybrid technique based on decomposition and heuristic methods is proposed, specifically as shown in Algorithm 19.

The input of this algorithm is a social network graphic, and the output is the upper and lower bounds of the graph. The steps of the algorithm are: initialize the settings; use an improved greedy algorithm to calculate the upper and lower bounds; when there is no solution, calculate the lower bound and then calculate the upper bound. The algorithm optimizes the coloring problem of social network graphics by calculating the upper and lower bounds.

5.2. Experimental results. Table 5.2 reports the results of the area under the curve of the PSO-PNNG cross-border e-commerce social traffic network multi-objective optimization algorithm and other benchmark methods in the real social network data set. In this study, it is found that the multi-objective optimization algorithm of cross-border e-commerce social traffic network proposed in this paper has better experimental results in real social network data sets.

Table 5.3 displays the average accuracy results of the multi-objective optimization algorithm of cross-border e-commerce social transportation network and other benchmark algorithms in the real social network data set. The findings demonstrate that, across all genuine social network data sets, the multi-objective optimization method of the cross-border e-commerce social transportation network put forth in this research has a high average accuracy value.

Two measures of accuracy are used: mean absolute error (MAE) and root mean square error (RMSE). Table 5.4 lists the MAE and RMSE values of the proposed PSO-PNNG multi-objective optimization algorithm and other benchmark algorithms on different real social network datasets. The higher the MAE and RMSE values, the lower the accuracy of the prediction optimization algorithm. Table 5.5 shows that the suggested PSO-PNNG multi-objective optimization algorithm for cross-border e-commerce social traffic network outperforms the other approaches in general.

This is because the PSO-PNNG cross-border e-commerce social network multi-objective optimization algorithm has the ability to respond quickly and optimize social networks in real time to a certain extent, and can also minimize the overall loss of calculation.

6. Conclusions. With the deepening of global economic integration, international trade and logistics activities show a trend of rapid growth. This study on the basis of cross-border electricity social network research, based on the improved particle swarm algorithm (PSO), put forward a kind of cross-border electricity social traffic network improvement PSO-PNNG multi-target recommended optimization algorithm, and in the environment of multiple real social network data simulation experiment and algorithm comparison, we found that

Note: The values shown in bold all indicate that the corresponding algorithm performs well.

the algorithm on multiple real social network data set has shown excellent performance. The experimental findings demonstrate that the PSO-PNNG multi-objective optimization algorithm, which is based on an enhanced PSO optimization algorithm, outperforms traditional techniques in terms of accuracy and efficiency. At the same time, the algorithm can respond quickly and achieve multi-objective optimization, effectively reduce computational losses, and can help enterprises improve the operational efficiency of cross-border e-commerce social networks. In the future, we can further explore the characteristics of social network data in order to continuously improve the optimization effect.

PE GAS PIPELINE DEFECT DETECTION ALGORITHM BASED ON IMPROVED YOLO V5

QIANKUN FU*, QIANG LI †, WENSHEN RAN ‡, YANG WANG §, NAN LIN ¶, AND HUIQING LAN ‖

Abstract. In order to improve defects detection efficiency in polyethylene (PE) gas pipelines and decrease leakage or other pipelines abnormalities in operation, this research proposed an improved YOLO(You Only Look Once) v5 detection model. First, the collected pipeline defect images were processed in grey scale, which improved the computational efficiency of the computer; then, Gamma transform and double filtering algorithms were applied respectively for image enhancement and noise reduction filtering of defects, which enhanced image quality and reduced image noise. Finally, the improved Sobel algorithm was applied to detect defective image edges and the defects in the image were segmented by adaptive threshold segmentation method to obtain binary images. The obtained binary images were employed to train the improved YOLO v5 detection model. The obtained experimental results showed that, compared with the original algorithm, the improved detection algorithm had better detection efficiency and higher robustness as well as higher recognition for common defects,improved YOLOv5 mAP and recall were 97.18% and 98.03%, respectively, the mAP has increased by 1.33% and the recall has increased by 3.83%,which can achieve the detection and identification of defect types of effects in PE gas pipes.

Key words: Defect detection; Image processing; Machine learning; YOLO v5; Attention mechanism

1. Introduction. Today, PE pipelines are widely being used as an economical and effective transportation means for oil, gas and urban water heating supply, which brings much convenience to human life as well as industrial and agricultural development and also produces great economic benefits [1]. This type of pipeline transportation has been used since 1860s, when the world's first crude oil pipeline was constructed in the state of Pennsylvania in the United States [2]. Today, after decades of development, pipeline transport industry has become the fifth largest means of transport after railways, roads, aviation and seaborne [3]. However, PE oil and gas pipelines are buried deep in the ground and are vulnerable to corrosion, cracks and other damage types in long-term in the presence of oil or gas and other substances [4]. In pipeline networks around the world, cracks and other damage forms in pipelines can lead to the leakage of liquids and gases, resulting in wasted resources, environmental pollution, and even explosions [5]. Due to the long time required for manual inspection of pipelines, pipeline robotics equipped with various inspection methods have been developed and applied [6]. Robots equipped with image recognition technology has become an increasingly popular method for online non-contact inspection in recent years. By utilizing image recognition technology for inspection, it is possible to clearly identify existing defects [7].

As time passed, image processing technology has rapidly come into prominence and at the same time, pipeline defect detection technology has also presented a diversified trend [8]. Dong et al. [9] developed an automatic pipeline weld defect identification technology applicable of quality identification and assessment of a series of defects in pipeline welds, with an identification accuracy rates of higher than 90%, which helped ensure the safe operation of pipelines. Wang et al. [10] introduced a framework for tracking multiple sewer defects in CCTV videos based on defect detection and metric learning. This fast method enabled high-accuracy detection of general 2D surface defects. Bondada et al. [11] presents a new method for automated inspection

of long distance pipelines using machine vision technology. The method identifies corrosion and quantifies the damage caused to help maintain pipeline integrity. Myrans et al. [12] developed a new method for automatic identification of detected fault types in pipelines. Their proposed method computed GIST feature descriptors for fault frames and applied RF machine learning classifiers to analyze frame contents and identify fault types. Ye et al. [13] introduced an image recognition algorithm using feature extraction and machine learning methods and applied support vector machines to classify pipeline defects with 84.1% overall accuracy. Fang et al. [14] developed a fault detection technique that applied an anomaly detection algorithm developed using unsupervised machine learning to a new pipeline visual inspection device. The video recorded by the device was regarded as a sequence signal, which was converted into a feature vector and then, defects were identified using a pipeline defect detection algorithm. The overall accuracy of the developed method was above 90%. Kumar et al. [15] developed a framework that used a deep convolutional neural network (CNN) to classify multiple defects such as root intrusion, deposits, and cracks in sewer closed circuit television (CCTV) images.

YOLO algorithm is also gradually becoming popular in pipeline defect detection thanks to the development of deep learning. Chen et al. [16] developed a Cycle-GAN-based sample enhancement strategy and an improved YOLO v5-based defect detection system for the detection of pipeline inner wall defects, which could detect common problems including oxide spalling, erosion, deposition, and infiltration. Zhao et al. [17] proposes a YOLOv3-based method for underwater pipeline oil spill point detection. Their developed network was able to quickly detect pipeline leakage points with high accuracy and low misdetection rate. Yan et al. [18] introduced an anomalous signal detection method (YOLO-PD) based on improved YOLOv7 which was able to effectively identify anomalous signals in pipelines with higher detection accuracy. Peng et al. [19] improved YOLO v5 algorithm and introduced an algorithm for pipeline leakage detection using CBAM(Convolutional block attention module) attention mechanism, thereby focusing more on identifying pipeline leakage characteristics and decreasing intricate background effects on detection outcomes. Yin et al. [20] developed a YOLO v3-based pipeline defect detection framework capable of detecting six common pipeline defects with mean average precision (mAP) of 85.37%.

In summary, the above mentioned computer vision-based inspection methods were consisted of three parts; namely, image preprocessing, feature extraction, and defect identification and classification. These methods were more effective in detection and required less labor. However, many current feature extraction methods are designed for specific defect types and can only recognize them, which limits their applicability. Furthermore, they suffer from low precision and high incorrect detection rate. Hence, this research developed a YOLOv5-based PE pipeline defect detection framework capable of extracting abstract features of defects on its own and accurately detecting and categorizing three types of defect; namely cracks, snaps, and holes. Accordingly, this research improved the existing modeling frameworks by adding an attention mechanism model and K-means++ algorithm and employed ablation experiments to validate the efficiency of the developed mod-el. It was found that unlike the original algorithm, mAP was increased by 1.33% and maximum confidence was enhanced by 0.2

2. Image Pre-processing. Pipe image pre-processing not only eliminates noise, but also improves distinction between pipeline backdrop and defects, decrease data complexity and highlight defect characteristics [21]. The image pre-processing approach employed in this research is illustrated Fig. 2.1.

2.1. Greyscale processing for pipeline images. Greyscale is the brightness value of each pixel in an image and is often applied to represent the darkness or lightness of a pixel. Grayscale images are usually easier to process compared to color images since they have only one channel while color images have three channels [22]. Compared to colored images, grayscale images use less memory and more swiftly perform computer tasks.

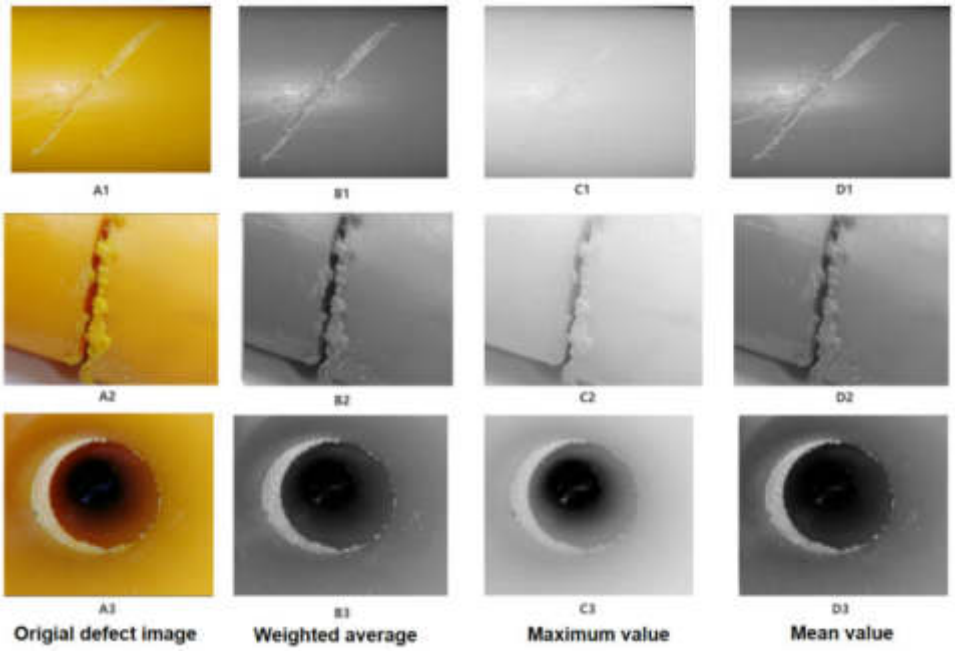

Fig. 2.2: Comparison of different greyscale processing methods.

The three prevalent methods to convert color images into grayscale ones are mean value, maximum value, and weighted average methods.

Maximum value method directly selects the highest-valued element from the color channels in images are red (R), green (G), and blue (B) as shown in equation(2.1).

$$R = G = B = \max(R, G, B) \tag{2.1}$$

Mean value approach averages the values in the three R, B, and G components. as stated in equation (2.2).

$$R = G = B = (R + G + B)/3 \tag{2.2}$$

Weighted average method relies on the sensitivity of human eye to the three colors R, B, G, as given in equation(2.3):

$$I(u, v) = 0.3 \times I_R(u, v) + 0.59 \times I_G(u, v) + 0.11 \times I_B(u, v) \tag{2.3}$$

Where: $I(u, v)$ indicates the coordinate's gray value, while $I_R(u, v)I_B(u, v)$ and $I_G(u, v)$ are pixel brightness levels for the three color elements of R, B and G, respectively.

Utilizing weighted average (Fig. 2.2B1-B3),maximum value (Fig. 2.2C1-C3) and mean value (Fig. 2.2D1-D3)techniques, the three initial defect image (Fig. 2.2 A1-A3) of holes,cracks, and snaps were processed in grayscale. It was found that weighted aver-age method was the most efficient technique for grayscale images. according to Fig. 2.2, pipeline defect image displays clear defect features and moderate brightness. Therefore, weighted average method was used for image grayscale in this research.

2.2. Enhancing images for pipeline defects. Enhancing the visual appeal of an image entails emphasizing its borders and key textural features, while minimizing the visibility of less significant sections, thereby slightly boosting image visual impact [23]. To improve grayscale image (Fig. 2.3A1-A3), Gamma transformation (Fig. 2.3B1-B3), global histogram equalization (Fig. 2.3C1-C3), and adaptive histogram equalization (Fig. 2.3D1-D3) were applied.

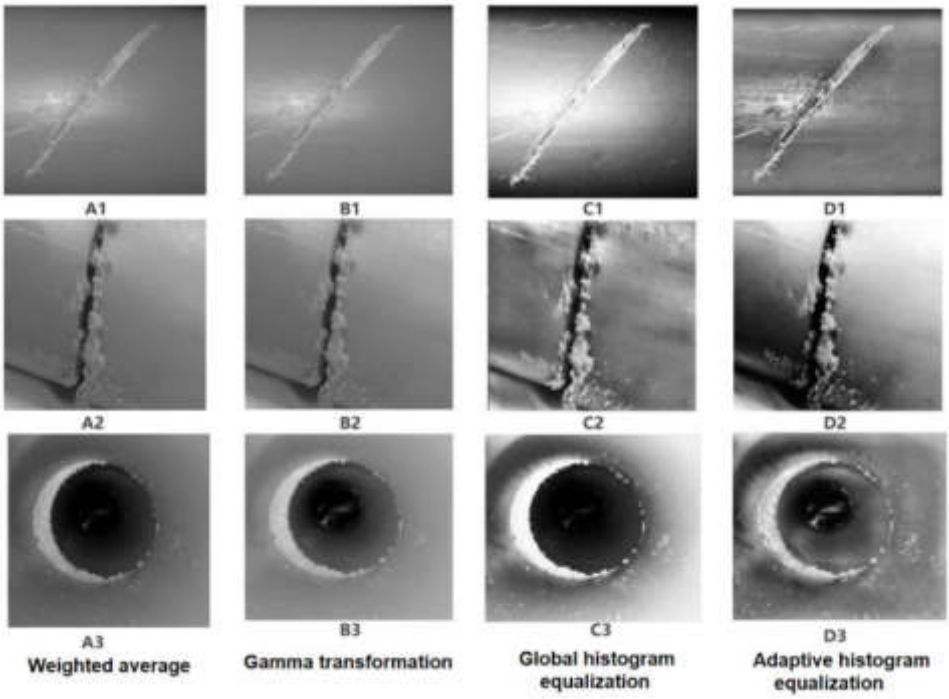

Fig. 2.3: Comparison of the effectiveness of different image enhancement algorithms.

It was seen from Fig. 2.3 that, compared to other algorithms, Gamma transformation created no distortion in pipe defect images and defect borders became more visible and prominent in the backdrop. Therefore, Gamma transform was applied to enhance contrast between pipeline backdrop and pipeline defects.

2.3. Filtering and denoising images of pipe defects. Due to environmental interference or equipment limitations, the final image is frequently susceptible to significant noise interference during image transmission process. Image denoising is a classic image restoration method which employs noise to predict clean images [24]. The above images (Fig. 2.4A1-A3) were denoised using bilateral filtering (Fig. 2.4C1-C3), Gaussian filtering (Fig. 2.4D1-D3), mean filtering (Fig. 2.4E1-E3) and median filtering (Fig. 2.4F1-F3).

Step-by-step processing is a popular approach for resolving complex noisy images [25]. A specific weighted average used in bilateral filtering employs Gaussian distribution to eliminate Gaussian noise from the image. However, elimination of Gaussian noise ignores salt-and-pepper noise and while adaptive median filtering excels at removing salt-and-pepper noise, its effectiveness falls when eliminating Gaussian noise[26]. There-fore, it was recommended to apply a dual filter (Fig. 2.4B1-B3), in which a median filter eliminated salt-and-pepper noise and then, a bilateral filter eliminated Gaussian noise. Unlike alternative filtering methods, dual filtering maintained edge details, removed noise points, and effectively preserved edges, as illustrated in Fig. 2.4 Consequently, this re-search utilized dual-filter noise reduction technique.

2.4. Edge detection of pipe defect image. Edge detection in images can help us better understand image contents, extract feature information, and achieve object detection and recognition.The traditional Sobel operator performs a weighted averaging operation on each pixel by applying a convolutional template (as illustrated in Fig. 2.5), followed by a differential procedure to obtain gradient values along X and Y directions. This algorithm cannot easily obtain the required detection outcomes and its localization precision falls short. Since the traditional Sobel algorithm has templates only along X (horizontal) and Y (vertical) directions, it is more sensitive to detect x and y edges [27]. The obtained PE gas pipe defect images included a high quantity of interfering data due to image compression and working environment and different forms and depths of defects

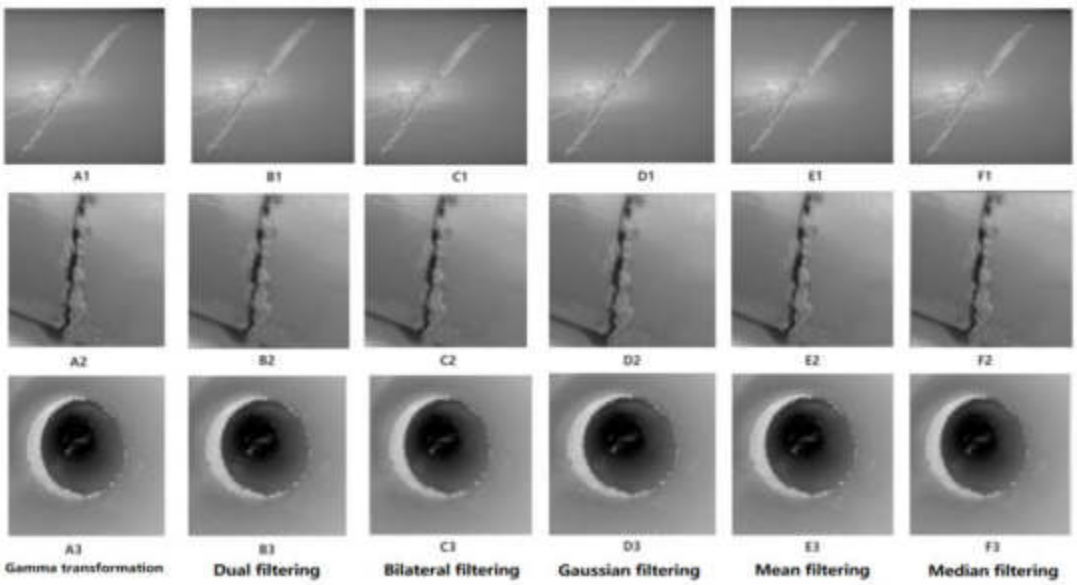

Fig. 2.4: Comparison of different image filtering algorithms.

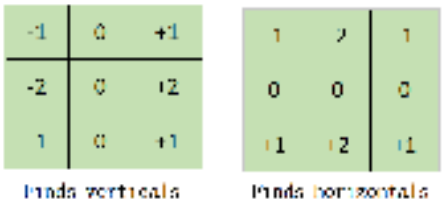

Fig. 2.5: Sobel operator template.

in the pipeline produced relatively tiny regional variations in defect image gray scale. Therefore, relying only on two directional operators for pipe defect edge detection was found to be inefficient and prone to missing edge information. Hence, it was proposed to add six more directions to traditional Sobel algorithm to enhance image edge pixel detection precision[28]. As illustrated in Fig. 2.6, this method enhanced image edge detection, boosted edge detection precision, and reduced erroneous edge chances.

On the above-displayed pipeline defect-filtered images (Fig. 2.7A1-A3), Sobel edge detection method (Fig. 2.7B1-B3), Prewitt edge detection method (Fig. 2.7C1-C3), and improved Sobel edge detection method (Fig. 2.7D1-D3) were applied for image border detection. Edge detection results of the three defects are illustrated in Fig. 2.7. In terms of result comparison, improved Sobel algorithm enhanced defect edge extraction, ensuring greater continuity and integrity, and fully revealed defect shape characteristics. Therefore, this research employed improved Sobel algorithm to identify edges.

2.5. Adaptive Threshold Segmentation. When faced with non-uniform lighting or irregular gray value distribution, the segmentation outcomes obtained with a global threshold are frequently unsatisfactory, whereas application of an adaptive threshold, also known as local segmentation, could provide favorable results [29]. The function of this concept was to determine local threshold based on the brightness distributions of various image regions rather than global image threshold. This allowed it to adaptively determine thresholds for various image regions; hence, it was called "adaptive thresholding method". Following edge detection, images (Fig. 2.8A1-A3) were processed through global threshold segmentation (Fig. 2.8B1-B3), Otsu threshold segmentation (Fig.

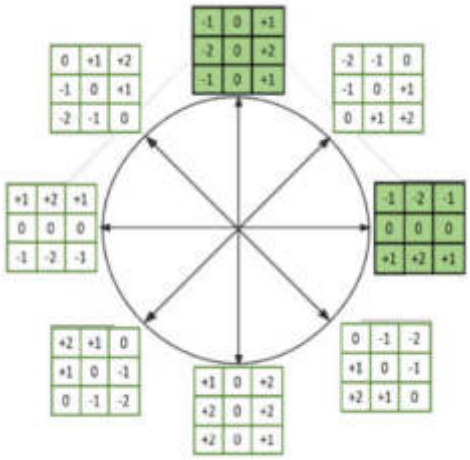

Fig. 2.6: Improved Sobel operator.

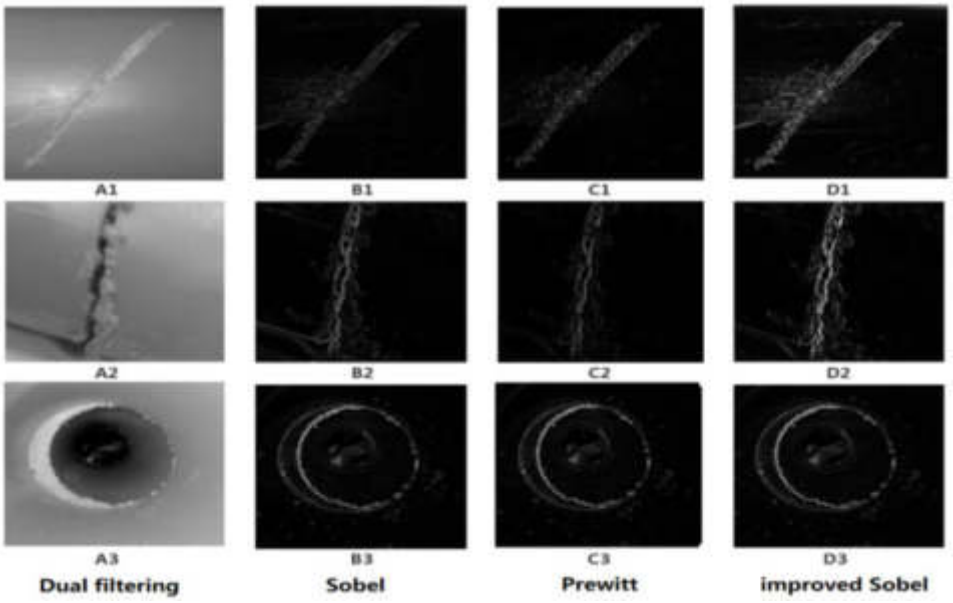

Fig. 2.7: Comparison of the effectiveness of different edge detection algorithms.

2.8C1-C3), and adaptive threshold segmentation (Fig. 2.8D1-D3). Through naked eye observation and using adaptive threshold pipe defects and backdrop could be distinguished to achieve optimal segmentation of PE gas pipe defects with minimal information interference. Therefore, in this research, adaptive threshold algorithm was applied for image division to obtain binary image.

3. Pipeline defect detection algorithm based on improved YOLOv5. YOLO v5 is part of You Only Look Once (YOLO) algorithm family. This algorithm has made some improvements on YOLO v4 and its speed and accuracy have been greatly improved [30]. The main idea of the algorithm was to use a single neural network model for target detection, by feeding the entire image into the model. The model was able to directly output the location and class information of the targets present in the image [31]. Three modules,

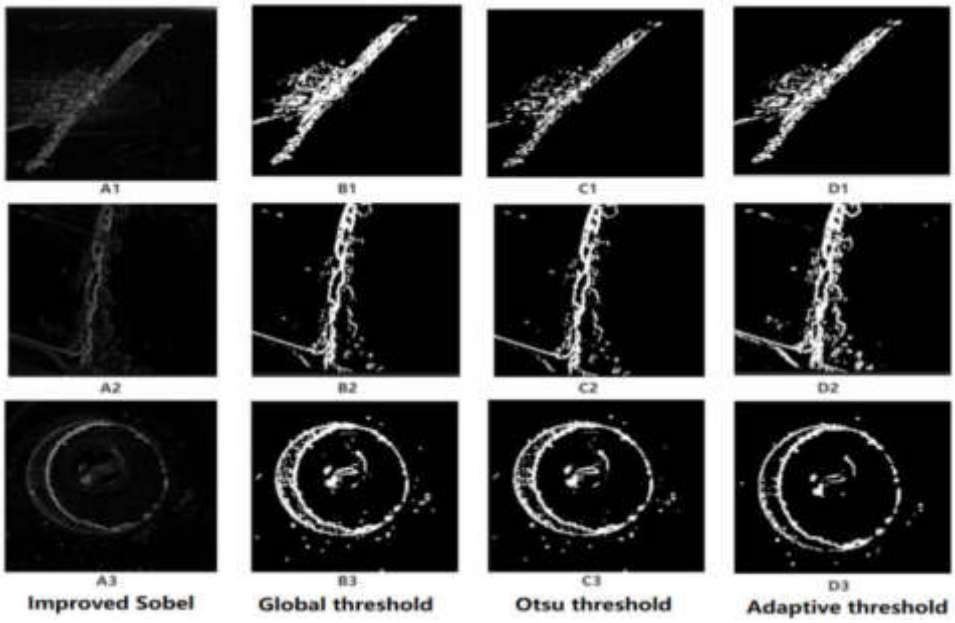

Fig. 2.8: Comparison of different threshold segmentation methods.

Fig. 3.1: Conv module structure.

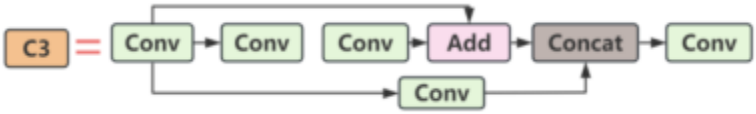

Fig. 3.2: C3 module structure.

namely backbone, neck, and head, make up YOLO v5 and use grids concept to detect targets.

3.1. YOLO v5 algorithm principle.

3.1.1. Backbone. Backbone is an image feature extraction network that takes input images and gradually extracts features through several convolutional and pooling layers [32]. The main structures of backbone are Conv module, C3 module, and SPP module, which play key roles in target detection algorithms.

1. Conv module. Convolutional neural networks frequently use conv module as fundamental module, which is mainly composed of Conv2d, BN layer and SILU activation function. High-level image features can be gradually extracted through these operations, which helps the network to learn various patterns and features in image and provide the necessary information for target detection. Conv module structure is illustrated in Fig. 3.1.

2. C3 module. C3 module can extract multi-scale feature information from receptive fields of various sizes. This is significant for computer vision applications such as target detection because it achieves higher accuracy and speed in shorter training times; therefore, it is extensively applied in target detection tasks. C3 module structure is illustrated in Fig. 3.2.

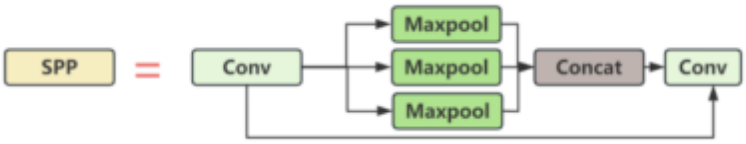

Fig. 3.3: SPP module structure.

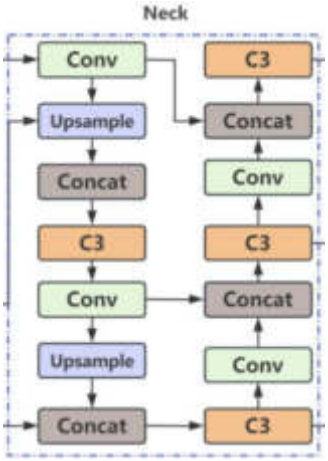

Fig. 3.4: Neck module structure.

3. SPP module. The role of spatial pyramid pooling (SPP) module is to perform multi-scale pooling operations on input feature maps to capture spatial information of different sizes. This helps the network better understand the contextual information of the target at different scales, improving target detection accuracy and robustness. The SPP module plays a key role in YOLO v5, helping the network to efficiently concatenate target features at different scales and improve detection performance. The structure of SPP module is illustrated in Fig. 3.3.

3.1.2. Neck module. Because the uncertainty of the size and position of an object in an image, a mechanism is required to handle targets of different scales and sizes. Feature pyramid is a strategy for dealing with multi-scale target detection, which could be realized by adding layers of characteristics at various scales to backbone network [33]. Feature pyramid network (FPN) serves to establish connections among different layers of feature maps and perform feature fusion and up-sampling operations to generate pyramid structures with rich semantic information and multi-scale features, helping the network better detect targets of various sizes and scales [34]. The structure of neck module is presented in Fig.3.4.

3.1.3. Head module. In YOLO v5, head module (shown in Fig. 3.5) is responsible for performing target detection task on the last layer of network feature map, which usually consists of multiple convolutional layers for extracting features and generating target detection results [35]. The head module in YOLOv5 applied a series of convolutional operations on the last convolutional layer to generate a bounding box for the target and a corresponding class confidence score. These predictions were applied to determine the presence of targets in the image and their corresponding classes.

3.2. Improvements to initial anchor box. YOLO v5 algorithm inherits the anchor box mechanism of previous generations of YOLO algorithm with the difference that YOLO v5 algorithm innovatively embedded adaptive anchor box mechanism. It significantly enhanced the efficiency of the algorithm [36]. However, the prior frame of YOLO v5 target detection network was based on the COCO dataset obtained by clustering

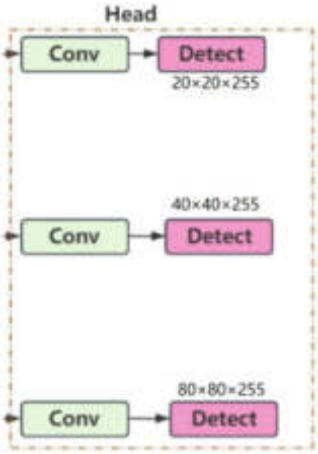

Fig. 3.5: Head module structure.

during training and large target detection in the dataset accounts for more. However, in the current detection scenario, small and medium-sized targets were predominate and were still mainly targeted as pipeline defective targets, which inability to fit well the anchor box acquired on the COCO dataset. The primary drawback of K-means technique is that the amount of clusters-K and the initial cluster centers need to be confirmed by themselves, and an unreasonable number of clusters and cluster centers will make the results uninterpretable. Therefore, this research recommended using K-means++ algorithm to recalculate the anchor boxes used in pipeline defect target identification to improve the accuracy of the algorithm.

3.2.1. K-means. The main principle of K-means algorithm is to first choose K cluster centers at random according to the principle of nearest neighbor to sample points to be classified into each cluster. Then, the center of mass of each cluster is recalculated through averaging method to determine new cluster center. Iterating is continued until the clustering results of all samples no longer change.

K-means clustering algorithm is consisted of the following main steps.

Step 1: Selection of clustering centers. K samples from dataset X are randomly selected as initial clustering centers;

Step 2: Calculation of Euclidean distance. Distances from all sample points to K cluster cores are individually calculated, the closest cluster core to the point is found, and the obtained core is attributed to the corresponding cluster;

Step 3: Updating the clustering center. After assigning all points to K clusters into which the dataset X is divided, the center of gravity (average distance from the center) of each cluster is re-computed and designated to be a new "cluster core".

Step 4: Steps 2 and 3 are repeated until each clustering center no longer changes.

3.2.2. K-means++. The original YOLO v5 algorithm integrated K-means and genetic algorithms in auto anchor, which performed the computation of the anchor value of the data before training was started. Based on the obtained best possible recall (BPR) value, it could be determined whether the dataset needed to recalculate the anchor[37]. K-means clustering algorithm required human intervention in determining the value of K. The result might not be a globally optimum solution, which greatly reduced the overall operating efficiency of the algorithm [38]. Therefore, in this research, it was decided to replace K-means algorithm with K-means++ algorithm to recluster the dataset which was optimized to decrease errors and improve detection algorithm accuracy. K-means++ algorithm is consisted of the following steps:

Step 1: The initial clustering center C1 is chosen at random from dataset X;

Step 2: The shortest distance $d(x)$ between each sample and the already existing clustering center is determined;

Step 3: The probability $P(x)$ hat each sample point would be chosen as the next cluster center is calculated

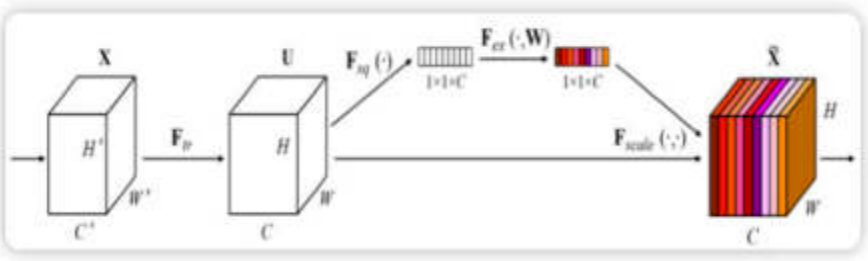

Fig. 3.6: SE module structure.

and then, the sample point with the highest probability value (or probability distribution) is chosen as the next cluster center $P(x)$, as stated in Equation 3.1

$$P(x) = \frac{d(x)^2}{\sum_{x \in X} d(x)^2} \tag{3.1}$$

Step 4: Steps 2 and 3 are repeated until a total of K cluster centers are screened;
Step 5: Calculation of the Euclidean distance. The distances from all sample points to K cluster cores are individually calculated, the closest cluster core to the point is found, and it is attributed to the corresponding cluster;
Step 6: Updating the clustering center. After assigning all points to the K clusters into which the dataset X is divided, the center of gravity (average distance from the center) of each cluster is re-computed and designated as a new "cluster core".
Step 7: Steps 5 and 6 are iterated until each clustering center no longer changes.

3.3. Fusion Attention Module. Due to its high detection speed and accuracy, YOLO v5 is frequently used in target detection and defect recognition applications. However, there is a certain error when detecting unclear features or small targets and images obtained in natural environments may have occlusion. Therefore, in order to address the aforementioned issues, it is required to increase the feature extraction capability of the detected targets. Adding attention mechanism in YOLO v5 is the most common way to enhance its feature extraction ability and despite the fact that it increases the total amount of parameters, it can improve accuracy.

3.3.1. SE module. Squeeze-and-excitation (SE) model is an attentional mechanism to enhance the performance of neural networks. It dynamically learns the importance of features among different channels and improves the network's attention to important features. The main functions of SE module are excitation and squeeze, which are obtained through a series of operations to obtain a weight matrix to reconstruct the original features [39]. The structure of SE algorithm is presented in Fig. 3.6.

3.3.2. CA modules. Channel attention (CA) module is designed to improve the feature representation ability of the network by learning the importance of features among various channels to increase the network's attention to specific features. By introducing CA module, the ability of the neural network to perceive critical features can be effectively improved, which in turn enhances network performance in various visual tasks [40]. The structure of CA algorithm is presented in Fig. 3.7.

3.4. CBAM module. Convolutional block attention module (CBAM) was designed to improve the performance of neural networks by focusing on both channel and spatial information. Channel attention is applied to learn the importance of features among different channels, while spatial attention is employed to learn the correlation among different locations within the feature map, thus allowing the network to focus more on important feature channels and spatial locations[41]. The structure of CBAM algorithm is illustrated in Fig. 3.8.

4. Analysis of experimental results. We allocated training dataset, validation dataset, and test dataset in the ratio of 7:2:1, with a total of 3365 images. The specific quantities are summarized in Table 4.1.

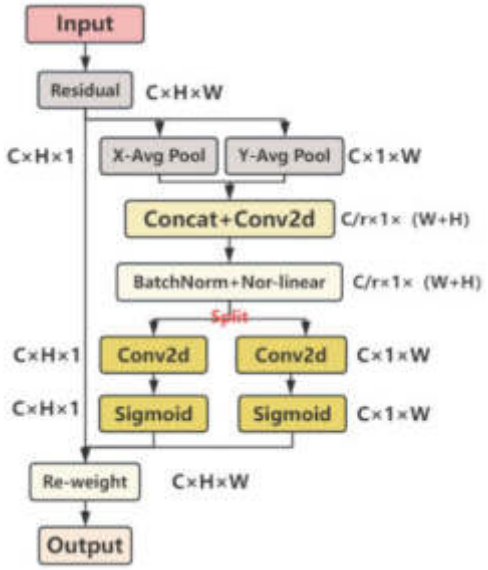

Fig. 3.7: CA module structure.

4.1. Setting parameters and experimental platform. The working environment is presented in Table 4.2 and the settings of the training parameters are given in Table 4.3.

4.2. Evaluation indicators. The experimental results of this research evaluated the performance of the improved algorithm in terms of mean average precision (mAP), recall, and precision. In target detection, mAP is applied to measure the detection accuracy of the model on multiple categories for evaluating the performance of the overall target detection algorithm where larger mAP values indicated better model performance. The

equations for recall, precision, and mAP are expressed below:

$$Precision = \frac{TP}{TP + FP} \tag{4.1}$$

$$Recall = \frac{TP}{TP + FN} \tag{4.2}$$

$$AP = \int_0^1 P(R)dR \tag{4.3}$$

$$mAP = \frac{1}{N}\sum_{i=1}^{N} AP_i \tag{4.4}$$

where TP, FP, and FN stand for true positives, false positives, and false negatives, respectively.

4.3. Comparative experiments and analysis of results. It was seen that training YOLOv5 model using preprocessed defective images improved mAP by 1.84% and training speed by 29% compared to the original algorithm, which showed that preprocessing of pipeline defect images improved the training speed and accuracy of the model.

Table 4.5 shows that the K-means algorithm to K-means++ method was successful in boosting overall algorithm detection precision, with mAP increasing by 0.48%.

YOLOv5s-K++-CBAM	95.79	97.73	96.06	7.22	15.6

Comparison of the results of adding different attention mechanism modules is given in Table 4.6 where CA module was found to have the best effect compared with other methods. CA module was added to YOLO v5 model and its structure is shown in Fig.4.1. The trained mAP function curve and loss function curve are illustrated in Fig. 4.2 and confusion matrix is presented in Fig. 4.3. Compared with the original algorithm, the improved YOLO v5 algorithm was better, with 1.33% increase in mAP and 3.83% increase in recall.

To further validate the performance of the improved algorithm, we conducted comparative experiments using two defect detection algorithms of YOLO v7 and YOLO v8. The obtained experimental results are presented in Table 4.7 and Fig. 4.4, with confusion matrix depicted in Fig. 4.5. The experimental results

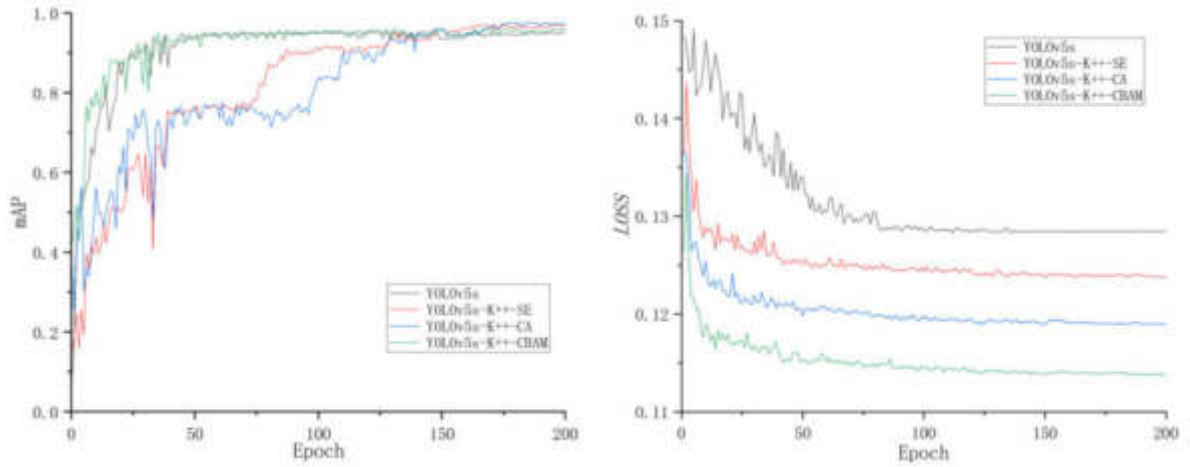

Fig. 4.2: Graph of the mAP and Loss for the different models.

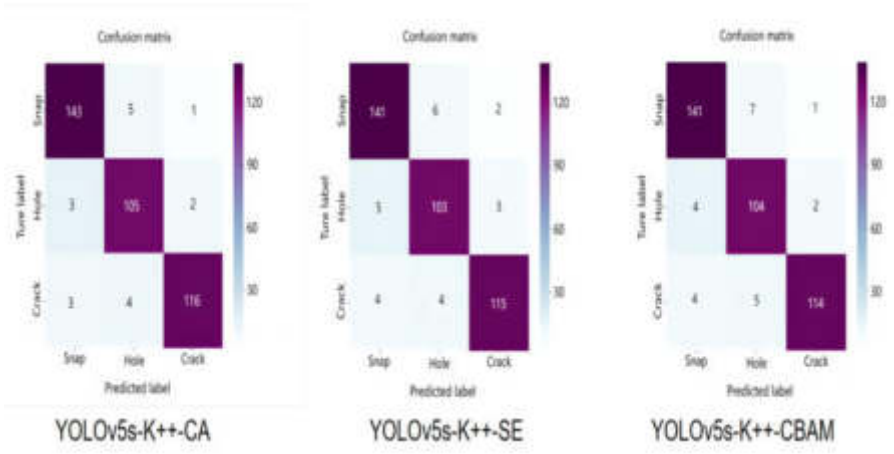

Fig. 4.3: Confusion matrix for different models of attention.

Table 4.7: Comparison of different detection algorithms.

Algorithms	mAP/%	Recall/%	Precision/%	Params/M	Time
YOLOv8	96.75	95.02	95.82	6.86	14.1
YOLOv7	96.29	94.91	95.61	6.95	14.6
YOLOv5s-K++-CA	97.18	98.03	97.1	7.22	15.4

demonstrated that improved YOLO model achieved higher mAP, precision, and recall compared to the remaining two algorithms, where mAP was 0.43% higher than that obtained from YOLO v8 and 0.89% higher than that of YOLO v7. Therefore, it could be inferred that YOLO v5s-K++-CA was an accurate and stable tool for pipeline defect detection. The developed method could be applied to detect pipeline defects and ensure pipeline safety.

Using trained pipeline defect detection model to detect gas pipeline defects, it was found that the improved

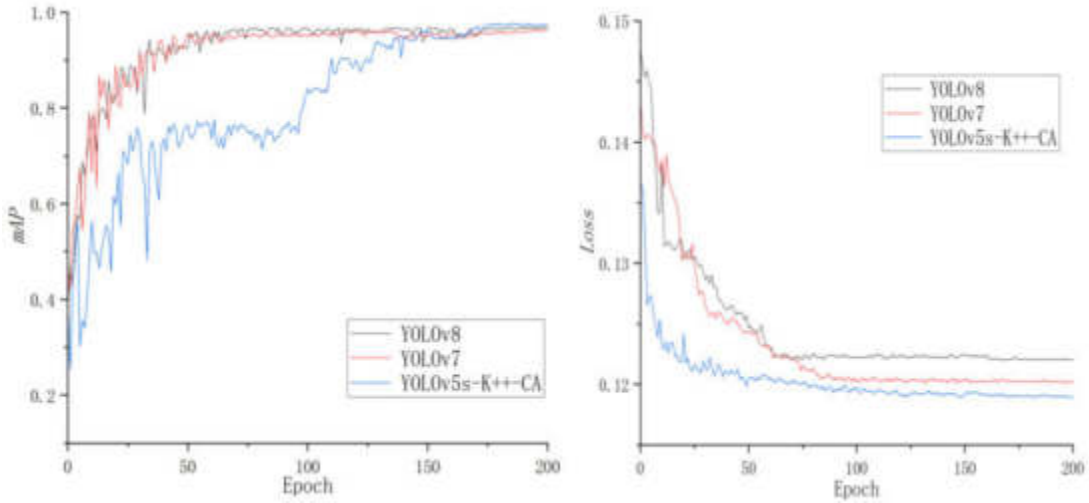

Fig. 4.4: Graph of mAP and Loss for the different detection algorithms .

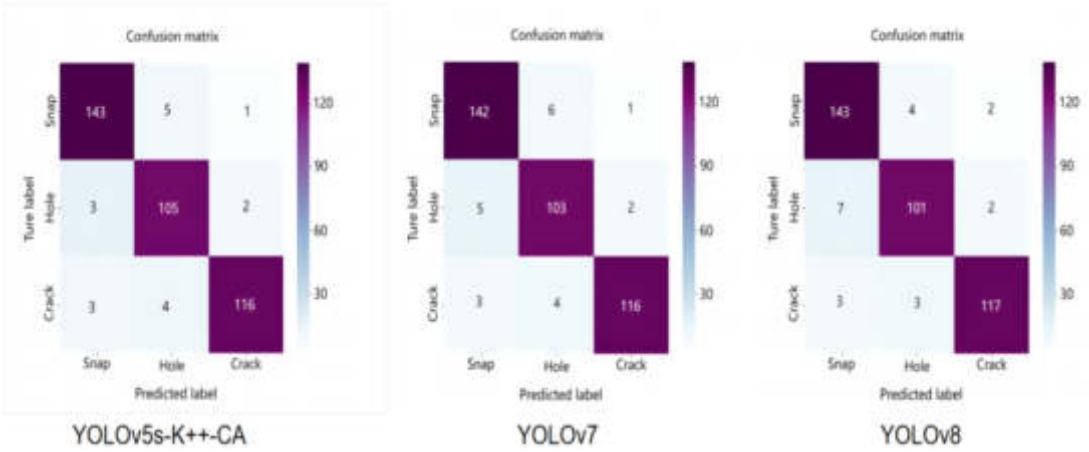

Fig. 4.5: Confusion matrix for different detection algorithms.

algorithm was able to provide much higher detection capability compared to the original algorithm. From Fig. 4.6, it was seen that the updated approach presented a greater confidence level compared to the original algorithm. For the three common defects of cracks, snaps, and holes, the developed method provided higher recognition rates and the maximum confidence was improved by 0.2.

5. Conclusion. To address the challenges of low natural gas pipeline defect detection accuracy and poor stability, we introduced an improved defect detection method based on YOLO v5 algorithm. Experimental results demonstrated that the improved YOLO v5 model exhibited strong robustness and precision in detecting pipeline defects and as a non-destructive testing method, it could be used to detect pipeline defects.

The primary conclusions of this research were as follows:

1. In response to frequent occurrence of varying degrees of leakage and other anomalies in oil and gas pipelines, through experimental simulation of different abnormalities in the pipeline, the data collection and manual marking production of corresponding data set, to lay the groundwork for utilizing target detection methods in studying pipeline leakage and other anomalies in the future.

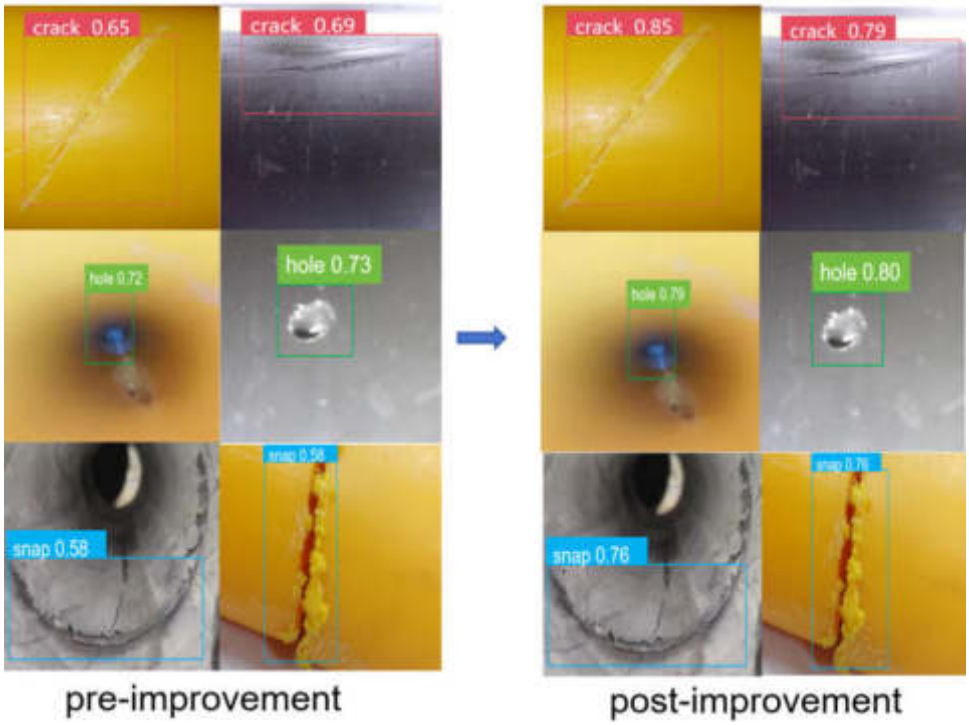

Fig. 4.6: Comparison the effect before and after model improvement.

2. To enhance the quality of pipeline defect images, first, images were in grayscale using weighted average method. Then, the contrast between pipeline background and any defects was enhanced by applying gamma transform. Finally, noise was reduced in images using dual filtering.
3. To simplify the data and enhance the training speed and effectiveness of the model, we utilized improved Sobel algorithm and adaptive thresholding method to detect defective image edges and threshold segmentation to generate binary images. Then the model was trained with binary images to reduce its dependence on color features, making the model more concerned with target shape.
4. In order to enhance the precision and efficiency of pipeline defect detection, YOLOv5's K-Means algorithm was improved and K-Means++ algorithm was employed to determine the initial center of the anchor frame. Introduction of CA attention mechanism enhanced the perceptual ability of the convolutional neural network in target detection, thus improving the accuracy and robustness of the detection process.

In order to achieve better detection results and make the model more practical, the dataset needs to be expanded to include various types and resolutions of pipeline defect images to further improve the ability of real-time pipeline defect monitoring and detection model structure needs to be optimized to make it more universally practical, which are considered as future works to be improved.

MRESGAT: MULTI-HEAD RESIDUAL DILATED CONVOLUTION ASSISTED GATED UNIT FRAMEWORK FOR CROP YIELD PREDICTION

SAHANA SHETTY *AND MAHESH T R †

Abstract. The importance of predicting crop yields has increased due to growing concerns of surrounding food security. Early forecasting of crop yields holds a pivotal role in avoiding starvations by estimating the food supply available for the expanding global population. Several Deep Learning (DL) and Machine Learning (ML) techniques are involved to develop effective and accurate crop yield prediction model. Nevertheless, existing models faces some limitations such as less accuracy, high error rate because of noisy data, high training time and extracted less effective features for prediction. To overcome these issues, the novel DL methodology is introduced for attaining high accurate crop yield prediction. Initially, the soil, weather and other resources big data are collected from the various agriculture field. In data collection phase, the input data of larger size are stored in the Hadoop platform for the purpose of storing as well as processing the entire data in a distributed manner. The data are pre-processed through the utilization of Missing value imputation and z-score based data normalization. From the pre-processed data, the optimal features are considered using Integrated Correlation Random recursive elimination (InCorRe) approach. Based on the previous soil and weather information, the suitable yield of crops can be predicted using Multi head Residual dilated convolution assisted gated unit (MResGat) model. Finally, the losses of the network model can be optimized using African vulture optimization algorithm (AVO). The proposed method is evaluated using the several performance metrics, which achieved 0.023% of MSE value and 0.036% of MAE values.

Key words: Deep Learning, Crop yield prediction, Hadoop platform, Multi head attention, Residual dilated convolution assisted gated unit, African vulture optimization and Integrated Correlation Random recursive elimination.

1. Introduction. Development minded formers have the experienced to predicting the crop yield with precision before introducing the computer technology. In order to achieve this, the farmers collected complete records of their fields during the growing and harvest seasons. Then, using their gathered knowledge and experience, they tried to determine the best plan of operation for the following year [1]. Nevertheless, the on-going smart agriculture utilized several data producing sensor and devices that leads to decision making and data driven process. The smart agriculture mostly developed for the remote sensing idea, which is possible by extracting the relevant data from the sensor fixed in the agriculture field [2]. Through the remotely sensing data the formers can predicted the crop yield for the upcoming years that helpful to make correct decision and avoid the loss of agricultural production [3].

Accurate yield estimations contribute both in minimizing starvation but also educating farmers' economical and decision-making processes. The crop yield prediction is essential to addressing current problems regarding food security by consideration of possible ongoing global climate change [4]. The evolution of affordable crop yields in Norway is based on various factors such as the agroclimatic conditions, soil quality, rainfall persistence, and other improved infrastructure. Increasing greater populations on the planet has caused it hard for farmers to produce food in larger quantities and of higher quality [5]. Crop yield prediction improves total agricultural productivity by educating farmers, policymakers, and stakeholders to make well-informed decisions and manage resources effectively [6]. Integrating ML, weather patterns, satellite images and historical data becomes essential for creating accurate models which encourage efficient and economically feasible farming methods [7]. The development of ML algorithms gained considerable amount attention when used with multispectral satellite imagery to forecast agricultural productivity [8]. ML techniques such as Support Vector Machine (SVM), Restricted Boltzmann Machine (RBM), Decision Trees (DT) and Artificial Neural Network (ANN) [9] are

†Department of Computer Science and Engineering, Faculty of Engineering and Technology, JAIN (Deemed-to-be University), Bangalore, 562112, India. (trmahesh.1978@gmail.com)

provide the correct prediction about the crop yield [10, 11]. However, the ML model plays an effective role in crop yield prediction the DL techniques has proven to more suitable for data mining platform, which more applicable to agricultural remote sensing studies and other applications [12]. The DL algorithms are more complicated than the basic regression models used in ML. The DL techniques are the sub-branch of the ML, which transform the original data on top of that it find the essential information from the hidden features retained dataset by applying the several layers in the DL model. The Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), Long Short-Term Memory (LSTM) are some DL techniques utilized for the crop yield prediction [13, 14]. DL models can achieve superior crop yield prediction capacities by including additional hidden layers [11]. The primary objective of the paper is to investigate the incorporating sophisticated neural network architectures by utilizing large datasets that include historical yield data, soil properties, and climate-related variables.

1.1. Motivation and Problem Statement. The increasing number of world population required to improve the agriculture production because of fulfil the food needs. So that effective crop yield perdition is required for prevent the famine. In recent year, several authors try to accurately predicting the crop yield using the DL and ML techniques through the weather and soil data. But due to the limitation of the existing techniques the effective crop yield prediction model is not attained. The existing techniques less accurate prediction with high error rate because of less effective features are utilized for the prediction model as well as raw data contained noises are not effectively removed from the dataset. The vanishing gradient issues are occurred and high training time is consumed by the existing model utilized in the crop yield prediction. Prediction model hyperparameters are not tuned in the existing work that leads to increase error prediction and provide unstable output. On motivating these issues the proposed methodology is introduced to attain the error free effective crop yield prediction.

The major contribution of the proposed method is described in the article.

* To utilize the big data for crop yield prediction, the soil, weather and other resources data's are collected from the different agriculture field and data's are stored in the Hadoop platform.
* To pre-process the data, Missing value imputation and z-score based data normalization is utilized that normalized the data as well as fill the missing value.
* To select the optimal features, Integrated Correlation Random recursive elimination (InCorRe) is utilized that decrease the training time.
* To predicting the crop yield, Multi head Residual dilated convolution assisted gated unit (MResGat) is used and model hyperparameters are tuned using African vulture optimization algorithm (AVO), which optimized the losses of network model.

The research paper is organized into five different section like Section 1 contained the basic details of the crop yield prediction methods. Section 2 contained the survey of recent crop yield prediction model with its drawback. Section 3 contain the detail explanation of crop yield prediction proposed methodology. Section 4 consists of dataset description, performance metrics, result and discussion. Section 5 contained the overcall conclusion of the proposed work with future work and references.

2. Related Work. Elavarasan et al. [16] suggested the Deep Recurrent Q-Network (DRQN) model predicting the crop yield production. The model utilized the water and soil and crop parameters to attain high accurate prediction. The DRQN model comprised of Q-Learning reinforcement learning algorithm and Recurrent Neural Network to calculate the crop yield. The data elements were feed the Recurrent Neural Network's stacked layers sequentially. The output values of the Recurrent Neural Network are mapped to the Q-values via a linear layer. The threshold and a number of parametric features were utilized to predict crop yield by the reinforcement learning agent. The DRQN model attained 17% of MAPE and 0.19% of MAE value. The training process efficiency was less in the DRQN crop yield prediction.

Khaki et al. [17] developed Deep Neural Network (DNN) for estimating the crop yield production. The DNN model effectively learn the environmental data, genes and historical data's complex and nonlinear relationship to attain accurate crop yield prediction. The model's performance has been demonstrated as slightly dependent on the precision of the weather forecast that indicated the significance of weather prediction methods. The DNN model attained 24.40% and 23.14% of RMSE value respectively in training and testing. The limitation of the model was it sometimes neglected the important features and consumes more time for crop yield prediction.

Saeed et al. [18] designed the CNN-RNN model for minimizing the challenges of crop yield prediction. The CNN-RNN model utilized environmental factors, crop genotype and management procedures and its corresponding interactions. The CNN-RNN model effectively captured the temporal dependence of the environmental element and it outperform in crop yield prediction with high accuracy. The weather and soil condition were accurately analyzed by the backpropagation that helpful to attain high performance in crop yield prediction. The CNN-RNN attained 9% and 8% of RMSE value respectively in corn and soybean yield prediction. High RMSE value was attained during the validation of the CNN-RNN model such as 24.5%.

Bhojani et al. [19] suggested the updated random weights, bias settings and an updated multilayer perceptron (MLP) neural network with a new activation function for crop production estimation by utilizing various weather parameter datasets. In order to enhance neural network performance and precise yield prediction, the model was evaluates the outcomes of several activation functions. The Updated MLP suggests three new straightforward activation functions including DharaSig, DharaSigm, and SHBSig. The suggested three model was outperformed to default sigmoid activation function. The model attained 13.46% of error in prediction and the estimation provided less effective result because of noisy dataset.

Dhivya et al. [20] developed the hybrid DL model for crop yield prediction. The hybrid model comprised of deep belief network and fuzzy neural networks system (DBN-FNN). The probability and statistic combined neural network such as DBN outperformed in the nonlinear system. The gradient diffusion issues were solved using the FNN model. The DBN-FNN model first used a productive DBN pre-training method for improved feature vector creation and model building. The prediction process was done by the FNN model and the DBN-FNN model attained 0.19% of MAE in training and 0.15% of MAE in testing. The hyperparameter were leads to not stable and less accurate prediction.

Vignesh et al. [21] suggested the Discrete Deep belief network with Visual Geometry Group (VGG) Network (DD-VGGNet) to predict the crop yield prediction. The model initially pre-processed using the Z-score normalization. Then features were extracted through the independent shearlet approach (ISA) technique. Tweak Chick Swarm Optimization technique was utilized to optimal feature selection. Finally the model used the DL DD-VGGNet for predicting the crop yield. The model evaluated by the Agriculture crop dataset that contained the 13,457 instances. The DD-VGGNet model attained 0.10 of MSE value in crop yield prediction. The DD-VGGNet model consumed more training time because of its network structure depth.

Thimmegowda et al. [22] designed the Simple multiple linear regression (SMLR) and artificial neural network models (ANN) for crop yield prediction. Weather datasets and Rice yield data from 1980-2021 were collected from the 11 districts in Karnataka. The ANN model accurately predicted the crop yield compared to the SMLR model. ANN model produced 4.1% deviated from the actual crop yield prediction. The MAE value attained among the 1.22 and 187.72 range. ANN model decreased the performance of prediction model because of its less effective training process.

Bhattacharyya et al. [23] suggested the sugarcane yield production by monitoring the soil moisture using the ensemble classifiers. The CNN, SVM and Gaussian probabilistic method (GPM) are integrated for predicting the crop yield. The ensemble technique attained high performance compared to traditional CNN model. The results of the ensemble model should helped farmers and agricultural authorities to increase productivity. Krishna River Plateau Dataset and Godavari River Plateau Dataset were used to evaluated the proposed classifies. The ensemble model attained 2.21% of MAE and 3.5% of RMSE value in sugarcane yield prediction. Ensemble model hard to lean and leads lower prediction accuracy.

Son et al. [24] developed the ML based Random Forest algorithm for early forecasting the rice crop yield by the analysis of remote sensing data. Initially, the data is pre-processed using the empirical mode decomposition (EMD) that normalized and smoothened the Normalized Difference Vegetation Index (NDVI) data from 2000 to 2018. Finally the random forest algorithm was employed to predict the crop yield. The ML model was evaluated using different performance metrics such as mean absolute percentage error (MAPE), root mean square percentage error (RMSPE), and Willmott's index of agreement (d) values. The model attained 9.3% of MAPE, 11.8% of RMSPE and 0.81d-value. Limitation of the model was it produced high error rate.

Abbaszadeh et al. [25] suggested the DL framework for accurate crop yield prediction. The framework contained the Bayesian Model Averaging (BMA) and group of Copula functions (COP-BMA) that combined the several deep neural network outputs such as 3DCNN, ConvLSTM. The framework was utilized to soybean crop

Table 2.1: Crop yield prediction models analysis

Author name & Reference	Methods	Dataset	Performance	Limitation
Elavarasan et al. [16]	DRQN	Manually collected dataset contain weather, ground water and soil data.	MAPE-17% and MAE-0.19%	Efficiency of the training process is less.
Khaki et al. [17]	DNN	Syngenta released several large datasets	RMSE Training-24.40%, Testing-23.14%	Time consumptions is high and feature selection model is not effective.
Saeed et al. [18]	CNN-RNN	Corn and soybean yield details contained dataset from 1980 to 2018	RMSE % corn yield- 9% and soybean yield- 8%	RMSE value is high during validation.
Bhojani et al. [19]	Updated MLP	Agriculture dataset.	Error-13.46%	Quality of the data are less.
Dhivya et al. [20]	DBN-FNN	Manually collected dataset contain weather, ground water and soil data.	MAE Training-0.19%, Testing-0.15%	Less accurate prediction
Vignesh et al. [21]	DD-VGGNet	Agriculture crop dataset	MSE- 0.10%	Consume more training time.
Thimmegowda et al. [22]	ANN	11 districts rice yield data in Karnataka and Weather datasets	MAE - 1.22 to 187.72 range	Performance of prediction model is less.
Bhattacharyya et al. [23]	Ensemble model	Krishna River Plateau Dataset and Godavari River Plateau Dataset	MAE - 2.21%, RMSE - 3.5%	Less prediction accuracy because of ensemble model.
Son et al. [24]	Random Forest	Multi-temporal Moderate Resolution Imaging Spectroradiometer (MODIS) data in Taiwan.	MAPE-9.3%, RMSPE-11.8%	High error occur in prediction.
Abbaszadeh et al. [25]	COP-BMA	USDA (United States Department of Agriculture) National Agricultural Statistical Services (NASS) repository	R2-0.81 RMSE-6.18 MAE-0.10	Higher RMSE value because of less quality data.

yield probabilistic estimation of over a hundred countries among three different states in the United States. The framework attained 0.81 R2 value, 6.18 RMSE value and 0.10 MAE value. Higher RMSE value was attained because the data' were not involved any pre-processing process. Table 2.1 contained the analysis of crop yield prediction model.

3. Proposed Methodology. Crop yield prediction is the one of the major key resource to increase the crop production and improve the economical level. Several DL and ML methods has been introduced for accurately predicted the crop yield. But it faces many challenges so overcome those challenges, the proposed method is developed using the DL technology. The architecture of the proposed method is given in Figure3.1. Initially, the soil, weather and other sources of wheat, rice and sugarcane crop big data are collected from various form. Then the collected data is stored in the Hadoop platform for processing the data in a distributed manner. After collecting the data, the data is pre-processed using the Missing value imputation and z-score based data normalization that decrease the noises presented in the input data. Then optimal features are selected through the InCorRe. By considering the historical soil and weather data, the crop yield is estimated through the MResGat. The prediction model losses can be optimized using the AVO. By applying these steps the proposed model effectively predicted the crop yield.

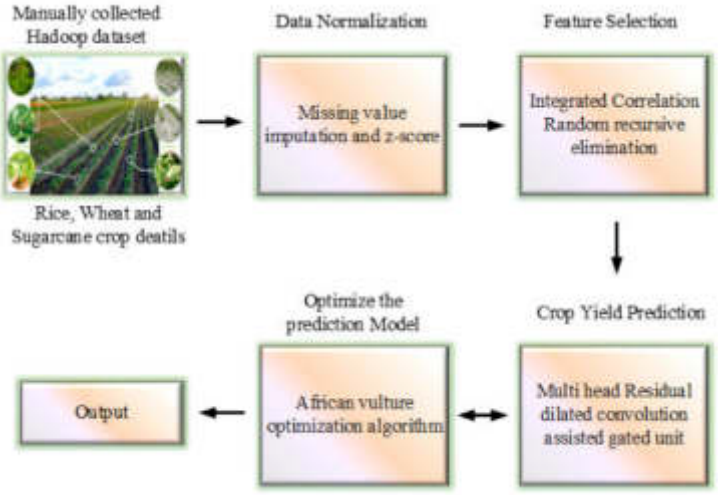

Fig. 3.1: Architecture of proposed methodology

3.1. Pre-processing using Missing value imputation and z-score based data normalization. The crop data's are rearrange and clear in the pre-processing stage, in this stage two different process can carried out such as missing value imputation moreover z-score normalization. There are a few values that are missing in the dataset, these are filled by employing the mean of all the non-missing values. The mathematical expression of the Missing value imputation has been expressed as below.

$$M_k = \frac{M_{k-1} + M_{k+1}}{2}, \quad k \in G \tag{3.1}$$

Here, M_k and M_{k-1} are represented as missing value and previous value obtained from the missing value, next value of the missing value is represented as M_{k+1} and natural number is denoted as $G = 1, 2, 3 \ldots$. Using this process the missing values are effectively filled in the dataset. In the normalization phase, data is resized to fit within a specific range. Several normalization techniques are available here, the z-score normalization is consider for normalized the crop yield dataset. The Z-score normalization is also denoted as statistical normalization. The normalized $h^{'}$ is computed as below.

$$h^{'} = (h - \mu) / \sigma \tag{3.2}$$

Here, μ represented as set of score's mean value and σ is denoted as standard deviation. Using the z-score normalization effectively clean the data then it fed into the feature selection process.

3.2. Feature Selection Integrated correlation random recursive elimination . In this work, the InCorRe technique is utilized to find the correlation across features to select the optimal feature from the dataset. The InCorRe is selected the important features effectively that are correlated with the accurate crop yield prediction. The pre-processed data's are involved for computing correlation among the features then it checks the percentage of negative and positive correlation of features. Consequently, in order to determine the specific function of each feature, which is important to determine the correlation among all features and the target feature (status). The correlation among the features can be estimated as below.

$$Cr[f_i; f_j] = \max_{|S_i| \cdot |S_j| < B} \frac{K[S_i; S_j]}{\log_2 (\min (|S_i|, |S_j|))} \tag{3.3}$$

Here, f_i *and* f_j are the two different features in the S feature's set. The empirical parameter are defined as $B = 0.6$. The $K[S_i; S_j]$ is estimated as below.

$$K[S_i; S_j] = \sum_{S_i, S_j} p(S_i, S_j) \log_2 \frac{p(S_i, S_j)}{P(S_i)P(S_j)} \tag{3.4}$$

Here, joint probability density and marginal probability density are respectively represented as $p(S_i, S_j)$ and $p(S_i)$ *and* $p(S_j)$. After calculating the correction among the features and selected the high correlated features from the pre-processed data. Then the Recursive Feature Elimination (RFE) introduced in InCorRe to eliminate the less important features. In the RFE the linear regression is selected for the recursively eliminate less important features and attained the final set of desired features. By constructing a regression line to the data, it determines the relationship between the two features. The linear regression line is expressed as below.

$$X = s * Y + t \tag{3.5}$$

Here, X and $Y$are respectively denoted as dependent features and independent features. The$s$ *and* t are denoted as slope and intercept respectively. The RFE is specify the amount of final features, based on this the RFE produced the final optimal features that increase the performance of the crop yield prediction.

3.3. Crop yield Prediction using Multi head Residual dilated convolution assisted gated unit . Four different modules are presented in the proposed crop yield prediction such as multi-head attention, time-dilated module, frequency-dilated module and prediction module. Initially the multi-head attention is employed for controlling the information mixing across different parts of an input sequence. The attention model provide the higher representation of the data and increase the performance of the prediction model. The multi-head attention makes it possible to handle numerous input sequence components in different ways that increase the performance of the prediction model. The primary elements of an attention function are a set of key-value pairs and a query, which map them to a weighted average result of all values. The input query and key with the dimension are represented as $Q_s$and K_s respectively. The attention mechanism output matrix is expressed as below.

$$Att(Q, K, V) = H\left(\frac{QK^y}{\sqrt{K_s}}\right) V \tag{3.6}$$

Here, key, value and query matrixes are denoted as K, V and Q respectively. Stacking several scaled dot-product attentions outcomes the multi-head attention. The previously mentioned queries, keys, and values can be projected linearly with time y so that various sub-space representations can be observed at different points. The projection process is attained parallel that can be display as below.

$$M\_HAtt(Q, K, V) = C\left(head_1, head_2, \ldots head_r\right) f^0 \tag{3.7}$$

Here, $head_l = Att\left(Qf_l^Q, Kf_l^K, Vf_l^V\right)$, $f_l^Q \in \Re^{s_{model} \times Q_s}$, $f_l^K \in \Re^{s_{model} \times Q_s}$,$f_l^V \in \Re^{s_{model} \times V_s}$ and $f_l^o \in \Re^{hs_V \times s_{model}}$. Attention layer and parallel head is represented as h. Compared to the single head attention, the multi head attention shows superiority and decrease the computational cost on top of that it helpful to speed up the network learning.

The network model contained 1D convolution consists of $featureMaps \times frequencyChannels \times timeSteps$ layout size's input and output layer. 1D convolution's input and output size are in $frequencyChannels \times timeSteps$ format. Each layer's hyperparameters are presented in the (kernel-Size, dilationRate, outputChannels) manner. Consider that all of the convolutions receive zero-padding. The prediction module and the time-dilated module both use batch normalization.

3.3.1. Frequency-Dilated Module. The frequency-dilated module comprises of four fixed 2D-convolution layer that gather the local spatial pattern of the input feature. The layers acquire the dilation at rates of 1, 1, 2, and 4, respectively, along the frequency direction. Subsequently, the features obtained by the frequency-dilated

module require an appropriate dimensionality transformation in order to accommodate 1D convolutions in the subsequent module.

Dilated convolution is expand the contextual information of the particular fields without losing resolution. The standard convolution operator $*$ that convolves the data with the $(2n+1)\times(2n+1)$size contained kernel$h$, which is denoted as below.

$$(P * h)(k) = \sum_{r+yt=k} P(r)h(t) \tag{3.8}$$

Here, $k, r \in \mathrm{Z}^2$,$t \in [-n, n]^2 \bigcap \mathrm{Z}^2$ and Z is represented as integers. An operator of the dilated version as denoted as $*_d$. The d -dilated convolution is expressed as below.

$$(P *_d h)(k) = \sum_{r+yt=k} P(r)h(t) \tag{3.9}$$

While applying kernels with rapidly increasing dilation rates, the scale of the receptive fields within dilated convolutions rises exponentially with the layer depth as opposed to the conventional convolutions. In the time-dilated convolution, one dimensional convolution r temporal convolution is employed. The dilated spatial convolution's asymmetric version is represented as the time-dilated convolution which not focus the frequency direction but the dilation focus the time direction. The dilated convolution produces a dilated spatial convolution having a kernel of size 5×5 in order to collect contextual information throughout the frequency dimension. Frequency-dilated convolutions are convolutions that participated in dilation applied to the frequency direction only, not the time direction. Nevertheless, the recent frequency-dilated convolution collect the context in both frequency and time direction.

3.3.2. Time-Dilated Module. To create the prediction model as the temporal dependencies, the several amount of residual blocks are introduced that execute the time-dilated convolution. These time-dilated modules are receive the input from the frequency-dilated module. The group of residual blocks are generate the rising edge wave to sequent increase of dilated rate. Two different following groups are repeat the similar pattern such as 1, 2, 4, 8, 16, 32; 1, 2, 4, 8, 16, 32; 1, 2, 4, 8, 16, 32. Aggregation of long-term contexts is achieved possible by residual block groups, which allow for exponential development of the receptive field while maintaining the input resolution. The prediction model utilized the type of skip connection considered in the WaveNet. Such skip connections provide all of the remainder block outputs from the time-dilated module to the next module, unlike the time-dilated module. The skip connection provide the training through the increase the data flow and enhance the gradients across the network.

The Gated Linear Unit is introduced in the work to overcome the issues of traditional gating techniques. Initially, gating strategies were intended to improve the information flow in an RNN over time. Controlling the long–term memory in the LSTM with RNN is attained through applying the forget gate and input gate. These gates avoid the issue of vanishing or exploding gradients that arises when time-propagation is used to train recurrent networks. The multiplicative unit underlying the convolutional estimation represented by LSTM gate is as follows.

$$\begin{aligned} x &= \tanh\left(z * K_1 + L_1\right) \otimes S\left(z * K_2 + L_2\right) \\ &= \tanh\left(u_1\right) \otimes \left(u_2\right) \end{aligned} \tag{3.10}$$

Here, $u_1 = z*K_1+L_1$, $u_2 = z*K_2+L_2$, biases is represented as L, kernel is denoted as K , the sigmoid function is denoted as S and the element-wise multiplication is represented as $\otimes$. Gating in the LSTM approach may allow for more complicated interactions by regulating the information flow within CNNs. LSTM-style gating gradient is given as below.

$$\nabla\left[\tanh\left(u_1\right) \otimes S\left(u_2\right)\right] = \tanh^{'}\left(u_1\right) \nabla u_1 \otimes S\left(u_2\right) + S^{'}\left(u_2\right) \nabla u_2 \otimes \tanh\left(u_1\right) \tag{3.11}$$

Here, $\tanh^{'}\left(u_1\right), S^{'}\left(u_2\right) \in (0,1)$, the primary sign represents differentiation. The vanishing gradient problem usually appears as the depth of the network grows and when using such gating, the downscaling factors $S^{'}\left(u_2\right)$

and $\tanh^{'}(u_1)$ make it harder to solve. To overcome these issues the Gated Linear unit is introduced that can be described as below.

$$\begin{aligned} x &= (z * K_1 + L_1) \otimes S(z * K_2 + L_2) \\ &= (u_1) \otimes (u_2) \end{aligned} \tag{3.12}$$

The Gated Linear unit gradient can be expressed as below.

$$\nabla [u_1 \otimes S(u_2)] = \nabla u_1 \otimes S(u_2) + S^{'}(u_2) \nabla u_2 \otimes (u_1) \tag{3.13}$$

Gradient flow is done without downscaling a path $\nabla u_1 \otimes S(u_2)$ using layers while keeping nonlinearity. The prediction model created a deep residual learning framework through the use of identity shortcuts, which significantly reduce the issue of the vanishing gradient. The bottleneck structure maintains performance stable while reducing the depth of the network. Through the use of exponential linear units (ELUs) and time-dilated convolutions in the common bottleneck residual block, the prediction model can enhanced the performance. The modified bottleneck residual block is improve the receptive domain by increase the middle layer kernel size. Furthermore, the proposed model change out rectified linear units (ReLUs) to ELUs for speed up learning and enhance generalization performance.

3.3.3. Prediction Module. Context of the input are combined systematically after completing the time-dilated module and frequency-dilated module. Using the combined context, the prediction module is execute the mask estimation. The prediction module contained the size 1 kernel included three convolutional layers. Among the three layers, two consecutive layers having ELUs and linear activations that were responsible to cross-channel pooling and dimension reduction respectively. The final prediction layer contained the sigmoid function and the ReLU function smooth estimation force the output of the network as positive. Figure 3.2 shows the structure of AVO-MResGat model.

AVO metaheuristic algorithm is developed depending upon the vulture hunting strategy. The AVO is employed with the prediction model to optimize the model moreover increase the performance of the crop yield prediction. To attain a best solution from the every group, the AVO initialized the population in the first stage that can be expressed as below.

$$P(l) = \begin{cases} BVo_1, & if\ M_l = n_1 \\ BVo_2, & if\ M_; = n_2 \end{cases} \tag{3.14}$$

Here, n_1 and n_2 are the pre-determined optimization parameter range among 0 and 1. If the $n_1 + n_2 = 1$, then a roulette wheel can be used to pick the optimal set resolution and to predict the probability of selecting the best option. This can be expressed as follows.

$$M_l = \frac{W_l}{\sum_{k=1}^{q} W_l} \tag{3.15}$$

Here, satisfied vultures is denoted as M, the numeric value β is 0, when α numeric value is one and vice versa. In the second step, the vulture hunger rate is computed. The vultures are currently hunting food by flying high. The vulture gathers additional groups close itself in order to obtain free food when its energy levels are low that can be given as below.

$$y = z \times \left(\sin^{\gamma} \left(\frac{\pi}{2} \times \frac{It_1}{\max_{It}} \right) + \cos \left(\frac{\pi}{2} \times \frac{It_k}{\max_{It}} \right) - 1 \right) \tag{3.16}$$

$$W = (2 \times \lambda + 1) \times r \times \left(1 - \frac{It_l}{\max_{It}} \right) + y \tag{3.17}$$

Here, the random value is signified as λ that varied from 0 to 1. The present iteration is referred as It_l, the fixed number set is described as r that shows the optimization operation, which creates the operation phases and exploration phases. The total amount of iteration is referred as $\max_{It}$, a random number ranging between -2 to 2

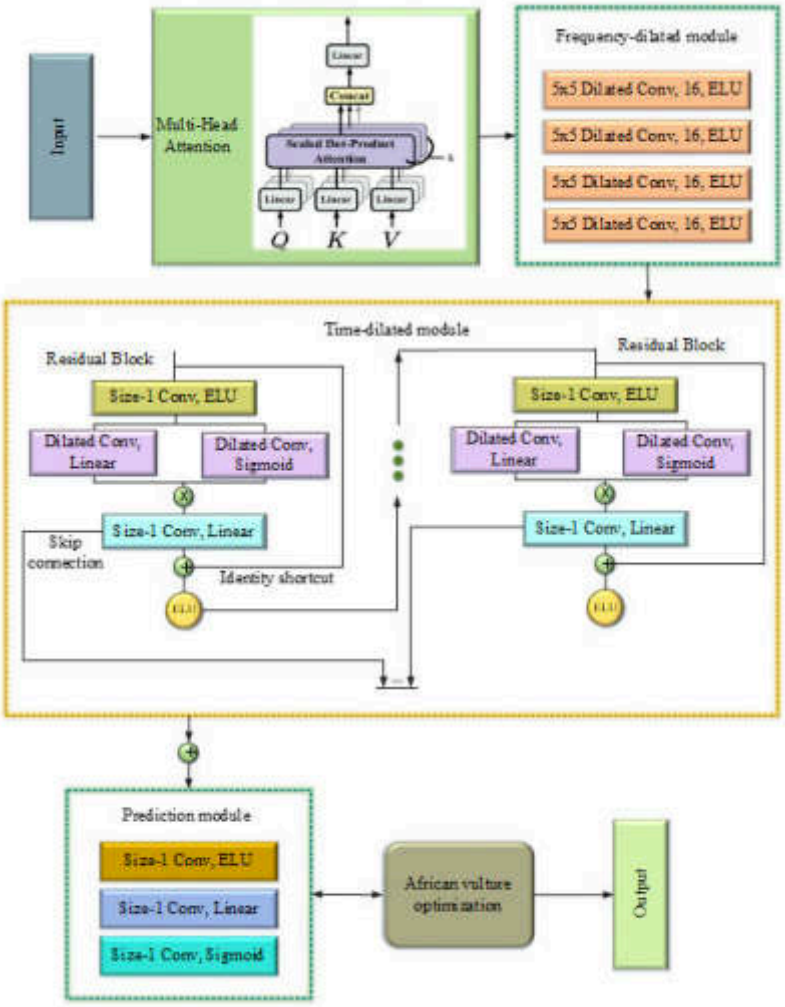

Fig. 3.2: Structure of AVO-MResGat model

is referred as x. If v reduce to zero, then the vulture is starving, or else if it rises to 1, then the vulture is satisfied.

In the third phase, vultures are random elements with two different plans and a parameter F_1 that selects the level and has a value from zero to one. Food exploration can be expressed as follows.

$$If\ F_1 \geq V_{F_1}:$$

$$P(l+1) = BVo(l) - S(l) \times P \tag{3.18}$$

$$If\ F_1 < V_{F_1}:$$

$$P(l+1) = BVo(l) - P + V_2 \times ((UrB - LrB)) \times V_3 + LrB \tag{3.19}$$

$$S(l) = |U \times BVo(l) - P(l)| \tag{3.20}$$

Here M referred to as the random movement of the vultures for protecting the food from other vultures, and that is established by $U = 2 \times V$, UrB and LrB are represented by the higher and minimum bound variable, respectively. The BVo consists of the best vulture, V_2 and V_3 denoted as two different random values that are limited from 0 to 1.

$$P(l+1) = S(l) \times (P + V_4) - x(l) \tag{3.21}$$

$$x(l) = BVo(l) - P(l) \tag{3.22}$$

The vultures' spiral motion can be expressed as follows.

$$a_1 = BVo(l) \times \left(\frac{V_5 \times P(l)}{2\pi}\right) \times \cos(W(l)) \tag{3.23}$$

$$a_2 = BVo(l) \times \left(\frac{V_6 \times P(l)}{2\pi}\right) \times \sin(W(l)) \tag{3.24}$$

$$P(l+1) = BVo(l) - (a_1 + a_2) \tag{3.25}$$

Aggressive conflicts and violent actions between the two sorts of food sources are occurring in order to search for food. If the $|P| < 0.5$ recognized span at the random integer (V_3) range from zero to one. If $V_{F_3} \geq F_3$, the objective was to collect various kinds of vultures around the food source. If $V_{F_3} < F_3$ the violent siege-fight is carried out. Vultures don't often go hungry, which causes intense competition among them for food that can be formulated as below.

$$D_1 = BVo_1(l) - \frac{BVo_1(l) \times P(l)}{BVo_1(l) - P(l)^2} \times P \tag{3.26}$$

$$D_2 = BVo_2(l) - \frac{BVo_2(l) \times P(l)}{BVo_2(l) - P(l)^2} \times P \tag{3.27}$$

Here, $BVo_1(l)$ and $BVo_2(l)$found the best vulture for the first and second groups. The vulture's present vector location is represented as $P(l)$, and it attained as below.

$$P(l+1) = \frac{D_1 + D_2}{2} \tag{3.28}$$

The above equation is used for calculating the vulture assembling. If $|E| < 0.5$, the healthy vultures up front lost their energy and they cannot stand on the others. Therefore, other vultures become violent because they get the food. From the main vulture, they move in several directions; it is formulated as follows.

$$P(l+1) = BVo(l) - |x(l)| \times P \times Levy(x) \tag{3.29}$$

The modification term is described as levy fight ($LevyF$).

$$LevyF(y) = \frac{n \times \sigma}{100 \times |u|^2} \tag{3.30}$$

$$\sigma = \left(\frac{\Gamma(1+\alpha) \times \sin\left(\frac{\pi\alpha}{2}\right)}{\Gamma(1+\alpha_2) \times \alpha \times 2\left(\frac{\alpha-1}{2}\right)}\right)^{\frac{1}{\lambda}} \tag{3.31}$$

Here, n and y represented as the two different random numbers among 0 and 1, $\alpha = 1.5$set as the constant value. The overall pseudocode for the proposed method is represented in Algorithm 20.

Through the process, the proposed model effectively predicted the crop yield more accuracy and less computation time.

Algorithm 20 Pseudocode for the proposed methodology

Input : Manually collected Rice, Sugarcane and Wheat Big data stored in Hadoop platform
Begin
Pre-processing
Step1: Missing value is filled by using the equation (1)
Step2: Normalized the data within the specific range using the Z-score normalization (equation 2).
//Pre-processed data
Feature Selection using InCorRe
Step 3: Find the Correlation among the features using the equation (3)
Step 4: Selected the High correlation features for RFE.
Step 5: Choose a machine learning model (e.g., linear regression) for RFE.
Step 6: Use RFE to recursively eliminate less important features.
Step 7: Specify the desired number of final features to be retained.
//Selected optimal features
Crop Yield Prediction using AVO-MResGat
Step 8: Higher level features are selected by the Multi head attention.
Step 9: Estimate the crop yield using the MResGat Network model.
Step 14: Network model hyperparameters are tuned using the AVO algorithm.
// Prediction output
Output: Crop yield prediction
End

4. Results and Discussion. The crop yield prediction performance of the proposed model is estimated through the several performance metrics. The proposed model analyzed over the manually created dataset and the superiority of the proposed model is proven by comparing the performance with the existing model.

4.1. Dataset Description. The manually collected dataset comprises of Rice, Wheat and Sugarcane crop yields data's. The data's are gathered over the different years and each month of the year. The different resources of crop growth such as Rain fall, pH, temperature, humidity, Electrical Conductivity, area of the crop and farm size (hectors) also presented in the dataset. The essential nutrients are measured and updated into the dataset such as Organic Carbon (OC), Available Nitrogen (N), Phosphorus (P), Potassium (K), Sulphur (S), Zinc (Zn), Iron (Fe), Manganese (Mn), Copper (Cu) and Boron (B). Finally, the collected crop data's are stored into the Hadoop and it accessed to predicting the crop yield.

4.2. Performance Metrics . The proposed crop yield prediction model is evaluated by using the different performance metrics such as Mean Squared Error (MSE), Mean Absolute Error (MAE), R-squared (R2) and Mean Absolute Percentage Error (MAPE). The performance metrics definition and corresponding mathematical expression is mentioned in this section.

4.2.1. MSE. MSE is calculate the average squared variance among the predicted value and actual values that can be expressed as below.

$$MSE = \frac{1}{M}\sum_{k=1}^{M}(q_k - \hat{q})^2 \tag{4.1}$$

Here $\hat{q}$ and $\bar{q}$ are denoted as predicted value and mean value of $q$respectively.

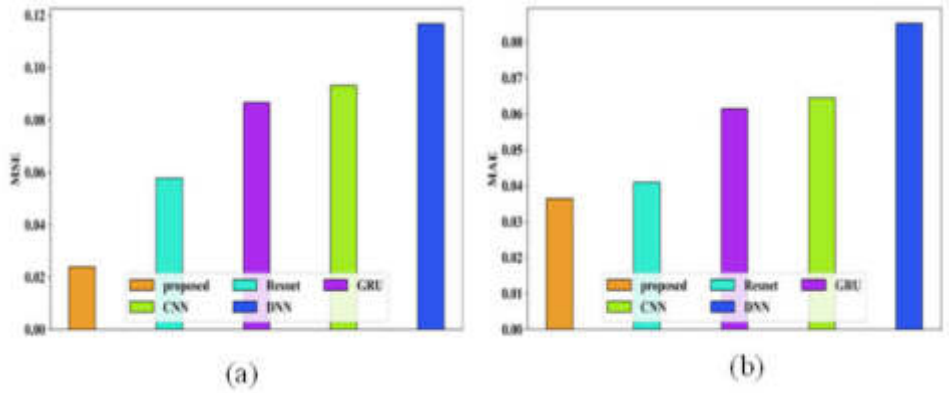

Fig. 4.1: Performance analysis based on (a) MSE and (b) MAE

4.2.2. MAE. MAE is computed the average absolute changes across the predicted value and actual values that can be mathematically expressed as follow.

$$MAE = \frac{1}{M}\sum_{k=1}^{M}|q_k - \hat{q}| \tag{4.2}$$

4.2.3. RMSE. A RMSE that shows that exact far apart of the expected outcomes from the observed values through average in a dataset, the mathematical expression of RMSE is mentioned as below.

$$RMSE = \sqrt{\frac{1}{M}\sum_{k=1}^{M}(q_k - \hat{q})^2} \tag{4.3}$$

4.2.4. R2. R2 shows the percentage of the dependent variable's variance could be predicted based on the independent variable. The equation for the R-squared is mentioned as below.

$$R^2 = 1 - \frac{\sum_{j=1}^{m}(x_j - \hat{x}_j)^2}{\sum_{j=1}^{m}(x_j - \hat{x}_j)^2} \tag{4.4}$$

Here, actual value's mean is represented as$\hat{x}$.

4.2.5. MAPE. The percentage that differs between expected and actual values is measured by MAPE and mathematical equation is given as below.

$$MAPE = \frac{1}{m}\sum_{j=1}^{m}\left(\frac{|x_j - \hat{x}_j|}{|x_i|}\right) \times 100 \tag{4.5}$$

These metrics are commonly used in evaluating the performance of regression models.

4.3. Performance analysis and comparison. The performance of proposed crop yield prediction is evaluated in this section to show the superiority of the proposed model compared with the other existing system. The different performance metrics are involved to estimate the performance of crop yield prediction over the manually collected dataset. Figure 4.1 contained the performance analysis based on the MSE and MAE.

MSE estimate larger mistakes because it treated severely than smaller error. In contrast to MSE, MAE is lesser sensitive to errors. Superior model performance is demonstrated with a lower MSE that values near

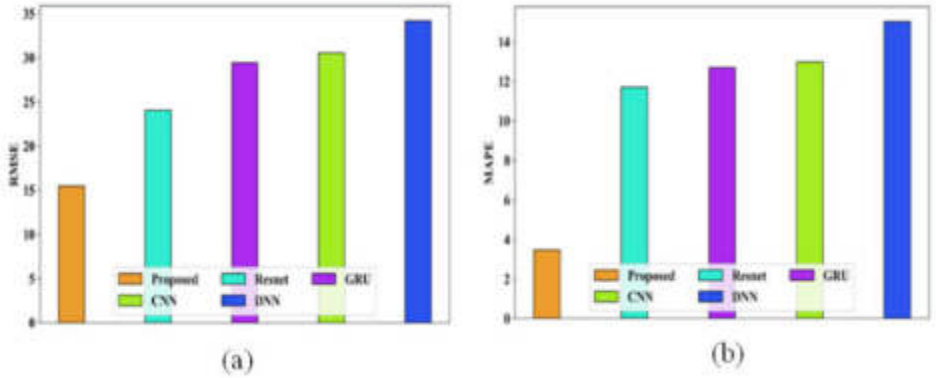

Fig. 4.2: Performance analysis based on (a) RMSE and (b) MAPE

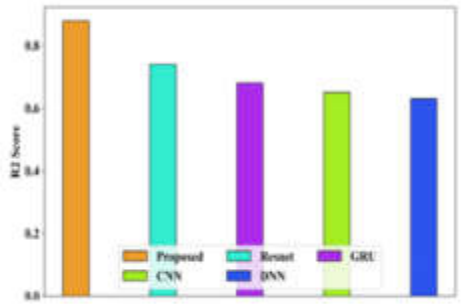

Fig. 4.3: Performance analysis based on R2 Score

to zero is most preferred. Like MSE, a lower MAE denotes better model performance because it shows the average amount of errors as well as it is simpler to understand. The proposed model attained less values in both MSE and MAE values such as 0.023 and 0.036 respectively. The proposed model has outperformed compared to other methods such as CNN, DNN, Gated recurrent units (GRU), residual network (Resnet). Figure 4.2 represented the RMSE and MAPE analysis over the crop yield prediction model.

The quality of the prediction model is measured using the RMSE value. MAPE is particularly helpful while dealing with data that has different scales, which estimate the percentage deviation among the actual and predicted values. Smaller RMSE and MAPE values are indicate the better accuracy in crop yield prediction. Based on the requirement the proposed model attained less 0.154% of RMSE value and 3.46% of MAPE value over the crop yield prediction. Figure 4.3 contained the R2 score analysis and comparison.

The R2 score estimate the goodness of the prediction fitting. The range of the R2 is set among the zero to one. A more accurate prediction is indicated by a higher R2 value, moreover the value of R2 equal to 1 shows that the model effectively predicts the dependent variable. The proposed model more effectively estimate the resources that are helpful to attain the high crop yield. The proposed model achieved 0.878 value in the R2-score that outperform compared to other prediction model. From the analysis the proposed model accurately predicting the crop yield over the manually collected dataset. Figure 4.4 consists of year wise analysis of wheat, rice and sugarcane production.

The proposed model address the time dependencies of the different crop yield such as Rice, Wheat and Sugarcane based on the number of years. From the 2018 to 2025, crop yield is predicted by the proposed model and it plotted in the above graph. Through the graph the accurate crop yield can estimated by the former. The proposed model estimation show that the wheat and sugarcane production is very high compared to the rice

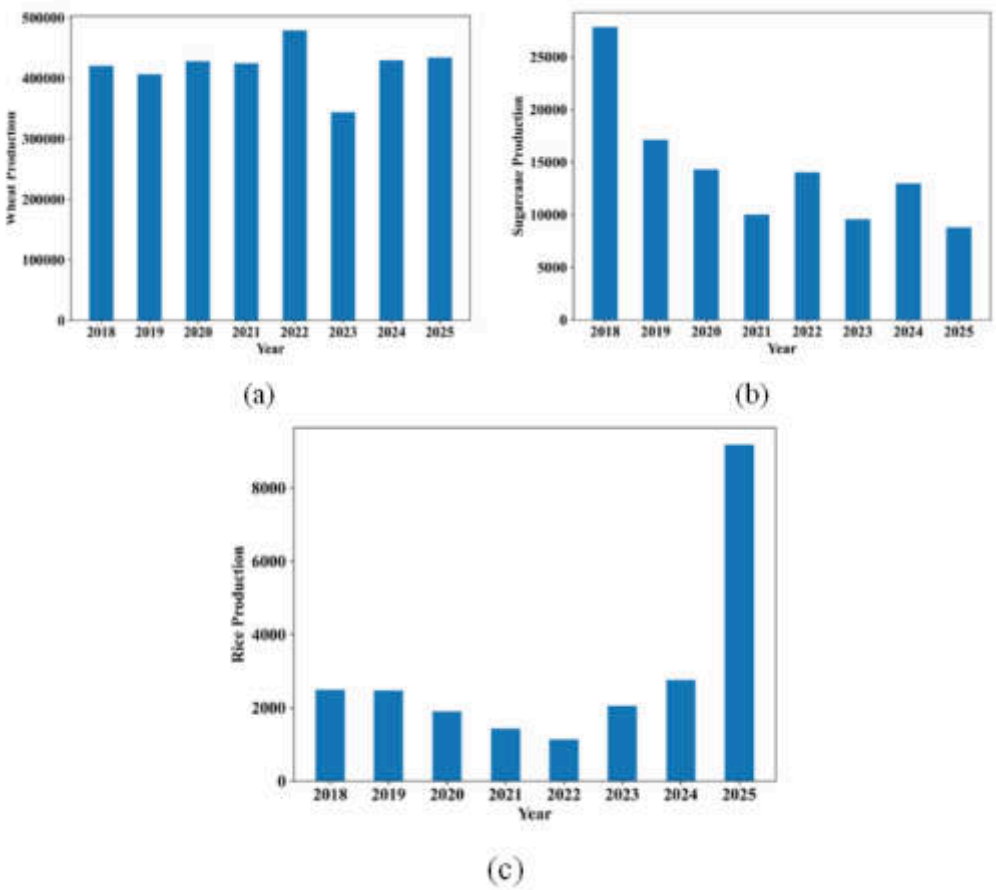

Fig. 4.4: Analysis of (a) Wheat (b) Sugarcane and (c) Rice Production at the 2018 to 2025

production. Through the analysis the former can move to cultivating more rice crop. The Wheat production is gradually increased in every year by year. At the same time the Sugarcane production is decreased in 2018 to 2021 but slightly prediction is increased in the year of 2022, like a same ratio its production is goes up and down from 2022 t0 2025. Nevertheless, the Rice production is extremely decrease from 2018 to 2022, at it gradually increased after the 2023. Figure 4.5 shows the fertilizers utilization in over the number of years.

The crop utilized fertilizers for increasing the production over the different years is analyzed in the above graph. Through the estimation the amount of fertilizers such as Phosphorus, Potassium and Nitrogen are indicated to the former for retain the crop yield. Compared to the Nitrogen and Potassium, the Phosphorus is used as lesser amount for the crop. According to the graph the maximum 991.4 nitrogen, 58.32 phosphorus and 693.332 potassium utilized for crop production. The correct amount of fertilized over the crop is essential resources for attain the high production. From the analysis, the proposed method accurately predicted crop yield by different factor presented in a collected dataset.

4.4. Discussion. Crop yield prediction plays a crucial role in agricultural planning and resource management. By leveraging data-driven models and advanced technologies, accurate predictions can be made regarding the potential harvest for a specific crop in a given region. By delving into the intricacies of DL models, this research seeks to enhance the accuracy and efficiency of crop yield predictions, thereby contributing to sustainable agricultural practices and addressing global food security challenges. Several ML and DL based crop yield prediction is developed by the various researches but it not fulfil the requirement of the accurate

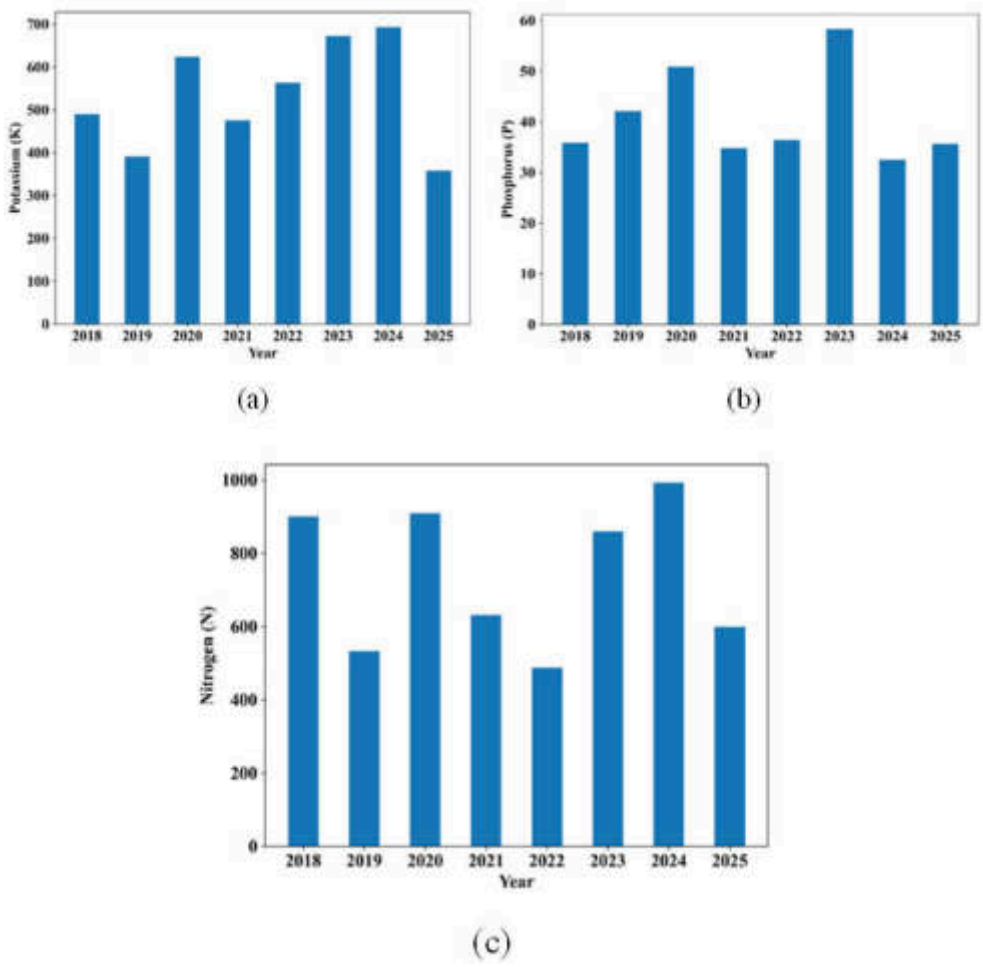

Fig. 4.5: Analysis of (a) Potassium (b) Phosphorus and (c) Nitrogen level at the 2018 to 2025

prediction. The existing crop yield prediction model not effectively done the training process which lead to less accurate prediction [16, 22]. The proposed MResGat model contained time-dilated module can perform the effective training while high data flow by the utilization of skip connection. The vanishing gradient and high computation time are another issues in the existing work [17, 21 and 23] that solved by introduce the ELU instead of ReLU which speed up the learning process and increase the crop yield prediction performance. The utilization of irrelevant features in the existing work leads to more computational time and produced high error in prediction [18 and 24]. The proposed model used the effective InCorRe approach that selected the optimal features which reduced the errors in the prediction model. The meaningless data or noisy data presented in the dataset caused the error occurrence in crop yield prediction [19, 25]. The proposed method used the Missing value imputation and z-score based data normalization pre-processing technique which fill the missing data with related data and normalized the data within the specific range. The pre-processing technique is increase the quality of the crop yield data and enhanced the prediction model performance. The some existing work given the unstable performance in prediction because of not perform the hyperparameter tuning [20]. The proposed model utilized AVO algorithm for hyperparameter tuning that decrease the prediction model losses. The proposed model attained 0.023, 0.036, 0.154, 3.46 and 0.878 values respectively in MSE, MAE, RMSE, MAPE and R20-Score. Table 4.1 contained performance comparison with the existing works.

By comparing the performance of proposed model with existing work, the proposed model prove that it

Table 4.1: Performance comparison with existing works

outperform in crop yield prediction with the minimum error. Thus crop yield prediction helpful to increase the crop production in upcoming years in agriculture field.

5. Conclusion. The crop yield prediction is essential to making the correct decision about the cultivating most suitable crop belonging to the available resources. The interconnected of DL and smart agriculture is forecasting crop yield which offer shape for the future of food production. The Proposed work developed the novel DL model for crop yield prediction. Initially, the rice, sugarcane and wheat crop production details are collected from the various agriculture field and stored it into the Hadoop platform as a big data which offers the data processing in a distributed manner. The gathered raw data initially pre-processed using the Missing value imputation and z-score based data normalization that increase the quality of the dataset. After that optimal features are obtained using the InCorRe that extracted the relevant features for the prediction process. Finally the MResGat model was predicted the crop yield and its network losses can be reduced through the AVO. Utilization of complete process involved in the proposed work help to increase the performance of the crop yield prediction. The proposed work evaluated by the different performance metrics and attained high performance such as 0.023% of MSE value and 0.036% of MAE values. The proposed model outperform compared to other existing methods. The future work, focus on the increase the performance by utilizing the more effective feature selection model.

PREDICTIVE ANALYSIS OF BREAST CANCER FROM FULL-FIELD DIGITAL MAMMOGRAPHY IMAGES USING RESIDUAL NETWORK

SI-YEONG KIM* AND TAI-HOON KIM†

Abstract. Breast cancer has been a significant contributor to cancer-related mortality, but advancements in early detection through regular mammography and improvements in treatment modalities have contributed to declining mortality rates in several regions. This study presents a novel approach to cancer diagnosis utilizing Full-Field Digital Mammography images through predictive analysis methods. By using predictive analytic techniques and mammography images, this study offers a novel way to cancer detection. The research involves the application of deep learning techniques to extract valuable insights from cancer images captured by mammography devices. The CBIS-DDSM (Curated Breast Imaging Subset of Digital Database for Screening Mammography) dataset including images from patients with varying types and stages of cancer, is collected and pre-processed to ensure uniformity and quality. Relevant features, including color, texture, and shape characteristics, are extracted, and a rigorous feature selection process is employed to identify discriminative markers. The Residual Network (ResNet) model is selected and trained on the dataset, with a focus on classification accuracy and robust predictive performance. Validation metrics, such as accuracy, IoU (Intersection over Union) score, dice score, and ROC (Receiver Operating Characteristic) curve are employed to evaluate the model's efficiency. After analysis, the proposed method had the best degree of mass lesion detection accuracy, at 99.24%. This research contributes to the advancement of non-invasive and efficient diagnostic tools, potentially enhancing early detection and intervention in cancer patients. The proposed method not only demonstrates promising results in terms of diagnostic accuracy but also emphasizes interpretability, seamless integration into clinical workflows, and adherence to ethical standards.

Key words: Breast cancer; ResNet; deep learning; mammography; residual networks.

1. Introduction. Breast cancer is a recognized global health problem due to its impact on individuals globally and its high occurrence. It is now the second most prevalent cancer worldwide and holds the distinction of being the leading cancer among women. Incidence rates exhibit variability across regions, with higher occurrences reported in developed countries. The disease not only affects women also manifest in men, although at a significantly lower frequency. Factors influencing breast cancer risk include age, genetic predisposition of BRCA1 (Breast Cancer gene 1) and BRCA2 (Breast Cancer gene 2) mutations, family history, hormonal factors, and lifestyle choices [1]. Screening programs, coupled with ongoing research on biomarkers and innovative imaging technologies, play pivotal roles in the early identification of breast cancer, enhancing treatment outcomes. Survival rates are closely linked to the stage at which the cancer is diagnosed, emphasizing the critical importance of early detection initiatives. To obtain the most accurate and up-to-date information on breast cancer statistics, referencing reputable sources such as the World Health Organization (WHO), American Cancer Society, International Agency for Research on Cancer is imperative for a comprehensive understanding of the current landscape of this pervasive disease [2].

Researchers are investigating novel technologies and methodologies to enhance the recognition and characterization of breast cancers. Other modalities, including as CT, MRI, and Positron Emission Tomography (PET) scans are frequently used for specialized cancer imaging. These imaging techniques aid in the diagnosis and staging of cancer by offering a more thorough assessment of the anatomy and pathology [5]. The detection of cancer via mammography images necessitates a careful consideration of various algorithms, each offering unique strengths and facing specific limitations. Traditional image processing algorithms, with their well-established techniques, provide efficient tools for enhancing and segmenting images, though they may struggle with adaptability to diverse patterns [6].

Machine learning (ML) algorithms excel in learning complex patterns, but their effectiveness relies heavily on large, labeled datasets for training. Deep learning (DL) algorithms, particularly Convolutional Neural Networks (CNNs), showcase remarkable capabilities to capture the hierarchical features but demand substantial computational resources and may lack interpretability [7]. Pattern recognition algorithms offer specialized expertise in identifying specific structures, while hybrid models and ensemble learning aim to harness the strengths of multiple approaches. Quantitative analysis algorithms focus on numerical assessments, and real-time processing algorithms cater to the need for immediate decision-making during mammography [8]. The selection of the algorithm is influenced by the specific diagnostic goals, available data, and computational considerations. Researchers often explore hybrid approaches, combining traditional and modern techniques, to enhance the accuracy and efficiency of cancer identification from mammography images. Ongoing advancements in Artificial Intelligence (AI) and computational imaging promise continued refinement and innovation in this critical domain of medical diagnostics. Furthermore, advancements in AI and ML have significantly contributed to the refinement of cancer identification in mammography images [10].

Automated algorithms can assist in the detection of subtle abnormalities, reducing the reliance on manual examination and potentially enhancing the efficiency of the diagnostic process. These algorithms are trained on large datasets, learning intricate patterns associated with various stages and types of cancers [11]. Their integration into clinical practice aims to provide not only accurate but also swift assessments, facilitating prompt decision-making and intervention when needed. In the evolving landscape of mammography, ongoing research focuses on improving the sensitivity and specificity of detection algorithms, refining their ability to discern precancerous lesions and early-stage cancers. The goal is to enhance the diagnostic yield of mammography, making it an even more valuable tool in cancer screening and surveillance [12]. Additionally, efforts are directed towards developing standardized protocols for image interpretation and reporting, ensuring consistency across different healthcare settings.

Predictive analysis of cancer using mammography images involves leveraging advanced data analytics and ML methodologies to extract meaningful insights from medical images captured by mammography devices [13]. The process begins with the collection of a diverse dataset, encompassing images from both cancer and non-cancer cases, covering various types and stages of the disease. Subsequently, thorough preprocessing is conducted to clean, normalize, and enhance the quality of the images. Relevant features such as color, texture, and shape characteristics are extracted from the images. Feature selection techniques are then employed to identify the most discriminative features. For classification, an ML model is selected, such as Support Vector Machines (SVMs) or Neural Networks, then trained on a split dataset consisting of training and testing sets [14]. Validation metrics, including accuracy and precision, are utilized to assess the model's performance. Continuous optimization, interpretability considerations, integration with clinical workflow, and adherence to ethical standards form integral parts of the process. The collaboration with healthcare professionals ensures the model's clinical relevance and adaptability in real-world healthcare settings.

The proposed Residual Networks (ResNets) have produced significant performance improvement in cancer prediction. It achieved or exceeded human-level performance in showcasing its potential. Residual Networks (ResNets) can handle very deep architectures is crucial for capturing intricate hierarchical features associated with cancerous tissues. ResNets improve the training efficiency of deep networks by reducing the vanishing gradient issue through residual connections.

The paper is organized as follows. Section 2 is a literature review, Section 3 is a methodological description, Section 4 is an explanation of the obtained results, and Section 5 is a conclusion to the research.

2. Literature Survey. A thorough review of the literature on predictive analysis methods for cancer diagnosis indicates a wide range of research projects involving different approaches to data analysis and ML. In order to increase cancer prediction models' overall performance, prognostic potential, and diagnostic accuracy, investigators have been diligently researching novel strategies. Here is an overview of some of the most significant issues and important findings from this field.SVMs, Decision Trees, and Logistic Regression were among the classical ML algorithms used in early research. SVM's use to lung cancer diagnosis was demonstrated by Li et al., 2019 [2]. SVM is effective in high-dimensional spaces and versatile for classification of cancer. Also, SVM is robust to overfitting. The algorithm is sensitivity to noise and outliers. It is having limited scalability while working with large datasets. In 2019, Zhang et al [11]. provided a model of the way to use Random Forests

to forecast cancer patients' probabilities of survival. The capacity to increase prediction accuracy attracted attention to Random Forests and Gradient Boosting. Ensemble method reducing overfitting and robust and versatile for various types of data. It is suitable for feature importance ranking. But Random Forest algorithm increases the computational complexity. This may lead to less interpretability due to ensemble nature.

The integration of genomic data and clinical information has been investigated for accurate cancer prediction. Dai et al., 2020 [14] illustrated the integrative analysis in breast cancer classification using Long Short-Term Memory networks (LSTM). It has the ability to store medical data that varies over time. Pham et al., 2020 investigated the use of LSTMs in outcome prediction. But LSTM requires a large amount of data. Hence, it is computationally intensive and the algorithm may suffer from vanishing/exploding gradient problems.

The interpretability of deep learning models in cancer pathology was the main emphasis of Yuan et al.'s 2019 study [4]. End-to-end learning is made possible by deep learning models, which make it possible to directly link input data to predictions. Deep learning models, if not properly regularized, can be prone to overfitting, especially when dealing with limited datasets. Overfitting may result in poor generalization to new, unseen data. Zhang et al., 2019 [15] looked into the use of deep convolutional autoencoders in breast cancer prognosis. He has investigated the use of deep learning architectures, including autoencoders, for feature learning in cancer detection. Autoencoder is an unsupervised learning method for feature extraction. Hence, it can capture complex patterns and representations. But it requires substantial data for training. Interpretability can be challenging. Because of the dynamic nature of cancer, investigations frequently use survival analysis approaches. Ching et al., 2018 [16] described a deep learning model for survival analysis that takes into account conflicting risks in cancer prognoses.

Convolutional Neural Networks (CNNs) and other deep architectures have been explored for image-based cancer diagnosis as deep learning has become more popular. Kooi et al., 2017 [3] showed the success of CNN in analyzing mammograms. Research efforts now center on the integration of data from several sources, such as genetic data, medical imaging, and clinical records. Integrative approaches are investigated for a thorough understanding of cancer biology was proposed by Wang et al., 2020 [17]. Interpretability is becoming more important when predictive algorithms are used in healthcare settings. As the use of predictive models in clinical settings becomes more critical, there is a greater emphasis on interpretability. CNN algorithms are excellent at capturing complex spatial patterns in images and suitable for learning hierarchical features. It can handle large amounts of data. But CNN requires significant computational resources for training. The algorithm may suffer from interpretability challenges.

Graph-based techniques, including Graph Convolutional Networks, have gained popularity. Graph Convolutional Networks (GCN) for Breast Cancer analysis was carry out by Wang et al., 2021 [6]. This study uses GCNs for histology image analysis. Interpretability in predictive models is critical for clinical application.

One growing topic in machine learning is transfer learning, which applies pre-trained models on large datasets. It enables to use huge datasets with pre-trained models for relevant tasks. Even with little labeled data, can improve performance. The performance of the algorithm depends on the similarity between the source and target domains. Hence, fine-tuning can be challenging. Hou et al., 2020 [18] investigated the use of pre-trained models in histopathological cancer classification. Lynch et al., 2018 provided a light on the difficulties and ethical concerns associated with deploying predictive models in clinical practice. In medical image analysis, transfer learning has been applied extensively. Bentaieb et al., 2019 investigated the transfer learning techniques to improve pathology image classification [19].

Data augmentation is critical for developing robust models. Esteva et al., 2017 [20] investigated the effects of various data augmentation techniques on skin cancer diagnosis. The problem of having little labeled data for machine learning model training can be solved by using Generative Adversarial Networks (GANs) to create artificial healthcare images. Augmenting datasets enhances model generalization. GANs facilitate the translation of medical images from one modality to another, aiding in cross-modal image synthesis. Guibas et al., 2017 [21] proposed the methodology to convert CT scans to MRI-like images. GANs can extract useful characteristics from medical images. Conditional GANs, in particular, allow for the generation of images with specified features. But, GANs might produce synthetic images that lack certain nuances present in real medical images. The algorithm learns from existing datasets, inheriting any biases present in the data. If the training

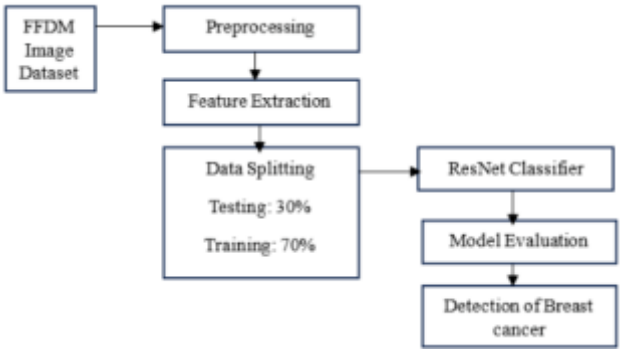

Fig. 3.1: Block diagram for predictive analysis of breast cancer of the proposed model.

data is biased, the generated images may also reflect those biases. It is sometimes referred to as black-box models, which make it difficult to interpret learnt features and comprehend how decisions are made. The use of synthetic data raises ethical considerations, as it may influence decisions in clinical settings. Ensuring the ethical use of generated data is crucial.

Chen et al. (2013) demonstrated a hybrid deep learning model for lung cancer prediction [22]. This model that combines deep learning and standard ML to predict lung cancer. Bharati et al., 2020 [23] introduced the integration of multiple deep learning architectures to improved predictive accuracy and it is compared with individual models. Combining the strengths of different models may enhance overall performance. Hybrid models often involve more complex architectures, which can increase the computational and training resource requirements. This complexity may also pose challenges in terms of model deployment and integration into clinical workflows. The creation and evaluation of cancer prediction algorithms frequently entail benchmark datasets and obstacles. Hoadley et al., 2018 described the Pan-Cancer Analysis of Whole Genomes (PCAWG) that contributes to the understanding of cancer genomics [24].

3. Proposed Methodology. The development of a predictive analysis algorithm for cancer diagnosis involves a systematic process rooted in ML methodologies. A comprehensive dataset, comprising patient records with diverse clinical information and diagnostic results, is collected and subjected to meticulous preprocessing to address data imperfections. Essential features contributing significantly to cancer prediction are then selected, employing methods like recursive feature elimination or univariate selection. The dataset is strategically split into training and testing sets to make assessing the effectiveness of the selected method easier. Subsequent training of the ResNet model to enhance predictive accuracy. The proposed approach aims to produce a robust and reliable predictive analysis algorithm capable of contributing to effective cancer diagnosis.

Figure 3.1 shows the block diagram for predictive analysis of breast cancer Full-Field Digital Mammography (FFDM) images using a Residual Network (ResNet). The first step in utilizing a ResNet to predict breast cancer from FFDM images is importing and processing the images. To improve clarity and uniformity, these photos are scaled, normalized, and converted to grayscale. Subsequently, a ResNet model, a specialized neural network intended to detect patterns indicating of benign or cancerous tissues, analyzes them. By using skip connections to facilitate effective learning, the ResNet model uses convolutional layers to extract information from the images. The model is trained on an identified image dataset, and its performance is assessed to see how well it can identify between benign and malignant instances. After undergoing validation, the model is applied to forecast the probability of cancer in fresh photos, providing a potent instrument for prompt identification and diagnosis.

3.1. Dataset. The CBIS-DDSM dataset consists of digital mammography images, including both Full Field Digital Mammography (FFDM) and digitized film mammography [25]. Images stored in the CBIS-DDSM database have been converted to the DICOM standard format. The dataset, which included 2478 mammography images from 1249 women, was uploaded on the CBIS-DDSM website. The details of the structured description

Table 3.1: Details of the dataset [25].

Field	Description	Example
Patient ID	The first 7 characters of images in the case file, used to uniquely identify each patient.	P123456
Density Category	Describes the breast tissue density, typically categorized according to the BI-RADS scale (1 to 4).	3
Breast	Indicates whether the mammogram is of the left or right breast.	Left
View	Indicates the view of the mammogram image.	CC or MLO
Number of Abnormalities	The number of abnormalities present in the image.	2
Mass Shape	Describes the shape of the mass (when applicable).	Oval
Mass Margin	Describes the margin of the mass (when applicable).	Circumscribed
Calcification Type	Describes the type of calcification (when applicable).	Punctate
Calcification Distribution	Describes the distribution of calcifications (when applicable).	Clustered
BI-RADS Assessment	BI-RADS score indicating the likelihood of malignancy.	4
Pathology	Indicates whether the abnormality is Benign, Benign without call-back, or Malignant.	Malignant
Subtlety Rating	Radiologists' rating of the difficulty in viewing the abnormality in the image (1 to 5).	3
Path to Image Files	The directory path where the image files are stored.	/path/to/images

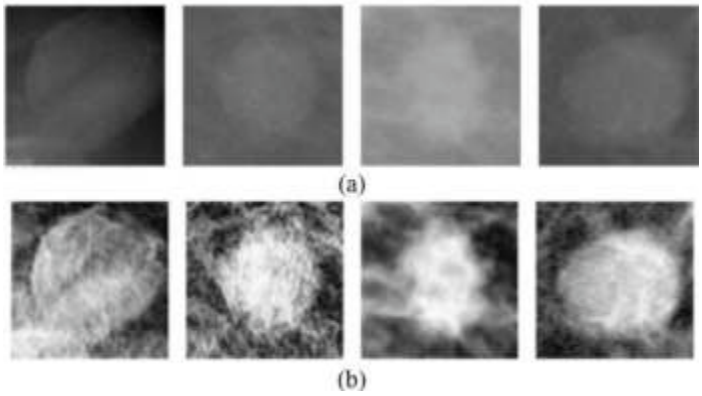

Fig. 3.2: Sample input images with malignant tumors in the CBIS-DDSM database [25] (a) Original Image, (b) Synthetic Image.

incorporating the patient details and image metadata from the CBIS-DDSM dataset is shown in Table 3.1.

In this investigation, every perspective was handled as a single image. Randomly divide the CBIS-DDSM dataset 80:20 at the patient level to produce separate test and training sets. An independent validation set was created by further splitting the training data, 85:15 this time. Combined, the training, validation, and testing sets had 1903 images. The CBIS-DDSM database contains the pixel-level annotations for the ROIs together with their pathologically verified labeling (malignant or benign). Additionally, it designates each ROI as a bulk or calcification. The GPU memory size limitation was the driving force behind the downsizing. Two patch datasets were created by sampling image patches from background areas and ROIs. Every patch had the same dimensions—224 x 224—and was sufficient to cover most of the ROIs that had been labeled. Five types of patches were identified: background, benign mass, malignant calcification, benign calcification, and malignant mass. The sample CBIS-DDSM database images are shown in Figure 3.2.

3.2. Preprocessing. The CBIS-DDSM database's Full-Field Digital Mammography (FFDM) images containing malignant tumors must pass through a preprocessing pipeline that includes many crucial steps to

guarantee consistency, quality, and appropriateness for deep learning research. To reduce variances brought on by various imaging settings, images are normalized to standardize pixel intensity levels. After the process of normalization, noise reduction methods, including median filtering, are utilized to eliminate artifacts and improve the quality of the image. This is a critical step in enhancing the features' visibility and improving the clarity of images used for analysis. Furthermore, methods of data augmentation are utilized to artificially expand the dataset, such as rotations, flips, scaling, and translations. The images are consistently improved and prepared by using this preprocessing pipeline, which makes them appropriate for further deep learning research to precisely identify and categorize malignant tumours.

3.2.1. Normalization. Normalization adjusts pixel values to a standard scale, typically between 0 and 1 or using a mean and standard deviation approach. The min-max normalization of the image is as follows.

$$Normalizedpixelvalue = \frac{Pixelvalue - Minvalue}{Maxvalue - Minvalue} \tag{3.1}$$

where Min value and Max value are the minimum and maximum pixel values in the image respectively.

3.2.2. Noise Reduction. Median filtering replaces each pixel's value with the median of neighboring pixel values within a defined window. The median filter operation F(i,j) at pixel (i,j) is computed as follows.

$$F(i,j) = median(pixels\ in\ window\ centered\ at\ (i,j)) \tag{3.2}$$

3.2.3. Data Augmentation. Techniques such as rotation, flipping, scaling, and translation introduce variations in the dataset. For example, scaling involves resizing an image by a factor α.

$$Scaled\ image = \ \alpha \times Original\ image \tag{3.3}$$

where α can be a random factor between predefined limits.

3.2.4. Contrast Enhancement. Histogram equalization adjusts the image's intensity distribution to enhance contrast. The transformation function T is defined as follows.

$$T(r_k) = \frac{\sum_{j=0}^{k} n_j}{N} \times L \tag{3.4}$$

where r_k is the intensity level, n_j is the histogram of pixel intensities, N is the total number of pixels, and L is the maximum intensity level of 255 for 8-bit images.

3.2.5. Edge Detection. Canny edge detection identifies edges based on intensity gradients. The edge strength(x,y) at pixel(x,y) is computed using gradients G_x and G_y is as follows.

$$EdgeStrength(x,y) = \sqrt{G_x(x,y)^2 + G_y(x,y)^2} \tag{3.5}$$

Images from the CBIS-DDSM must be preprocessed using these procedures in order to be ready for further analysis. Each phase advances the interpretability of precise diagnosis and improves image quality.

3.3. ResNet (Residual Neural Network) architecture. In the context of cancer diagnosis, the ResNet architecture, known for its ability to model channel interdependencies effectively, can be adapted as a powerful tool for medical image analysis. To employ ResNet for cancer diagnosis, a representative dataset comprising medical images related to the specific cancer type of interest must be gathered. Following dataset preparation, preprocessing techniques, including resizing and normalization, ensure the uniformity and quality of the images. The ResNet model is then fine-tuned on this medical imaging dataset, leveraging transfer learning with pre-trained weights, typically from a large dataset like ImageNet. During training, an appropriate loss function and metrics are selected, and hyperparameter tuning is conducted to optimize model performance. Validation on a separate dataset assesses the model's generalization capabilities, while testing on a held-out set evaluates accuracy and reliability. Interpretability methods are crucial for understanding the model's decision-making process, especially in medical applications where trust is paramount. If applicable, the trained ResNet model can

be integrated into the clinical workflow, with continuous monitoring and updates to ensure ongoing improvement and adaptation to evolving data patterns. Collaboration with healthcare professionals is essential throughout the development and deployment phases to align the model with clinical needs and standards.

The core of ResNet consists of bottleneck blocks, each comprising a series of convolutional layers with varying filter sizes. These blocks enable the network to capture complex hierarchical features essential for accurate image classification. Additionally, ResNet introduces a Feature Pyramid Network (FPN), facilitating the aggregation of features from different scales. This approach enhances the model's ability to discern both local and global contextual information, contributing to its robust performance. This nested structure allows the model to capture multi-level contextual information efficiently. Furthermore, the split-attention mechanism is employed, dividing feature maps into groups and enabling the network to attend to distinct parts independently. This innovative design enhances the model's capacity to learn diverse and complementary information within the feature maps. Ultimately, the architecture concludes with an output layer that produces the final predictions, making ResNet well-suited for image classification tasks, including cancer prediction. While a detailed diagram offers a more comprehensive understanding, this textual overview highlights the key components and strengths of ResNet in leveraging attention mechanisms and hierarchical features for enhanced performance in complex classification tasks.

3.4. Algorithm to detect breast cancer using ResNet. Algorithm to detect cancer from mammography Images using ResNet is described as follows. This algorithm outlines the major steps involved in detecting cancer from mammography images using a ResNet model. It includes data loading, preprocessing, model building, training, evaluation, prediction on new data, and post-processing steps. The specific implementation details, such as the ResNet model architecture and preprocessing functions must be determined by taking into account the demands of the cancer detection as well as the deep learning framework of choice.

Algorithm 21 Algorithm to detect breast cancer using ResNet

Input: Mammography images (Array of mammography images)
Output: Predicted labels (Array of predicted labels for each image)
Step 1: Import necessary libraries and modules and perform preprocessing
Step 2: Load and preprocess mammography images
Step 3: Split the dataset into training and testing sets
Step 4: Build the ResNet model for breast cancer detection
Step 5: Compile the model
Step 6: Train the model on the training set
Step 7: Evaluate the model on the test set
Step 8: Make predictions on new mammography images
Step 9: Post-processing and visualization of results
Step 10: Output the predicted labels for cancer presence in mammography images

3.5. ResNet Model Architecture. The quick training process, flexibility to different image sizes, and shown cutting-edge performance in computer vision tasks all contribute to their usefulness in cancer prediction. Furthermore, the transfer learning capability of pre-trained ResNets on huge datasets enables the leveraging of knowledge from general image classification tasks, making them valuable tools for medical image analysis.

The residual block structure in Resnet is shown in Figure 3.3. This schematic diagram highlights the ResNet model's unique architecture for analyzing Full-Field Digital Mammography (FFDM) images by outlining its layers and linkages. The architecture demonstrates the incorporation of residual blocks, which provide efficient learning of complex properties essential for detecting putative malignant areas. The ResNet framework's components are all expertly designed to maximize breast cancer detection accuracy, showcasing the framework's potential as an effective tool for medical image analysis.

As ResNets remain at the forefront of advancements in deep learning for accurate and reliable cancer predictions from medical imaging data. The inclusion of skip connections in ResNets enhances model generalization, preventing overfitting and ensuring robust performance on diverse patient populations.

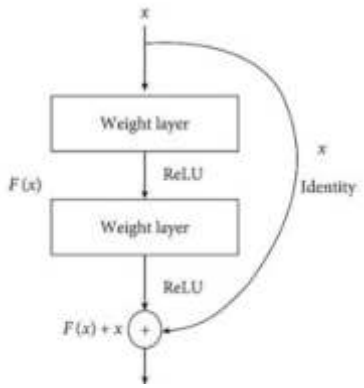

Fig. 3.3: The residual block structure in Resnet

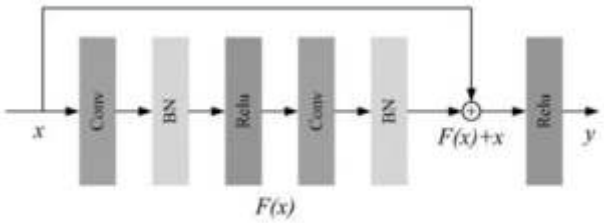

Fig. 3.4: The architecture of Resnet for breast cancer detection

The architecture of Resnet for breast cancer detection is shown in Figure 3.4. These blocks are key components that enable the effective transmission of information across the network, hence facilitating deep learning. The network can learn residual mappings from each residual block's skip connections, which enables it to extract and use significant characteristics from Full-Field Digital Mammography (FFDM) images.

Input. As shown in Figure 3.3, the architecture starts with the input layer, representing the input image or feature map. Let Xbe the input tensor corresponding to a mammography image to the ResNet block.

Residual Block. The output is computed as $F(X) + X$, where $F(X)$is the output of the residual function.

$$Output = ReLU\left(W_2 \,.\, (W_1.X + b_1) + b_2\right) + X \tag{3.6}$$

Here W_1 and W_2 represent the weight matrices. b_1 and b_2 are the bias terms, and the activation function for rectified linear units is known as ReLU.

Loss Function. The binary cross-entropy loss is a widely used measure for binary classification, and it is calculated as follows.

$$Binary\ cross-entropy\ loss = -\frac{1}{N}\sum_{i=1}^{N}[y_i \cdot \log(\widehat{y_i}) + (1 - y_i) \cdot \log(1 - yi)] \tag{3.7}$$

Here, y_i is the true label (1 for cancer, 0 for non-cancer). $\widehat{y_i}$ is the predicted probability, and N represents the number of samples.

Backward Pass (Backpropagation). Final layer produces the output of the network, which could be the predicted class probabilities in the case of an image classification task. Calculate the gradients of the loss in relation to the final output as follows.

$$\frac{\partial L}{\partial Output} = \frac{\partial L}{\partial H(X)} + \frac{\partial L}{\partial X} \tag{3.8}$$

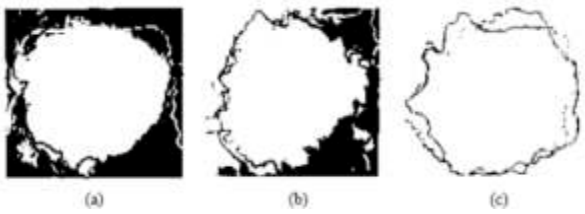

Fig. 3.5: Segmented masses through the proposed Resnet architecture. (a) Ground truth, (b) segmented results, (c) Final segmented result.

Backpropagate these gradients through the ResNet block. $\frac{\partial L}{\partial H(X)}$ influences the gradients through the ReLU and the linear transformation, and $\frac{\partial L}{\partial X}$ directly influences the gradient through the skip connection.

Update Weights (Gradient Descent). Update the weights using the gradients computed during backpropagation. W_2 and b_2 are updated based on $\frac{\partial L}{\partial H(X)}$. W_1 and b_1 are updated based on $\frac{\partial L}{\partial X}$.

Optimization. Gradient descent or its variants, such as Adam or RMSprop, are commonly used optimization algorithms in deep learning. The general update rule for weights W is given as follows.

$$W_{new} = W_{old} - \alpha. \triangle_W Loss \tag{3.9}$$

where α is the learning rate, and $\triangle_W$ Loss is the gradient loss in relation to the weights. Learning rate plays a crucial role in the optimization process. Too high a learning rate may cause the model to converge slowly or even diverge, while too low a learning rate may result in slow convergence. Adaptive learning rate algorithms, dynamically adjust the learning rate during training based on the historical gradients.

Regularization. Regularization techniques, such as L2 regularization, may also be applied.

$$Loss_{total} = Loss_{original} + \lambda. \parallel W_i \parallel_2^2 \tag{3.10}$$

where λ is the regularization strength and $\parallel W_i \parallel_2^2$ represents the squared L2 norm of the weights.

Convolutional Layer. The convolutional layer uses spatial filtering, shown in Figure 4, to extract low-level information from the input image. $LetW_{conv}$ denote the convolutional filters, tb_{conv} the biases, and σ is the convolution operation. Then the convolutional output is denoted as follows.

$$Convolutional\ Output = \sigma(W_{conv} * X + b_{conv}) \tag{3.11}$$

Batch Normalization (BN). Batch normalization is used to keep deep neural networks stable and train them faster. It normalizes the inputs to a layer to reduce internal covariate shift. The mathematical operations of batch normalization include normalizing the inputs μ and σ the mean and standard deviation, scaling and shifting the normalized inputs using learnable parameters (γ *and* β).

$$Batch\ Normalization\ Output\ (x) = \gamma.\frac{Convolutional\ Ouput - \mu}{\sqrt{\sigma^2 + \epsilon}} + \beta \tag{3.12}$$

Activation Function (ReLU). The activation function imparts nonlinearity into the output. In this instance, the Rectified Linear Unit (ReLU) is frequently utilized.

$$ReLU\ Output\ (Y) = max(0,\ Batch\ Normalization\ Output) \tag{3.13}$$

The ReLU function outputs the elemenet-wise maximum of 0 and the Batch Normalization output. Figure 3.5 depicts the contours of their ground-truth images, as well as the contours of the ResNet segmentation output images.

Table 4.1: Inputs applied for evaluation of the proposed method.

Input	Description	Value
Age	Age of the patient at the time of imaging.	45 years
Gender	Gender of the patient. (Usually female for breast cancer).	Female
Tumor Size	Size of the detected tumor in the mammogram image.	1.5 cm
Tumor Shape	Shape characteristics of the tumor (e.g., round, irregular).	Irregular
Tumor Margin	Margin characteristics of the tumor (e.g., circumscribed, spiculated).	Spiculated
Calcification	Presence and type of calcifications within the breast tissue.	Microcalcifications
Mass Density	Density of the mass observed in the imaging.	High Density
Breast Composition	Overall composition of the breast tissue (e.g., fatty, dense).	Dense
Learning Rate	Learning rate schedule and initial value.	0.001 with Step Decay
Loss Function	Loss function used for training (e.g., cross-entropy loss).	Binary Cross-Entropy
Epochs	Number of epochs for which the model is trained.	60
Batch Size	Number of samples per batch during training.	32
Dropout Rate	Dropout rate for regularization to prevent overfitting.	0.5

4. Results. The ResNet architecture layer construction has specific requirements. The convolution layer is typically used to implement the feature learning model. In addition to the convolution layer, the ResNet design contains layers for batch normalization, activation, and pooling. After the convolution layer, batch normalization is utilized, followed by the activation layer, which employs the ReLu function. The convolution layer in each ResNet architecture is divided into five layers by residual blocks. Only at the start of feature learning, or after the first convolution, and at the end of feature learning, or after the previous convolution, are pooling layers implemented before being included in the classification layer. The confusion matrix was performed on the Resnet patch classifiers, as illustrated in Figure 6. With the highest likelihood, patch classifiers predicted that all five classes would fall into the appropriate categories. The background class was the simplest to classify, whereas malignant calcifications were the hardest. Malignant masses were more likely to be misdiagnosed as malignant calcifications than benign calcifications. The most common misidentifications were of benign calcifications as background, then malignant calcifications. Malignant tumors were more likely to be mistakenly identified as benign masses and benign masses as malignant masses or background, depending on the patch classifier.

Table 4.1 shows the list of inputs and hypothetical values for evaluating breast cancer prediction from Full-Field Digital Mammography (FFDM) images using a Residual Network (ResNet).

In order to derive significant insights, the performance of the ResNet model was examined using the CBIS-DDSM dataset. The IOU score, Dice score, accuracy, and other quantitative indicators provide a numerical evaluation of the model's overall efficiency. More granularity was provided by taking into account the precision-recall curve and area under the ROC curve (AUC-ROC), which provided an in-depth understanding regarding the compromises between sensitivity and specificity at various categorization thresholds.

One of ResNet's major achievements is that it can conduct enhanced feature extraction because of its skip connections and deep layers, which enable low-level and high-level features to be learned simultaneously. This is important for cancer imaging because precise identification of minute variations in tissue properties is required. Furthermore, ResNet's skip connections make it easier to train extremely deep networks by guaranteeing that gradients may pass through the network without decreasing, which promotes steady and effective training procedures.

ResNet offers notable benefits for applications like as digital mammography-based breast cancer prediction because to its residual connection deep design. It can use many layers to capture complex patterns in breast cancer images because it can solve the vanishing gradient problem and efficiently train very deep networks. Compared to shallower topologies, ResNet may be able to attain greater accuracy because of its depth.

Moreover, learnt features may be reused across layers but not in ResNet due to skipping connections. This feature reuse helps to lessen overfitting while also improving the network's capacity to retrieve pertinent characteristics suggestive of breast cancer. ResNet contributes to the creation of models that generalize well

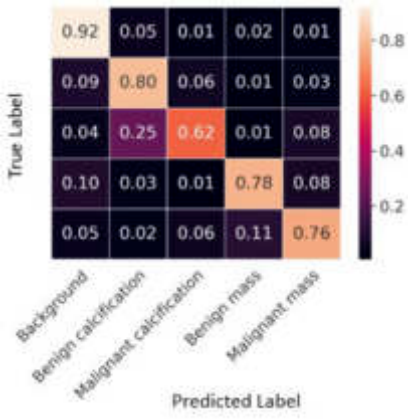

Fig. 4.1: Confusion matrix analysis of patch classification for Resnet.

to new data by enabling more steady gradient flow during training, which is a crucial need in medical image analysis.

The confusion matrix analysis of patch categorization carried out using the ResNet model is shown in Figure 4.1. The accuracy and incorrectness of the model's classification of image patches is shown graphically in this matrix. With regard to the accuracy and dependability of the ResNet model in differentiating between several types of breast tissue patches, it provides a comprehensive understanding through the counts of true positives, true negatives, false positives, and false negatives.

The segmentation and classification are assessed using the F1-score, commonly referred to as the Dice similarity score. Eqn. (9) which displays this score, is a combined average of the intersection between areas and the total areas. The IoU score, sometimes referred to as the Jaccard score, is an additional assessment measure that is explained in eqn. (10). When all of the masses' surrounding pixels are accurately segmented, a binary mask with a high Dice and IoU score is created from the segmented contour of the mass lesions. This represents an acceptable segmentation performance.

$$Dice\ Score(X,Y) = \frac{2 \times (X \cap Y)}{X + Y} \tag{4.1}$$

$$IOU\ Score(X,Y) = \frac{A \cap B}{A \cup B} \tag{4.2}$$

To evaluate the proposed system based on accuracy metric as the mean IoUscore for correctly identified ROIs in accordance with a 90% overlap criterion, referred to as the IoU_{90} score in eqn. (4.11). According to the definition given, the final accuracy is the end-to-end accuracy for the two steps is given in eqn. (4.12).

$$IOU_{90}Score(X,Y) = \left\{ mean(IOUScores(X,Y \forall ROI), \quad if IOUScore(X,Y)90 \right\} \tag{4.3}$$

$$Accuracy = Detected\ Accuracy\ Rate \times IOU_{90}Score(X,Y) \tag{4.4}$$

The segmentation performance across different methods is shown in the Table 4.2. Tsochatzidis et al.'s UNet achieved intermediate IOU and Dice scores, indicating that it is successful but still has space for development. In comparison to UNet, Deeply Supervised U-Net (DS U-Net) performs better, with higher IOU and Dice scores. R-UNet and Conditional Residual UNet show improvements in segmentation accuracy by enhancing IOU and Dice scores even more. In comparison to all other approaches given, the proposed ResNet obtained the

Table 4.2: Comparison of the proposed architectures and state-of-the-art methods.

Authors	Methods	IOU Score(%)	Dice Score (%)
Tsochatzidis et al., [9]	UNet	72.2	56.5
Ravitha et al., [26]	DS U-Net	79	83.2
Dhungel et al., [27]	Deep structured output learning	82.9	66.87
Abdelhafiz et al., [28]	R-UNet	90.5	89.1
Li et al [29]	Conditional Residual UNet	92.72	82.65
Proposed Method	ResNet	99.16	98.88

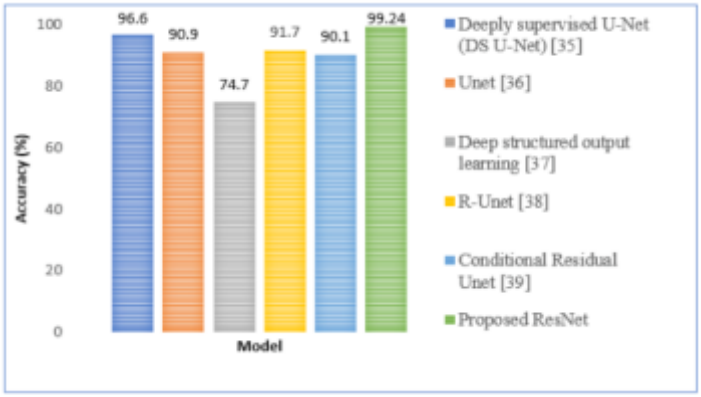

Fig. 4.2: Performance comparison of Accuracy (ACC) measures with competitive methods.

highest IOU Score of 99.16% and Dice Score of 98.88%, demonstrating higher accuracy in properly segmenting malignant tumors.

Table 4.2 illustrates the remarkable efficacy of the ResNet model when it pertains to breast cancer identification on the CBIS-DDSM dataset. The model's overall accuracy provided a general measure of its ability to correctly classify mammograms into normal and abnormal cases, reflecting a solid foundation in capturing the dataset's inherent patterns

The model's predictions were broken down into true positives, true negatives, false positives, and false negatives in the confusion matrix, demonstrating the granularity of the analysis. This indicated particular instances of misclassification in addition to demonstrating the model's accuracy in identifying positive and negative situations. Examining false positives and false negatives at the individual instance level unearthed patterns and potential sources of error, contributing to a targeted strategy for model refinement. Figure 4.2 depicts an analysis of the proposed technique, which yielded 99.24% accuracy (ACC) of for mass lesions.

The area under the ROC curve (AUC-ROC), shown in Figure 8 depicted the robust discrimination between positive and negative cases across various classification thresholds. This metric is particularly valuable in assessing the model's consistency in assigning higher probabilities to true positive cases than to true negatives, indicative of its ability to handle imbalanced datasets and prioritize sensitivity.

ResNet is potential enough to identify subtle patterns indicative of breast cancer is enhanced by a larger dataset, which enables it to learn from a more comprehensive and diverse group of samples. The model's capacity to provide accurate predictions on new and unknown data is enhanced by training it on a broad range of scenarios, which teaches it to extract characteristics that are useful in a variety of circumstances.

ResNet can efficiently learn hierarchical representations of features, ranging from simple edges and textures to more intricate patterns and structures pertinent to breast disease, by utilizing a deep network structure with numerous layers. This depth enables the model to incorporate minute characteristics found in mammograms, including architectural deformities or microcalcifications, which are essential for precisely detecting malignancy.

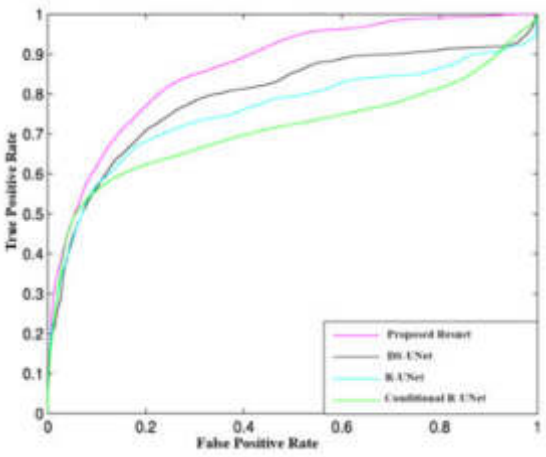

Fig. 4.3: AU-ROC cure analysis of the proposed method vs. competitive methods.

The accuracy of the ResNet model in detecting breast cancer on the CBIS-DDSM dataset is demonstrated by the performance of the Receiver Operating Characteristic (ROC) curve in conjunction with other assessment criteria. Plotting the true positive rate against the false positive rate across several categorization thresholds, the ROC curve demonstrated the model's continuously strong discriminatory performance. This discriminative capability was further measured using the Area Under the ROC Curve (AUC-ROC), which demonstrated the model's capacity to discern between normal and abnormal situations. The robust AUC-ROC score substantiated the model's consistent prioritization of true positive cases over false positives, a critical characteristic in medical scenarios where sensitivity is paramount. The CBIS-DDSM dataset performance evaluation of the ResNet model showed a stable and flexible system with good accuracy. The model is positioned as a potential tool for breast cancer diagnosis in medical applications due to its thorough evaluation and quantitative measurements.

The proposed research has the potential to completely transform the way that cancer is identified, making it easier to use and more convenient than existing diagnostic procedures. In the field of cancer diagnosis and therapy, the combination of mammography with predictive analysis creates new opportunities for early identification and intervention, which enhances patient outcomes.

5. Conclusion. Predictive analysis of Full-Field Digital Mammography images using ResNet holds immense promise for the future of cancer screening and diagnosis. ReNet algorithm can learn from large datasets of labeled Full-Field Digital Mammography images, achieving higher accuracy in distinguishing benign from malignant lesions compared to traditional methods. This can reduce the need for invasive biopsies and unnecessary procedures. By addressing the challenges and ensuring responsible development and implementation, it allows for earlier identification and better treatment results for cancer patients. This method of diagnosis has a possibility to safeguard lives. In the context of predictive modeling, ResNet is often used as a predictive model. It is especially well-known for its performance in image classification tasks, in which the objective is to anticipate the category or class of a new image. By reducing the impact of the vanishing gradient issue, residual connections facilitate the training of extremely deep networks. In conclusion, the analytical results of the ResNet model on the CBIS-DDSM dataset involved a meticulous exploration of quantitative metrics. This comprehensive approach aimed not only to assess the model's performance but also to extract actionable insights, fostering a continuous improvement cycle for its deployment.Deep neural networks, like ResNet models, are by nature complicated models. It is difficult to comprehend how they make their predictions, which is significant in clinical settings where choices have an influence on patient care. Although they can improve interpretability, strategies like Layer-Wise Relevance Propagation (LRP) and attention mechanisms could not completely meet physicians' needs in this regard.

INTELLIGENT RECOMMENDATION ALGORITHM FOR PRODUCT INFORMATION ON E-COMMERCE PLATFORMS BASED ON ROBOT CUSTOMER SERVICE AUTOMATIC Q&A

RONG FU* AND XIAOYAN ZHOU†

Abstract. In order to enhance the shopping experience of customers and retain them, thereby increasing sales volume, the author proposes the research topic of an intelligent recommendation system for product information on e-commerce platforms based on robot customer service automatic question answering. Firstly, starting directly from the question itself, the system can provide feedback to customers by simply segmenting the questions submitted by customers and matching them with semantic templates; Secondly, the system automatically builds and updates the user's personalized knowledge base, using this to predict user purchasing tendencies and achieve the function of recommending products to customers. The implementation of the intelligent shopping robot system has passed 365 question and answer tests on 5G mobile phone sales terms, and is feasible in the professional field. The experimental results indicate that, when the number of training corpora increased to 300, the accuracy of the system was 0.85, 0.90, and 0.98 using 100, 2003, and 300 tests respectively. Such a system is perfect for natural language processing, so we can improve the system by expanding and improving the knowledge base. The intelligent shopping robot recommendation system studied by the author is still in the analysis and demonstration stage, sincerely hope that the processing method used in this project can have reference significance for similar recommendation systems in the near future.

Key words: Robots, Automatic question and answer, E-commerce platforms, Information intelligent recommendation

1. Introduction. The customer service system has evolved from telephone consultation to instant messaging consultation, then to the question answering system of natural language processing with artificial intelligence, it has gone through a long process of development. The intelligent customer service based on language intelligent processing technology solves the problem of increasing service demand and dispersed customer sources, reducing the response speed and processing efficiency of traditional customer service to customer service needs, breaking through the bottleneck of customer service development, promoting the transformation of service methods, and further optimizing customer experience [1].

As an emerging development direction of automatic question answering, intelligent customer service system is an industry oriented automatic question answering system based on large-scale knowledge processing, involving knowledge management, natural language understanding, logical reasoning and other technologies, which can provide an effective technical means for communication between enterprises and a large number of users. In addition, intelligent customer service systems can effectively reduce labor costs, enhance user experience, and provide users with more convenient and comfortable services.

It can also establish a fast and effective natural language based technical means for communication between enterprises and a large number of users, and provide statistical analysis information required for lean management [2]. The intelligent customer service robot provided by the intelligent customer service system can automatically respond to simple customer service needs, achieve a humanized human-machine dialogue experience, divert manual traffic, reduce customer service pressure, improve response rate, and improve customer satisfaction, which is increasingly receiving attention from enterprises.

In order to actively respond to relevant national science and technology innovation policies, the "National Science and Technology Management Information System Public Service Platform" built by the Institute of Scientific and Technical Information of China was officially launched for service in September 2015 [3]. As an external window and service platform for national scientific research projects, the system needs to address various problems faced by researchers, however, with the increase of projects and rapid policy updates, it is

*The School of Business, Xi'an International University, Xi'an, 710077, China (Corresponding author, RongFu768@163.com)
†The School of Business, Xi'an International University, Xi'an, 710077, China (XiaoyanZhou7@126.com)

difficult for manual customer service to cope with various problems, therefore, building an intelligent Q&A system for the platform is one of the effective solutions. With the development of speech recognition technology and its widespread application in daily life, users have put forward higher requirements for speech recognition in terms of vocabulary and specific people. Researchers have begun to study speech recognition with large vocabulary and non-specific people, and many new technical challenges also need to be solved. For example, the larger the vocabulary of a speech recognition system is, the larger the glossary is required. In this case, it is particularly important to select and establish appropriate templates, which is more difficult to process; Voice information is different for different recognizers. Semantic information is also different when the same person says the same thing at different times [4]; if there is some noise information in the speech signal, the results of speech recognition will also produce errors. Therefore, traditional template establishment and matching methods are no longer suitable for new environments.

In the 1980s, speech recognition researchers successfully broke through the barriers of large vocabulary, non-specific individuals, and speech continuity. Among them, the representative one is the Sphinx speech recognition system developed by Carnegie Mellon University, which is the world's first large vocabulary, non-specific continuous speech recognition system, and has high speech recognition performance. At this point, statistical methods are the mainstream method in speech recognition technology. Among them, representative speech recognition systems include the Naturally Speaking system successfully developed by DragonSystem, the Nuance Voice Platform system developed by Nuance, VoiceTone from Sun, and Whisper from Microsoft [5].

2. Literature Review. Almost all large e-commerce systems, such as Amazon, eBay, Dangdang, etc., use various forms of recommendation systems to varying degrees. However, with the vigorous and rapid development of e-commerce websites, the products provided to customers have almost exponentially increased. For customers, facing these "rich" information, they are no longer able to quickly obtain the products they want from personalized recommendation service systems, the services of personalized recommendation systems have shown to lag behind customers' shopping needs. Since the 21st century, due to the popularity of the Internet, computer processing of natural language has become an important means of acquiring knowledge from the Internet. Almost all modern people living in the information network era have to deal with the Internet, and more or less use the research results of natural language processing to acquire or mine various kinds of knowledge and information on the vast Internet, therefore, countries around the world attach great importance to relevant research and have invested a large amount of manpower, material resources, and financial resources [6].

The intelligent shopping robot system is a requirement for e-commerce innovation. The traditional e-commerce model has developed to the extreme, Chinese e-commerce websites represented by Alibaba, Taobao and others have encountered development bottlenecks, how to get the goods they want more quickly, how to solve the adhesion between merchants and customers, how to let customers experience the pleasure of shopping, how to let more consumers participate in online shopping, how to involve more farmers in e-commerce transactions has become an urgent issue that needs to be addressed. The development of e-commerce in China requires a disruptive innovation revolution.

Currently, almost all large e-commerce systems, such as Amazon, CDNOW, eBay, Dangdang, etc., use various forms of recommendation systems to varying degrees. With the vigorous and rapid development of e-commerce websites, the number of products provided to customers has almost exponentially increased. For customers, facing these "rich" information, they are no longer able to quickly obtain the products they want from personalized recommendation service systems, the service of personalized recommendation systems has shown to lag behind customers' shopping needs. In an increasingly competitive environment, intelligent shopping robot systems can effectively retain customers and improve sales on e-commerce websites.

Zhang, X proposed a collaborative filtering recommendation algorithm to improve the user model. Firstly, the algorithm takes into account the scoring differences caused by different user scoring habits when expressing preferences, and adopts a decoupling normalization method to normalize user scoring data; Secondly, considering the forgetting transfer of user interest over time, a forgetting function is used to simulate the forgetting law of scores, and the weight of time forgetting is introduced into user scores to improve the accuracy of recommendations; Finally, improvements were made to the similarity calculation when calculating the nearest neighbor set. On the basis of Pearson similarity calculation, an effective weight factor is introduced to obtain a more accurate and reliable nearest neighbor set [7]. Sharma, S. N extracts tweets or comments from the database

Fig. 3.1: Personalized recommendation algorithm structure diagram of intelligent shopping robot system

through preprocessing, which includes three processes: word segmentation, stemming, and space deletion. In the process of semantic word extraction, the semantic words in the dictionary will be extracted by matching with the extracted keywords. The next process is feature extraction, extracting the joint holographic entropy and cross holographic entropy of all keywords, and further conducting feature selection based on conditional holographic entropy. Finally, a deep belief network (DBN) is used to classify the selected features, which is a high-performance deep learning algorithm [8]. Qi, X adopts an intelligent information retrieval method based on human-computer interaction (HCI-IRM). The proposed method focuses on customer satisfaction, which is the main success evaluation indicator. It identifies the set of related records at a given time in the set. The main goal of information retrieval systems is to obtain information [9].

In addition, for some small sellers, such as shops on Taobao, employees are still traditionally employed to do online customer service. Firstly, due to time constraints on users' purchases of goods (the service hours of online customer service are usually from 9:00 pm to 9:00 am), a portion of customer traffic will flow away; Secondly, hiring online customer service will increase payment costs, which is a significant expense for small businesses. If intelligent shopping robots are used to replace online customer service, it will save sellers a lot of costs.

3. Detailed description of recommendation algorithms for intelligent shopping robot systems.

3.1. Algorithm Overview and Structure Diagram . The first step is to obtain the user's current purchasing tendency based on their basic information or purchase logs, in preparation for recommendations.

The second step is to compare and analyze the current purchasing tendency data with the product feature data, obtain the user's current preference for product features and recommendation reference groups, and combine the product feature database and product recommendation evaluation function to make the current recommendation [10].

The third step is to make real-time recommendations based on the dynamically updated user personality knowledge base, guiding users to be satisfied. The structure of the recommendation algorithm is shown in Figure 3.1.

3.2. Explanation of concepts and formulas in algorithms.

3.2.1. Product characteristics. The requirement for product features in this algorithm is that product features are objective and descriptive, and these features are consistent with the descriptions in the product knowledge base that records product features, such as price, color, pixels, etc [11]. In order to describe product features, the product feature database we have established can be represented by vectors as follows:

$$P(m) = (f_{11}, \cdots, f_{1k}, \cdots, f_{ik}, \cdots, f_{ij}), m = 1, 2, 3, \cdots, M \tag{3.1}$$

M is the total quantity of a physical product (such as a mobile phone) m, i is the product feature number (such as color, price), and j represents the jth feature value of feature i (white, 2000 yuan), the meaning of feature k is that the feature domain of each product feature is not fixed, and each f_{ij} is represented by a true or false value. If the product has this feature, the value is 1, otherwise it is 0.

3.2.2. Current purchasing tendencies of users . Generally speaking, users always frequently inquire about the products they care about when purchasing, reflecting their willingness to purchase. Therefore, we believe that among all the product categories that users are currently consulting, the one with the highest number of inquiries is the user's current purchasing tendency, and the type of product also belongs to the category of product features. Therefore, the user's current purchasing tendency is also a feature entity of product features. For the feature entity set $K = (K_1, \cdots, K_i, \cdots, K_n)$ of category features, the user's current purchasing tendency $K_t = K_i$, and K_i are the category feature entities with the highest number of user inquiries [12].

3.2.3. User preference for product features. Analyze the user's preference for product features based on their purchase logs during a certain period of time, and then assign corresponding weights to these product features based on their preference, that is, the user's current preference for features.

The definition of favoritism is as follows: Statistical analysis of some product features purchased by users during a certain time period, preference C_i for feature i; The ratio of the number of features i included in the product purchased by the user to the total number of features in the purchased product is calculated using the formula:

$$C_i = \frac{m_i}{\sum_{j=1}^{n} m_j} \tag{3.2}$$

Among them, n represents the number of statistical product features (such as the brand and color of the phone), m_j refers to the number of products purchased by users within a certain period of time that contain a certain feature [13].

3.2.4. Similarity matrix of product feature entities.

(1) Similarity of entities. Let the user's ratings of feature entity i and feature entity j in the M-dimensional space be expressed as the similarity S (i, j) between feature entity i and feature entity j in vectors $\overline{i}$ and $\overline{j}$, respectively

$$S(i,j) = cos(\overline{i}, \overline{j}) \tag{3.3}$$

$$cos(\overline{i}, \overline{j}) = \frac{\overline{i} \cdot \overline{j}}{||\overline{i}|| \times ||\overline{j}||} \tag{3.4}$$

Among them, the numerator is the inner product of two feature entity rating vectors, and the denominator is the product of the modules of the two feature entity rating vectors.

The rating matrix is considered as a rating on an m-dimensional space, $u_1, \cdots, u_m$ represents m types of products (such as m different models of mobile phones). If a user does not rate a feature entity, the user's rating for that feature entity is set to 0.

(2) Similarity Matrix of Product Feature Entities. For the feature entity set $I = \{i_1, i_2, \cdots, i_{n-1}, i_n\}S$ of a certain feature, use matrix S to represent the similarity matrix. The similarity value is calculated using formula 3.2.

Through observation, it is not difficult to find that matrix S has the following characteristics:

$$S(i,j) = S(j,i) = 1 \tag{3.5}$$

Therefore, only upper triangular matrix or lower triangular matrix can be considered in the calculation, which is conducive to simplifying the calculation[14].

3.2.5. Recommended values for product feature recommendation groups . Multiply the similarity in each feature similarity matrix by the preference of the product features in the recommendation group, and then add them to obtain the recommendation value of the recommendation group, expressed in RV. The calculation formula is as follows:

$$RV_{ij} = \sum_{i=1}^{n} S_{m,n} \times C_m \tag{3.6}$$

Among them, i represents the i-th reference group, j represents the recommended group for group j, and $S_{m,n}$. The similarity between feature entity m of a certain feature and feature entity n, which is the element in the product feature entity similarity matrix, C_m is the user's preference for feature m, and n is the number of selected main features.

3.3. Personalized recommendation algorithm based on product features . We determine the user's current purchasing intention based on the number of inquiries they make about a certain product during human-machine communication, and use the feature entity with the highest number of inquiries as the user's current purchasing intention. For example, for the entity feature set K=Huawei, Samsung, Apple..., firstly, based on the consulting statistics of current users, it can be concluded that the user's current purchasing tendency is: K==Apple. Secondly, by analyzing customer purchase logs, the preference degree C of each feature is calculated using formula (2), and then sorted based on the size of the preference degree value, considering the accuracy of the calculation, only the features with preference ranking in the top n are used for recommendation in actual recommendations. For example, by analyzing the purchase logs of a user during a certain period of time and calculating according to formula (2), the sorted result is: The preference for brand, color, weight, and corresponding features is 0 285 0. 197 0. 135…

3.4. Recommended Reference Group for Obtaining Features . After obtaining the user's preference for features, first sort the preference horizontally, through further analysis of user purchase logs, the physical features of each feature are vertically sorted based on the number of customer inquiries. Each set of feature entities serves as a basic recommendation reference group. Select the first n basic reference groups as the recommendation basis[15]. Consider further expanding the scope of recommendations, we can cross the features of each group of feature entities with the highest similarity and those with a preference ranking second to others to form a new feature recommendation group. If we take the first n groups, theoretically we can obtain n recommended reference groups. For example, the features sorted based on preference values are: brand, color, weight.

3.5. Calculate the recommended value of the recommendation group for product recommendation . After obtaining the recommended reference group, recommendations can be made based on the first group and the recommended value of the recommended group can be calculated. Based on the reference group, recommend the recommendation group through the similarity matrix of each feature.

The reference group itself is the first recommended group obtained, because the entities of each feature have the highest similarity (similarity of 1) in the similarity matrix [16]. Then find the feature with the second highest similarity in the similarity matrix, which can result in the 2nd, 3rd, and i-th groups, here, i is related to the recommendation accuracy and can be limited according to actual needs. Then, based on the formula for calculating the recommended value, relevant calculations can be performed to obtain the recommended value for the recommended group. Taking the first set of reference groups as an example, because the similarity of the same entity features between the first set of features is 1, the first recommended group obtained is the first set of reference groups themselves, namely apples, white, according to the formula, the recommended value is RV11=1 * 0.285+1 * 0.197+... next, for the first reference group, find the second most similar feature in the similarity matrix of each feature, for example, in the brand similarity matrix, after comparing and searching, it is found that Samsung ranks second to Apple, with a value of 0.82, in the color similarity matrix, black comes next to white with a value of 0.62, and other features follow suit, so, through the first reference group, the second recommended group was obtained, namely Samsung, black, according to the formula, the recommended value is RV12=0.82 * 0.285+0.62 * 0.197+... The same method can be used to obtain the recommended group and its recommended value RV based on the i-th reference group.

3.6. Product recommendation based on recommendation group. The feature recommendation groups were obtained above, and all recommendation groups were sorted according to their recommendation values. Select the feature recommendation group ranked in the top n as the recommendation group for users. At this point, the user's current purchasing intention (i.e. the feature entity of the category feature) is combined with the recommended n sets of feature recommendation groups to obtain n products. Then, based on the obtained n products, the product feature knowledge base is matched, if the product exists, recommend it. Otherwise, add the recommendation group one by one after the recommendation value reaches n digits, and

Table 4.1: Experimental results of the first group

Number of training corpus	Number of evaluation corpus	Returns the number of correct answers
100	20	14
100	50	40
100	80	72

Table 4.2: Experimental results of the second group

Number of training corpus	Number of evaluation corpus	Returns the number of correct answers
200	20	15
200	50	42
200	80	73

then continue to recommend and match until it is added to the recommendation group with the recommendation value ranking last. For example, RV11 ranks first and calculates that the type of entity that customers are currently inclined to purchase is an Apple phone, based on the combination, the features obtained are white, etc. Then, based on the features, match the product feature library. If there are products that meet the feature conditions, recommend them. If it does not exist, proceed to the next group of recommendations [17].

4. Experimental Results and Analysis. The training data for this experiment comes from 365 5G mobile phone store Q&A phrases provided by PT37 company, which means the training set consists of 365 question answers. The test data adopts 100 randomly selected questions from user question records.

(1) The first group of experiments.

1.Training corpus 100, evaluation corpus 20

2.Training corpus 100, evaluation corpus 50

3.Training corpus 100, evaluation corpus 80

(2) Second set of experiments.

1.Training corpus 200, evaluation corpus 20

2.Training corpus 200, evaluation corpus 50

3.Training corpus 200, evaluation corpus 80

(3) The third group of experiments.

1. Training corpus 300, evaluation corpus 20
2. Training corpus 300, evaluation corpus 50
3. Training corpus 300, evaluation corpus 80

(4) Group 4 Experiment.

1. Training corpus 300, evaluation corpus 100
2. Training corpus 300, evaluation corpus 200
3. Training corpus 300, evaluation corpus 300

The statistical results of the first group of experiments are shown in Table 4.1.

The statistical results of the second group of experiments are shown in Table 4.2.

The statistical results of the third group of experiments are shown in Table 4.3.

The statistics of the fourth group of experimental results are shown in Table 4.4.

Set the number of evaluation corpora to fixed values (set to 20,50,80 respectively), and gradually increase the number of training corpora (100200300) to obtain Tables 4.5, 4.6, and 4.7.

Summarizing Tables 4.5, 4.6, and 4.7 it is clearer to see the trend of increasing the number of training corpora and testing expectations, resulting in an increase in system accuracy.

Table 4.3: Results of the third group of experiments

Number of training corpus	Number of evaluation corpus	Returns the number of correct answers
300	20	18
300	50	46
300	80	78

Table 4.4: Experimental results of the fourth group

Number of training corpus	Number of evaluation corpus	Returns the number of correct answers
300	100	93
300	200	192
300	300	294

Table 4.5: The number of evaluations in Table 5 is 20, and the number of training corpora gradually increases from 100 to 300

Number of training corpus	Number of evaluation corpus	Returns the number of correct answers	Accuracy
100	20	14	0.7
200	20	15	0.75
300	20	18	0.9

Table 4.6: The number of evaluations in Table 6 is 50, and the number of training corpora gradually increases from 100 to 300

Number of training corpus	Number of evaluation corpus	Returns the number of correct answers	Accuracy
100	50	40	0.8
200	50	42	0.84
300	50	46	0.92

Table 4.7: The number of evaluations in Table 7 is 80, and the number of training corpora gradually increases from 100 to 300

Number of training corpus	Number of evaluation corpus	Returns the number of correct answers	Accuracy
100	80	72	0.85
200	80	73	0.9
300	80	78	0.975

Through the comparison and analysis of the experimental results in Tables 4.5, 4.6, and 4.7, we can clearly see that the accuracy of the system is constantly improving under the condition of increasing question/answer knowledge pairs [18].

Especially when observing Table 4.7 obtained from the fourth group of experiments, when the number of training corpora increased to 300, 100, 200300 tests were used to predict the evaluation, and the accuracy of the system was 0.85, 0.90, and 0.98, respectively, as shown in Figure 4.1.

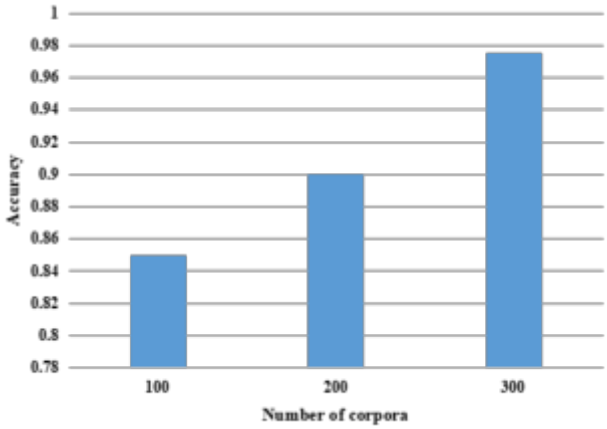

Fig. 4.1: Accuracy of the system

Such a system is perfect for natural language processing, so we can improve the system by expanding and improving the knowledge base.

The intelligent shopping robot recommendation system studied by the author is still in the analysis and demonstration stage, sincerely hope that the processing method used in this project can have reference significance for similar recommendation systems in the near future[19].

5. Conclusion. The author proposes natural language processing algorithm based on semantic template and personalized recommendation algorithm based on knowledge base. The natural language processing algorithm based on semantic template proposed by the author is more accurate and effective than the traditional natural language processing algorithm. The recommendation algorithm proposed by the author starts from the user's personal basic information and past purchase logs, analyzes the user's purchase behavior, obtains the user's current purchase intention, and updates the user's personalized knowledge base by tracking and recording the user's consultation and browsing behavior, it continuously makes real-time recommendations for the user, and ultimately recommends products that meet their interests.

FUZZY BASED DECISION-MAKING ALGORITHM FOR SOLVING BIG DATA ISSUES IN SMART CITIES

WEINING LI*AND HUI ZHU†

Abstract. To better provide urban services and build an increasingly sustainable architecture, big data can be used to make more efficient use of current assets while enhancing the caliber of services offered to local inhabitants. However, there are several challenges to incorporating big data into existing infrastructure. Therefore, this research aims to determine the problems associated with Big Data's effectiveness in developing intelligent towns and to investigate the connections between those difficulties. The 14 issues with Big Data were found through a literature study, and the precision was checked by feedback from professionals. Next, we employ a combined approach based on fuzzy interpretation, Structured simulation, and the Fuzzy Making Decisions Trial and Assessment Laboratories to decipher the connections between our identified problems incorporating Big Data into the development of smart cities is hampered, as shown by the analysis of links between challenges, primarily by the heterogeneous inhabitants in developed cities and the lack of connectivity. The findings of this study will provide creative city practitioners and policy planners with the information they need to successfully tackle these obstacles, clearing the way for the widespread adoption of smart city technologies. This research is a first step towards creating an interpretive structural model of the difficulties brought on by Big Data in cutting-edge urban planning. The study attempts, in part, to use this paradigm to better understand the relationship among the highlighted issues.

Key words: Big Data, Difficulties, Environmental Sustainability, Intelligent towns, Fuzzy DEMATEL, and Fuzzy Interpretation Structured Modelling (fuzzy ISM)

1. Introduction. The innovative town concept offers a practical solution to the issues of rapid global urbanization. The IoT, artificial intelligence (AI), and information analysis are just a few of the latest technological advances cities worldwide are exploring to improve a wide range of services municipalities provide. Municipalities also aggressively promote the use of digital technology to advance modernization and the creation of novel business models, with the goals of strengthening regional economies and enhancing social well-being. The smart city market is growing, but there is a concomitant fragmentation of smart city markets and programs, which raises concerns about administration, environment coordination. Transforming a municipality into a "smart city" is a lengthy and complicated endeavor that necessitates the involvement of several stakeholders and the ability to evaluate the potential of numerous novel digital technologies to improve a wide range of municipal operations. The smart city's management and leadership are significantly taxed as a result. This research aims to aid municipalities in accomplishing this objective by providing a smart city conceptual model [1,2,3,4].

In order to help participants in smart cities guide their communities towards a smart city supported by data and digital technologies, SCCM studies complex smart cities from both an organizational and a technical perspective. SCCM considers four main factors: strategy, technology, governance, and stakeholders. Each central element is accompanied by supporting aspects, which collectively generate substantial connections and provide a comprehensive and methodical approach to smart city strategy, creation, and deployment [5-6]. To enhance smart city design and ecosystem governance, this study created and presented a smart city conceptual model (SCCM). The Smart City Change Management (SCCM) framework was created because urban areas lack the resources to manage sophisticated smart city ecosystems and the rapid advancement of digital technologies. These issues cause a high rate of premature smart city initiatives to collapse once project funding has been depleted. The primary goals of the Smart City Capacity Model (SCCM) include

†Department of Human Resources, Guilin University of Technology at Nanning, Nanning, Guangxi, 530001, China (Corresponding author, HuiZhu9@126.com)

- aiding smart city professionals in developing a long-term smart city vision and strategy,
- easing the management of multiple stakeholder interactions and digital technologies, and
- assessing potential dangers and costs

The ultimate goal of SCCM is to help remove barriers to the creation of creative business models and the creation of value inside smart city ecological systems while also empowering smart city stakeholders to better plan and assess smart city efforts. SCCM consists of the four main components, as well as the sub-components of strategy, technology, governance, and stakeholders. SCCM generates meaningful interrelationships between its various elements and subdivisions and offers a thorough framework for the design of smart city initiatives and environments [7,8].

Though there are many challenges to overcome, smart cities are increasingly turning to Big Data Analytics (BDA) to maximize their usage of existing infrastructure. Therefore, the primary purpose of this study is to examine the significant challenges that prevent BDA from being used to build smart cities [9,10]. To reach our objective, we first had to catalog the 13 roadblocks to BDA acceptance, and then we used the Best Worst Method (BWM) to rank them in order of importance. According to the results, three main factors are holding back the use of big data analytics (BDA) in creating connected cities: the intricate nature of the data, the need for a framework for using BDA, and appropriate technology. This research's most noteworthy contribution is its proposed technique for analyzing the barrier to BDA adoption associated with smart city growth. Regulators and managers may find the established method helpful in examining the barriers that prevent BDA adoption in smart city planning, design, and development. The study's findings can be used to facilitate the rapid growth of smart towns by removing these stumbling blocks. In order to provide better services to their citizens, smart cities are the subject of this research, namely how BDA can be included in their development. To this end, a systematic approach has been created to identify and prioritize the most critical barriers to implementing BDA. Two steps are used to determine the BDA barrier: a review of relevant literature and advice from subject matter experts. Once problems have been isolated, the BWM ranks them according to severity. The finding demonstrates that data difficulty, the lack of a framework for adopting BDA, the lack of technological solutions for BDA, and the lack of efficient processing platforms for massive volumes of data are significant challenges. Government officials and city planners invested in the innovative city development process should focus on overcoming these most pressing barriers [11,12,13,14].

Experts in sectors as varied as environmental protection, technological innovation, structural engineering, and others are being asked to weigh in on the selected criteria' relevance, reliability, and interconnectedness . After deciding on what dimensions and criteria will make up the hierarchy, the IF-AHP approach is used to assign weights to each. In conclusion, the emergence of smart cities is evaluated using the IF-DEMATEL method, which considers the relative importance of many factors in shaping this development. The proposed framework illustrates how smart living and governance, smart economy, and smart environment are the bedrock for the successful implementation of smart city efforts [15].

An investigation found that the outcomes of IF-AHP are frequently used to build immediate decisions by identifying the significance and priority of the parameters and criteria that affect smart city development . If the IF-DEMATEL results analyze the complex interdependencies between the parameters and requirements and classify them as causes and effects, the impact of making choices could be enhanced for a more extended period. This study provides a methodology for improving the performance of cities, particularly in developing nations, and its findings are similar to those of previous studies [16-18]. It also identifies preference dimensions and regions that can be used. This research aims to help policymakers by comparing the current situation to that of competitors and identifying the areas that need development to ensure longevity.

The rapid expansion of cities to satisfy the requirements of an ever-increasing population has resulted in various issues, including an increase in pollutants and congestion, an absence of sustained sustainability, and an effect on the natural environment. The idea of "smart cities," including "intelligent convergence systems," has been proposed as a potential solution to these issues. The concept of a "smart city," which would be based on communication, knowledge, and technology, arose to mitigate the adverse effects of industrialization. In light of this, a significant amount of effort has been put towards creating metropolitan areas that are more considerate of the environment and cleaner [19]. Still, there is a pressing need for extensive research into the difficulties associated with developing and evaluating intelligent cities in developing nations, particularly in

Africa. The only way to judge the success of such endeavors and the degree to which they were successful is through meticulous examination and contrast based on pre-existing criteria. As a result, this research aims to investigate and assess the most important aspects and requirements for SCD in the context of Morocco's intelligent cities. Let us hope that this study will assist us in reaching our objective.

2. Related Work. This article uses Nigeria's economy as an example to give a fuzzy-synthetic analysis of the obstacles to achieving the promised land of connected cities in developing countries. Defining and outlining the country's problems is a necessary first step toward establishing intelligent cities. The research adopted a method of deductive reasoning informed by progressive philosophy [20]. A planned survey was used to collect information from professionals in the built environment involved in delivering publicly funded buildings in Nigeria. Based on the previous research, we isolated and examined six problems associated with innovative city development. In addition to the issues of the economy, society, technology, and the environment, there are also governance-related issues. Cronbach's alpha was used to check for internal uniformity, the Shapiro-Wilks test to ensure data were normally distributed, the Kruskal-Wallis H-Test to ensure homogeneity and the Fuzzy synthetic assessment test was used to provide a holistic analysis of the challenges involved in becoming a smart city. It was determined that each of the six factors examined might significantly affect future smart city development in Nigeria. More specifically, environmental, technological, social, and legal difficulties are rising to the forefront. The adopted fuzzy synthetic approach provides clear and practical insight into the obstacles that must be overcome before the objective of building smart cities in underdeveloped nations can be realized. The present discussion on "smart municipalities" has paid less attention to Nigeria than it should have. This paper provides a solid theoretical foundation for future research on developing smart cities in developing countries, particularly in Africa, where conditions are similar to those observed here because it lays a solid theoretical groundwork for further study [21]. According to the study's conclusions, the country has much more important issues to deal with before it can even begin to explore the potential of urban renewal. High development, rapid population expansion, poor infrastructure, impoverishment, insufficient laws and rules, financial turmoil, and weak administration are the only issues plaguing today's world. Therefore, the results are instructive for the government and other stakeholders accountable for the city's development and the issues that must be resolved. This is an essential factor for politicians to consider if they care about fostering social equality for their constituents [22,23].

However, despite these limitations, the study still provides essential insights into the challenges involved in innovative city development. The strategy employed is what matters most. A mixed-method approach, beginning with the Delphi methodology to assess the difficulties identified in the primary literature and then moving on to extra statistical assessment techniques, may prove useful in future studies[24]. This will facilitate a more nuanced understanding of the challenges connected with smart city growth. One of the essential things that can be done to increase social responsibility is to integrate social, economic, and ecological perspectives. One of the most commonly claimed goals of smart city activities is to improve the standard of living of local citizens. By expanding the SCCM to include social and political factors, we may create smart cities that are both resilient and sustainable. Indicators that can be utilized to measure and assess the various smart city activities are also highlighted to aid in the management of innovative city initiatives and guarantee their achievement [25,26].

This research was undertaken to contribute to the continuing conversations about planning's place in the development of smart cities, make the argument for rethinking the tech-centric definition of a smart city, and give city planning a more prominent voice. The key dispute is that integrating city planning with three types of technology and science can significantly benefit residents. Examples of such fields include Big Data, spatial information systems, and Data Science. These three areas are coalescing into what is being called "Geospatial Artificial Intelligence." Here are the two broad policy objectives: to 1) make city services and operations more efficient and 2) raise everyone's standard of living [27].

The paper also defines a focused on people theoretical structure that shows how interdisciplinary collaboration between urban planning and the three technological-scientific domains can improve management practices and achieve smart-city policy objectives. Our research methodology will include an in-depth analysis of the current research on the topic. The paper reviews the exciting developments that have recently occurred at the crossroads of urban development and geo-artificial information. Also, it highlights the challenges that prevent

geo-artificial intellect from successfully integrating into intelligent cities' creation, construction, and supervision. This study argues for reconsidering the smart city from an angle with a lower emphasis on technology to add to the continuing conversation about intelligent city construction in the modern era. We are going to finish the article having accomplished both of these goals [28,29].

In order to achieve the four overarching policy objectives, this paper proposes a people-centric framework for the bright city concept that leverages collaboration between urban planning and the academic fields of Big Data, Geographic Information Technology and Systems, and Data Science to form a new discipline known as Geospatial Artificial Intelligence (GeoAI): Objectives include, but are not restricted to 1) improving the quality of life for all city residents; 2) enhancing the effectiveness of urban services and operates; 3) addressing the critical social, environmentally friendly, and financial problems that threaten to destabilize urban systems at all scales; and 4) contributing to the creation of geographic information, data, and expertise on human-environment behavior. This article lays the groundwork for a new understanding of knowledgeable urban development by demonstrating how our proposed human-centric, GeoAI-enabled city-building structure can address not only the technical-instrumental challenges but also the socio-political, normative, and ethical concerns that currently and in the future plague urban areas [30].

There are two points here that should be kept in mind. The suggested structure is based on the idea that planners should have a more significant hand in designing, constructing, and administrating future intelligent cities, which will be run in part or entirely by distributed computer systems and ingrained digital sensors and actuators. Intelligent towns' development, design, and oversight can incorporate human aspects, collaborative leadership, and contextually aware criteria. When assessing the smart-city agenda's short- and long-term effects on the economy, environment, society, and built environment, planners are in a prime position to take a holistic view [31]. Our position is that planning should play a substantial role in implementing GeoAI and other smart-city technologies to safeguard the public interest and the needs of marginalized communities. Although we share these beliefs, we recognize that other academics may disagree and that the future role of architects in smart cities is still an open subject [32].

Furthermore, designers have historically played a significant role in various corporate and public spheres; nevertheless, other disciplines may eventually dominate these sectors. Second, many scholars have worked tirelessly over the past decade to close the gap between planning for cities and urban design (design-based, mechanical organizing) and the policy-based, socioeconomic planning commonly known as urban planning. The disciplines of city planning and urban design are vastly different. Additionally, the growth of zoning reforms, particularly the rising acceptance of form-based code, has created new circumstances to reconcile the design-oriented and policy-based realms of planning. The advent of form-based code and the development of zoning reforms contributed to this possibility. Motivated by these changes, this paper proposes a new paradigm for urban planning as a profession that combines urban design and urban planning. The document also offers a comprehensive strategy for future development. Still, we are realistic about how difficult it will be to achieve the necessary level of regional cohesion. Planners can come from a wide range of educational and occupational backgrounds, and their career goals and foci of study reflect this diversity. Planning experts may also view the built environment from different perspectives. We also believe that the confluence of planning many practices and research activities can be aided by establishing a clear vision and well-defined policy goals. The study's four policy goals stimulate cross-disciplinary cooperation and apply to various planning specializations.

It is clear from the research projects described in the study that GeoAI has opened up vast opportunities for collaboration between professionals and researchers in the field and between urban planners and researchers from other disciplines. Future studies may try to ascertain whether or not the use of GeoAI will influence the precision with which plans are executed[33].

The paper demonstrates how GIScience could methodologically and theoretically shape a GeoAI-based approach to planning, building, and managing intelligent cities through several analytical and practical examples. The concept of "smart cities" is a backdrop for these illustrations. For instance, our findings suggest that Critical GIS may enhance any GeoAI-based analytical framework focusing on smart cities. This is because Critical GIS promotes equity and social justice as the fundamental values of future smart cities by providing novel socio-spatial and technical tools for better visualizing spaces of flow, association, and network (Batty, 2013a). In addition, the article elucidates the challenges that smart cities face while trying to use GIScience solutions.

For instance, the potential for GeoDesign to function as an effective planning support tool in the context of smart cities was proven in Section 3. GeoDesign not only paves the way for a straight, concerted city planning framework to tackle multifaceted planning tasks with communities but also provides a platform for meaningful civic engagement and deep public participation. It helps to address acute challenges that will face cities in the future, such as interchange congestion and air pollution. However, we recognize that the success of GeoDesign depends on a vast number of parameters, much like the success of any other SDSS product. Factors including public confidence in planning authorities, local expertise in relevant fields, and institutional and organizational hurdles play a role. These and other variables can make it hard to use organizational aids effectively in the actual world [34].

This research also suggests several future lines of examination at the crossroads of developed city preparation, GeoAI, and Big Data, such as how government agencies can use geospatial AI to find health disparities, evaluate community requirements, distribute resources equitably, or predict economic classes. Shifts like development in communities while safeguarding the desires of the most marginalized residents? To reduce the overall building costs related to reasonable housing while expanding its beneficial financial and social consequences, how could SDSS methods maximize growth rewards and funding processes and discover properties ideal for housing construction. How can local transportation organizations use GeoAI's features to plan a multi-modal transportation network that accomplishes objectives like decreasing carbon footprints while increasing the availability of dwellings, amenities, and employment possibilities? How can we use the SDSS to locate ecologically fragile regions and human communities at risk from global warming? How can city planners prepare for recovery following a disaster and the possible relocation of sensitive neighborhoods? How can they build scenarios to lessen the impact of disasters? Because it is based on a literature review, the number of obstacles that can be identified is limited. The procedure has this downside. Prioritization is based on the expert's input, which might be biased depending on the expert's working level and can come from various disciplines. It is also possible to use fuzzy and grey theories to deal with the partiality of expert input, which is one of the drawbacks of research. Including instances from developing countries would significantly increase the reach of this inquiry. Future work may use Interpretative Structural Modelling (ISM) or Integrated Structural Modelling (TISM). Future studies could explore the observed barriers by employing various multicriteria decision-making (MCDM) techniques, such as the Base Criteria Method (BCM), CoCoSo, or others. The results of this research are expected to help people better understand the BDA barriers in modern urban areas.

In the case we have been given, the IF-AHP is used to analyze the problem's structure and to calculate the scores of the quantitative and qualitative dimensions/criteria using the ambiguous values provided by the experts. Later on, MCDM employs IF-DEMATEL to build the structural relationship among measurements and criteria. Intuitionistic fuzzy set theory helps deal with the vagueness of human language and the uncertainty of expert opinion. The results suggest that 'Smart Living and Governance' and 'Smart Economy' significantly influence SCD in Morocco.

The proposed approach prioritizes improving intelligent cities' decision-making capacities by understanding the dimensions/criteria and situations that distinguish smart cities from conventional ones. The managerial ramifications, results, findings, constraints, and potential future applications are also discussed.

The primary goal of this research is to examine the most critical factors and aspects that affect smart city development projects in poor nations, focusing on the Moroccan context. A novel framework employing the IF-AHP and IF-DEMATEL approaches has been created for this purpose. First, we conduct a comprehensive literature review and document review on creating smart cities to collect the most important criteria.

3. Research Methodology. Elements of fuzzy ISM and DEMATEL are combined into the approach that is discussed in this research. It is good knowing that the ISM and DEMATEL approaches are both powerful and valuable instruments that facilitate the process of decision-making. In order to convert the contextual link between variables into a hierarchical and fundamental model, the ISM technique takes an interpretive and iterative approach. If researchers want a deeper understanding of how the variables interact with one another, they could consult the structural model. The fuzzy information support model (ISM) was chosen for this investigation because it makes more efficient use of the subjective aspects of expert judgment. In addition, based on fuzzy logic, the ISM technique provides flexibility for the expert's preliminary evaluation to be adjusted and improved.

The direction of the link between complicated variables has been better understood with the help of fuzzy DEMATEL approaches. This investigation uses both fuzzy ISM and fuzzy DEMATEL in its methodology. This method makes it possible to investigate cause-and-effect relationships to shed light on the intricate dynamic between the various decision-making factors. A few case studies have been conducted to evaluate the novel combination of ISM and DEMATEL techniques. Both fuzzy ISM and DEMATEL can classify decision factors according to their driving and reliance power.

In contrast, fuzzy DEMATEL can also classify decision elements according to their predominance and connection. Using these strategies, the complex relationship can be uncovered even in an area with much mist. Even though it is successful at building a causal model between the many components of the system, the Fuzzy Integrated Systems Model (FISM) has some drawbacks in that it cannot quantify the strength of the links between the various components of the system. The DEMATEL methodology makes it possible to do statistical research on links. In order to obtain information that is useful, this study employs an approach that is a combination of fuzzy ISM and fuzzy DEMATEL. Figure 1 visually represents the study design's three distinct stages.

Phase I. Difficulties to implementing Big Data in smart city initiatives are identified and validated. At this point, we have used a method that incorporates both previous research and the insights of subject matter experts.

Phase II. Examining how the various obstacles to implementing Big Data in smart city initiatives are interconnected. First, the fuzzy ISM-MICMAC method is used to explore the historical interaction among the major issues, and then, based on their driving and dependent powers, these difficulties are sorted into several categories.

Phase III. Classification of the problems found. In this step, the link of causality between the complicated issues is analysed via a chart, using the fuzzy DEMATEL technique. Furthermore, difficulties are sorted into a reason and impact category based on the prominence and effect score. Administrators will benefit from this classification when developing an approach to fully exploit Big Data's potential applications in smart cities.

By holding a workshop to develop solutions to problems identified in the literature, this research makes the most of the participants' varied areas of knowledge. Later, in fuzzy DEMATEL, experts aimed to construct a contextual link in order to evaluate the difficulties differently based on the relative importance of each. A total of eight professionals with extensive experience managing Big Data and smart cities initiatives took part in this exercise. The following section will elaborate on the fuzzy ISM and fuzzy DEMATEL approaches.

4. Proposed Methodology.

4.1. Building Structures using Fuzzy Interpretation. The ISM method is widely used for modeling and categorizing interdependencies between different parts. Integrated system simulation, or ISM, creates a holistic, systematic model from a set of constituent pieces that are conceptually distinct but operationally interdependent. ISM considers the connections between parts of a system while creating a model. This method converts abstract ideas about a system into a concrete, hierarchical model that may be easily understood. The fundamental understanding of fuzzy inference and support mechanisms (ISM) uses several people's knowledge to construct a multifaceted model. It was implemented in earnest in the 1970s. Many researchers have used this instrument during their soft modeling investigation of intelligent businesses. Researchers provided a grading and value system based on a scale from 0 to 1, with 0.1 indicating fragile interaction dominance, 0.9 indicating extreme dominance, and 0.5 indicating a medium degree of domination. This was done using the Fuzzy ISM method in mind. Only a robust correlation will be considered, as measured by this metric. Fuzzy ISM adds value because it helps decision-makers focus on what matters. Here is a rundown of the broad procedures utilized in Fuzzy ISM in figure 4.1.

In the first step of the process, a conceptual self-interaction matrix, also known as an SSIM, is created by investigating the underlying connections between the previously obtained issues from the research. Second, we develop an initial reachability matrix based on the SSIM by employing this binary representation of the language signs. The third phase in the process involves the generation of a final accessibility matrix once it has been established whether or not the initial matrix of reachability had any bidirectional interactions. In the process's fourth step, the final reachability matrix is converted into a fuzzy reachability matrix by determining which relationships are the most dominating. Step 5 involves classifying the barriers according to their levels

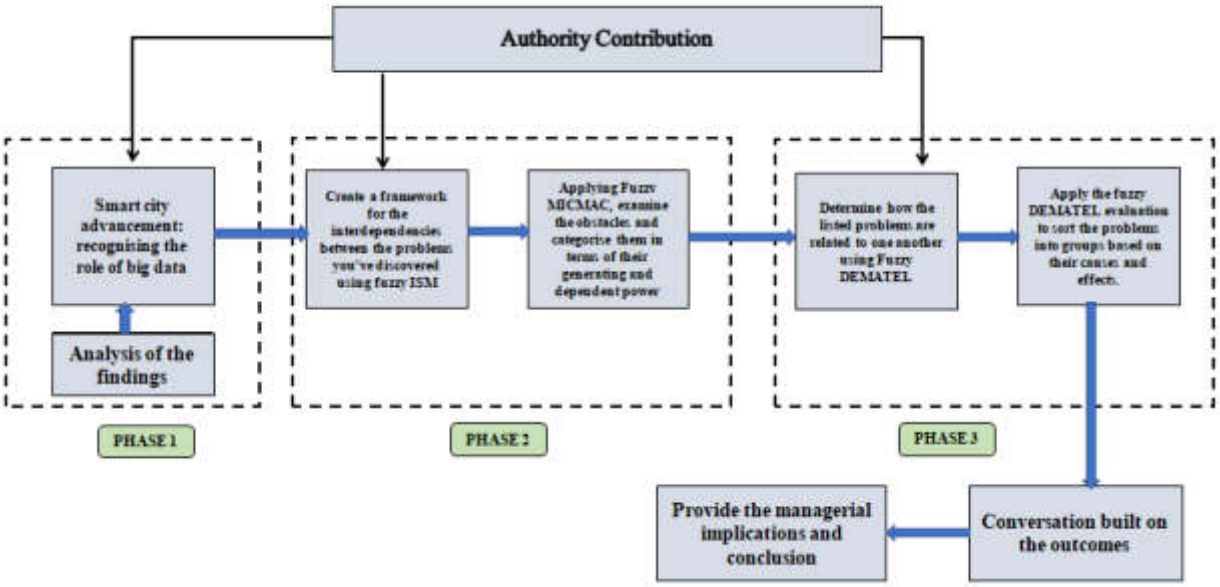

Fig. 4.1: Study design and rationale provided

of complexity. The sixth phase is creating the Fuzzy ISM model by classifying the challenges encountered. The newly developed Fuzzy ISM model is subjected to a thorough examination in Step 7 to identify and correct any theoretical errors.

4.2. Fuzzy DEMATEL. Between 1972 and 1976, researchers at the Battelle Memorial Institute's Geneva center developed a device called DEMATEL. This technique uses a causal graph to investigate the interconnections between the various parts. This strategy is often used to examine the connections between the many factors in reaching a choice. The authors used this technique to analyze the impact of the Internet of Things on the supply chain, evaluate the barriers to sustainable end-of-life practices, analyze the external barriers to refurbishment, benchmark the implementation of logistics management, and evaluate strategies to reduce the risk of sewer exfiltration. This strategy was used to accomplish all of these goals. The simulation allowed the researchers to examine the connections between the many obstacles to environmentally responsible supply chain management in the leather sector. The fuzzy DEMATEL model was also used to examine the challenges of getting Halal certification. The subjective character of the specialist's inputs led to an analysis that, in some places, reached a result that needed to be more transparent and correct. The fuzzy set theory provides a powerful tool to deal with uncertainty and imprecision. It gets its name from the inherent fuzziness of the underlying notion. Therefore, we combine the more conventional methods of ISM and DEMATEL with the fuzzy number to use the qualities that a fuzzy number gives. Triangular fuzzy numbers, trapezoidal fuzzy numbers, or both are commonly combined with MCDM techniques. Due to their computational simplicity, Triangular Fuzzy Numbers (TFNs) will be incorporated into this investigation alongside the DEMATEL. Breaking down the fuzzy-DEMATEL method into its parts yields the following.

Step 1. Build a matrix to determine what factors should be considered when evaluating language skills.

The expert's input is utilized to establish a five-point linguistic scale that is then used to create an assessment matrix of linguistic influence. Each expert had to weigh the significance of a single element against that of others (in this example, each barrier). In this statement, a_{ij} stands for "factor x greater than factor y". In the straight inflectional matrix, the values of the diagonal elements are all zero (that is, 0, 0, 0). It is possible to receive a non-negative n3n matrix from a single expert in the form of $A^k = [a^k_{xy}]$. In this way, we gather H matrices from H specialists in the field, with indices $A^1, A^2, A^3, \cdots, A^H$.

Step 2. Discover what matrix (A) represents the initial fuzzy direct relations.

Applying the three-dimensional (x, y, z) representation of the TFNs, we can calculate the fuzzy initial direct connection matrix $L = [b_{ij}]_{t\times t}$ using Equation 4.1, which we then use to do the linguistic evaluation.

$$b_{ij} = \frac{\sum_{k=1}^{H} a_{ij}^{k}}{H} \tag{4.1}$$

where "H" indicates the overall amount of expertise and "a_{ij}^{k}" represents the weight given to "i" by "j" in the opinion of the kth expert, "i" and "j" are both considered in the formula. Matrix "L" is unsuitable for matrix operations since its elements are fuzzy numbers. As a result, there is a need to convert hazy figures into more precise ones. Matrix operations require these fuzzy numbers to be defuzzed. For the purpose of defuzzification in this research, we use Equation 4.2 and the weighted average technique.

$$a_{ij}^{k} = \frac{1}{6}(s + 4t + u) \tag{4.2}$$

Step 3. Acquired the basic direct-relation matrix and normalised it to N.

$$[M]_{n\times n} = T \times [X]_{n\times n} \tag{4.3}$$

$$\text{where } T = min[\frac{1}{max\sum_{j=1}^{n}|x_{ij}|}, \frac{1}{max\sum_{i=1}^{n}|x_{ij}|}] \tag{4.4}$$

The [N]-by-[N] matrix, where every component's result is between 0 and 1.

Step 4. Utilise the entire Connection Matrix "R" Calculation in Equation 4.5.

$$[R] = [N][I - N]^{-1} \tag{4.5}$$

The identity matrix is denoted by "I" here.

Step 5. Equations 4.6 and 4.7 are used to determine the causative variables:

$$K = (c_i)_{n\times 1}[\sum_{i=1}^{n} t_{ij}]_{n\times 1}\forall_j \tag{4.6}$$

$$L = (d_i)_{1\times n}[\sum_{j=1}^{n} t_{ij}]_{1\times n}\forall_i \tag{4.7}$$

where "c_i" is the element-sum of the ith row of the matrix [R], and "i" is the factor whose influence (direct and/or indirect) is being measured. Similarly, the total effect (direct and indirect) that factor j got from the other factors is represented by d_j, which is the sum of the components in the j^{th} columns of the matrix [R].

Step 6. The significance (D_i) and neutral influence (F_i) rating are used to create a causal diagram. These ratings are determined by plugging values into Equations 4.8 and 4.9.

$$D_i = r_i + c_j|_{i=j} \tag{4.8}$$

$$F_i = r_i - c_j|_{i=j} \tag{4.9}$$

The significance of the degree of factor i is illustrated by the "$r_i + c_j$" phrase. The "$r_i - c_j$" word, on the other hand, illustrated the overall impact; the value added by element i. The value of "$r_i - c_j$" also determines where a given causal component falls inside a given effect group. If "$r_i - c_j$" is positive, then the component is part of the cause group; otherwise, it is part of the effect group.

5. Experimentation and Results.

5.1. Examination of Big Data difficulties in creating smart cities. In this piece, we'll dissect the intricate web of interdependencies that arise from using Big Data to build smart cities.

5.2. Implications of Big Data's Uncertainty in Fuzzy ISM Simulation for Smart City Growth:. The subsequent portions represent the discovered difficulties associated with using Big Data in the creation of smart cities according to the stages of fuzzy ISM approaches.

1. Correlation between problems in circumstances. First, with the aid of expert opinion in an idea engineering workshop, a conceptual correlation is formed between the highlighted difficulties through pairwise comparisons. L, M, N and O signs are utilised to complete the alphabetic SSIM, where

L- Both (i) and (j) are affected by (i), but not vice versa;

M- Both (i) and (j) are affected by (i), but not vice versa;

N- The (i) and (j) challenges are bidirectional challenges;

O- Problems (i) and (j) stand alone, unrelated to one another.

2. A matrix of possible actions in a fuzzy system is created. The SSIM matrix is subsequently transformed into a matrix consisting only of 0s and 1s; this matrix is called the initial accessibility matrix. The following are the guidelines for constructing the initial accessibility matrix.

a.If the value in cell (i, j) is V, then the value in cell (i, j) is 1, and the value in cell (j, i) is 0;

b.if the value in cell (i, j) is O, then the value in cell (i, j) is 0, and the value in cell (j, i) is 0;

c.if the (i, j) cell is X, then (i, j) = 1 and (j, i) = 1;

d.if the (i, j) cell is A, then (i, j) = 0 and (j, i) = 1;

e.if the (i, j) cell is Y, then (i, j) = 0 and (j, i) = 1;

It displays the results of this conversion to a fuzzy accessibility matrix, which takes into account the dominance of the links among difficulties. The strength and interdependence of different obstacles can be calculated by adding up the rows and columns of the fuzzy accessibility matrix.

3. Classification by level. In this stage, three sets are built using the final accessibility matrix: the reachability set, the antecedent set, and the intersection set. The range of difficulties that can be achieved includes the work at hand and any tasks inspired by it. The initial set includes not only the difficulties themselves but all the factors driving that task. Neither the accessibility set nor the initial set includes the problems unique to the intersection set. When a task's reachability set and intersection set yield identical results, the problem is classified as Level I and taken out of further iteration consideration. The data gleaned from this test was then used to shape the design of the subsequent levels.

Each iteration comes with varying difficulties, each tailored to a specific challenge.

Once the initial eight iterations have been completed, difficulty levels are assigned to each task, and the digraph is built by placing the tasks in the proper levels. The challenges of the first level can be found at the very top of the digraph. As the digraph's hierarchy decreases, the level number rises in tandem with it. The digraph is shown here in its transformed state as a hierarchical and structural model.

In line with the leveling, the fuzzy ISM model provides evidence of relative importance. All the other problems that arise when using Big Data to build intelligent cities stem from the two underlying difficulties, "Smart City diverse population" and "Technologies for Big Data and infrastructure faults," located at the bottom of the framework. The "Information intricacy" problem has progressed to the second level of the model's architecture. Level 1 problems, which include "Data Planning and Analytical Challenges" and "Information Interpreting Problems," have little impact on the model. All the other variables in the model serve as drivers for these. Its ability to motivate and rely on others is a sign that it is deeply intertwined with other problems.

The results of fuzzy ISM show how problems with innovation can impede the evaluation of enormous data sets and give rise to new challenges. Therefore, to mitigate the impact of other challenges, it is necessary to employ error-free systems and architecture.

5.3. MICMAC analysis. MICMAC is an abbreviation for "Matriced'Impacts cruises-multiplication applique," which means "cross-impact matrix multiplication used for categorization." Here, we use MICMAC to study the 14 tests that went into establishing the ISM model. According to Haleem and Khan (2017), the MICMAC analysis is performed to ascertain how much of a driving and dependent power the issues in a system

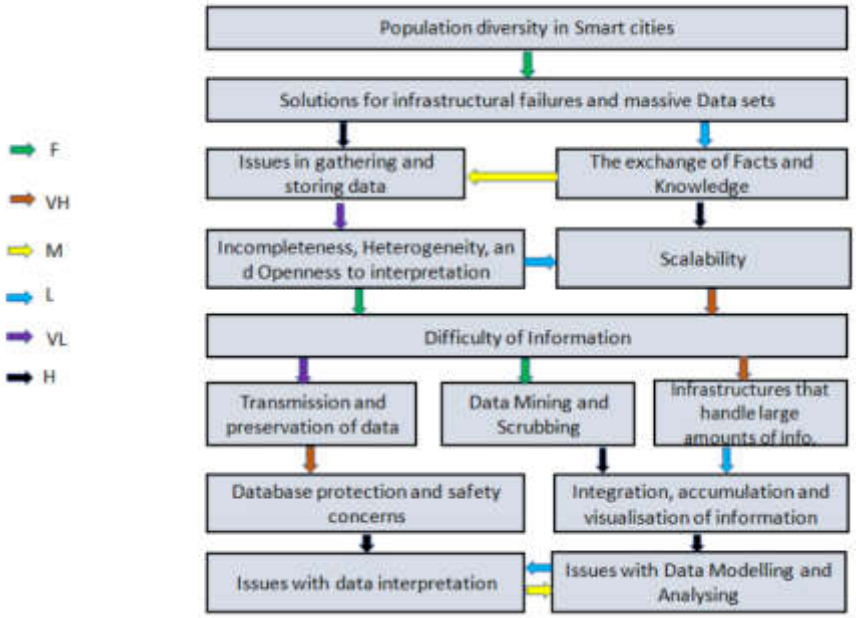

Fig. 5.1: Big Data problems in smart city development using a Fuzzy ISM-based model

have. See Figure 5.1 for a visual representation of this concept. In a two-dimensional in-nature rectangular plane, the dependence power is plotted along the abscess and the power that drives along the ordinate. Here, the impetus comes from a string that spans all pertinent challenges in figure 5.1.

Similarly, the sum of the ones in each column stands for the reliance on strength. The degree to which a difficulty can be overcome indicates its potential as a motivating factor. Reliance Power is a similar metric that assesses the impact of additional issues on the central ones. We have identified the root causes of all fourteen problems and established their interconnectedness. In addition, the challenges are partitioned into four distinct groups using this method. In the Table, we will see the results of the MICMAC inquiry.

5.4. Fuzzy DEMATEL analysis. This subsection will determine, through the use of the fuzzy DEMATEL methodology, the nature of the causal relationship among the aforementioned challenges that Big Data poses to the development of smart cities. The professionals evaluated the issues by placing each issue on a scale according to how important it was in comparison to the other issues using a language scale. An individual matrix is generated as a result of the responses provided by the specialists. After that, these matrices are transformed into a fuzzy connection matrix through the application of the triangular fuzzy number. In addition, the responses of the specialists are combined to produce the Overall Direct- Relationship Matrix, denoted by the letter A. In a later stage, the standardized direct-relationship matrix, which is denoted by T and is derived by applying Equations 4.3 and 4.4 is obtained.

Figure 5.2 depicts the 2-dimensional rectangle surface used in MICMAC analysis, with the dependent energy on the circumference and the motor force on the centre point. Here, the impetus comes from the total number of ones in the column for all the relevant tests. Similarly, the dependency strength is the total number of ones in the tables.

After that, the total relationship matrix (T) for each obstruction is computed by using Equation 5, together with Equations 4.6 and 4.7.

The total relation matrix (T) is then used to determine the sum of each row and column, which is then stated by the variables K and L in the appropriate manner. Ri is a representation of the overall effect that the difficulty has had on the other difficulties, and Cj is a representation of the net influence that the subsequent difficulties have had on the previous difficulties. Following the determination of the values of R and C for each

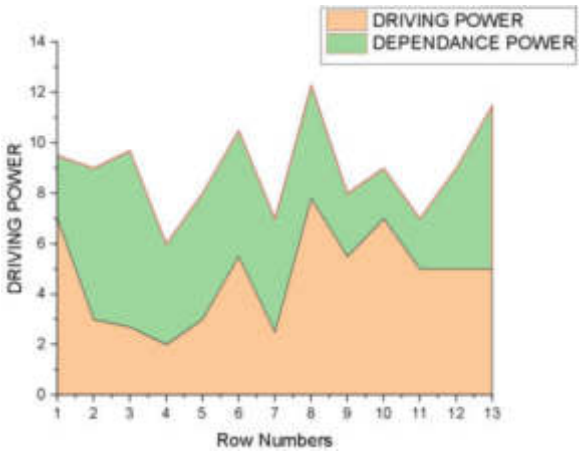

Fig. 5.2: Reliance diagram for difficult situations

row and column, Equations 4.8 and 4.9 are applied in order to compute the prominence (Di) and the net effect (Fi). The ultimate cause and consequence of each test are both decided by "Di." If Di is in a favorable position, then it is thought that the challenge will produce the net cause; however, if Fi is in an unfavorable position, it is thought that the challenge will produce the net impact. Table 12 illustrates the association that exists between the two variables. The K and L values, which also reflect the natural effect that each challenge has on the system, are used to determine the importance order of the challenges. This order is based on the K and L values.

The importance of the ranking of the challenges presented by Big Data for the development of smart cities has been calculated as follows, based on the "prominence" value: Data Organisation and Mobility Problems (13) > Big Data Computing Systems Problems (7) > Interpreting the Data (12) > Data visualization and Assessment (11) > Data incorporating, Grouping, and displaying (10) > Data Collection and Capturing (8) > Data Collecting and Grabbing (Knowledge Retrieval and Elimination (Similarly, the challenges are classified according to their "effect" values) The level of complexity (K L). With reference to the diagram of causes and effects, the following are the most critical challenges, listed in descending order of the influence they have on the situation: Smart City population variety (6) > solutions for large information and infrastructure faults (3) > heterogeneous surroundings, discrepancy, and adaptability (4) > performance, availability, and longevity (5) > knowledge and data exchange (2) > data collecting and recording (8). In a similar vein, the difficulties that are being impacted by this factor are mentioned below in ascending order: Data visualization and evaluation (11) > Interpretation of information (12) > Data safety and confidentiality (1) > Data swapping, gathering, and representation (10) > Storage space of data and Shipping Problems (13) > Obtaining data and disinfection (9) > Big Data Recognising Systems Concerns (7) > Data challenges (14). The data gathered in this manner were presented to a panel of industry professionals in order to gain further insight, which will be detailed in the next section.

5.5. Discussions on results. Big Data is essential in planning and evaluating cities' amenities, including traffic control, medical care, schooling, security for the public, and visitor attractions. The implementation of big data serves as a potent decision-making tool by delivering reliable data and lowering the operational expenses of administration. According to the study's findings, the "Diverse inhabitants of Smart cities" is the most critical obstacle that must be overcome before Big Data can be effectively applied to creating an intelligent environment. According to Osman (2019), having an array of people and an extensive population contribute significantly to the volume and variety of collected data. The programs that use big data must continue to move in the appropriate direction to address the problems that threaten the sustainable development of communities. The next set of difficulties will require considerable expenditures in both equipment and software to support the analysis of tens of millions of recordings in real-time. One of these issues will be ensuring the creation

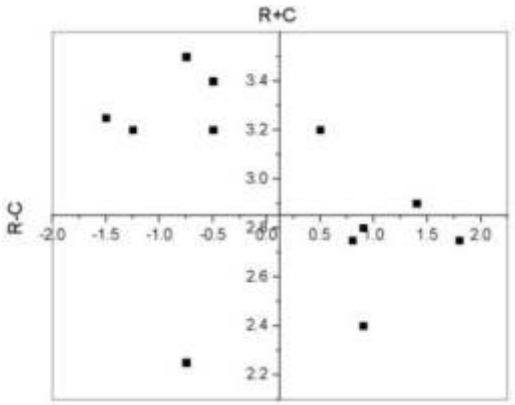

Fig. 5.3: Growth in smart cities and the difficulties of using big data: a cause and effect diagram

of methods for Big Data analytics, including the detection of infrastructural problems. The findings of this research are backed by prior research that looked at how big data could be used in the construction of smart cities. According to Al Nuaimi et al. (2015), the inhabitants of a city affect Big Data applications because the amount of data will expand and might grow extremely large. According to Khan et al. (2017), for a Big Data application to be practical, it must integrate the many city agencies responsible for arranging for and taking care of assets consumption in figure 5.3.

However, transferring information and facts between departments is challenging because every division maintains its confidential data, which they are hesitant to divulge to other departments. In addition, difficulties arise when attempting to share information with other organizations due to privacy concerns connected to the gathering and utilization of data. A significant quantity of data is collected from various locations; most of this data can be processed and compacted without jeopardizing the primary purpose of data collection. Due to the massive nature of Big Data, which makes it challenging to store in its entirety, its contents should be filtered so that it does not throw away any of the details.

Data collection presents a considerable problem since data are frequently time- and space-connected, requiring great care. Protecting one's safety and confidentiality in a smart city that uses Big Data is a significant concern. It is essential to prevent improper utilization of data that may contain sensitive or private data, such as that which relates to the actions of individuals or the authorities' decisions. According to Rathore et al. (2018), organizations that are in charge of offering a variety of smart services are required to implement a high-security standard across the entire network. In the context of a smart city, "Big Data" refers to documents such as financial information, health and medical records, and personal histories, all of which have the potential to provide detailed perspectives of the people they represent. The unauthorized use of this kind of data for the purpose of earning a profit violates the privacy of citizens. In smart cities powered by Big Data, one of the most significant challenges is the implementation of rules that protect the inhabitants' right to personal privacy. In a similar vein, Zoonen (2016) stated that data-driven city services, despite the fact that they will make the city environment less polluted, more prosperous, and more environmentally friendly, will destroy the creativity and deviance of the people who live there, as well as the workers and visitors. It should come as no surprise that urban Big Data plays a vital part in fostering wellness and ensuring the continuation of equitable growth. In opposition to the more conventional strategy of storing data first and processing it afterward, real-time data analytics is becoming a steadily significant tool. On the other hand, in order to get insights from the data in real-time, innovative methods and presentation approaches are required.

In addition, the present-time data analysis calls for a powerful Big Data processing infrastructure equipped with enormous processing and computing capacity. Software systems need to be secure, dependable, and error-tolerant for extremely heavily data-driven usage. A new media for storage is required because of the proliferation of data coming from various sources in a smart city ecosystem.

Another one of the challenges involves moving the data from its storage location to the platform where it

will be processed. Analyzing data in real-time and conveying knowledge of relevance are necessary steps in this process. Collaboration, accumulation, and depiction of numerous sources as erroneous, lacking, and using the proper format constitutes another critical challenge that needs to be handled. This obstacle must be overcome. The facts that must be made decisions cannot be revealed by the data. The statistical analysis of big data arrives at the inherently complicated problems of being complex and messy. It is only possible to derive reliable details from urban data by managing the data quality. Since data gathering in a smart city ecosystem relies on crowd funding, digital information is stored in different independent databases with distinctive file types. This is because inaccuracy and disparity issues impair the decision-making process's potential. Big data is being utilized to improve the delivery of services in today's cities, which are also referred to as equitable, inclusive, and resilient towns in contemporary writing. The use of available resources will be maximized if a comprehensive and dependable plan is developed to address the issues of integrating Big Data applications within a smart city context.

6. Conclusion. Through fuzzy information systems modeling (ISM), the challenges posed by Big Data in developing smart cities have been explored and examined. It has been determined that "Smart City diversified demographic" and "Technologies for Big Data and infrastructural problems" are key obstacles and that resolving these problems can alleviate a great deal of the problems that have been identified. Participants can use the methodology in this article to better comprehend the challenges related to Big Data's inclusion in smart urban growth. For the establishment of smart towns to move forward beyond hindrance and at more incredible speed, it is helpful to solve these obstacles in an ideal manner; doing so requires a deeper view of how these challenges interact with each other using DEMATEL's fuzzy logic.With the proper handling and evaluation of the Big Data produced in smart cities, many of the current challenges experienced by smart cities might be avoided, allowing for their widespread acceptance.Constraints include 14 culminating obstacles, increasing the likelihood that specific critical actions will not be completed.

The specialists' inputs, which come from many various areas of study, are highly subjective, and this poses a severe problem. Both the ISM and DEMATEL provide a picture of the interplay between Big Data problems in the context of developing countries. Some identified problems may have the most significant impact in the here and now, but as technologies develop, those advantages may wane or become obsolete. Future research can use the modeling of structural equations to test and refine the fuzzy ISM-based hierarchical model. In addition, several decision-making frameworks can be used to investigate the identified issues. Case studies that map challenges with potential solutions provide a means of digging further into the research's findings. The highlighted challenges that can be a barrier for smart cities can be detailed by examining the various categories that can benefit smart city entrepreneurs and officials. It is hoped that this study will help fill in some gaps in our understanding of the challenges Big Data presents to the growth of smart cities and the integration of both the public and private spheres.

TWO ENERGY-EFFICIENT BACKHAULING SOLUTIONS FOR SMALL CELL NETWORKS OF 5G USING GREEN COMMUNICATIONS

HAILI XUE*

Abstract. To meet the problem of ever-increasing wireless data congestion, the fifth-generation (5G) wireless communication system is projected to employ tiny cellphone networks for the needs of consumers heavily. One of the most significant elements of 5G networks will be sustainable interactions, as the quantity of power utilized by the information and communication technology (ICT) sector is expected to rise significantly by the end of the century. Therefore, scientists have focused much attention in recent years on developing strategies for designing small cell networks that use electricity optimistically. In addition, service providers need energy-efficient backing-up technologies to aid in using packed tiny cells. This research presents an interaction model that is well-suited to 5G HetNets and has a low power footprint. The model here accounts for an internet connection's contact and backup portions. We create and present a mathematical framework to calculate the optimum number of tiny mitochondria that need to be maintained active at numerous hours of the day to minimize power consumption while still satisfying quality of service requirements set by customers. Our investigation into the backhaul's electrical consumption led us to discover and put forward two energy-saving backing-up methods for 5G HetNets. Computer simulations show that the provided sustainable communication framework can reduce energy consumption by as much as 49% compared to the status quo.

Key words: 5G, Energy Savings, Green Communication Studies, Packet Backhauling, and Small Cell Networks (SCNs)

1. Introduction. The heterogeneous network, often abbreviated to "HetNet," is a hybrid wireless network that uses high-powered macrocells and numerous low-power tiny cells (including micro, pico, and femto). This increases the network's signal-to-interference-plus-noise ratio (SINR), increasing link toughness and the quality of service (quality of service) as it is closer to the end user. Widespread frequency recycling can significantly reduce the issue of inadequate bandwidth when used in a HetNet [1]. Another major challenge for 5G researchers is finding ways to reduce energy consumption by over 90 percent. According to recent studies, the ICT industry consumes 4.8 percent of global power production. By 2020, it is expected that 100 million SCNs would consume 4.3 TWh of energy. Energy-efficient solutions for the next generation of wireless communication standards have been the subject of "Green Communications and Networking" research. This is done to address the issue of the ever-increasing need for electricity [2].

An increasing number of uncoordinated and lightly loaded active SCNs may increase the power consumption of the access network, even though SCNs help alleviate the bandwidth scarcity issue in HetNet. This conclusion from the 5G HetNet might be compared to the current state of the electricity market. An intelligent network classification in the electric power industry consists of generation facilities, consumption facilities (also known as load/demand), and transmission and distribution networks. The demand curve changes dramatically from one hour to the next. Using historical data, the innovative grid system generates a demand and load forecast for the upcoming generations [3].

An optimization approach uses this forecast as a constraint to save costs without compromising on safeguards against blackouts at all hours of the day. In a HetNet situation, the demand spectrum is set by the amount of information requested by users, and the link to the internet (acting as the delivery system) ensures enough capacity to provide the required quality of services. In this context, cells might be seen as potential broadband providers. Maintaining regular operation of all tiny cells during the entire day and overnight is the only way to guarantee that customers can access the maximum potential throughput. This would result in higher operating costs and a surplus of accessible bandwidth during periods of low demand. Therefore, in a 5G HetNet and the chronological fluctuation of transport requests, location-based variability (for example, differing traffic volumes in distant places) may be leveraged to put units into a sleep state. The result is more

*XinXiang Vocational and Technical College, Xinxiang, Henan, 453200, China (HailiXue3@163.com)

effective utilization of the network's resources. The reason for this is the regional and temporal variability of traveler demand. It would be a gain since the result would be less money spent on running the business and less power used. Because of this, we looked into the problem and built an analytical model to determine how many operational SCNs are needed to match the data demand at different times of the day. The goal was to make 5G access networks more energy efficient while keeping their service levels the same [4].

Saving electricity in the network's access and backhaul is necessary to benefit from HetNet's power-efficiency features fully. There will be a growing need for various backing-up solutions to transport the traffic generated by tiny cells in 5G HetNet systems to the central network. Cable, wireless, or a hybrid design utilizing several technologies may be used for these backhauling purposes. Connecting all SCNs to the leading network through a direct high-capacity physical link (such as fiber optic cable) is difficult and expensive. Millimeter wave (mmWave) technology is a viable alternative to wireless backhauling systems. mmWave technology runs at extremely high frequencies (65–85 GHz). While these two technologies are not interchangeable, they have the same goal: reducing the energy required to convey traffic to the network core. The issue of increasing backhaul power consumption has received considerable attention from service providers due to its impact on total network power budgets. Recent data shows that the backhaul is one of the most significant issues with future 5G HetNets for roughly 55 percent of service providers. We also explore the authority needs of alternative backup designs and provide two responses, one for a hardwired passively optoelectronic network (PON) and the other for a network that uses millimeter-wave technology, as well as to the environmentally friendly 5G connectivity infrastructure approach we have described [5]. First, we offer an entrance-backhaul architecture that illustrates how to connect unreceptively optical networking modules with 5G connection units, which reduces the overall power required to operate the entire network. In our second suggestion, we illustrate how mm waves backup devices and 5G SCN devices may be integrated to reduce energy consumption significantly. We also provide analytical approaches to estimating the total energy consumption of these two options. The quality-of-service (quality of service) features of the 5G eco-friendly telecommunication model are also investigated. Two of them are latency and fluctuation.

2. Related Works. The dense distribution of small-cell systems is a defining feature of the future wireless networks being utilized to provide the necessary capacity boost. Based on the proven concept of hierarchy HetNets, microcells are deployed in areas covered by macro base stations (eNBs) to provide enough local bandwidth. Furthermore, small-cell networks establish multi-hop architectures using high-capacity backhaul lines running on millimeter-wave groups, decreasing information transfer costs. The unchecked deployment of a large number of small cells, however, can raise operating expenses and contribute to carbon dioxide emissions, highlighting the growing need for green connectivity. This paper proposes a dynamic optimization approach for 5G networks that are heterogeneous to decrease the total energy use of these networks without compromising on range or capability. In order to meet the quality of service constraints of consumers while retaining the most significant possible energy savings, the model provided here determines when tiny cells should be switched ON or OFF. The task is completed by minimizing the use of both carriers and energy. In order to allow for continuous dual-hop communication, we also proposed a multi-hop backhauling approach to make optimal use of the current network of small-cell systems. The results of the simulations indicated that considerable amounts of power might be saved in various traffic situations while still satisfying capacity standards for both regular and irregular distribution methods of the equipment being used. The simulation results also show space for the system's data rates and energy consumption enhancements[6]. The proposed technique improves the overall electrical utility to meet the quality of service restrictions by building a suboptimal CA and using an efficient communication strategy in the dynamic multi-hop/dual-hop backup network. This is done so that the quality of service restrictions may be satisfied. The simulation results demonstrated a significant improvement in throughput, with an average increase of 33 percent for random user distributions and 28 percent for hotspot user distributions. Because of the effective CA technique, spectrum efficiency improved.

Energy-efficient 5G NOMA networks have come a long way, but there are still many concerns and challenges to be solved. Beamforming may be considered with user scheduling and power optimization (PO) in the EE RA approaches for NOMA with MIMO. Internet algorithms may also be used to find the optimal answers to a problem. Furthermore, the subsequent phase may represent the traffic pattern's factors, such as duration and lag limitations. Sometimes, examining BS and UE power use independently may be instructive. To sum up,

the goal of the future study will be to develop a reliable model that can efficiently handle incorrectly specified variables and link shifts caused by alterations in backhaul relationships due to rapid fading, atmospheric conditions, or temporary failures of links and nodes. In particular, this model will aim to handle improperly defined variables and link variations well [7].

With the advent of ultra-dense tiny cell networks in telecommunications, researchers have been presented with a significant new challenge. Experts in this field are trying to figure out how to reduce the enormous spike in energy consumption resulting from backing up data collected by SCNs to the main networks. Here we examine the problem of environmentally friendly backing up in a 5G wireless communications system that relies on an inactive optoelectronic system and millimeter wavelength (mmWave) backing up to link its various customers and services. Our technique relies on the finding that PON and mmWave technology provide different estimates of energy efficiency under certain load conditions. PON technology delivers more energy effectiveness than mmWave innovation under heavy load circumstances, whereas mmWave innovation excels under low load conditions. Since traffic loads change during various times of the day and night, more than a constant backhauling strategy is required to provide the required data rates and the lowest possible energy usage. In order to determine the backhauling strategy that consumes the least amount of energy over the day for each of the distinct periods, we create an optimization challenge that factors in the anticipated hourly traffic load [8].Due to the complexity of the optimization problem, we also provide a heuristic approach that uses few resources while yielding satisfactory results.

The simulation outcomes show that the proposed approach may deliver energy savings of as much as 30% over the status quo. This research set out to determine whether or not it would be possible to provide a low-power solution for a 5G network by using passive optical network (PON) and millimeter wave (mmWave) backup techniques. We modeled the electrical consumption of both backhaul systems using analytical tools. The next step was to develop an optimization strategy for reducing backhaul's overall power usage as much as feasible without compromising service quality. We showed that combining PON and mmWave technologies has the potential to save much energy (as much as 34 percent in the experiment's findings) and has additional advantages generally recognized by researchers and the industry. Our findings may pave the way for further research into eco-friendly 5G network backhauling techniques. We also accounted for the time required to implement the most effective approach. We devised heuristics that offered an acceptable solution in a timeframe comparable to real-world execution. The proposed backhaul solution is adaptable enough to be employed in C-RANs, even though the system framework for this study only included conventional SCNs. To do this using the suggested mathematical model, a baseband unit and regional broadcast units may replace the MBS and SCNs, respectively [9]. Our ongoing research on C-RANs will go further into this topic and other avenues for conserving power. Hierarchical wireless networks can offer substantial data productivity, widened coverage, and enhanced EE by means of spatial density using microcells and the adoption of substantial multi-IMO antenna arrays. However, HetNets' electrical usage is expected to rise due to the ultra-dense installation of tiny cells, making network administration more difficult. First, we will examine why high energy consumption poses one of the biggest problems for wireless communication networks. We also study the numerous enabling methods that fall under the various EE techniques utilized in wireless HetNets and classify them accordingly. Review the earlier work on EE approaches used in HetNets, drawing on the organizations mentioned above as a basis and referencing the key results and suggestions from the research mentioned above. Additionally, EE measures for evaluating usage rates and efficiency trade-offs are included in this study [10]. In the last section of this study, we address prospective future areas of study for electromagnetic contamination in ultra-dense diverse networks. Ultra-dense tiny cells, MIMO, and network-based multiple pathways adaptability are the newest additions to global mobile phone networks. These developments were made to deal with the exponential increase in data traffic. One of the obstacles to implementing ultra-dense HetNets is the substantial amount of energy used inside the connections. The difficulty of managing networks is an additional issue. The linked corpus of academic research encompasses a large amount of work that tackles these difficulties, focused on the many stages of network deployment and operations.However, the difficulty introduced by new technologies in cellular communications suggests that current solution-finding techniques will likely become less optimum in future generations.In conclusion, several directions for further study into eco-friendly communication are provided. It is envisaged that the findings of this research will serve as a practical guide in the design of future

systems, including environmentally friendly 5G networks, 6G wireless connections, and others [11].

Scientists have faced a substantial new difficulty with the emergence of ultra-dense small cell networks (SCNs) in the communications industry. Experts in this area are working on solutions to mitigate the significant energy usage increase caused by backhauling information from SCNs to the leading network. In this paper, we examine the issue of green backhauling for a 5G wireless communication network that uses passive optical network (PON) and millimeter wave (mmWave) backhauling to connect its different users and applications. Our technique relies on the finding that PON and mmWave technology provide different estimates of energy efficiency under certain load conditions. PON technology delivers more energy effectiveness than mmWave innovation under heavy load circumstances, whereas mmWave innovation excels under low load conditions. Since traffic loads change during various times of the day and night, more than a constant backhauling strategy is required to provide the required data rates and the lowest possible energy usage. In order to determine the backhauling strategy that consumes the least amount of energy over the day for each of the distinct periods, we create an optimization challenge that factors in the anticipated hourly traffic load.Due to the complexity of the optimization problem, we also provide a heuristic approach that uses few resources while yielding satisfactory results [12].

The simulation outcomes show that the proposed approach may deliver energy savings of as much as 30% over the status quo. This research set out to determine whether or not it would be possible to provide a low-power solution for a 5G network by using passive optical network (PON) and millimeter wave (mmWave) backup techniques. We modeled the electrical consumption of both backhaul systems using analytical tools. The next step was to develop an optimization strategy for reducing backhaul's overall power usage as much as feasible without compromising service quality. We showed that combining PON and mmWave technologies has the potential to save much energy (as much as 34 percent in the experiment's findings) and has additional advantages generally recognized by researchers and the industry. Our findings may pave the way for further research into eco-friendly 5G network backhauling techniques. We also considered the time needed to execute the ideal solution and developed a heuristic approach to provide a near-optimal solution in near-real time. Although the system model for this research considered standard MBS and SCNs, the offered backhaul solution is flexible enough to be used in C-RANs [13]. This may be achieved in the context of the proposed analytical model by switching out the MBS and SCNs for a baseband unit (BBU) and remote radio heads (RRUs). Our current investigation into C-RANs will investigate this issue and other energy-saving techniques. Through spatial densification with microcells and adopting large MIMO antenna arrays, heterogeneous wireless networks (HetNets) can provide high data throughput, expanded coverage, and improved EE. The ultra-dense deployment of small cells, on the other hand, is predicted to increase the energy consumption of HetNets and make network management more challenging. To that end, the first phase of this research is to pinpoint the specifics that make the problem of excessive energy consumption one of the gravest challenges in wireless communication networks. In addition, we categorize the many EE techniques used in wireless HetNets and investigate the various enabling approaches that come under each technique. Using these groups as a foundation, provide a summary of prior work on EE techniques utilized in HetNets, complete with citations to the essential findings and recommendations from the abovementioned studies. In addition, this research presents EE metrics for gauging energy consumption rates and performance compromises. Future research directions for electromagnetic interference (EE) in ultra-dense heterogeneous networks are discussed in the last portion of this paper. The newest technologies added to wireless mobile communication networks are ultra-dense small cells, multiple-input multiple-output, and network-oriented multipath adaptation. These innovations were introduced to accommodate the skyrocketing growth in data traffic. High energy usage inside the links is one of the challenges to adopting ultra-dense HetNets [14]. The complexity of network management is also a problem. The related corpus of academic research contains a substantial amount of work that addresses these challenges, focusing on the different phases of network implementation and operations.

As part of this review, we have included some of the most recent research on EE techniques used in wireless mobile networks. Several alternative facilitating tactics for each approach have also been proposed. Suggestions for a secure and optimal system design of cutting-edge wireless technologies have also been provided, focusing on the most important contributions made under each method. New wireless technologies can better use these rules when they are developed. Power consumption and data rate expressions are also provided to illustrate the

fundamental EE maximization problem further. The fundamental measures used to evaluate EE performance in HetNet were also discussed, and a summary was presented. In conclusion, several directions for further study into eco-friendly communication are provided. It is envisaged that the findings of this research will serve as a practical guide in the design of future systems, including environmentally friendly 5G networks, 6G wireless connections, and others [15].

3. Materials & Methods.

3.1. Framework for Energy-Efficient Transport Infrastructure Management . The overall energy utilization of a 5G connection system is equal to the sum of the individual base installations' energy consumption times their density in the network. This model will allocate a minimum amount of operational SCNs to provide the lowest possible access network energy use for a given traffic characteristic. This hypothetical scenario will consider peak loads with different sorts of visitation. The problem may be stated mathematically as follows:

$$MinimizeQm + \sum_{p=2}^{p} \sum_{l=1}^{l} Q_p^l, M_p^l \tag{3.1}$$

According to the transmitting influence, which is capped at the highest amount determined by an internet administrator and restricted to a certain amount, this issue is sometimes referred to as the limitation of ability expenditure.

Due to the multimodal character of the subchannel distribution of resources, the achievable set is irregular in the optimization dilemma stated, which is a combined integers non-linear programming issue (MINLP). The issue is NP-hard, meaning it cannot be solved in pseudopolynomial duration. Using dual Lagrangian decomposition (LDD), which can lead to a nonzero dualism discrepancy, one can discover both the primary and dual remedies for a problem. However, as the number of subchannels increases, the dual nature difference shrinks. By relaxing the criteria, we make solving the problem easier. The requirement can now take on any number from zero to one. Because of the potential temporal complexity, large-scale network service providers may be unable to use the established efficiency approach when tackling the immediate time distribution of resources. Using past information, the optimized model accounts for the day's maximum traffic volume in each hour. After that, the network decides which SCNs ought to remain operational at distinct moments of each day to fulfill the needs of traffic [16-19]. This is accomplished while maintaining a low amount of electrical usage. Since the optimization model only needs to be run once in the next 24 hours, it can play a crucial role in network planning. To ensure that the framework does not negatively impact the level of service due to burst traffic and changes in loads in contrast to a typical load, we use the highest daily congestion pattern instead of a typical traffic load profile. We utilize the OPTI MATLAB package to help us find the optimal answer. The method of optimization is broken down into its parts and summarized in Algorithm 1.

By determining the optimal amount of SCNs to use at every moment of the day, we demonstrate how to lower the electrical power use associated with access systems. Both access points and backhaul networks contribute to the total energy requirements of the 5G HetNet. The article discusses the power needs of the various backhauling strategies. Consuming fiber to the nodes with extremely fast electronic customer accordance second generation soluble fiber to the structure with microwaved, and dietary fiber to the developing with 12 Gbps apathetic visual system are just a few instances. Then, we will discuss two varieties of backhauling that may be surprisingly power-efficient during certain hours of the day [20].

3.2. Proposed System Model. This section provides an architecture model and the mathematical framework for calculating the energy utilization of a 5G HetNet's accessible infrastructure. In order to maintain consistent frequency effectiveness across a mega cell, three different sections—sections 1, 2, and 3—are employed. Region 1, which has a high signal-to-interference-noise ratio (SINR), can attain higher spectrum financial viability. In contrast, Region 3, which does not have a significant SINR, continues to have inadequate harmonized efficiency. This research investigates the split spectrum approach to reduce cross-tier entanglement in q-tier HetNets. The formula for allocating the spectrum that is accessible W across macrocell base stations and other base stations of varying tiers is as follows: Wx = qW. If q equals p, q is the spectrum's allotment aspect, and q $>$ 0. We considered the static reuse of frequencies technique to avoid interference among mobile phones on the

Algorithm 1. An approach towards resource management and planning that minimizes energy consumption
Step 1. The algorithm takes user input, including the user, traffic class, and macrocell subzone.
Step 2. The result is the minimum number of active SCNs (Small Cell Networks) needed to handle the need for traffic while minimizing energy use.
Step 3. The program performs repeated loops throughout a whole day.
Step 4. The procedure for determining how much bandwidth is needed (in Wrm) is shown.
Step 5. No SCNs are necessary if the amount of desired bandwidth is less than or equal to the amount of accessible broadband (Wm). Every starting station's SCN count is reset to zero by the procedure at the beginning of each tier.
Step 6. The method determines the amount of surplus bandwidth (We) by subtracting the bandwidth that is accessible from the needed broadband if the latter is more than the former.
Step 7. Next, a strategy for optimization is used to establish the necessary number of functioning SCNs for each BS in each tier.
Step 8. This is something the algorithm does every hour.
Step 9. The algorithm has reached its endpoint.

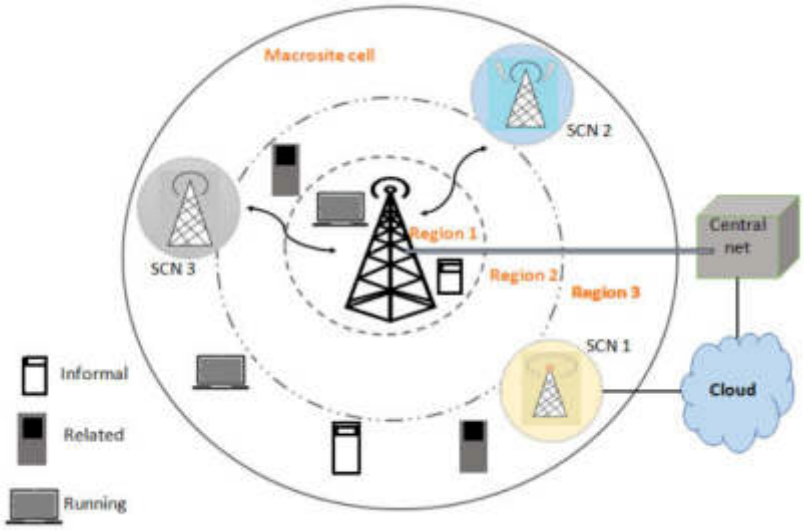

Fig. 3.1: A 5G HetNet System Model

same tier in 5G HetNets. In this tactic, nearby cells avoid disrupting one another's service by using different frequencies in the electromagnetic range. As shown in Figure 3.1, a 5G HetNet structure has a central macrocell center station located inside layer, with a layer of J array of SCN stations situated above it.

To avoid interference between cells, the whole spectrum W is partitioned into Nsb transverse smaller bands (number of times repetition fraction). During this study, we account for the spatial and temporal variations in the characteristics of network activity. This is useful for researching networking providers' energy consumption under light and substantial loads [21]. This breakdown accounts for three distinct streams of information and records: those that are actively being discussed, those that are being actively streamed, and those that are in the distance. Multimodal congestion, such as voice and video conference calls, has the highest priority and is very susceptible to interruptions. Broadcast communication (with moderate prioritization) contains items like broadcast music and video but is less time-sensitive than informal traffic. However, email, FTP, and telnet are examples of low-priority ambient traffic. This third traffic category uses the internet after the first two have been satisfied when latency requirements are less strict. It is expected that the aggregate volume of traffic

would exceed the bandwidth accessible in a macrocell throughout peak times; nevertheless, SCNs can be used to assist in alleviating this problem. However, if cells from various tiers do not cooperate, there may be an abundance of accessible broadband at the cost of an increase in the needed power. Integrated administration can help with this problem by figuring out how many SCNs are needed and then using them all. If we want to minimize the amount of energy the connection system uses, it is necessary to determine the exact capacity requirement at every moment of the day [22,23,24,25,26].

3.3. Network Integration Analysis Framework. Here, we will discuss calculating a macrocell's frequency needs using the recommended architecture and its usage characteristic. The connection network's energy usage may then be modeled with these equations. Following is an inventory of the nomenclature systems used in this study. A 5G multi-tiered HetNet search for the Q set. There are j-base observatories in the SCN's j group. Members of the area index for the A sub-zone. The Z subset is set at index z. position t in the Traffic type T set. The u integer identifies members in the U set.

Energy transmitted by the base station (BS) to a customer's equipment may be expressed as:

$$Q_{rx} = Q_{sx}.r^t\psi \tag{3.2}$$

where the transmitted authority, the transmission journey from a user equipment to a base station, the route degradation element, and the decay factor are denoted by Q_{rx},r,t and ψ correspondingly. It is possible to modify this value for additional research, such as tiny-scale aging or multiple paths aging.

Any apparatus for user u linked to sub-zone z can be written as uz (or just u for short). The Customer Equipment Unit u's SINR (received signal-to-interference-noise ratio) at a macrocell center station may be calculated below.

$$\gamma_z(u) = \frac{E[Q_{rx,z}(u)]}{J_z(u) + \sigma^2} \tag{3.3}$$

w here $Q_{rx,z}(u)$ represents the signal obtained strength for a particular user u inside a specified sub-zone z, the most potent SINR result is used to associate with the consumer. We suppose that the disruption $J_z(u)$ is continuous within a specific duration and explore the split spectral technique to eliminate interaction amongst macrocell BS and SCNs. Despite sacrificing generalization, we will assume that all users experience noise level 2, and we will ignore the transmitter's noisy barrier.After generating a prediction of canal performance from the bandwidth attenuation variable, we use the highest capacity network state technique to modify the modulation process and encoding strategy. The best possible transmission strategy aims to optimize link performance by choosing the optimal modulating and encoding following SINR levels that enable the most incredible performance under the given channel circumstances. With less reactivity to error likelihood, a high bit-rate technology like voice and video broadcasting might benefit. We calculate the glyph failure chance and the component failure chance for a given programming sequence. Then, we determine the properly acquired block utilizing the highest probability operation, which is then converted into the user's potential downstream bandwidth as:

$$\eta_z(u) = \frac{M_C^Z(u), S_C', M_{sym}, log_2(L)}{U_f}, [1 - Q_{block}] \tag{3.4}$$

where $M_C^Z(u), S_C', M_{sym}, L, Q_{block}$ and U_f the rate of the modified code and transmission system, the amount of downstream OFDMA symbols, the sequence of modification, the likelihood of blocks with errors, and the length of an OFDMA framework.

Hence, the calculation for the entire frequency used by a macrocell is as follows:

$$X_m^r = \sum_{z=1}^{Z} \omega_z \tag{3.5}$$

Our research aims to discover a solution to the issue of traffic jams by analyzing the needs of giant cells and small cell networks separately. The theory underpinning this approach is that additional power consumption is

warranted since the static capacity of SCNs is higher than the tremendous amount of power transmitted from the macrocell. All SCNs enter sleep state when the needed quantity of resources falls below the macro-tier wavelength [27].

For one individual u in a given sub-zone z, we may calculate the transmitted energy $Q_{tx,z}(u)$ using the formula below.

$$Q_{tx,z}(u) = [(2^{\theta z} - 1).\frac{J_z(u) + \sigma^2}{g_z}] \tag{3.6}$$

where g_z is the stream strength that should be used. The allowed range for the transmitted power is between 0 and $Q_{tx,z}x$ (43 dBm). Then, we can calculate the modem power, which is the changing capacity of a macrocell base station's signal in relation to the number of customers [28].

$$Q_{tx}^{dynamic} = \sum_{u=1}^{U} Q_{tx,z}(u) \tag{3.7}$$

To calculate the 5G access network's EE, we use the formula:

$$Energy_{hetnet} = \frac{\sum_{z=1}^{Z} d_z}{Q_{hetnet}} \tag{3.8}$$

3.4. Consumption Model for HetnetsS Using backhauling options. A heterogeneity network (HetNet) uses macrocells, microcells, and picocells in addition to traditional small cells to increase range and performance. Because of the many nodes in a HetNet and the consequent requirement for effective energy administration, HetNets' electrical consumption is an issue of paramount importance.

Scientists have offered various theories to answer the problems of HetNets' excessive electricity consumption. An example of such a model is the "Modeling for HetNet Electrical Consumption with Backhauling Technologies." This model considers the backhaul lines, which are in charge of linking the tiny cells to the leading network, and optimizes the power consumption of HetNet installations [29].

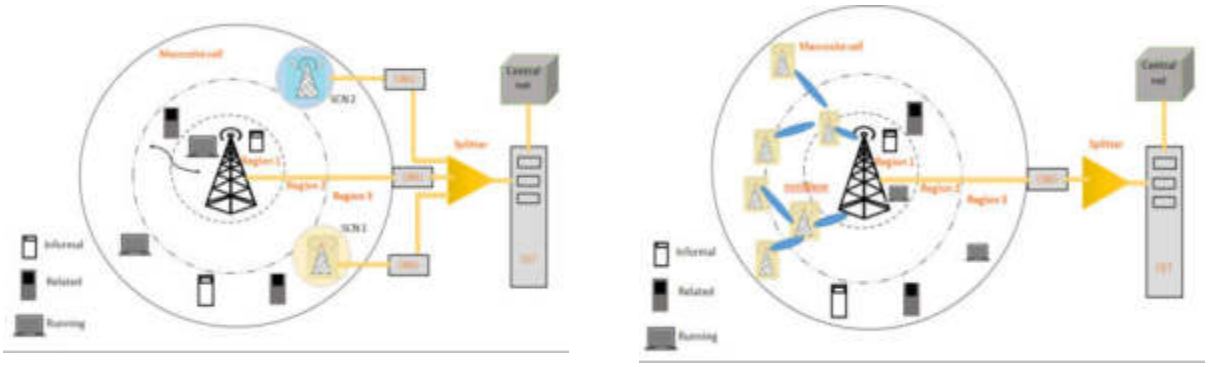
The model considers several variables that affect HetNet energy usage, such as:

- The total number of macrocells, microcells, and picocells used and their corresponding transmit powers.
- The volume of data traffic provided by a given cell affects the energy needed to run the base station.
- Fiber optics, microwaves, and wireless backhaul are all examples of backhaul technologies with varying power requirements.
- The number of hops in the downlink network, the length of the links, and the bandwidth of each connection all makeup what is known as the backhaul topology.

The model aims to determine the HetNet and backhaul network topology that simultaneously reduces electrical consumption and satisfies quality of service criteria. It may use heuristic algorithms or integer code to find the best answer. The "Model for HetNet Power Consumption with Backhauling Solutions" might have different settings and characteristics based on the study's or company's goals. These models let researchers and network architects understand their energy habits, compare potential installation options, and settle on the most power-efficient HetNet architectures [30].

3.5. Point-to-point Ethernet over fiber optics. The Third Generations Partnership Project (3GPP) endorses the usage of the Ethernet over IP connection for backing up communications. This design supports a centrally located or distributed deployment of the Internet switching at the aggregate node. Figure 2a shows that all of the existing wlan base stations (both MBS and SCN) submit their data to a central aggregating transition, from which it is sent to the central system. All downlink interconnections in this method, from the base stations to the aggregating change and from the aggregating shift to the core system, are carried through fiber optics. A photonic small-form-factor adaptable connection links the switch with an Ethernet port. There are two main ways to classify a switch's electrical load. The first part of the model stands in for the switch's backplane, which is not affected by network activity [31].

The other variable relies on the switch's capacity to handle backhaul information. All switches are considered the same, each base station uses an identical downstream screen, and the transmitting rate across



(a) Suggested PON Solution

(b) Suggested mmWave Solution

Fig. 3.2: Solution for Backup Suggested

all downstream surfaces is identical. Super-fast digital subscriber line version 2 with fiber to the aggregation point solutionFiber to the Node (FTTN), also known as Very High-Speed Internet Subscriber Line version 2, and Very High-Speed Digital Subscriber Line are two technologies that are often used in telecommunications networks to provide end-users with high-speed Internet access. Figure 4.2b illustrates a hybrid approach that provides high-speed connections using fiber optics and copper wiring in the same construction [32].

In this configuration as shown in figure 3.2b, the backhauling of each SCN is handled by a highly rapid connectivity virtual telecommunication line version two (VDSL2) modem coupled to a virtual telecommunication line accessing multiplexing. The DSLAM, or electronic subscription line access multiplexer, is often installed in a distant telecommunications interchange and is responsible for interconnecting numerous digitized subscription line (DSL) terminals on behalf of individual customers to a fast speed digital messaging network. VDSL2 can provide rates of as high as 200 Mbps when there are less than 350 meters of separation between the DSLAM and the VDSL2 transmitter. The DSLAM and the macro BS are connected by cable to a converter that can manage 1 Gbps across point-to-point optical lines. Optical SFPs connect to the conversation port of a fiber exchange. The fiber exchange aggregates data from many network connections into one data internet, which is then sent across a transmission rate of optic connections and SFP+ connectors to the network's base [33].

3.6. Combination of a microwave and fiber optic solution. Fiber to the Building (FTTB) is an internet design that describes running cables made of fiber optics right into an establishment or a group of buildings. Ethernet cables used in a fiber-to-the-building installation terminate at an Optical Network Unit (ONU) or an Optical Network Terminal (ONT) inside the structure. From there, the high-speed data is sent to specific users through the Internet or other suitable methods. The enormous amount of information generated on the connection channel side of a HetNet is backhauled using this hybrid system, which combines fiber and electromagnetic techniques. Clustering may be split into two distinct types.In this setup, the SCNs are combined through ultra-fast Ethernet associations to a gigabit Ethernet switch (GES), and the GES is connected to a fiber switch over a one Gbps optical cable link.The fiber switching and the GES can talk to one another thanks to an SFP interface. Various consolidation points, often hubs with converters within, are used for backing up macro ground stations. The traffic from MBSs and SCNs is aggregated accordingly via a fiber switch and an electromagnetic hub. The wireless transceivers and ten gigabits per second optical fiber cables transport the combined data to the network's nerve center. Fiber changers or electromagnetic hubs might be used as accumulation sites. Passive optical networking at 10 Gbps and fiber to the premises [34].

This solution uses GPON (gigabit passive optical network) equipment to develop a fiber-to-the-building (FTTB) architecture. The data from the radio backup is sent to the foremost networking using an active photonic network structure. The SCNs are connected to a GES (gigabit Ethernet switch) through fast Ethernet (FE) cables. A gigabit Ethernet (GE) port is hardwired to the ONU, allowing GES data to be sent to it. An

ONU is connected to the MBS by a fiber optic cable with a bandwidth of 1 Gbps. All ONUs' traffic is combined using passive divides before being sent to an optical line terminal (OLT) and onward to the main networks. The OLT transmits ten gigabits per second to the ONUs on the downlink, while the ONUs share resources at 1.5 Gbps in the uplink manner. The amount of data passing through the Ethernet switch Pmax sw establishes the maximum power consumption (about 300 W) of the optical P2P Ethernet solution. The fiber switch, with its 300-watt capability, and the DSL access multiplexer, with its 85-watt output, contribute significantly to the total power consumption model for an FTTN + VDSL2 system's backhaul. Three high-power combination nodes, one with a microwave switch, the pulse width sw (53 W), and the other a fiber switching PF sw (3000 W), comprise the FTTB + MW system. In the FTTB + 10 GPON setup, the gigabit Ethernet Switch (50 W) is the solution's most power-hungry component. Based on these analyses, we know that many factors contribute to excessive power usage over the backhaul and are inspired to develop two unique, energy-saving alternatives. In the following two parts, we will go through the various possibilities [35,36].

3.7. Passive optical networks as an effective means of conserving energy. An energy-efficient Passive Optical Network (PON) solution is a telecommunications technology that optimizes power consumption while providing high-speed broadband connectivity. PON is a fiber optic network architecture using passive components to share optical fibers among subscribers. By implementing energy-efficient practices and technologies, PON solutions minimize power usage and contribute to environmental sustainability. Each SCN in this configuration is linked to an ONU through the optical fiber connection. Passive divides are used to link ONUs to an OLT. For 11 GPON technology, we consider the rack/shelf OLT paradigm, where an OLT is maximally configured to execute layer-2 aggregate. Each OLT has 72 GPON ports (2.4 Gbps/port), a shelf rack, 9 line cards, and SFP+ stacks [37].

3.8. Millimeter wave technology with low power consumption. To connect SCNs to MBS, we use the mm waves technological unlicensed 60 GHz frequency band in this approach. Optical line terminals receive traffic from a Multi-Band Switch (MBS) through a fiber networking unit. SFP+ devices and an 11 Gigabit optical fiber link send the merged packets onto the central system. Therefore, every connection on the SCN is forwarded via mm-Wave, while the remainder is transported over PON. The 60 GHz mm-Wave band has an upper limit of 35-decibel EIRP (adequate isotropic radiated power). To ensure that the collected information is sent efficiently via a backhaul link while maintaining the lowest possible SINR, we additionally examine a flexible modulator and code technique or AMC. We consider the execution loss Li, the shading loss, and the diminution loss for this layout. Oxygen consumption in the environment is predicted to cause a reduction of 17 dB/km. In comparison, precipitation at a rate of 49 mm/h is estimated to cause a 19 dB/km dispersion, ensuring a supply of 99.995% [38].

3.9. Model For Network QoS. The number of devices required to be backed up by the network's components, such as routers, firewalls, switches, and bridges, is expected to skyrocket in the coming years. Traffic and queuing are recognized as inevitable features of networks with packet switching. Inadequate packet filtering prevents the network from managing burst demand and guarantees poor performance by introducing unpredictable delays (also called jitter) when packets travel across systems. The usual latency and jitter of a 5G HetNet will be analyzed in this section.We investigate Stochastic transmission landings with an unlimited length of packet propagation in the downstream channel (from the core network to the user). Propagation, transmission, and queuing delays are the three subcomponents that comprise the total network latency. Jitter, or variation in delay, is another essential quality of service feature of a telecom network. It is the standard deviation of a single pair of packets' difference in spacing at the receiver against the spacing at the sender. Maintaining the network's quality of service (quality of service) requires as little jitter as feasible [39].

4. Experimentation and Results. This part of the article will examine and show the electrical power utilization, cost-effectiveness, and quality of service (throughput, latency, and fluctuations) of the suggested small cell access infrastructure and their backup technologies.

4.1. Constructing a Model. We evaluated the system's performance by running simulations in Network Simulator 2 in the suggested system. The proposed layout for 5G networks featured a central MBS with a radius of 1 km. The first zone extended from the focal point to 300 meters, the second from the center to a

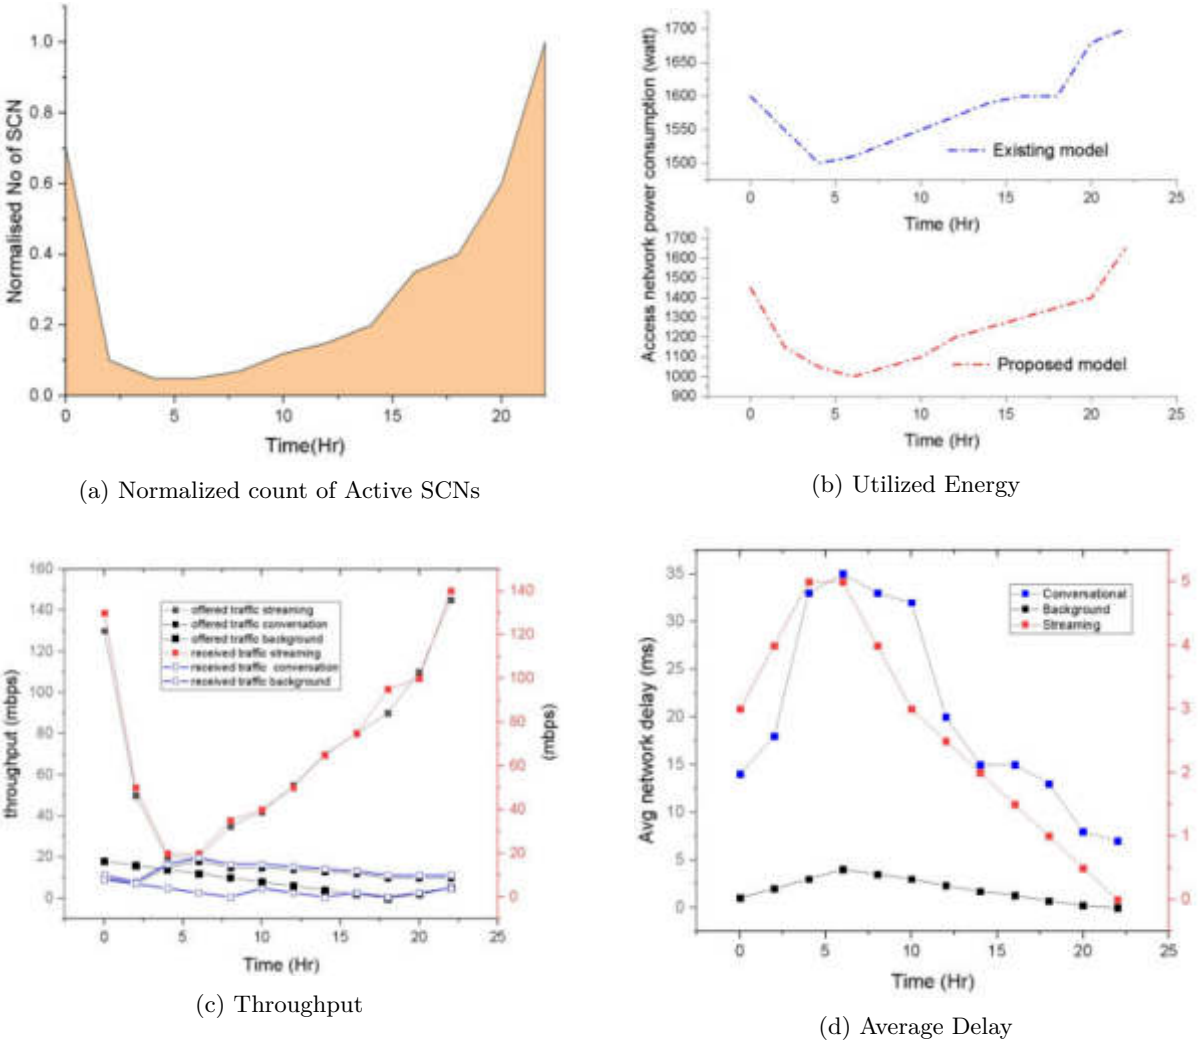
length of 500 meters, and the third from the center to a Kilometer range. All the little cells were supposed to have the same size and shape, a circle, and to be arbitrarily dispersed over the area encompassed by the macro cells to help maintain the expanded network's ability. We used the 4GPP transmission model to create realistic scenarios in various real-world settings. Distribution power was checked and changed hourly to guarantee that the needed capability was always fulfilled, and the daily forecast was calculated at the beginning of each day. The macrocell's signal was sent via directional antennas, whereas the SCNs' antennae were omnidirectional. When the SCN locations were finalized, it was anticipated that the influx of new users would occur with the formation of exclusive subscription circles[40].The modeling framework accounted for three categories of data transfer: informal, broadcasting, and ambient. Conversational traffic, such as telephone and video conferencing calls, is susceptible to delays and is thus given higher priority. The user datagram protocol (UDP) simulated this traffic so that a real-time, bidirectional, continuous bit rate (CBR) agent could evaluate its efficacy.Streaming music and video, which have a medium priority, are less affected by delays than higher priority traffic. This type of traffic uses a unidirectional variable bit rate over the user datagram protocol. In contrast, the files transfer protocol sources were used with a TCP agent for the low-priority traffic. Simulation purposes required us to assume that user packets would be 71 bytes in size for chatty users, 1000 bytes for streamers, and 70 bytes for background users. The highest possible user bit rate in each period was 64 kbps, 4 Mbps, or 0.5 Mbps. Normalization peak traffic volumes are distributed over time and time again throughout the day. A Poisson distribution was used to represent call arrival, and the peak traffic load was adjusted to match the profile for a suburban area. Access network simulation settings are listed in detail in Table 4.1a. In addition to testing the two proposed solutions and the four existing solutions in NS-2, we compared their results. The appropriate topology and technology are considered while defining the backhaul links [41].

Compared to other technologies, such as mmWave, microwave (500 Mbps), and VDSL2 (300 Mbps), optical fiber reports a bandwidth of 2600 Mbps. Not only must access networks be set up but backhaul networks as well. The available backhaul network simulation parameters are listed in detail in Table 4.1b.

4.2. Evaluation of the Access Network. In the last section, we analyze methods for determining the optimal number of SCNs to keep online to reduce the network's total electrical usage. Figure 4.1a depicts the median amount of active SCNs, with the percentage of active SCNs rising from 0% at 6:00 am to 35% at 4:30 pm and 65% at 8:30 pm. At 10:30 pm, we are finally at one hundred percent. They were able to incorporate a load factor [0,1] for every half-hour of the working day by aggregating the greatest, least, and average amount of traffic over a week, where 0 suggests that weight-dependent elements are sleeping and one suggests that the cell uses the most incredible amount of electricity. While they provided a heuristic, the quality of service restrictions of daily overcrowding should have been considered in their study.

In contrast, we estimate the number of operational SCNs based on broadband demand following quality of



(a) Normalized count of Active SCNs

(b) Utilized Energy

(c) Throughput

(d) Average Delay

Fig. 4.1: Evaluation of the Access Infrastructure

system constraints at various times of the day, leading to reduced energy consumption without a corresponding drop in service quality.

As seen in Figure 4.1b, which shows the relationship between accessibility network electricity use and time, the proposed HetNet model reduces the number of active SCNs by as much as 50% during relatively quiet times (from 2 am to 10 am) and by close to 17% during high traffic times (from 6 pm to 9 am), which is a significant improvement in energy efficiency. Even at its highest use time (10 pm), the new approach still consumes 3% less power than the present method, highlighting the significant power reductions.

Thus, the suggested system may be desirable for 5G HetNet operators, especially in network design and managing resources. We strictly prioritize high-priority conversing traffic, and medium-priority streamed traffic entering the connection so that their respective throughputs may be accurately measured. The connection's capacity is checked as part of the call authorization procedure to ensure no calls are missed. Outages may occur if the available downlink data rate needs to be increased to meet the required traffic volume. Quality of service for conversational traffic is confirmed by a slight discrepancy between offered and received traffic, as seen in Figure 4.1c. Until 10 am, the streaming traffic load is proportional to the offered load.

As seen in Figure 4.1c, the chasm widens during rush hour and stays that way until 10 pm. In our system concept, the number of active SCNs contributes to preserving the quality of service for both high- and medium-priority substantive and streaming traffic. We determine the typical end-to-end latency for various services, especially voice and video calls and live broadcasts. As shown in Figure 4.1d, even though service demand is highest between 12 pm and 10 pm, the average delay for both voice and video traffic is surprisingly slight during those hours. Streamed communication is more delay tolerant than conventional traffic[42].

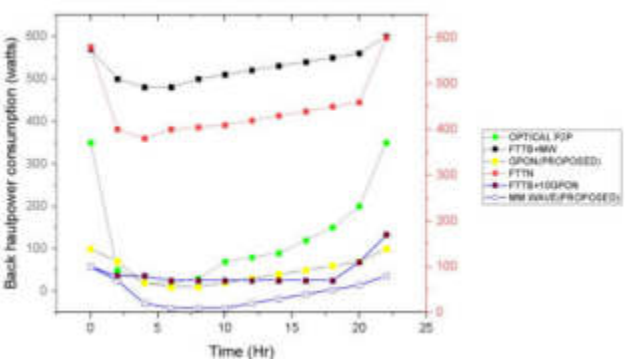
4.3. Evaluation of Backhaul Networks . Here, we show simulation findings regarding how much electricity is used and how efficiently different backhaul options use that power. Keep in mind that each of the twenty-four-hour intervals is accounted for with the identical backup traffic volume. Figure 4.2a compares downlink power across many systems at different times of the day. Using electrical switches (such as fiber and electromagnetic exchanges) increases power consumption for the FTTB systems compared to others. Our suggested wireless mmWave solution uses less power than any other current solution during low (02 am to 10 am) and average traffic times (12 pm to 6 pm). The justification is that a communication power of less than 11 dBm is needed when using 60 GHz mmWave equipment and presuming an expanse of 100 m between SCNs.

For this approach, the total backhaul power is determined mainly by the amount of power used for transmission. As shown in Figure 4.3a, the total backhaul power consumption may reach a maximum of 20 W when the low traffic hours (01 am to 9 am) due to the concentrated need for SCNs. Our suggested wired PON system uses less energy than any other solution during peak use times (8:00 pm to midnight), as shown in Figure 3.4a. Given the increase in power consumption from very dense SCN installations, the suggested wired PON system uses the least backup power at peak traffic load (10 pm). In contrast, the mmWave option requires more energy than the FTTB + 10 GPON solution. Throughout low traffic times (02 am to 10 am), as shown in Figure 4.3a, our suggested PON has an energy use difference of nearly fifty W compared to the present FTTB with 12 GPON solution and a power expenditure differential of 33W throughout the heavy traffic hours (07 pm to 01 am). During low traffic, such as midnight, the relative power savings between the two configurations may approach 37 percent. Compared to the current optical P2P Ethernet system, the suggested PON offers savings of over 50% during almost all peak traffic times. This demonstrates that our two suggested models are efficient regarding energy use at different times of the day [43].

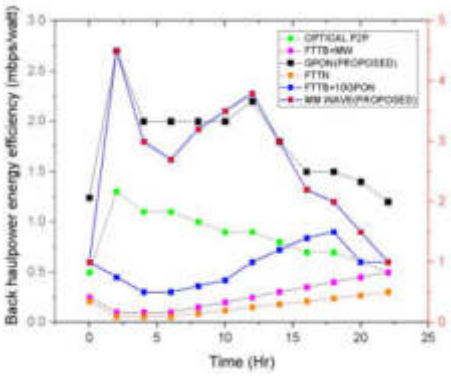
The aggregate ability of the switch rises exponentially with the number of SCNs, while the backhaul utilization of electricity does not in the optical P2P Internet system. As can be seen in Figure 4.2a, backup electrical usage for the FTTB With 20 GPON infrastructure remains constant throughout times of low (from 2:00 AM to 10:00 AM) and intermediate (from 12:00 PM to 6:00 PM) traffic. This is made possible by the broad consolidated transition capabilities. These evaluations show that the mmWave solution has a lower power consumption rate during low and medium traffic times of the day. Our research also shows that at times of low to medium traffic, the mmWave solution is preferable, while the PON solution is preferable during times of heavy traffic.

Next, we will discuss the downstream energy efficiency for different strategies, as seen in Fig. 4b. Efficiency in downstream usage is calculated by dividing performance by the amount of electricity required to send information from the base systems to the telecommunications center. Keep in mind that the capacity of the connection and backup networks has stayed the same. The findings indicate that the mm-wave structure is the best power-efficient backing-up choice throughout a minimal and moderate demand period of 2:30 am to 6:30 pm. The recommended connected PON network can handle heavy traffic from 8 pm to midnight at up to 1.5 Mbps/W speeds. The most unexpected result of this research is that the downlink electrical consumption of the suggested mmWave increases practically exponentially throughout little traffic hours (06 am to 11 am) and then visibly decreases throughout moderate to high demand times. The theory behind this is that throughout periods of minimal traffic, downlink energy use will not skyrocket as much as transmission [44].

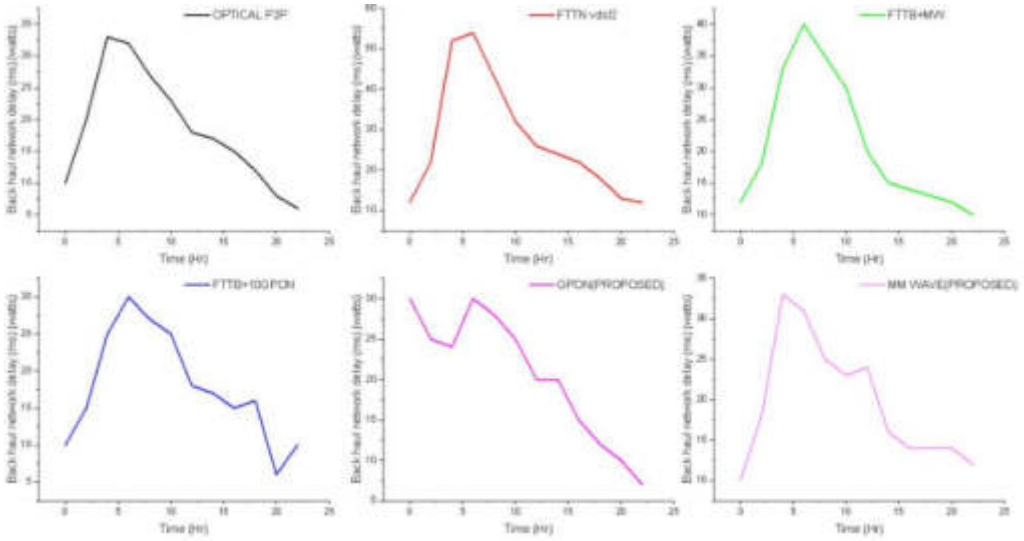
On the contrary, the growing quantity of SCN installations causes a rise in the amount of standby power used throughout times of heavy and light activity. Considering these assessments, the mmWave method is the most ecologically sound alternative between moderate to light traffic hours (from 2:00 am to 7:00 pm). At the same time, the suggested PON is the most energy-effective solution during the peak-traffic period (from 8:00 pm to 12:00 am). Figure 4.2c displays the median end-to-end downlink latencies for every network, displaying a clear pattern of decreased delay by moving congestion from low to elevated periods (6:00 am to 11:00 pm)



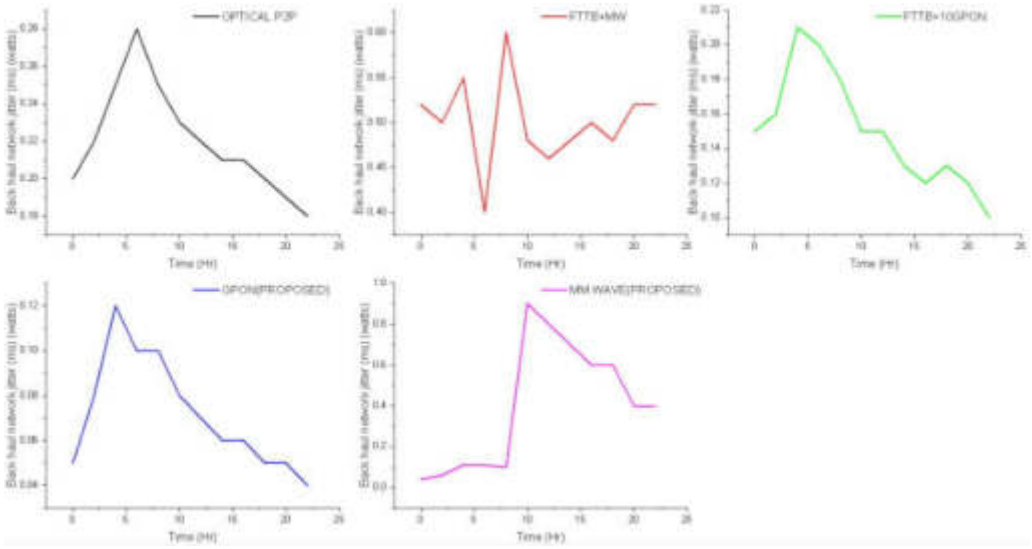
(a) Power Consumption



(b) Energy Efficiency



(c) Average Delay



(d) Average Jitter

Fig. 4.2: Investigation of the Backup System

due to several active SCNs. This trend was seen while moving congestion from times with low demand to times with elevated congestion.

Our recommended PON technology provides less latency at high-traffic times (11 pm), whereas the recommended mmWave technology behaves similarly to other existing systems. Due to DSL's capacity limits, the mean delay while using FTTN + VDSL2 is more excellent than when using alternative options. Figure 4.2d shows that all systems, except for the FTTN + VDSL2 option, fluctuate almost the same typical delay.

As further evidence of the superior level of service, we found that the mean jitter for both of our proposed solutions is below 0.01 ms throughout all times.

4.4. Model Analysis in Media. The power usage of the connection network and the energy expenditure of the connection to the backhaul connection were provided in the two paragraphs preceding this one in the order that they appeared. In this part, we compare the computation network usage of electricity and power utilization of the suggested network systems and those already in use.

Figure 4.3a demonstrates that our proposed green communications architecture uses roughly 47 percent less power than the alternatives of optical P2P and FTTB + 10 GPON during periods of minimal usage (from 2:30 am to 10:30 am). These findings are presented here so that comparisons may be made.

These savings might potentially amount to a median of around 80 percent when contrasted with the other network systems. The simulation results also show that our eco-friendly communication model consumes roughly 34 percentage points less power than the systems in use today, with the sole exception of the FTTB + 10 GPON. This is the case at the time of day when demand is at its highest, which is around midnight. Looking at Fig. 8b makes it abundantly evident that the proposed solutions we have developed are 33 percent more energy-efficient than the other solutions currently in place. This is the case even during periods of low usage. Even during the busiest period of the day, which is ten o'clock at night, the solutions we have shown are 12 percent more energy-efficient than any other available choices. Based on these findings, we were able to arrive at the opinion that the solution that we have proposed makes use of a reduced amount of energy and are better in terms of power consumption compared to competing options [45].

Figures 4.3c and 4.3d show the results of our investigation into the total end-to-end averaged latency of the network and jitter for both solutions we have shown. Even during the busiest hours of the day (midnight to eight in the evening), the typical delay of each choice is less than thirty milliseconds. The total jitter in the network, which measures variance in latency, is not very high (it is less than 0.4 milliseconds at all traffic periods), indicating that the network is doing well. Figure 4.3a demonstrates that the power consumption of the network is at its maximum level when it is operating at peak efficiency during the peak period. This is because, at the peak period, there is a need for the most significant number of active SCNs. As a result, this situation has arisen. In order to be able to meet the demand at the peak period, the passive optical and mm Wave downlink elements need to be able to function at an elevated capability than they usually would. The impact of this high bandwidth accessing and backup communication working together to generate less common delay and jitter can be observed in Figures 4.3c and 4.3d. This effect can be seen as a result of these two types of communication working together. One may argue that this is beneficial to the structure as a whole [46].

5. Conclusion. Connection capacity using microcells is generally anticipated to significantly reduce the data rate shortfall problem of 5G systems. However, larger systems provide a new difficulty in the form of higher power consumption. These analyses aimed to examine network complexity's impact on electrical consumption from both the gateways and downstream connection perspectives. Based on our findings, we developed a mathematical framework for 5G connection networks that consider daily traffic fluctuations and calculates the optimum number of active SCNs required at various periods. We proposed an energy-saving access connection remedy and offered two backhauling alternatives to reduce energy use. Our studies reveal that our sustainable telecommunications solution utilizes fewer resources than existing options. A key lesson from this research is the potential for sleep-mode approaches to duplicate parts to address the increased energy consumption associated with network denaturation. Our strategy fits the mold of similar approaches. The research also confirmed that several backup systems ensure minimal power consumption even during peak use. Our subsequent research will analyze when traffic backups should switch from one way to another to minimize overall energy consumption. We will look at whether or if the BS storage technologies will allow for longer sleeping times to minimize electricity use further.

SIMULATION OF MOTION NONLINEAR ERROR COMPENSATION OF CNC MACHINE TOOLS WITH MULTI-AXIS LINKAGE

XIANYI LI*

Abstract. In order to solve the problem of nonlinear error for a dual rotary table five-axis CNC machine tool due to the linkage of rotary and translational axes, the simulation of motion nonlinear error compensation for a multi-axis linkage CNC machine tool is proposed. The adjacent points in the tool position file are selected as the tool position points for building the model, and then the nonlinear error model resolved by the harmonic function is established according to the error distribution in the classical post-processing. The nonlinear error between the two tool position points is quickly predicted by the analytical expression of this model, and the real-time error compensation of the intermediate interpolation points is realized. Finally, MALTLAB simulation analysis is performed on the tool position file of an impeller part machining to verify the effectiveness of the proposed algorithm. The experimental results show that it can be seen from the distribution curve of the nonlinear error that it is about 10% after compensation as before compensation, thus verifying the effectiveness of the nonlinear error compensation mechanism. The correctness of the nonlinear error analysis and compensation method and the effectiveness of post-processing are verified.

Key words: nonlinear error, error compensation, CNC machining, post-processing

1. Introduction. Five-axis CNC machine tools are used for machining complex and high-precision surfaces and are widely used in equipment manufacturing, aviation, aerospace and other fields, as the relative motion of the tool and workpiece completes the cutting action. As the machine tool needs to use a large number of discrete linear segments to approximate the contour curve of the workpiece in the process of machining, coupled with the movement of its rotary axis, it will cause inconsistency between linear interpolation and nonlinear motion and generate nonlinear errors, which affects the machining accuracy of CNC machine tools and thus requires effective compensation and control [1]. In NC machining, a series of linear segments are used to approximate the surface of a part linearly. For machining without rotation axis, the tool processes the parts along the piecewise linear trajectory, and the accuracy requirements can be met by setting the tolerance in advance. However, for machining with rotary axes, when the machine tool motion axis to do linear interpolation motion, motion synthesis makes the tool path deviate from the linear segment, forming irregular curves. The error generated at this time is called non-linear error. When processing the curvature of a large change in the free surface, the impact of the error is particularly prominent. Nonlinear errors are difficult to measure and compensate afterwards, but they can be modeled and estimated in advance and pre-compensated to improve the accuracy and quality of the workpiece. The modeling and compensation of nonlinear errors is therefore a key technology in the post-processing of CNC machining [2].

Five-axis machining greatly expands the machining capability and range of machine tools and significantly reduces repositioning errors. Five-axis machine tools play an irreplaceable advantage in the field of impeller blade, complex surface, mold development, etc. Because of the flexible tool attitude control, domestic and foreign research and machine tool manufacturers have conducted many aspects of five-axis machine tool research, the kinematic analysis of the machine tool orthogonal structure has been basically perfect, but in the five-axis machine tool non-linear error research, there are many aspects need to be improved [3]. The rotary axis of 5-axis CNC machine tools can change the direction of the tool axis according to the machining requirements, which can improve the machining efficiency of the machine and reduce the number of clamping of the parts. However, the structure of five-axis machine tools is complex, so there are many technical difficulties in the actual machining. Based on the nonlinear errors generated by the five-axis linkage and the structural characteristics

* School of Mechatronics and Energy Engineering, NingboTech University, Ningbo, Zhejiang, 315100, China (Corresponding author, XianyiLi6@163.com)

of the dual rotary table five-axis machine, the main research of this study is to establish the compensation method and kinematic model of this type of machine [4].

In the multi-axis CNC machining of complex surfaces, due to the influence of machine tool rotary axis motion, the tool trajectory of adjacent tool points is not an ideal interpolated straight segment, but a spatial curve connecting the straight segment, and the difference between them is called nonlinear error. The existence of nonlinear errors can seriously affect the machining accuracy of the surface, so scholars at home and abroad have conducted many studies on the analysis and compensation of nonlinear errors.

2. Literature review. Nonlinear error is a common problem in the five-axis linkage CNC machining process. The reason is that the five-axis linkage CNC system is not continuous trajectory control, but discrete point control. Based on the processing accuracy requirements, CAM software generated tool position file scatters the free curve into tiny linear segments, but due to the five-axis CNC machine tool rotation axis (such as table rotation or tool swing) to join, the trajectory between adjacent tool position points in the actual machining process is a spatial curve instead of a straight line, thus causing a nonlinear error. Therefore, the analysis and compensation of nonlinear error is needed for multi-axis CNC machining [5]. In-depth analysis of the distribution characteristics of this error, two nonlinear error compensation methods based on the workpiece coordinate system and the machine coordinate system are proposed, namely the front nonlinear error compensation method and the back nonlinear error compensation method. These two error nonlinear error compensation methods are to compensate the error in advance and improve the machining quality of the parts. The front nonlinear error compensation method first obtains the posterior processing points of the machine tool coordinate system according to the known tool position points in the workpiece coordinate system, while sampling uniformly in both coordinate systems [6]. Then the post-processing of the sampled points in the workpiece coordinate system and the sampled points in the machine coordinate system are used to construct a compensation vector, which is pre-processed and calculated to obtain the error of the uniformly sampled points, and finally the pre-nonlinear error compensation method is constructed from the sampled points and the tool position points to predict the ideal tool curve trajectory. The method interpolates the curve tool trajectory in the work coordinate system, and then obtains the interpolation points in the machine coordinate system by the classical post-processing, so as to reduce the nonlinear error [7]. The posterior nonlinear error compensation method first selects two points in the tool position file as the tool position points for establishing the compensation method, and then establishes the posterior nonlinear error compensation method according to the maximum error distribution in the middle of the two tool position points in the classical post-processing, and finally the analytical function equation of this compensation method is used to quickly predict the nonlinear error between two adjacent points in the tool position file, so as to realize the real-time error compensation of the intermediate interpolation point.

Five-axis linkage machine structure is complex, with more types of machine tools. It is basically in the three-axis machine tool based on the addition of two rotary axes. The machine is equipped with different control systems. The tool position files generated in the post-processing system comes with CAE or CAD software may not be directly used in CNC machining. It needs to use the post-processing system to convert the tool track file into a specific machine can identify the CNC machining code. Therefore, post-processing has an important role in multi-axis machining [8].

At present, foreign high-grade CNC systems provide a rotary tool center point programming function, which aims to reduce nonlinear errors and improve machining accuracy. However, the core algorithms of these functions are not disclosed. For the characteristics of dual rotary table five-axis CNC machine tools, this study establishes the analytical expression of the nonlinear error model of this type of machine tools, and further proposes a nonlinear error compensation mechanism with RTCP compensation effect. Finally, the effectiveness of this compensation mechanism is proved by MAT-LAB simulation analysis with the impeller as the simulation model.

3. Methods.

3.1. Dual rotary table 5-axis machine post processing and non-linear errors.

3.1.1. Dual rotary table five-axis CNC machine tool machining process. The general five-axis machining process involves CAM software generating a tool position file in the workpiece coordinate system, post-processing it to obtain the corresponding numerical control code (NC code), and then loading the machine

from the NC code for machining. The points in the Workpiece Coordinate System (WCS) are then converted to Machine Coordinate System (MCS) points after compensating and post-processing.

3.1.2. Dual rotary table five-axis CNC machine tool reverse motion model. The reverse motion model of five-axis CNC machine tool with double turntable is established, namely, the coordinate values in the workpiece coordinate system are known, and the translation quantity of the three translation axes and the momentum of the two rotation axes of the machine tool are solved [9].

$$\begin{aligned} c\theta_A = arccos\theta(\frac{u_z}{L});\\ \theta_C = arctan(\frac{u_x}{u_y});\\ S_x = cos\theta_C \cdot (P_x - m_x) - sin\theta_C \cdot (P_y - m_y) + m_x;\\ S_y = sin\theta_C \cdot cos\theta_A \cdot (P_x - m_x) + cos\theta_A.\\ cos\theta_C \cdot (P_y - m_y) - sin\theta_A \cdot (P_z - m_x) + m_y;\\ S_z = sin\theta_A \cdot cos\theta_C \cdot (P_x - m_x) + sin\theta_A \cdot cos\theta_C.\\ (P_y - m_y) + cos\theta_A \cdot (P_z - m_x) + m_z; \end{aligned} \tag{3.1}$$

where θ_A denotes the angle of rotation of the axis A; θ_C denotes the angle of rotation of the axis C; P_x, P_y, P_z denotes the translation distances of the axis X, the axis Y and Z.

3.2. Nonlinear error modeling and compensation. In this study, the harmonic function is selected as the basis of the polynomial according to the distribution characteristics of the nonlinear error. In order to simplify the function model, the first-order polynomial is selected for modeling, while the mathematical analytic parameters of this model are determined according to the nonlinear error data obtained from simulation experiments, so as to establish the mathematical model of this error.

3.2.1. Non-linear error compensation algorithm. The purpose of error compensation is to find the interpolation point corresponding to the point with the maximum permissible value of error on the nonlinear error model, and then further obtain other locations where the data points need to be reinserted for error compensation. The expression of the nonlinear error model is taken as the compensation function, and the compensation point of the error can be easily found [10].

Considering that the maximum value of error calculated according to the model can truly reflect the accuracy of the workpiece during actual machining, while the maximum allowable value of error characterizes a maximum limit of the accuracy of the machined part, if it exceeds this range, the workpiece may not meet the design requirements and cannot be used, so the basic rules of the nonlinear error compensation algorithm are given in this study.

The magnitude of the maximum value of the error calculated from the model is compared with the maximum allowable value of the error. If the maximum value of the model is larger than the maximum allowable value of the error, the nonlinear error compensation is performed, otherwise, no compensation is performed [11].

3.2.2. Nonlinear error modeling process. The above analysis establishes the harmonic function model and nonlinear error compensation mechanism to predict and compensate the nonlinear error at the interpolation point, and the specific process is shown in Figure 3.1, which is divided into three modules, namely, the post-processing module, the nonlinear error modeling and compensation module, and the nonlinear error calculation and comparison module.

The dashed box in the figure is the general post-processing module, which firstly interpolates the tool position points linearly, and then substitutes the interpolated points into the inverse kinematic model of the dual rotary table five-axis CNC machine tool proposed in this study to obtain the classical post-processing points, that is, the coordinate points and tool axis vectors in the workpiece coordinate system are converted into the coordinate points in the machine coordinate system and the angular displacement of the two rotary axes; the solid box is the modeling and compensation module of nonlinear error. In this study, a real-time prediction nonlinear error model is established and compensated; the dotted box is the nonlinear error calculation

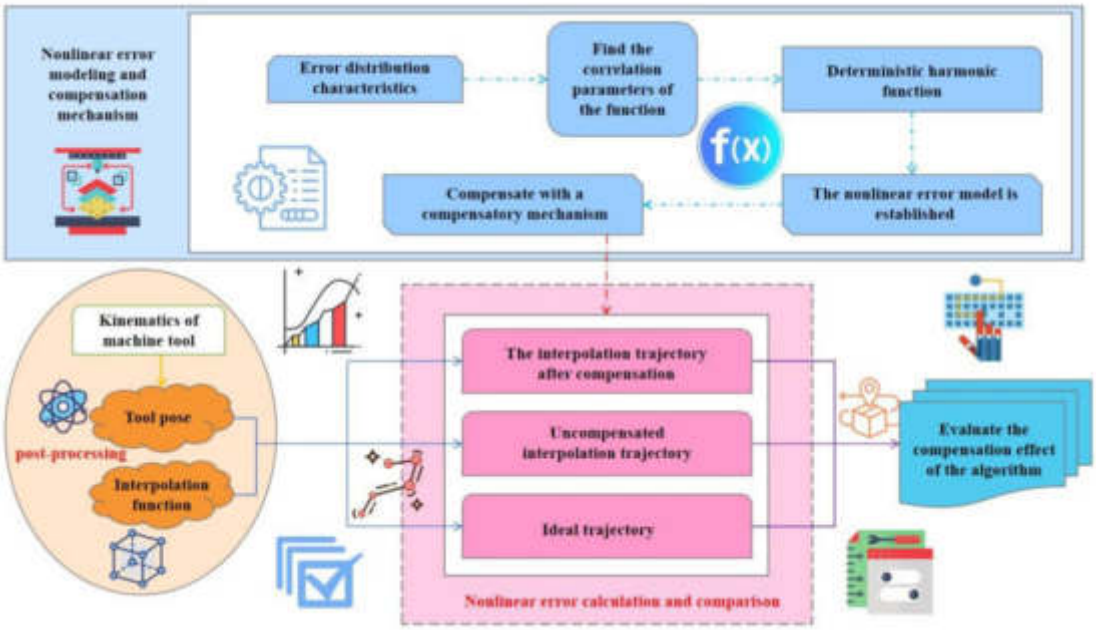

Fig. 3.1: Error modeling and compensation flow

Table 3.1: Interpolation point nonlinear error ε mm

Number	1	2	3	4	5	6	7	8
ε	0	0.1699	0.3235	0.4608	0.5819	0.6867	0.7752	0.8473
Number	9	10	11	12	13	14	15	16
ε	0.9032	0.9428	0.9660	0.97290.9635	0.9378	0.8957	0.8373	
Number	17	18	19	20	21	22	23	
ε	0.7626	0.6716	0.5643	0.4407	0.3009	0.1447	0	

and comparison module, which compares the nonlinear errors of different trajectories, mainly comparing the interpolated trajectory and numerical values, the interpolated trajectory part is to compare the compensated interpolated trajectory, the uncompensated interpolated trajectory and the ideal trajectory in the machine tool coordinate system, and the numerical part is to compare the compensated trajectory and the uncompensated trajectory on the two-dimensional graph. The numerical part is to compare the compensated trajectory and the uncompensated trajectory on a two-dimensional plot [12].

3.2.3. Substitution and post-processing of tool position points. The parameters of the tool point (all in mm) are as follows. $P_0 = (-191.4037, 11.3508, 7.6182)$, $U_0 = (0.00639, -0.036377, 0.99927), P_1 = (-191.4057, 13.5159, 7.9093), U_1 = (0.006393, -0.068922, 0.99960)$ where P is the tool position in the workpiece coordinate system and U is the tool axis vector in the workpiece coordinate system. Linear interpolation is used to substitute these interpolation points into equation 3.1 to find out the corresponding post-processing points. In this study, the ideal trajectory is approximated as a straight line, and the nonlinear error is the deviation of the actual tool position trajectory to the straight line. The calculated nonlinear errors are shown in Table 3.1, which gives 23 interpolation points and their corresponding nonlinear error values. Figure 3.2 shows the distribution of the nonlinear error values of the interpolation points, where the horizontal coordinate is the interpolation point in the middle of P_0 to P_1 and the vertical coordinate d is the value of nonlinear error.

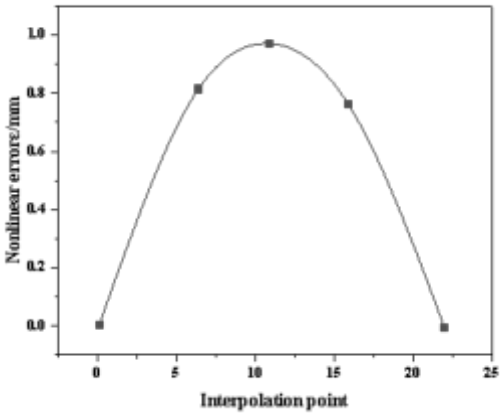

Fig. 3.2: Non-linear error distribution

3.2.4. Harmonic function modeling. According to the characteristics of the nonlinear error distribution, the approximation is based on the harmonic function, and the specific expression is

$$P(x) = \sum_{1}^{m} A_j \cdot sin(kx) + B_j \cdot cos(kx), m = 1, 2, 3, ..., n_0 \tag{3.2}$$

Where A_j, B_j is the amplitude of the harmonic function and m is the order of the polynomial. In this study, the first-order polynomial is used to approximate the nonlinear error for simplicity of calculation. The error at the first and last two points is zero, and the initial value is $b_j = 0, m = 1, x = \pi$. Then equation 3.3 can be reduced to

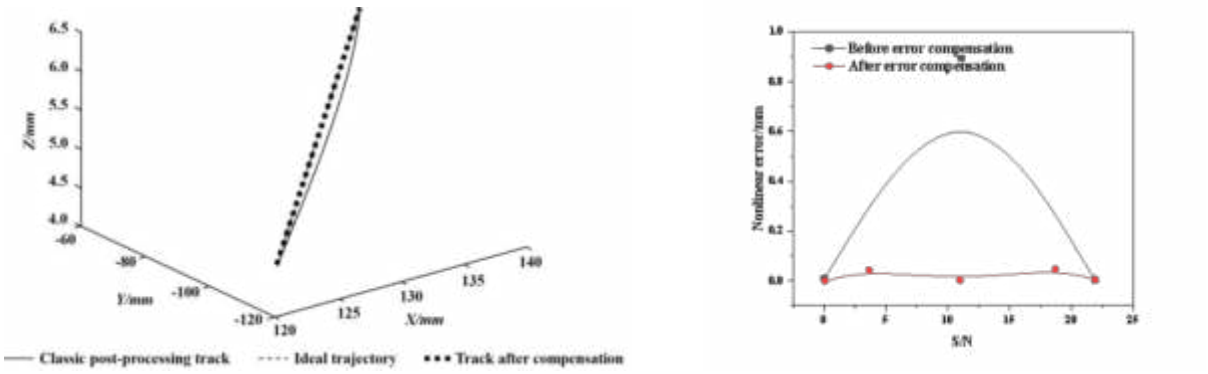
$$\begin{aligned} A_j = P'_{mid} - \frac{(P'_1 + P'_0)}{2}; \\ k = \frac{x_i - x_0}{x_1 - x_0}; \\ P(x) = A_j \cdot sin(k \cdot \pi). \end{aligned} \tag{3.3}$$

Where A_j is the amplitude of the nonlinear error function, and the amplitude of the harmonic function is selected as the error at the midpoint, because the maximum value of the nonlinear error is distributed in the middle of the knife position point, so A_j is the ideal linear midpoint $(P'_0 + P'_1)/2$ to the midpoint of the post-processed is the vector of This is the relative position of the ULR point, and the nonlinear error at the ULR point can be derived from the corresponding position [13].

3.2.5. Nonlinear error harmonic function compensation mechanism. In this study, data matrices are constructed in MATLAB, and these matrices are used to store the three-dimensional data of the post-processing points after the nonlinear error compensation. The compensation function ε is P(x), and the harmonic function error model can be obtained from equation 3.3. The distribution of nonlinear errors is predicted according to the nonlinear error model for nonlinear error compensation, and the analytical formula is

$$\begin{aligned} \varepsilon = P(x) \\ P_\lambda" = P'_\lambda - \varepsilon_0 \end{aligned} \tag{3.4}$$

The matrix is derived by equation 3.3 P_x^t of the error compensation value, and substitute into equation 3.4 to get the post-processing point after compensation. The residual nonlinear error between the uncompensated



(a) Toolpath diagram in the machine coordinate system (b) Nonlinear error distribution of post-processing points

Fig. 3.3: Distribution of tool trajectory and non-linear error at the verification point

and this compensation are compared, as shown in Figure 3.3a, the forked dotted line is the uncompensated tool trajectory, the dotted line is the compensated tool trajectory, and the solid line is the ideal trajectory; the dashed line in Figure 3.3b is the uncompensated tool trajectory error, and the star dotted line is the compensated tool trajectory error [14].

3.3. Data simulation and experimental validation. A typical 5-axis machined part, an impeller, was selected for verification. The impeller's blades are free-form, so multi-axis machining is required in The multi-axis machining mode generates the machining tool position file of the workpiece. In this study, a section of the main blade machining tool position file of the impeller is selected for verification [15].

The machining mode is used to export the data of the entire machining tool position file $P(x, y, z)$ is the spatial coordinate of the tool point, $U(i, j, k)$ is the spatial coordinate of the tool axis vector. A section of tool position file with 20 tool points is selected for verification, as shown in Table 3.2.

MATLAB is used to calculate all intermediate interpolation points, and the post-processing points are obtained by post-processing. The nonlinear error of each post-processing point due to rotary axis linkage is calculated by the harmonic function model of nonlinear error, and then the nonlinear error compensation mechanism proposed in this study is used to compensate the error of the post-processing points [16].

4. Results and Discussion. The tool position points in Table 3.2 are linearly interpolated and post-processed (Eq. 3.1) to obtain the coordinate information of the five axes of the machine and the position of the interpolated trajectory in the machine coordinate system. Figure 4a shows the comparison of tool trajectory, where the dashed line is the curve without compensation and directly post-processed, and the solid line is the trajectory after compensating the error with the nonlinear error compensation function proposed in this study, and the dotted line is the ideal trajectory. Figure 4.1b shows a partial enlargement of Figure 4.1a, which shows that the solid line is closer to the dotted line than the dashed line, i.e., the curve using the proposed nonlinear error compensation method is closer to the ideal trajectory than the uncompensated curve [17].

The distribution curve for the nonlinear error shows that it is about 10% after compensation as before compensation, thus verifying the effectiveness of the nonlinear error compensation mechanism.

In order to address the nonlinear errors generated by the linkage of rotary and translational axes in a dual rotary 5-axis CNC machine tool, this study proposes an analytical model to predict and compensate for the nonlinear errors in real time. The first-order harmonic function is selected for fitting, and the analytical expression of the distribution of the harmonic function error model is established with the first and last two points and the middle point with the characteristic that the maximum value of this error is distributed at the middle point [18].

The simulation results show that the nonlinear error vector compensation according to the harmonic func-

tion model can effectively improve the error magnitude, and the peak of the nonlinear error compensation using the nonlinear error harmonic function compensation mechanism does not exceed 0.5, and the peak of the uncompensated trajectory error exceeds 4.5, and the error is effectively improved [19,20].

5. Conclusion. In this study, a simulation for compensation of nonlinear error of multi-axis linkage of CNC machine tool motion is proposed. The nonlinear error model established by using harmonic function investigated in this study in the machine tool coordinate system needs to calculate the coefficients of the harmonic function. For the nonlinear error generated by the linkage of rotary and translational axes in a dual rotary five-axis CNC machine tool, an analytical model for real-time prediction and compensation of nonlinear error is proposed. The first-order harmonic function is selected for fitting, and the analytical expression of the distribution of the harmonic function error model is established with the first and last two points and the

middle point with the characteristic that the maximum value of the error is distributed at the middle point. The nonlinear error vector compensation based on the harmonic function model can effectively improve the error size.

COMPUTER SIMULATION AND SIMULATION OF MECHANICAL AND ELECTRICAL EQUIPMENT BASED ON ARTIFICIAL INTELLIGENCE ALGORITHMS

YING ZHANG*

Abstract. The computer in mechanical and electrical equipment can now detect equipment faults through simulation thanks to the advancement of artificial intelligence (AI) technology, which makes it convenient to monitor mechanical and electrical equipment. This paper begins with a quick introduction to Agent and the Agent system, explains how Agent is applied in the current context, then analyzes the hierarchical fault diagnostic model, identifies its flaws, and suggests improvement techniques. To increase the model's accuracy and speed of operation, the contract net model and D-S (Dempster-Shafer) evidence theory are then incorporated. Finally, simulation experiments are used to confirm the accuracy and consistency of this model. According to the experimental findings, this optimization model runs at a pace that is noticeably faster than that of other models when subjected to the same workload, demonstrating the model's efficacy. Models 1, 2, and 3 are put side by side to demonstrate how clearly multi-task processing may cut down on the model's running time. In the second experiment, samples of mechanical and electrical equipment defect data are taken from two groups. The results of the comparative experiments demonstrate that the optimized model in this work can be reliable up to a maximum of 0.91 and a minimum of 0.63. It is demonstrated that the model in this work is rational by the fact that among the four types of fault prediction, the optimized model's reliability is significantly greater than the traditional model's. The research described in this publication therefore has some reference value for computer simulation of electromechanical equipment.

Key words: Artificial intelligence, Mechanical and electrical equipment failure, Computer simulation, Agent system, D-S evidence theory, Hierarchical fault diagnosis model

1. Introduction. Modern mechanical and electrical equipment has a higher degree of automation than ever before, and as its size and complexity increase and its subsystems become more closely correlated, these factors all contribute to an overall increase in automation. As a result, diagnosing equipment faults has never been more challenging [1]. The likelihood of failure has also substantially enhanced, and its expressions are numerous. A problem source may also set off a chain reaction that results in more failure. Additionally, modern businesses now strive to achieve safe and stable functioning of large-scale, complex electromechanical equipment, early fault prediction, predictive maintenance management, and minimization of economic losses brought on by faults and maintenance. Finding appropriate condition monitoring and fault diagnostic methods is, thus, a significant study area for scientists and technology professionals. The study of robots, language recognition, picture recognition, natural language processing, and expert systems all fall under the umbrella of the computer science subfield of artificial intelligence (AI). The science and technology behind AI have advanced significantly since its inception, and its range of applications is likewise growing [2].

Saufi et al. (2019) once developed a solar array model to simulate potential fault types in the real functioning of the array and gather fault data. Four rows and three columns of simulated photovoltaic arrays were established in the computer in accordance with the extensive study of the power generation principle and array connection structure of photovoltaic cells, combined with the on-the-ground investigation in Zichuan Xinmingzhu Photovoltaic Power Generation Center. Based on research into the factors that lead to array failures, a failure operation state was simulated, the output characteristics of the array in each failure state were compared to those in the normal failure-free state, and real-time failure operation data were acquired [3]. Using this information as a foundation, Park et al. (2020) proposed a stacked method of creating a countermeasure network to address the issue of imbalanced categories in fan data sets. They also carefully took into account the correlation and timing of fan data characteristics when creating new samples. Using this technique, data is

* King Hon College, Zhengzhou Railway Vocational and Technical College, Zhengzhou, Henan, 450052, China. (YingZhang661@163.com)

generated gradually while maintaining both the strong and weak correlations between attributes. Additionally, while the cyclic neural network is built, the generators and discriminators for the countermeasure network are formed, and the time series properties of the data are recorded. The random forest technique is employed in the background to filter out the highly significant characteristics, which lowers the difficulty of model development and speeds up model training.

The model is broken down into two stages: in the first stage, samples are trained in groups according to the findings of the analysis of correlation coefficient and maximal mutual information coefficient, and feature subsets of the appropriate groups are formed. The poor correlation between the features of each group is adjusted to provide minority sample data with high simulation in the second step, where each group of feature data obtained in the first stage is spliced as input [4]. In addition to using neural networks, Qiao et al. (2019) improved the K-nearest neighbor approach and created sub-blocks using the mutual information between variables to extract the local information of the process, resulting in more identical information for the variables in the sub-blocks. Based on this, a defect detection model using the K closest neighbor approach is created for each variable sub-block, and the Bayesian inference method is utilized to combine the detection findings of each sub-block, improving the overall detection effect. Additionally, the Mahalanobis distance-based fault diagnosis method is used.

The source variable generating the error is identified and isolated by computing the Mahalanobis distance between each variable in the sample and its mean value. Final evidence that this method has a greater warning rate than the conventional fault detection method comes from the Tennessee-Hysmans process simulation experiment [5]. Ju et al. (2021) presented a fault detection method of generative countermeasure network with coded input to address the issue that the standard fault detection method based on generative countermeasure network uses random noise as generator input and the network training impact is not good. After dimension reduction, the hidden variable information is used as the input to the self-encoder, which is then introduced. In order to address the issues with defect detection methods' high computation costs and sensitivity to outliers, a novel statistical calculation method based on self-hidden encoder's variable extraction is proposed. The simulation results using the Tennessee-Hysmans process and real coal mill process demonstrate that the suggested strategy can enhance the network training effect [6].

Based on the foregoing context, this paper first introduces Agent and its system and describes its use and flaws; Second, a description of the hierarchical fault diagnosis model is provided, along with optimization recommendations. Thirdly, the classical model is optimized by mixing neural networks, and the Dempster-Shafer (D-S) theory is briefly explained. Finally, comparative experiments are used to confirm the validity and effectiveness of this approach.

2. Establishment of computer simulation model for electromechanical equipment.

2.1. Agent and Agent system. One of the most significant research areas in the field of artificial intelligence is agents and agent systems, which has a wide range of potential applications. Although the concept of an agent has long been debatable, all academics concur that agents have autonomy. The notion of Agent is therefore utilized to define what is considered to be a conscious intelligent system, and cognitive elements like belief, ability, intention, and commitment in the process of human activity are used [7,8]. Figure 2.1 depicts its composition and model structure.

Agent is an abstract word that can represent all sentient entities. It is also known as the Belief Desire Intention (BDI) model. It can be used to describe not only robots but also intelligent software, objects, and people. Typically, an agent exists in an environment, observes the environment using its own sensors, and then acts on the environment using effectors. Even if a single agent is active and autonomous, it is unable to exist in the environment on its own and must interact with other agents there in order to complete its tasks. The Agent's structure specifies the components that make up the agent, how the components communicate with one another, and how the agent is implemented using hardware and software.

Deliberate agents make decisions through logical deduction, reactive agents make decisions through direct mapping from scenarios to actions, and hierarchical agents make decisions through BDI. In general, the structure of agents can be divided into the following four types: reactive agents, BDI agents, deliberate agents, and hierarchical agents. In order to make decisions, BDI agents operate data structures that reflect their beliefs, wishes, and intentions, while hierarchical agents use various tiers of software, each of which partially implements

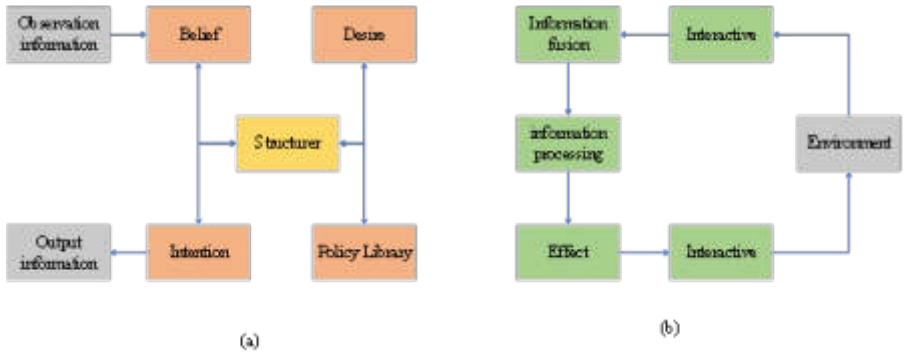

Fig. 2.1: Agent composition and structure diagram (a) Agent composition; (b) Agent structure diagram

reasoning about the environment. The thinking Agent is the most frequently employed of these four categories. Due to the complexity of the multi-agent system environment, each agent's information about the environment differs in the distributed fault diagnosis system for large-scale complex electromechanical equipment. Information fusion technology can be used to process numerous data sources, and the collaboration of different agents can lead to more thorough and accurate problem diagnosis results.

The developed multi-agent system uses a variety of sensors to gather data, which is then processed in a consistent format before information fusion is performed. Additionally, the system's agents can communicate with one another to collaborate and coordinate, creating a stable and effective system. The multi-agent system is broken down into three layers in this paper through analysis: the data processing layer, the primary diagnosis layer, and the information fusion layer. These layers each contain several roles [9,10]. Because Agent roles' duties vary, it is necessary to model them in accordance with the tasks that each position is responsible for. Figure 2.2 depicts their structures:

The foundation of the system environment, which is used to gather the system's original signals, is the data collection agent. To provide the system with the preprocessed original environmental information, the information processing agent preprocesses the original signal and applies various feature extraction techniques depending on the task scenario. The major duties of the data collection and information processing agent include gathering machine state data and giving the diagnosis system the original data. In multi-agent systems, the Management Agent is crucial for understanding the overall state of the entire system. Establishing the job, mastering the evaluation criteria for the breakdown of diagnostic tasks, assessing the diagnostic agents in the system, and formulating cooperation rules as the cornerstone for efficient coordination and collaboration among agents are some of its special functions [11]. Neural networks make up all different types of defect diagnosis agents, and each diagnosis agent has a unique diagnosis technique. They are able to fulfill the diagnosis function in accordance with the circumstances by extracting features from the original environmental information. Their specialized duties include receiving information from information processing and data gathering agents in accordance with the properties of environmental information. Accept the management agent's orders and carry out the tasks in accordance with the specifications and its own algorithm.

2.2. Hierarchical fault diagnosis model. The original signal is captured by the data collection agent in the agent system, and the feature is extracted by the information processing agent. The management agent executes global management, selects the appropriate data collecting and information processing agents, and decides the necessary diagnosis approach based on the job scenario. Next, a variety of tasks are assigned, and then various diagnosis agents are chosen depending on the contract network's bids. The specific fault diagnosis analysis then gets underway [12]. Figure 2.3 illustrates its hierarchical structural model.

This paradigm, which is abstract in nature, can be used to create distributed fault diagnosis systems for a variety of intricate electromechanical devices. However, the deployment of this paradigm must vary for various application contexts and diagnostic objects. The main challenge for the practical implementation of the model

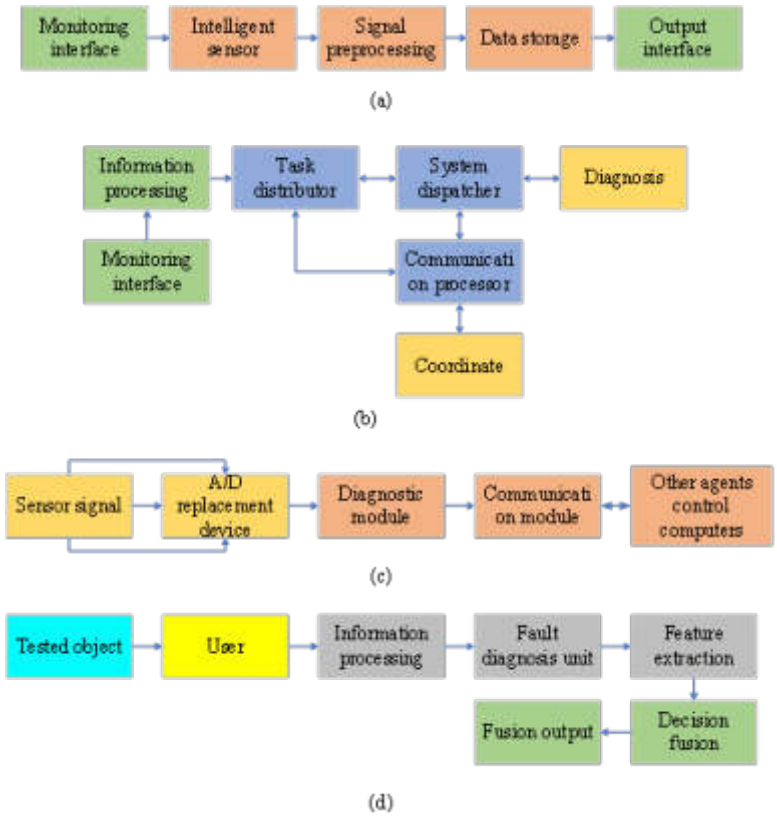

Fig. 2.2: Composition of roles in Agent model (a) Data acquisition and information processing structure; (b) Internal structure of management agent; (c) Fault diagnosis internal structure; (d) Fault diagnosis fusion structure

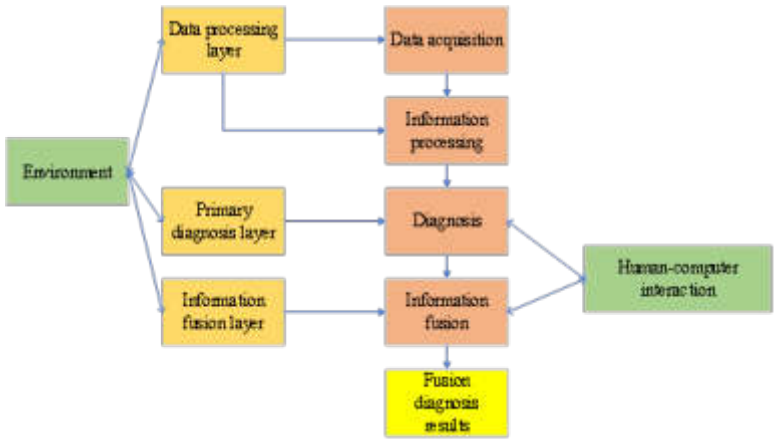

Fig. 2.3: Multi-level structure model

is to address its adaptability, or the flexible deployment of the model in various applications. A large-scale, intricate electromechanical system is made up of many different subsystems, and each subsystem has a large

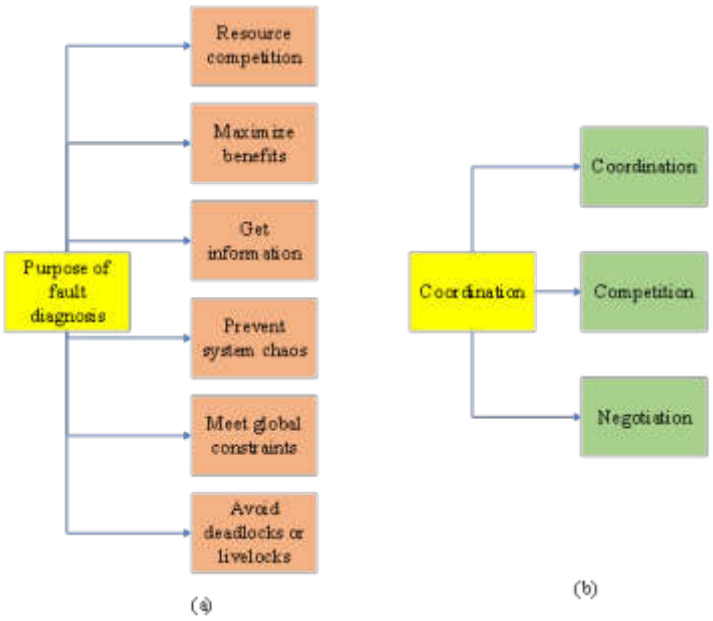

Fig. 2.4: Cooperation mode and purpose (a) Purpose of collaboration; (b) Collaborative approach

number of devices. Each gadget varies in complexity and has a number of parts. An efficient solution to address the system's overall state monitoring, fault diagnosis, and predictive maintenance is to build a distributed fault diagnosis system using a multi-agent system. However, the architecture and locations where devices are put vary amongst various complex systems. Important issues in practical application include how to design computers to properly monitor various devices, how to deploy various Agent on the network, and how to establish up a monitoring network in accordance with the unique characteristics of various systems [13].

Modern mechanical equipment fault diagnosis has gone through a number of stages, including distributed online diagnosis, remote distributed diagnosis, single-machine online diagnosis, centralized online diagnostic, and off-line diagnosis. There are benefits and drawbacks to each step. One of them, off-line fault diagnosis, has the advantages of economy, convenience, and flexibility, but the drawbacks are that it cannot fully obtain mechanical equipment operation information and cannot resolve single-machine on-line fault diagnosis in time when encountering sudden faults, not to mention that it is too expensive. While sharing information and saving money are benefits of centralized online fault diagnosis, real-time diagnosis is not very good. The advantages of distributed online fault diagnosis include strong real-time performance and inexpensive costs, but the drawback is that the system as a whole is not flexible [14].

The study of AI is currently focused on distributed artificial intelligence (DAI), which uses several agents. Studying the cooperation between several Agents is thus a crucial task in distributed AI systems. It can work together to accomplish tasks that a single Agent cannot. Figure 2.4 illustrates its cooperation strategy and goal.

The interaction between diagnostic agents and fault information as it exists now, as well as the coordination and collaboration among diagnostic agents, are all part of online network fault diagnosis. Due to the intricacy of the diagnosis task, the distributed fault diagnosis system's fault diagnosis agents are dispersed across several geographic regions and must collaborate with one another to perform the mission [15]. It is common for Agents with varying expertise and skills to work together to complete diagnostic tasks. Task distribution can be a dynamic process including ongoing dialogue, and the completion of the overall task is ensured by the release of each subtask. The contract network protocol should be used for negotiation during this process.

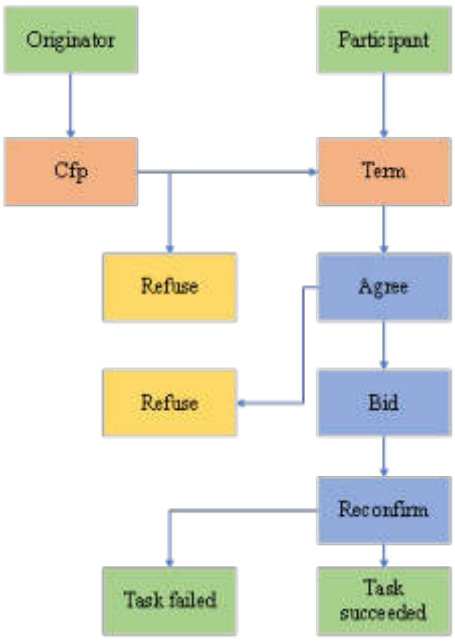

Fig. 2.5: Optimized sequence diagram

2.3. Contract net model. The contract net concept is the most well-known technique of collaboration. The fundamental tenet of the contract net model is that tasks are assigned by competitive bidding among Agents, and that tasks are distributed and bargained during the competitive bidding process utilizing a communication system. There are four basic stages to the collaboration process based on the traditional contract network: First, the task initiator notifies the task participants of a tender request. Second, the task participants respond to the initiator's request within the allotted time frame and those who do not respond within that time frame assume that they will give up bidding. Thirdly, the task initiator chooses one or more successful bidders, notifies those who have won the bid, and notifies those who have not. The participants that won the bid eventually respond that they failed and were eliminated [16]. The time required can be estimated if there are numerous task initiators and participants with limited resources, and if the next task can only be negotiated after each task is finished in a first-come, first-served order. The task execution pace will be significantly increased, nevertheless, if these tasks are negotiated simultaneously to the fullest extent possible, taking into account each Agent's capabilities [17].

In order to efficiently utilize the resources of each Agent, this study proposes the Contract Net Protocol Based on Posting Commitment Time (P-CNP). Figure 2.5 displays the timing diagram that has been optimized.

At this point, the sponsor assesses the applicants, places them in a queue, and then prioritizes sending the inquiry information, reconfirming the bidder's ability to actually accomplish the assignment. It transfers the query information to the next participant when the person being queried provides the rejection information or goes beyond the minimum time limit, which can save a ton of time and system resources [18].

2.4. Fault diagnosis method based on multi-layer spatio-temporal information fusion. The target of mechanical defect detection now exhibits several novel properties such as time-varying, nonlinear, lagging, complexity, and fuzziness due to the ongoing advancement of modern science and technology. It frequently happens that every type of problem occurs at the same time when a system malfunctions. As a result, there will be several occurrences like erroneous identification and omission if people attempt to monitor the working conditions and detect the various defect characteristics in complex systems just using theoretical methods and information [19].

Making the performance of the entire information system greater than that of the component subsystems

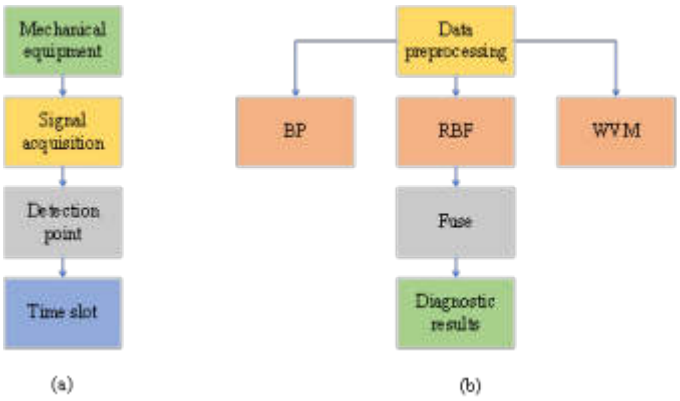

Fig. 2.6: Multi-layer spatiotemporal domain information fusion fault diagnosis model (a) Data acquisition model; (b) Diagnosis and fusion model

is the fundamental idea behind and place where information fusion begins. Their redundant or complementary information in time or space is reasonably merged according to specified criteria through the logical control and utilization of numerous information sources [20]. In the fault diagnosis system, the fusion technology of multi-sensor information can increase the fault diagnosis accuracy of the system, improve the accuracy of state estimation, improve the detection performance and increase the reliability of diagnosis results, and maximize the scheduling of the system and the utilization of information resources based on sensor resources. As a result, a novel Multi-Tier Time Space Domain D-S Information Fusion Diagnosis Model (MT-TS-DS) model is developed by incorporating neural networks with D-S evidence theory.

In the process of diagnosing a specific fault, samples are taken at adjacent time intervals of the same monitoring point, the features are extracted, and the results of the diagnosis are given in order to avoid the diagnosis uncertainty brought on by different sampling times at the same monitoring point of the same piece of equipment. The results from various time periods are then combined using D-S fusion as the foundation for the aforementioned spatial fusion. This multi-layer time-space D-S information fusion defect diagnosis technique employs neural networks and D-S evidence theory. Figure 2.6 displays the diagnostic model for it.

Its sub-neural network local diagnosis process is primarily focused on the various operation state information of mechanical equipment in various time periods. It uses various sensors to collect the operation data of the equipment and then extracts the fault information's characteristics through time domain analysis and wavelet decomposition, creating various fault feature vector spaces and corresponding fault type spaces. Then, for each defect feature vector space and related fault type space, a matching neural network is built, and it is trained using experimental samples. The parameters, such as training duration and training times of each neural network, are received during the test for each trained sub-neural network, which supplies the D-S information fusion with the essential parameters. The goal of the global diagnosis is to compile the findings from each neural network's diagnosis in one place. This allows the D-S evidence theory's evidence space to be generated, and numerous diagnosis findings in the same operating state can be considered different evidence components. The identification space is then built according to the different equipment fault types, and the basic probability assignment function is used to determine the potential probabilities of each fault type. The diagnosis conclusion is then reached after applying the D-S evidence theory fusion rule to determine the probability distribution of the total failure type based on the failure type probabilities of each D-S evidence element.

The most crucial stage is to analyze and handle the motor fault signal after it has been captured by the fault signal acquisition system. The feature vector of the fault signal is created after the fault signal has been extracted using time domain analysis and wavelet decomposition, and it is used as the input vector of the following neural network. The fault signal's characteristic vector, which is susceptible to non-stationary signals, is taken into account by the time domain analysis method using the parameters of the time domain amplitude domain. The mechanical equipment fault signal is divided by the wavelet analysis method into numerous

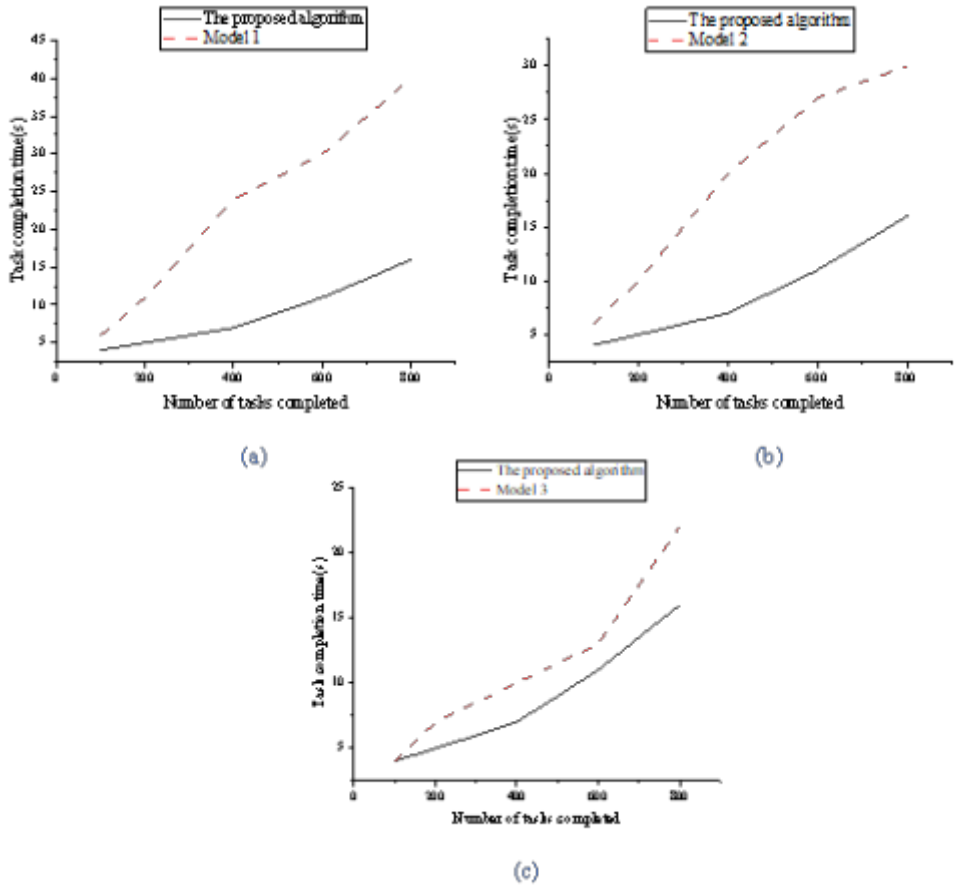

Fig. 3.1: Comparison of task completion time (a) Comparison between the proposed model and model 1; (b) Comparison between the proposed model and model 2; (c) Comparison between the proposed model and model 3

independent frequency bands, and each band's energy is then sent to the neural network as an extracted feature vector. Both time domain analysis and wavelet decomposition are effective techniques for extracting features from mechanical defect signals.

3. Comparison of experimental results between computer simulation optimization of electromechanical equipment.

3.1. Comparison of task completion time results between traditional model and optimization model in this paper. The number of Agents is set to 20, and the number of tasks is set to 100, 200, 400, 600, and 800. In this paper, model 1 is a traditional model, model 2 is an access policy base model, model 3 is a model with task parallel processing and a delay waiting mechanism, and model 4 is an optimized model. Figure 2.7 depicts their comparative experimental results.

According to Figure 3.1, under the same number of tasks, the time required to complete the task is the shortest, and as the number of tasks increases, the time increase rate of the optimization algorithm in this paper is also the slowest, which is more stable than the traditional model. According to their data, model 1 and model 2 take longer to complete tasks than model 3 and this model, which also demonstrates the benefits of multi-party task processing and can significantly save space resources and time loss in the environment of secondary confirmation.

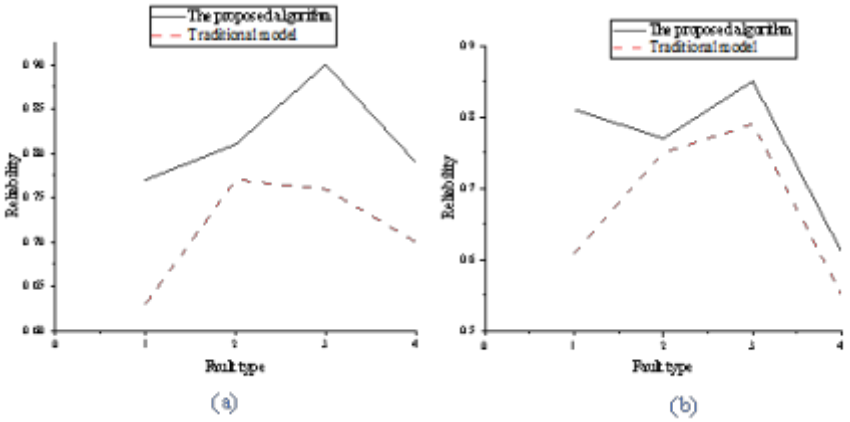

Fig. 3.2: Credibility comparison (a) Comparison of the results of the traditional model and the proposed model in sample 1; (b) Comparison of the results of the traditional model and the proposed model in sample 2

3.2. Comparison of reliability of fault diagnosis results between traditional model and this model. As samples, two types of mechanical and electrical equipment fault information are chosen, with the equipment cracking being 1, the equipment aging being 2, the functional failure being 3, and the excessive pressure being 4. Finally, their dependability is determined. Figure 3.2 depicts the experimental results.

Figure 3.2 shows that the reliability of the optimized algorithm in this paper is higher than that of the traditional model, with the highest reliability being 0.91 and the lowest being 0.63, but it is also higher than the traditional model's recognition rate. Meanwhile, the model in this paper has the highest reliability in identifying functional failure, according to the image, because the model in this paper is diagnosed using a neural network. If the failure information is not responded to, it is automatically deferred to the next information. Because functional failure causes errors in subsequent information data, the model has a higher recognition degree of functional failure.

4. Conclusion. A wide range of cutting-edge technologies can be used in conjunction with the broad utilization of mechanical and electrical equipment. AI is one of the most commonly used technologies in mechanical and electrical equipment, and current research is focused on using computer simulation to conduct experiments to identify mechanical and electrical equipment defects. As a result, this paper begins by introducing Agent and the Agent system, then goes on to detail Agent's current applications in mechanical and electrical equipment, explain the hierarchical fault detection model and its current drawbacks, and finally propose an optimization strategy. To increase the efficiency of this model's computation, the contract net model is once more detailed and added to the optimization model in this work. The dependability and logic of this model are then tested through trials before the multi-temporal spatial information fusion diagnosis technology is integrated into the model. The experimental findings demonstrate that the optimized model in this research runs at a significantly higher speed than competing models when subjected to the same workload, demonstrating the model's efficacy. The ability to multitask can shorten the model's running time, as seen by a comparison of Models 1, 2, and 3. In the second experiment, samples of mechanical and electrical equipment defect data are taken from two groups. The experimental findings demonstrate that the optimized model in this work can have a reliability between 0.63 and 0.91. The reliability of the four fault types predicted is substantially higher than that of the conventional model, demonstrating the soundness of the model used in this paper.

This paper also suffers from a number of flaws. On the one hand, the MT-TS-DS model completes multi-source information fusion using neural network technology and D-S evidence theory, and the fusion effect is ideal. On the other hand, other intelligent information processing technologies, such as support vector machines, have not been considered, and the fusion of other technologies will be taken into account in subsequent research. Nonetheless, the fault diagnosis experiment in this work only takes into account four fault kinds; however,

future research will also enhance the corresponding problem categories, increasing the experiment's credibility.

THE SECURITY AND PROTECTION SYSTEM OF ELECTROMECHANICAL EQUIPMENT IN SMART CAMPUS USING THE IMPROVED DATA MINING ALGORITHM

ANYUAN HE*

Abstract. In order to improve the maintenance and management efficiency of campus electromechanical equipment and reduce or even avoid the safety risks brought by campus electromechanical equipment, this work uses the data mining algorithm to design the security and protection system of campus electromechanical equipment. First, this work constructs the campus electromechanical equipment classification model using the Bayesian algorithm of data mining algorithm and designs a simulation experiment to verify the effect of the classification model. Then, the security and protection system for the campus electromechanical equipment is designed. It includes the system business process, system function design, system core module's function design and system implementation. Finally, a simulation experiment is designed to verify the system's performance. The results show that: (1) Bayesian algorithm is superior to the K-Nearest Neighbor (KNN) algorithm in both classification effect and running time. (2) When the browser concurrency in the system increases, the server processor and memory usage also increases, but the value meets the expected requirements. It shows that the system has a certain browser concurrency-bearing capacity. Moreover, as the browser concurrency of the system increases, the response time of the test also increases, but the value meets the expected requirements. This work aims to improve the maintenance efficiency of campus electromechanical equipment and provide a reference for the safety protection work of electromechanical equipment in other enterprises or units.

Key words: data mining, campus electromechanical safety, Bayesian algorithm, K-Nearest Neighbor algorithm, simulation experiment

1. Introduction. Foreign developed countries have studied the informatization of equipment management since the 1970s. At present, the equipment management system has been quite popular abroad, especially in the United States. Many public places, such as hospitals, schools and enterprises, have used information technology to varying degrees, and the management of instruments and equipment is quite standardized [1]. The Asset Management Solution equipment operation management system developed by Fisher-Rosemount is relatively complete [2]. The Maximo equipment management system developed in the United States takes preventive maintenance as the means and cost management as the core to achieve economic optimization and benefit maximization. Currently, the system has been applied worldwide, with over 5000 installations in major enterprises, especially in safety, education, aerospace, medical, and machinery manufacturing [3]. Moreover, foreign scholars consider using the knowledge base to summarize common faults, thereby helping users automatically find and solve faults. Such systems are often referred to as expert systems [4]. The early expert system is adopted to help medical staff make medical diagnoses and help managers make decisions on problems. They usually need to establish a perfect knowledge base and inference rules to give corresponding conclusions according to the problem phenomenon. This kind of system has been widely used in fault management systems worldwide.

China starts relatively late in the research of equipment information management. Since the 1980s, in response to enterprise development needs, some domestic scholars have conducted research on equipment management informatization. Over the years, enterprises and universities in some regions of China have developed lots of excellent equipment management software, which has improved the efficiency of fixed asset management and made certain technological progress. The software all have the functional modules required by general enterprises to manage equipment and instruments, including basic equipment information management, equipment bidding and purchasing, equipment operation and maintenance prompts, equipment repair forecast and

*Information Technology Center, Nanjing University of Aeronautics and Astronautics, Nanjing, 210016, Jiangsu, China. (AnyuanHe9@163.com)

repair cost estimation, equipment depreciation and scrapping, which basically achieve automatic management [5]. For example, Guangzhou Zhengtai PMISS.0 equipment integrated management system can realize the integrated management of equipment information [6]. HSWZ001 construction equipment management software of Tsinghua Sware Company computerizes the establishment of equipment archives account, account accounting, equipment maintenance and equipment scrapping [7]. The College Teaching and Scientific Research Instrument and Equipment Management System developed by the Beijing University of Chemical Technology, which many colleges currently use, can complete the accounting management of equipment and the task of reporting various data required by the Ministry of Education [8]. Besides, Zhao et al. (2021) pointed out that the equipment manager can use the electronic information platform to access the equipment data with the highest efficiency through the establishment of electronic equipment drawings, technical manuals, and parameter report archives for the convenience of equipment repair and maintenance. Moreover, this kind of electronic archive is easier to preserve than paper materials [9]. Huazhong University of Science and Technology has developed an equipment information management system based on Java EE technology architecture on the basis of traditional architecture. Java EE is a crucial development platform directly built based on the Java 2 standard [10].

In summary, the current equipment management informatization in China has just started. Moreover, equipment management in China is deeply affected by the traditional management mode. The equipment automation level of many schools and units is still deficient, and they do not pay enough attention to equipment information processing, so there is still a big gap compared with foreign countries. Based on this, this work studies the safety protection of campus electromechanical equipment based on a data mining algorithm. The innovation is to use the improved statistical classification algorithm of data mining algorithm - Bayesian algorithm to classify and recognize campus electromechanical equipment. This algorithm has a good classification effect. This work aims to improve the management level of the electromechanical equipment fault prediction and maintenance plan generation system in colleges in the maintenance process to reduce or even avoid the security risks brought by campus electromechanical equipment.

2. Theoretical basis and model design.

2.1. Research on classification model of electromechanical equipment based on Bayesian.

(1) Bayesian classification. Bayesian classification is a classification method based on the classical Bayesian probability theory using the knowledge of probability statistics [11]. Its main idea is to predict the possibility that an item to be classified belongs to each category through Thomas Bayes, and take the category with the greatest possibility as the category of the item to be classified. Thomas Bayes is the conditional probability of random events h and D:

$$P(h|D) = [P(D|h)P(h)]/P(D) \tag{2.1}$$

$P(h|D)$ refers to the conditional probability of event D when event h occurs. It indicates the probability of event h under the premise that event D has occurred [12].

The Bayesian classification covers many types of algorithm models, of which naive Bayesian classification algorithm and Bayesian network are two commonly used. Naive Bayes classifier (NB algorithm), which is a supervised learning method, is a simple and effective classifier. In some application fields, its performance is comparable to that of artificial neural networks and decision trees. The algorithm assumes that attributes are independent based on Bayesian probability. This assumption greatly reduces the construction complexity of the Bayesian application model and makes it suitable for classification tasks in data mining. Meanwhile, this assumption also limits the application scope of the algorithm to some extent [13, 14].

(2) Bayesian-based equipment classification model. The specific goal of the classification management of campus electromechanical equipment is to maximize the accuracy of equipment classification for existing or new campus equipment and minimize the time spent on equipment classification.

Thereby, the NB algorithm (naive Bayesian classification algorithm) is used as the classifier of campus equipment to classify and manage thousands of school equipment [15]. Figure 2.1 displays each module of the classifier and the specific classification process.

Figure 2.1 suggests that the overall classification process of the equipment management system can be divided into three modules.

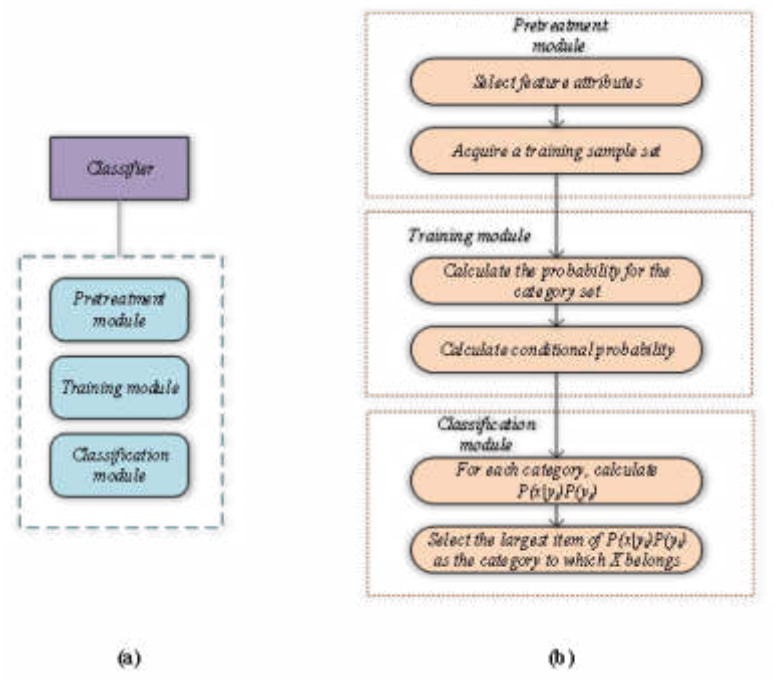

Fig. 2.1: Each module of the classifier and the specific classification process (a) Text classifier module diagram; (b) Classification process of the equipment management system

The first module is the pretreatment module of classifier construction. The main goal of this module is to select the characteristics that can best represent the equipment category from the numerous electromechanical equipment lists of the school. First, each item of data on the equipment list is input as a set of text data to be classified. Then, according to the classification problem's specific situation, the set's feature attributes (these attributes are the attributes that can describe the equipment features) are selected. The classified feature attributes are appropriately taken as the feature attribute set of the classifier to be constructed in the next step. Moreover, it is also essential to randomly select a part of the data to be classified from all the unclassified data object sets to be classified as the sample set, and manually classify the sample set, so that the training sample set is obtained after classification.

The above description reveals that this stage requires manual classification of the training sample set, which is the only part of the NB algorithm that requires manual implementation. This result will greatly impact the construction of the subsequent classification model. It can be said that the quality of the relevant equipment feature attribute set output by this module and the training sample set obtained through manual classification determines the classification quality of the constructed NB algorithm. This module is the basis of the NB algorithm.

The second module is the classifier training module. This module aims to generate the classifier of instances, so this module is also the core of the entire NB algorithm. At this time, the classifier calculates the occurrence frequency of each category in the training samples manually classified previously. The prior probabilities of each feature attribute corresponding to each category are also calculated together, and then these probabilities are recorded for the next classification stage. In this stage, the input is the feature attribute set and the training sample set, and the output is the classifier.

The third module is the classification module. The main goal of this module is to use the classifier produced in the second stage to classify other object data to be classified except for the training sample set. The working objects of this module are the constructed equipment classifier and other data objects to be classified. The data object to be classified has a functional mapping relationship with its category, which is the final output.

(3) Bayesian-based mathematical model for equipment classification. The classification of campus electromechanical equipment is briefly described as follows. A large number of teaching equipment purchased by the school can actually be classified into different equipment categories. For example, according to the category of electromechanical equipment, they can be divided into electronic products and instruments. They can be divided into special equipment and general equipment according to the department using the equipment. They can be divided into consumables and low-value consumables according to equipment cost. Therefore, the above equipment classification problem can be described by the following formalized mathematical model:

1. $x = \{a_1, a_2, a_3, , a_m\}$ is set as a campus device to be classified. Each a is a feature attribute of x used to describe the characteristics of this device, such as projection, computer, and optical fiber.
2. There is equipment category set $C = \{y_1, y_2, y_3, , y_n\}$, such as electronic products and instruments, special equipment and general equipment.
3. The conditional probability $P(y_1|x), P(y_2|x), , P(y_n|x)$of the equipment to be classified for each equipment classification is calculated.
4. If $P(y_k|x) = max\{P(y_1|x), P(y_2|x), , P(y_n|x)\}$,$x \in y_k$.

The above problem description shows that the key to solving the problem now is how to calculate the conditional probability of the device object to be classified for each existing device classification in step 3.

The process of step 3 can be divided into the following sub-processes to solve this problem:

1) From all the equipment sets to be classified, it is necessary to randomly find a subset of the equipment objects to be classified, and manually classify them into each equipment category. The set thus obtained is called the training sample set.
2) The conditional probabilities of the characteristic attributes $a_1, a_2, a_3, , a_m$ of each device corresponding to each device category $y_1, y_2, y_3, , y_n$ are calculated, counted and estimated.
3) If the feature attributes of each device are conditionally independent, the following deduction can be made according to Thomas Bayes:

$$P(y_i|x) = \frac{P(x|y_i)P(y_i)}{P(x)} \tag{2.2}$$

For all equipment categories, the denominator is equivalent to a constant, and the numerator can be maximized. It is assumed that each feature attribute is conditionally independent, so the following equation is obtained:

$$P(x|y_i)P(y_i) = P(y_i)\prod_{j=1}^{m} P(a_j|y_i) \tag{2.3}$$

Hence, the classification of campus equipment can be solved through the above mathematical calculation logic. Figure 2.2 is the architecture of the electromechanical equipment classification mathematical model based on this.

(4) Design of simulation experiment.

Naive Bayesian and K-Nearest Neighbor (KNN) classification algorithms are the most commonly used in text classification. They are both relatively simple and effective classification algorithms. The two algorithms have the same advantages and disadvantages in most text classification experiments. In this experiment, the two algorithms are applied to the actual equipment classification, and the common equipment data in the school equipment inventory are adopted to compare the classification accuracy and time efficiency. According to this, this experiment selects a college as the research object and conducts a simulation experiment design for 200 pieces of electromechanical equipment owned by it. In the experiment, 100 pieces of electromechanical equipment are randomly selected as the training sample set, and the equipment names in the training sample set are manually sorted and classified. The training sample set is divided into six categories: consumables, low-value consumables, instruments and meters, electronic products, special equipment, and general equipment.

2.2. Design and research of campus electromechanical equipment management system. The last section is to use the Bayesian algorithm in the data mining algorithm to design and research the campus electromechanical equipment classification model. This section will further design the security and protection

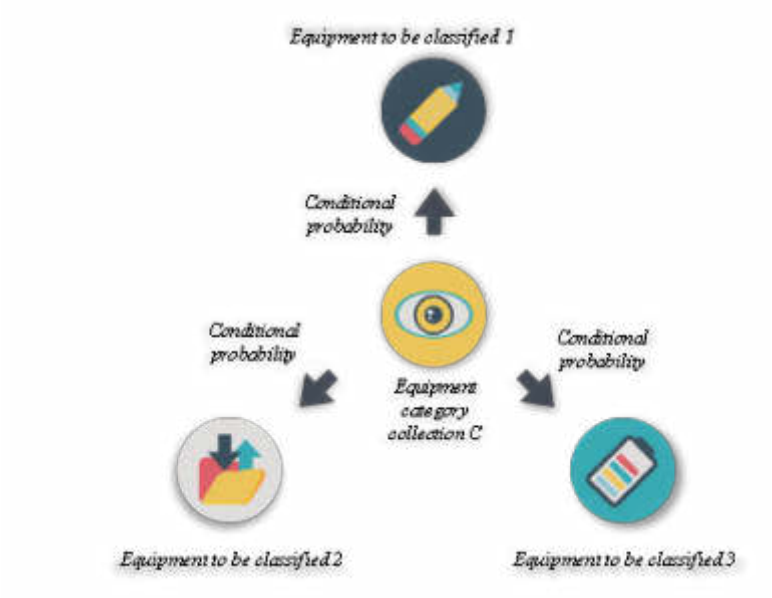

Fig. 2.2: The mathematical model

system of campus electromechanical equipment. It aims to realize fault prediction and intelligent maintenance of campus electromechanical equipment through the system.

2.2.1. System business process analysis.

1) Business process of equipment routine check management. Figure 2.3 presents the designed business process of routine equipment checks according to college's current management characteristics of electromechanical equipment.

Figure 2.3 suggests that the participants in the process of routine equipment checks include the equipment supervisor and the equipment administrator. Equipment routine check refers to the periodic inspection and maintenance of various equipment parameters in equipment management [16]. The equipment supervisor assigns routine check business to specific equipment administrators in routine equipment checks. The equipment administrator needs to set the routine check object, add specific routine check parameters, set specific check cycles, process the routine check data effectively, and finally view the corresponding check report.

2) Process analysis of fault declaration and maintenance management business. Figure 2.4 shows the designed fault declaration and maintenance business process.

Figure 2.4 suggests that in the fault declaration and maintenance management business process, the equipment user department first applies for the equipment fault, then fills in the corresponding application form and submits it to the equipment management department for declaration and approval. The approved information shall be fed back to the equipment user department to formulate a maintenance plan for the failure. The failure repair needs to be approved and submitted to the equipment repair department. Then, it is submitted to the repair and material preparation department. After the repair is completed, it needs to be submitted to the equipment user department for acceptance and settlement.

3) Consigned processing business management process. Consigned processing refers to directly delegating the corresponding equipment maintenance work to the relevant third-party units for specific equipment maintenance when the corresponding technical difficulties or the maintenance department's maintenance workload is too large to complete the corresponding maintenance tasks on time [17]. In the process of consigned processing, the user department of the equipment first makes a repair plan for the equipment, and then the equipment management department approves the plan. After that, the equipment maintenance department proposes corresponding consigned processing suggestions based on the repair task.

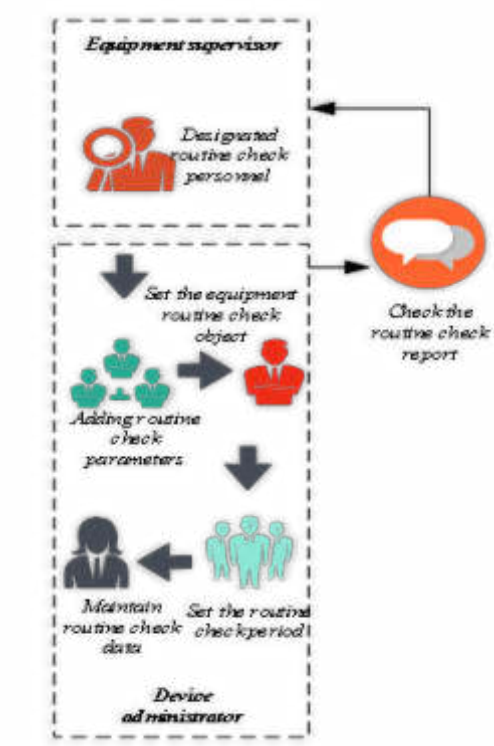

Fig. 2.3: The business process of routine check management

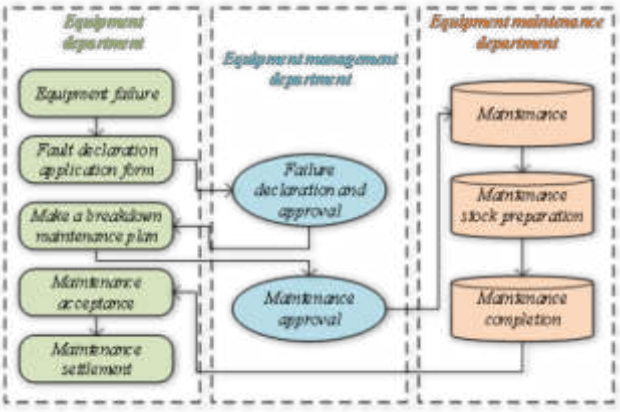

Fig. 2.4: The process of fault declaration and maintenance management business

2.2.2. System functional requirements analysis.

1) Analysis of routine check management requirements. Equipment routine check management is a significant module in the management system of college equipment fault prediction and maintenance plan generation. It mainly assists in the management of basic equipment routine check information during the college equipment failure prediction and the generation of maintenance plans, including the management of routine check position information, equipment routine check object information, equipment routine check data entry management,

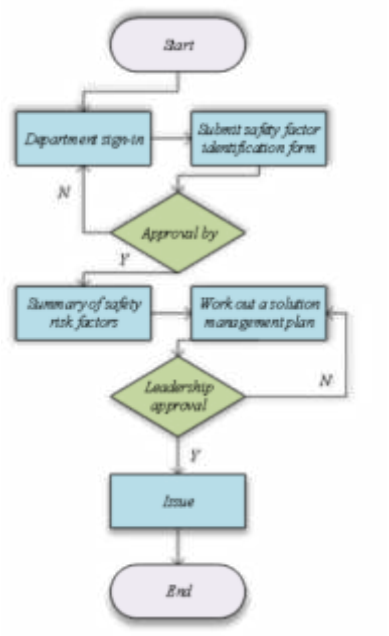

Fig. 2.5: Flow chart of fault prediction and early warning management

and routine check data maintenance.

2) Demand analysis of failure maintenance management. Fault maintenance management is an important module in the management system of college equipment fault prediction and maintenance plan generation. It is mainly used to assist in the management of basic fault repair information during the college equipment fault prediction and maintenance plan generation, including the management of account information in the repair process, the management of consigned processing settlement information, the management of consigned processing order information, and the management of acceptance processing information.

3) Demand analysis of fault prediction and early warning management. The risk early warning management of failures is a crucial module in the management system of college equipment fault prediction and maintenance plan generation. This module is mainly adopted to predict, warn, analyze and manage equipment failures in the process of equipment failure prediction and maintenance plan generation in colleges. The failure risk in the college equipment failure prediction and maintenance plan generation can be avoided in advance by using the model and algorithms.

2.2.3. Function design of main modules of the system.

1) Fault maintenance management design. The fault repair management module first needs to process the newly added fault repair application form, and then click the information to save it. If it fails to save, it needs to submit it again for saving. For those saved successfully, it is essential to go directly to the next step to approve the application form, and then apply for confirmation of fault repair. Only those approved can apply for fault repair. Otherwise, the application needs to be submitted again.

2) Design of fault prediction and early warning management. In order to complete the prediction of equipment failures and the generation of maintenance plans in colleges, it is necessary to establish a perfect risk assessment system and information-based evaluation method. Figure 2.5 is the designed flow chart for fault prediction and early warning management process.

2.2.4. System function realization. The platform of this system includes a hardware platform and a software platform. Table 3.1 shows the specific composition of the platform.

Table 2.1: Composition of system hardware platform and software platform

2.2.5. Simulation test of system performance. Table 2.2 shows the hardware and software test environment of the system.

According to the system test environment given in Table 3.2, the final performance test of the system is required during the delivery of the final system. After the corresponding tests, it can be confirmed whether the system can be synchronized with the user's requirements in the actual operation process. The main tool used is Load Runner when testing the performance of the designed management system for college equipment failure prediction and maintenance plan generation. The main indicator information in the performance aspect mainly includes the capacity of the relevant business system in terms of load, some capabilities in terms of the corresponding capacity, and the response time information of the specific business system. By running the Load Runner tool, the system is tested in different time periods, and different access frequency levels (10/min, 100/min, 1000/min and 5000/min) are tested, different operation types (specific operations such as adding, deleting, modifying and querying data information) are tested, and finally the indicator information of the business system in the actual operation process is recorded.

3. Model and system performance test results.

3.1. Classification results of college electromechanical equipment based on the Bayesian algorithm.

3.1.1. Comparison of equipment classification effects under different algorithms. Figure 3.1(a) displays the specific distribution of training sample equipment data under each equipment category through simulation experiments. x-axis is the equipment category and y-axis is the number of training samples. Figure

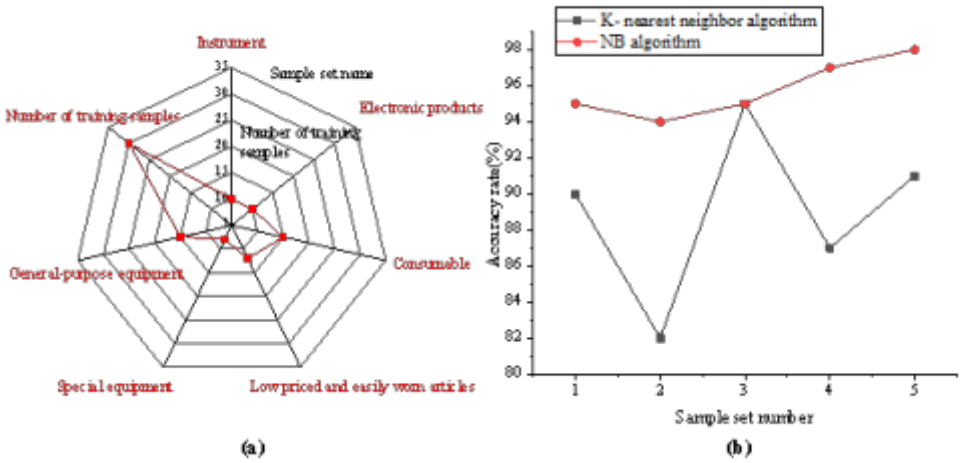

Fig. 3.1: Equipment distribution results of training samples and comparison of equipment classification effects under different algorithms (a) Equipment distribution diagram of training sample; (b) Comparison results of equipment classification effects under different algorithms

3.1(b) shows the classification effect under the two algorithms.

Figure 3.1 shows that under the same sample set, the classification effects of the two classification algorithms are significantly different, and the accuracy of the Bayesian algorithm is higher. It suggests that the Bayesian classification (NB algorithm) is obviously superior to the KNN algorithm in terms of equipment classification.

3.1.2. Comparison of running time required for equipment classification under different algorithms. In order to further compare the classification efficiency of the two algorithms, the running time of the two algorithms for classification is compared based on the same equipment sample set. In the experiment process, the method of gradually expanding the size of the equipment sample set is adopted, so that the running time of the two classification algorithms under equipment sample sets with different sizes is obtained. Figure 3.2 presents the specific experimental comparison results.

In Figure 3.2, the x-axis represents the extent of the sample set increase, and the y-axis represents the time spent running the algorithm. Figure 3.2(a) represents the KNN algorithm, and Figure 3.2(b) is the NB classification algorithm. When the x-axis sample set value is smaller than 100, the running time of the two algorithms is similar. Because of the simplicity of the algorithm, there is little difference. With the increasing number of sample sets, when the value reaches 2500, the running time of the KNN algorithm is significantly longer than that of NB. It shows that the NB classification algorithm is better than the KNN algorithm.

The above experimental results show that the Bayesian-based equipment classification model studied has a shorter running time, higher classification accuracy and better performance than the KNN algorithm.

3.2. Performance test results of security and protection system for campus electromechanical equipment. The system is tested according to the given hardware and software environment. Figure 3.3 displays the system performance.

Figure 3.3 reveals that when the browser concurrency in the system is 10, 100, 500, 1000, and 5000, the server processor utilization reaches 23%, 33%, 49%, 54%, and 67%, respectively, while the memory utilization reaches 23%, 43%, 56%, 64%, and 75%, respectively. It shows that the system has a certain browser concurrency-bearing capacity. Moreover, as the browser concurrency in the system increases, the response time of the test also increases, but the values are in the standard state. To sum up, the system has achieved the expected goal through the experimental test, the degree of perfection of the whole system has passed the test, and the whole system is in a stable operation state.

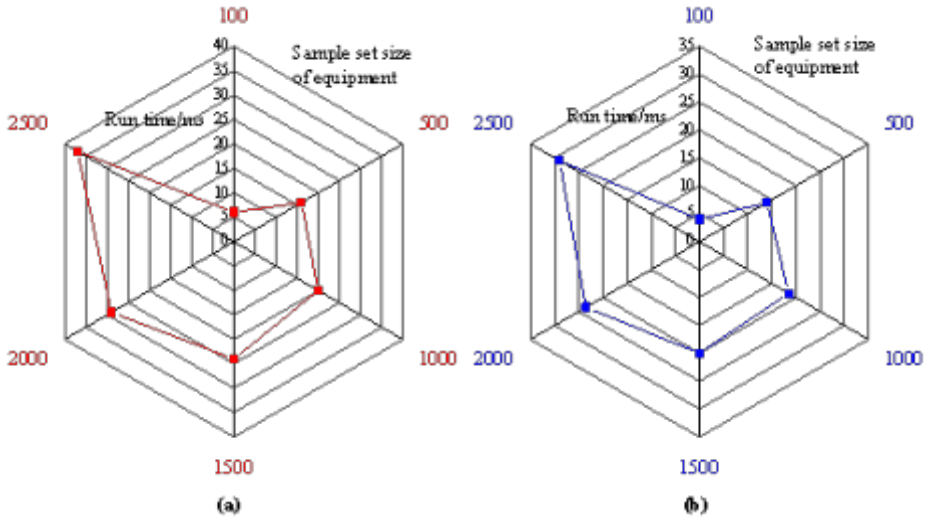

Fig. 3.2: Comparison of the algorithm running time (a) Running time of KNN algorithm; (b) Running time of NB algorithm

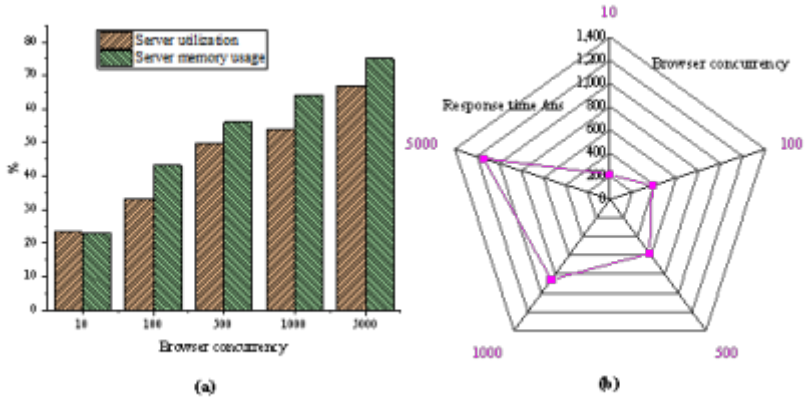

Fig. 3.3: System performance test results (a) System processor and memory usage; (b) System response time

4. Conclusion. In order to achieve the efficient management of campus electromechanical equipment security, this work uses the Bayesian algorithm in data mining technology to effectively classify the electromechanical equipment in colleges. Then, the safety management system of electromechanical equipment in colleges is designed. Finally, the simulation experiment is set to test the classification model and the system's performance.

The results show that: (1) the improved statistical classification algorithm - Bayesian algorithm can be used to efficiently classify electromechanical equipment. (2) The college electromechanical equipment safety management system designed has good processing performance, and can realize the intelligent safety management of electromechanical equipment. The research disadvantage is that the business of the actual college equipment fault prediction and maintenance plan generation system is relatively complex, while the core function modules of the college equipment fault prediction and maintenance plan generation system designed here are relatively simple, and some complex functions cannot be realized. Thereby continuous improvement is needed in the

subsequent design. This work aims to improve the efficiency of the department's actual work, provide good services for users, and provide beneficial help for the intelligent safety management of campus electromechanical equipment.

EDGE COMPUTING METHOD FOR FALSE DATA INJECTION ATTACK DETECTION IN ELECTROMECHANICAL TRANSIENT SIMULATION GRID

GANG YANG*, YING ZHANG†, LILI ZHAO‡, LIMIN ZHANG§, AND NA ZHANG¶

Abstract. Because edge computing is close to the terminal, it has significant advantages of low latency and high-security real-time control and has huge application prospects in the current popular smart grid. Because its edge side is close to the terminal, it can also effectively avoid the risk of information leakage when control instructions or communication data are transmitted to remote cloud center servers over a long distance. However, edge devices have a greater probability of encountering false data injection attacks (FDIAs) from illegal terminals because of their proximity to terminals. The transient electromechanical situation of the smart grid due to FDIAs is analyzed under edge computing. Due to the characteristics that the status values of grid nodes have temporal correlation before and after and spatial correlation between nodes, the Long Short-Term Memory (LSTM) for training time series data is selected to predict the status values of grid nodes in advance. The FDIA detection method is also proposed based on the LSTM network. By calculating the predicted value at each historical moment and the root means square error (RMSE) of the system state estimation at that moment, the detection threshold of the scheme is calculated through the cumulative distribution function of RMSE. Simulation experiments are conducted on the Institute of Electrical and Electronics Engineers (IEEE)-14 node standard system. The detection rate is as high as 99.71%, which verifies the effectiveness of the proposed FDIA detection scheme. This paper studies the security threat of FDIA to the stable power system operation and provides theoretical analysis and practical reference for other power grid security protection strategies.

Key words: power grid, electromechanical transient, edge computing, Kalman filtering, LSTM neural network

1. Introduction. The core national infrastructure is the most vulnerable object to network attacks, which is related to the stability and security of the whole society. The power system is the most critical infrastructure in modern society because it is the energy source of most other infrastructures [1]. With the development of information technology, the smart grid based on classic power system components and now mature information and communication technology are more convenient to operate and manage, but also particularly vulnerable. Since the 21st century, due to the attacks on information and communication networks, power grids in many parts of the world have been involved in major security threats many times [2]. In September 2019, the intranet of the Kudankulam Nuclear Power Plant in Tamil Nadu, India, was infected with malware. In April 2020, Energias de Portugal (EDP), a Portuguese multinational energy company, was attacked by Ragnar Locker's blackmail software. In June 2020, Brazilian power companies were attacked by Sodinokibi ransomware. The Venezuelan power system suffered multiple network attacks from 2019 to 2020, leading to large-scale blackouts in many places [3]. Therefore, it is particularly important to focus on strengthening the security construction of power grid facilities and the internal security protection of power enterprises. Power system state estimation can effectively guarantee the operation and control of the power system and provide accurate and real-time state information for the system. Hence, the management system can successfully perform different control and planning tasks [4]. False data injection attacks (FDIA) manipulate data without affecting system code is more difficult to detect than intrusion methods such as malware injection, leading to a greater security threat to the power grid system.

In order to ensure the safe operation of the smart grid, it is necessary to detect and defend FDIA, and scholars have conducted a lot of in-depth research on this issue. Boyaci et al. (2021) studied the detection and location of invisible FDIA in the power grid. They proposed a method based on a graphical neural network

to identify the existence and location of FDIA. The proposed method uses an autoregressive moving average graph filter to detect and locate FDIA in power systems automatically. Many simulations and visual displays show that the proposed method is superior to the existing methods in FDIA detection and positioning [5]. Prasanna Srinivasan et al. (2021) proposed a position detection technology based on deep learning to identify FDIA continuously. False information is captured by an error data detector incorporating convolutional neural networks (CNNs). The results show that position detection can be performed in different noise and attack environments, improving the current recognition accuracy [6]. Li et al. (2021) studied the security problems of physical network systems under dynamic load change and false data injection attacks and proposed an adaptive sliding mode controller. The effectiveness of the proposed elastic defense strategy was verified through simulation [7]. Jorjani et al. (2021) implemented various methods of FDIA on the state estimator to recover the pre-attack value of the attacked grid variables based on the iterative optimization method. They proposed a framework of recovery quality index to evaluate the performance of recovery algorithms. Simulation results show that the proposed method performed satisfactorily on different test bus systems [8]. Umar and Felemban (2021) analyzed the impact of FDIA on power generation cost and the physical composition of power systems and introduced a new FDIA strategy to maximize the power generation cost. They proposed a rule-based FDIA detection and prevention mechanism for such attacks to mitigate the threat of attacks on the power system [9]. Ding et al. (2021) developed a recognition scheme based on deep learning to detect and mitigate information corruption, implemented a conditional deep belief network to analyze time series input data, and used captured features to detect FDIA. The simulation verified that the detection mechanism had good performance and was superior to other mechanisms in terms of FDIA detection accuracy and robustness [10]. Based on the research of edge computing and smart grid FDIA, this paper analyzes the attack principle of FDIAs and their impact on the power grid system. The recurrent neural network and LSTM are introduced. The advantages of the latter in time series data prediction are analyzed. Then, a state value prediction model is proposed based on LSTM neural network. Finally, the proposed FDIA detection scheme based on the LSTM network is successfully verified through simulation experiments.

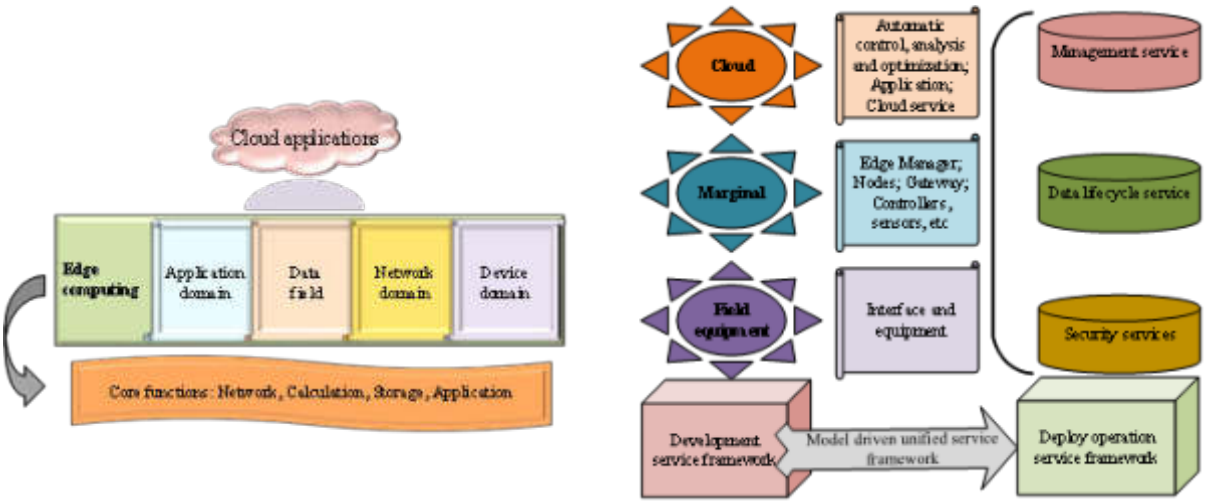
2. Method.

2.1. Edge computing. Akamai first proposed edge computing in 1998. It is between physical entities and industrial connections. It uses the open platform of the network, computing, storage, applications, and other core capabilities to provide the nearest end services. Because its applications are launched at the edge, it can respond to network services faster and has significant advantages of low latency and high-security real-time control [11]. Its core performance and architecture reference diagram are shown in Figure 2.1:

In Figure 2.1(a), because the edge server is close to the terminal device, it can provide services more quickly to ensure lower latency. On the one hand, the edge server reduces the bandwidth pressure during data upload, and on the other hand, it reduces the energy consumption of the Elastic Compute Service (ECS). Its low latency and high communication efficiency make it widely developed and applied, including the Internet of Vehicles (IoV), intelligent transportation, smart grid, and other fields [12]. In Figure 2.1(b), the problems found in edge computing are mainly in computing performance and security. Because of the complexity of the edge environment, devices deployed at the edge will be more vulnerable to attacks. Especially when one of the devices is attacked, the attacker can obtain the key information stored in it, thus causing various internal attacks. The most harmful is the false data injection attack, which will not only waste limited communication and computing resources but also seriously affect the availability of the data.

2.2. Smart grid and FDIA. Smart grid refers to the intelligentization of a power grid, which is based on a high-speed integrated two-way communication network and uses more excellent sensing and measurement, equipment, control methods, and decision support system technology to make the power grid system more reliable, safe, economical, efficient, and environmentally friendly [13]. False data injection attack FDIA is a new attack method. It has strong deception, malice, and purposefulness that can bypass traditional system detection, change and forge data in edge devices, and finally affect the calculation results and cloud decision-making. The FDIA model diagram and FDIA attack model diagram under edge computing are shown in Figure 2.2.

Figure 2.2 (a) shows the entire FDIA process. Attackers extract data from the routing of intelligent power



(a) Edge Computing and Core Performance (b) Reference Architecture of Edge Computing

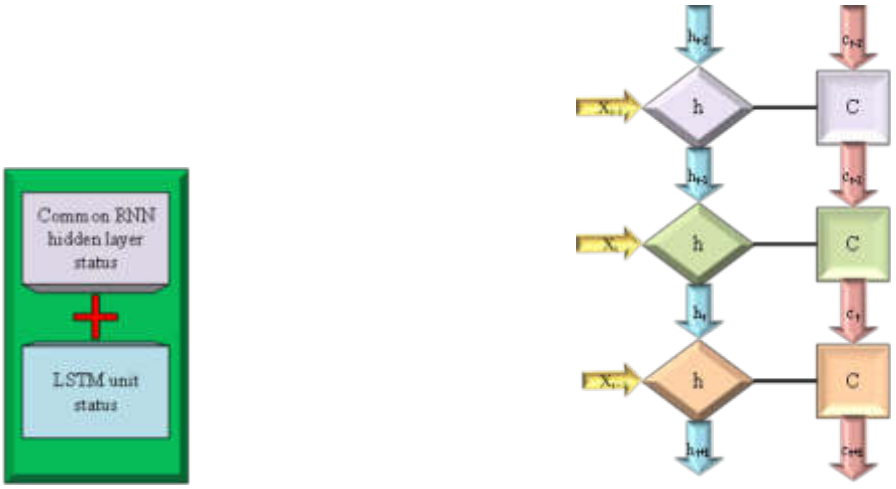
(a) FDIA process (b) FDIA model in edge computing scenario

Fig. 2.2: FDIA attack model diagram

terminals and initiate FDIA, which affects the edge devices in computing, and then affects the state estimation. FDIA can avoid bad data detection, impacting accident analysis, economic dispatch, and other decision-making schemes. In short, the process and purpose of FDIA are that the attacker tampers with the measurement data of the attacked terminal, which leads to deviation in equipment state estimation, resulting in electromechanical transient and reduced accuracy [14]. In Figure 2.2(b), in the edge scenario, FDIA can forge a lot of false data through edge devices and allow these false data to be aggregated, affecting the accuracy of the aggregation results. The edge layer will send the aggregation results to the cloud, and the cloud will make the final wrong decision because of the error aggregation results uploaded. FDIA will be more covert and destructive, bringing huge economic losses to society [15].

2.3. Deep learning and LSTM neural network. Deep learning is an important classification of machine learning. The advanced deep learning technologies are mainly CNNs and cyclic neural networks in graphics and word processing. With the development of the smart grid, deep learning technology is applied to the smart grid with huge output data, which can conduct feature extraction and result from prediction through many sample training. In the cyclic neural network model, each time series data has a hidden layer state at the



(a) LSTM hidden layer (b) LSTM hidden layer expansion diagram

Fig. 2.3: The case of LSTM hidden layer

index position, which is sensitive to short-term input. When the interval is closer, it can retain more historical information data [16]. In addition, a state is added to the hidden layer of the LSTM neural network, which is used to retain memory for a longer time and is generally called a unit state. The hidden layer of the LSTM neural network and its expansion diagram are shown in Figure 2.3.

In Figure 2.3 (a), the LSTM hidden layer has one more unit state c, than the original recurrent neural network state h. The hidden layer is expanded according to the time dimension. At time t, LSTM has three inputs, in which the input value at time t is X_t. The output at time $t-1$ is h_{t-1}, the united state is C_{t-1}, the output at time t is h_t, and the united state is Ct. In order to control this long-term state, there must be three switches, namely the so-called door. When the output of the gate is a 0 real vector, the information representing the past time at this time is not allowed to pass. If the output is 1, it can pass completely [17]. The schematic diagram of the three-door control units of LSTM is shown in Figure 2.4.

In Figure 2.4, g represents the activation function, and there are three doors to the information in the state of the control unit c. The forgetting gate determines how much information in the cell state at the previous moment will be retained in the cell state at the current moment. The input gate determines that the input value information of the network at the current time remains in the united state currently. The final output gate is used to determine the amount of information from the unit state at the current time to the output value. The LSTM network is good at processing the state value data with obvious time series in the smart grid. Additionally, the LSTM can retain or discard historical time information in a targeted way. In particular, the closer the state value in the historical time is to the real information, and the more obvious the false information is so that it can be effectively detected. This allows it to have a good prediction effect on the state value of the smart grid. The closer its prediction of the state value is to the real state value, the more the false data will be unable to hide and will be effectively detected.

2.4. FDIA detection scheme based on LSTM. This section is based on the LSTM to train the historical state value data of nodes in the smart grid that have not been attacked by false data injection so that the next node state value can be accurately predicted. Then, false data can be detected. FDIA detection scheme based on LSTM is shown in Figure 2.5.

In Figure 2.5, the status values of each node in the distribution network are obtained, and historical status value data is generated. Then, the node state value is calculated by the system state estimation module of the distribution network system and the Newton-Raphson power flow. These data mainly include node voltage

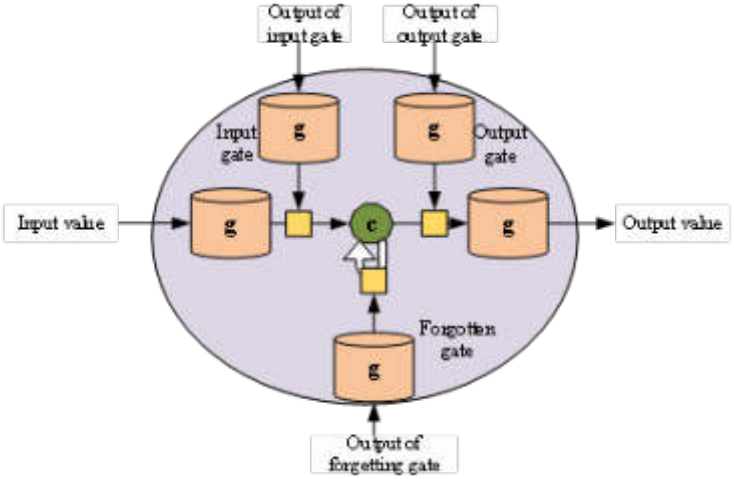


Fig. 2.4: LSTM Gating

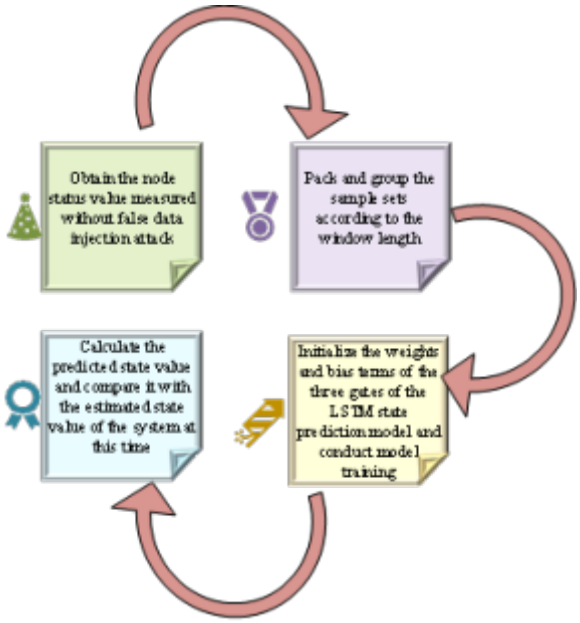

Fig. 2.5: FDIA detection scheme flow based on LSTM

amplitude and node voltage phase angle. The historical state value data involved is a data set composed of the state values of each node at the current time and in the previous period. Next, the data set to be trained is packaged into multiple groups. The window length of the training set is determined. Then, the historical time state value of the window length is used to predict the next time state value. The LSTM state is initialized with the data to predict the weights and bias terms of the required model's input gate, forgetting gate, and output gate. The input and output samples in the training sample set are respectively used as the input and output of the LSTM state prediction model. Then, the loss value in the training process is used to realize the continuous optimization of the weight parameters, and the established LSTM state prediction model is obtained. Finally,

according to the results of root mean square error (RMSE) and detection threshold comparison between the predicted value of LSTM and the estimated state value of the system state, whether a false data injection attack occurs is determined. After the results are obtained, if a false data injection attack is detected, the detection results will be fed back to the manager of the smart grid system. Then, before the system fixes the attack vulnerability, the estimated state value of the system is used as the state value at the detection time to ensure the stable operation of the smart grid. Then the next step of FDIA detection is carried out.

3. Results and discussion.

3.1. Setting of simulation experiment environment. Because the power grid's historical state value is adopted, individuals cannot obtain its real data. It is necessary to simulate the state value of the power grid when it is stable. The simulation experiment is carried out on the Institute of Electrical and Electronics Engineers (IEEE)-14 node standard system, and the network structure, line parameters, and the true values of system nodes are known. The node state value is estimated by the power system state estimation method. The simulation environment uses MatlabR2021 and MATPOWER power simulation packages. The LSTM training environment is python 3.9, tensorflow2.9.1, and Keras2.9.0.

In order to verify the performance of the improved fuzzy control P/N local path planning algorithm, the simulation experiment carried out three simulation experiments on the software of MatlabR2018a. The map scene used is a grid graph in which the obstacles in the path are marked as black areas. White areas represent the free space that the robot can move. In addition, the grid graph coordinates are refined to 10 times to improve the accuracy of simulation environment modeling. The simulation experiment conditions are set as the distribution of obstacles in the map is unknown. The simulation robot, which is regarded as a particle, simulates the motion of a differential mobile robot in the motion process. The robot can detect obstacles in the front and on the left and right sides in real-time so as to obtain the coordinates of the current robot's starting point and destination, as well as its own real-time coordinates, running speed, and angular velocity. Its initial heading angle parameter is set as 45°.

3.2. Analysis of simulation results. After the LSTM state value prediction model is trained, the sample input values of each group are transferred to the construction model to obtain the prediction values. The RMSE between the calculated prediction values and the corresponding output of this sample input is calculated. The cumulative distribution of the error is shown in Figure 3.1.

In Figure 3.1, the mean square error of the predicted value and the system estimate obtained from the LSTM state prediction model is specifically distributed between 0.014 and 0.05. So, the detection threshold can be set as 0.050, thus, false data can be detected. If the RMSE between the model's predicted value and the system's estimated value does not meet the threshold detection conditions. That is, it is inconsistent with the probability distribution of the historical RMSE. Then, it can be confirmed that the estimated value of the system is false data. That is, the grid system is attacked by false data injection. Since the LSTM state prediction model is mainly used to predict the estimated value of the system state estimation method, it will be affected by the measurement noise of the power grid. When the noise is greater, the fluctuation of its estimated value will be greater, and the prediction effect of the LSTM, on the contrary, will be weaker. Assume that when an attacker attacks the power grid with false data injection, the specific attack mode will change the state value of some nodes, which is called transient electromechanical phenomenon. When the model is set to different thresholds and attacks of different amplitudes, the final detection effect of this detection method is shown in Figure 3.2.

In Figure 3.2, no matter the size of the detection threshold, when the attack amplitude is relatively small, such as at 5%. Even if the detection threshold is set as 0.05, 87.6% of the detection results can be obtained. But for the actual attacker, if the attack amplitude is too small, the gain will not be large, so the impact of power grid fluctuation will be small, and the attacker's goal will not be achieved. Therefore, the actual attack amplitude is more than 10%. In Figure 3.2, when the attack amplitude is 15%, the detection model's detection rate is 99.71%, which can completely achieve the expected target of detection.

3.3. Comparison of results of different detection methods. In general, the measurement noise of the power grid will be large, so the attack vector constructed by attackers can easily be hidden by the measurement noise. Therefore, this paper is dedicated to detecting and analyzing state values to effectively avoid the bad

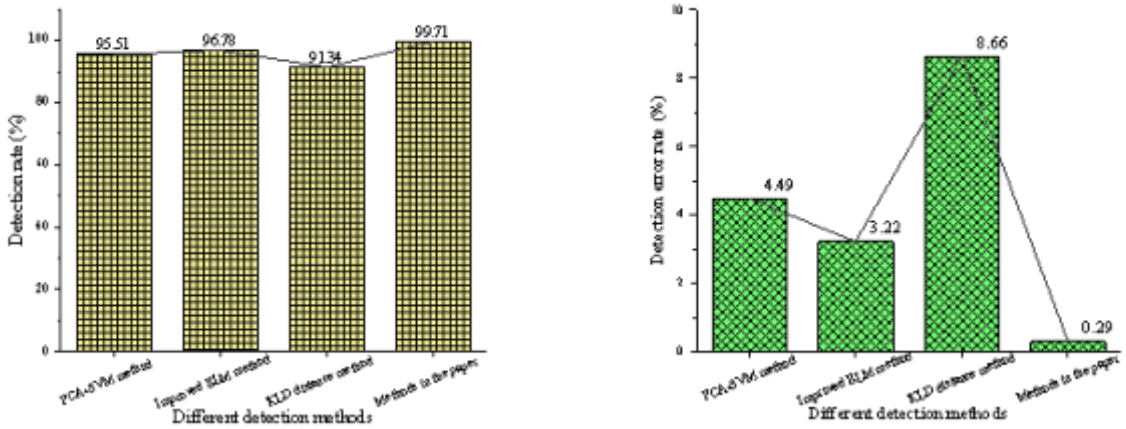
Fig. 3.2: Comparison of detection results under different detection thresholds

results of false data being covered up. The results of this method are compared with those of other FDIA methods, as shown in Figure 3.3.

In Figure 3.3, the proposed false data injection attack detection based on LSTM has significant advantages over other traditional detection. It not only has a higher detection rate but also has a lower false detection rate, which fully proves the progressiveness of the detection method proposed.



(a) Comparison of detection rates of different methods (b) Comparison of detection error rates of different methods

Fig. 3.3: Comparison of results of various FDIA detection methods

4. Discussion. In order to further illustrate the detection advantages of the proposed method when it is attacked by false data injection when facing an electromechanical transient simulation power grid, this paper compares and analyzes the research results with others. Li et al. (2022) proposed an FDIA detection method based on secure federation by combining Transformer, federated learning, and Paillier cryptosystem. The detection model is trained cooperatively using the joint learning framework and the data from all nodes. Data privacy is protected by keeping the data local during training. The effectiveness of this method is verified through experiments [18]. Yin et al. (2021), in the face of the false data injection attack on the FDIA of the smart grid, paid more attention to the spatial relationship between the bus/line measurement data. They proposed a microservice framework oriented to the sub-grid. They used it for FDIA detection in the AC model power system by integrating a well-designed spatio-temporal neural network [19]. Chen et al. (2022) proposed an FDIA detection method based on vector autoregression to improve the safe operation and reliable power supply in smart grid applications. It mainly combines the vector autoregression model and the measurement residuals based on infinite norms and two norms to analyze the FDIA detection under the edge computing architecture [20]. By analyzing the above detection methods and the principle of this method as well as the simulation results, the smart grid under edge computing is of great significance in FDIA attack detection. It is more suitable for FDIA attack detection under large-scale grid structures and small amounts of false data injection attacks and has higher accuracy and robustness.

5. Conclusion. False data injection attack FDIA can attack the power grid system more covertly, while the traditional detection methods cannot get effective detection. For this reason, this paper proposes a smart grid FDIA detection method based on LSTM in the face of electromechanical transient caused by attacks under edge computing. After introducing LSTM and analyzing its advantages in forecasting time series data, the proposed model has a higher detection rate and robustness. These conclusions lay a solid theoretical and practical foundation for the future development of detection algorithms. However, this paper still has the following shortcomings. Firstly, this paper studies the design based on the direct current (DC) power model. Additionally, the real nonlinear power system is linearly simplified, while the false data is only simulated and synthesized by adding Gaussian noise to the standard data. So, the final simulation detection effect is ideal. Therefore, in future work, this paper should first introduce the real data of the power grid for research and optimization. Additionally, it still needs to migrate the detection scheme to the alternating current (AC) model, simulate the different effects of various real network attacks, and develop a more active defense. Finally, this

paper is hoped that the research results can provide some reference for the future FDIA detection and defense research of smart grids.

ONLINE MONITORING SYSTEM OF ELECTROMECHANICAL TRANSIENT SIMULATION DATA OF DISTRIBUTION NETWORK BASED ON EDGE COMPUTING

JUNLIU ZHANG *

Abstract. The current distribution network is developing toward the direction of information and intelligent distribution Internet of Things (IoT). In order to explore the online monitoring system for transient electromechanical simulation of distribution networks, this paper is based on the equivalent model of generator sets. Firstly, it describes the relevant theoretical knowledge of edge computing, designs the distribution IoT based on edge computing, and briefly introduces its network architecture. Secondly, based on the discrete-time domain equivalent model of generators, the electromechanical transient simulation distribution network is constructed by introducing the machine network division of the power network. Finally, the Western System Coordinating Council (WSCC)-3 units and 9 nodes are taken as an example, and simulation experiments are conducted under two fault simulation conditions to verify the effectiveness of the simulation model. The results show that under the two fault simulation conditions, the results of equivalent model simulation of generator terminal voltage and relative power angle change are like those of the Power System Analysis Software Package (PSASP). The changing trend of the two is similar and stable. After the PSASP results are stabilized at a value, the simulation results fluctuate extremely up and down the value. For example, under fault condition 1, the changing trend of the relative power angle of the No. 2 generator is first fluctuating and then becomes stable. After violent fluctuation, the relative power angle tends to be stable from about 20s to -12.35°. The result of PSASP software is stable at -12.35°. The transient electromechanical simulation of the generator equivalent model can provide some ideas for the online monitoring system of the distribution network.

1. Introduction. With the rapid development of China's economy and the extensive application of the 5th Generation Mobile Communication Technology (5G), industrialization has gradually covered all parts of the country. The scale of China's power grid is growing day by day. Its safe and stable economic operation for a huge power network has become an urgent problem in modern power system research [1]. As an effective method to analyze the dynamic stability of a power system, transient electromechanical simulation is widely used in system design, planning, operation, and dispatching [2]. However, as a nonlinear dynamic system with a complex structure, it is particularly difficult to analyze and deal with its operation process and behavior characteristics [3]. Additionally, the scale of data continues to expand, and the efficiency requirements of data processing and computing are also getting higher and higher. Cloud computing can no longer meet these needs, and the edge computing model came into being. Edge computing is used to design distribution networks. Its simulation system has good research significance.

There are many types of research on distribution network simulation systems. Hayes et al. (2020) proposed a co-simulation method of distribution network and local peer-to-peer energy trading platform to solve the problem that the power platform did not fully solve the potential impact of peer-to-peer energy trading and other local power trading mechanisms on the control, operation, and planning of distribution network. The system uses a blockchain-based distributed double auction trading mechanism, and the distribution system simulator is connected to the peer-to-peer energy trading platform. The proposed collaborative simulation method is demonstrated through the case study of typical European suburban distribution network. They found that this method can be used to analyze the impact of point-to-point energy transactions on network operation performance, and moderate point-to-point transactions will not significantly impact network operation performance [4]. Bozorgavari et al. (2020) proposed robust planning of distributed battery energy storage systems from the perspective of distribution system operators to improve network flexibility. The problem is modeled as a nonlinear program. The first-order expansion of the Taylor series on the power flow equation is then used to linearize.

*State Grid Shanxi Electric Power Company, Shanxi, Taiyuan, 030021, China (Corresponding author, JunliuZhang3@163.com)

They used polygons to linearize the circle inequalities and proposed the equivalent linear programming model. In addition, in order to model the uncertain parameters in the proposed problem, including the predicted active and reactive loads, energy and charge-discharge prices, and the output power of renewable resources, a robust optimization framework based on bounded uncertainty is proposed in the next step. Finally, the proposed scheme is applied to the 19-node MV CIGRE benchmark grid through GAMS software to study the capability and efficiency of the model [5]. Liang et al. (2020) proposed a fault line selection method based on adaptive convolutional neural networks (CNNs) for distribution networks by improving the pooling model to shorten diagnosis and fault operation time when a ground fault occurs in a small current system. Experiments show that this method improves the network feature extraction ability. The secondary fault location is identified using the fault location principle at both ends. The fault data obtained from the Simulink simulation is taken as the training set, and an adaptive CNNs model is built based on the TensorFlow framework. The results show that the model has a higher fault identification rate and faster convergence speed. It can be used as an auxiliary hand for distribution network fault diagnosis [6]. These researchers use deep learning algorithms to research and improve the distribution network in terms of point-to-point energy trading platform, distributed battery energy storage system of the distribution system, and fault diagnosis of the current system. However, there are few types of research on online monitoring of transient electromechanical simulation of distribution networks. Therefore, this paper analyzes the electromechanical transient simulation model of the distribution network from the perspective of the generator unit equivalent model.

Based on the equivalent model of generator sets, this paper first introduces the relevant theoretical knowledge of edge computing, designs the distribution IoT based on edge computing, and briefly describes its network architecture. Secondly, according to the practical generator set model, the mathematical model of the synchronous generator set is equivalently transformed. The discrete-time domain equivalent model of the generator set suitable for transient electromechanical simulation is established. At last, based on the discrete-time domain equivalent model of generators, the electromechanical transient simulation distribution network is constructed by creatively introducing the machine network division of the power network. The validity of the simulation model is verified by designing fault simulation experiments.

The design of transient electromechanical simulation for generator set equivalent model can provide a new thinking path for the online monitoring system of the distribution network. This paper is analyzed in four parts. Section 1 is the introduction, which leads to this paper's research purpose and significance by introducing the research background and current research status. Section 2 is materials and methods, and the theoretical basis of this research is briefly described, such as edge computing, distribution Internet of Things (IoT), generator set equivalent model, etc. The electromechanical transient simulation model is built based on the generator equivalent model. Section 3 is the simulation experiment design, through the simulation experiment of the Western System Coordinating Council (WSCC) 3 units and 9 nodes under two fault simulation conditions, compares with the results of the Power System Analysis Software Package (PSASP) software and draws the experimental conclusion. Section 4 is the conclusion, which summarizes the main results and achievements, and points out the shortcomings and prospects for future research.

2. Electromechanical transient simulation based on generator unit equivalent model.

2.1. Distribution IoT architecture based on edge computing. Edge computing is a new method of network edge computing. The concept of "edge" refers to any network resources, computing, and storage in the path between the cloud center and the data source. The European Telecommunications Standardization Association has defined the reference architecture, engineering implementation guidelines, and typical service scenarios of edge computing originating from the 5th Generation of Mobile Communication Technology [7]. Edge computing means that in order to reduce the burden of the cloud computing center on the edge network side near the intelligent terminal device, the computing power of the intelligent device itself and the allocated computing resources are used to process and store a certain amount of data, so as to reduce the burden of the cloud computing center and realize the more efficient and stable operation of the IoT system [8]. Even in a network environment composed of computers and systems delivered by different manufacturers, edge computing technology can realize the interoperability of different operating systems and communication protocols, devices of different manufacturers, and technologies with different principles.

With the continuous development and improvement of computer technology and the technical architecture

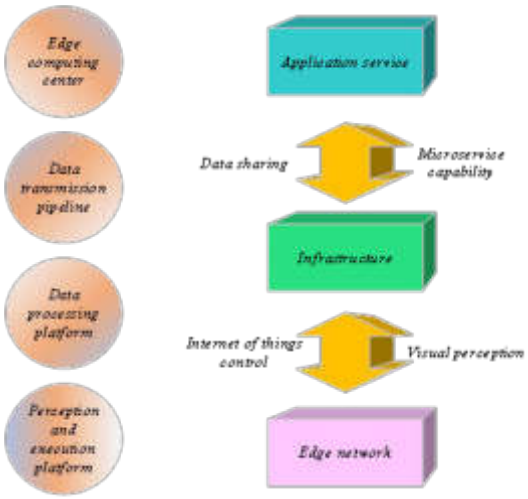

Fig. 2.1: Architecture of power distribution IoT

of the IoT, edge computing, as a technology to reduce the load and burden of cloud computing centers, has increasingly entered the vision of researchers. For the distribution IoT, using edge computing technology, many processing processes can be completed at the "end" layer through edge servers, intelligent terminals, and other devices, which can greatly improve the efficiency of the system in processing data, receiving user feedback timelier and effectively, and improve the user experience [9]. The breakthrough of edge computing technology is of great significance to the distribution of IoT. Suppose edge computing technology is properly used in the IoT architecture. In that case, many initial data processing processes can be completed at the edge, reducing the burden on the cloud center, improving the overall data processing efficiency of the IoT, and responding to user needs faster. Therefore, using edge computing technology to achieve optimal scheduling and allocation of computing resources in the distribution IoT can complement and cooperate with the cloud computing center to jointly improve the operation efficiency and stability of the distribution network [10].

In 2019, State Grid Corporation of China formally put forward the strategic goal of "building a comprehensive business ubiquitous power IoT". It aims to improve the optimal operation level of the power system comprehensively and better meet the social power demand by using advanced technologies such as "cloud, large, material, mobile, and smart". The power distribution IoT is an important implementation of the ubiquitous power IoT in the distribution field [11]. Compared with the traditional distribution network, the IoT has the characteristics of the extensive interconnection of terminal devices and edge servers and a comprehensive dynamic and flexible perception of power consumption status. The IoT can realize the real-time intelligent perception of the real-time operation status and digital operation and maintenance of the distribution network, manage all aspects of power equipment, efficiently process the collected information and make rapid intelligent decisions. The power distribution IoT can more efficiently mobilize the active participation of resources from all walks of life, enhance the core competitiveness, and adapt to the demand of power grid enterprises for distributed energy storage and use [12,13]. The architecture of the power distribution IoT is shown in Figure 2.1.

In Figure 2.1, the distribution IoT consists of four parts: edge computing center, data transmission channel, data processing platform, and sensing and execution platform. The cloud computing center is the computing center platform for IoT distribution. Based on the high-performance edge computing platform computer, it uses big data, artificial intelligence, and other technologies to meet the needs of massive, intelligent terminals, edge server devices plug and play, multi-data fusion, and other needs. The cloud computing center provides high-performance computing services, model management, data cloud synchronization, and other functions to the distribution network terminal devices. The data transmission pipeline is used to efficiently transmit a large amount of data in the distribution network, which can be divided into two parts: the remote communication

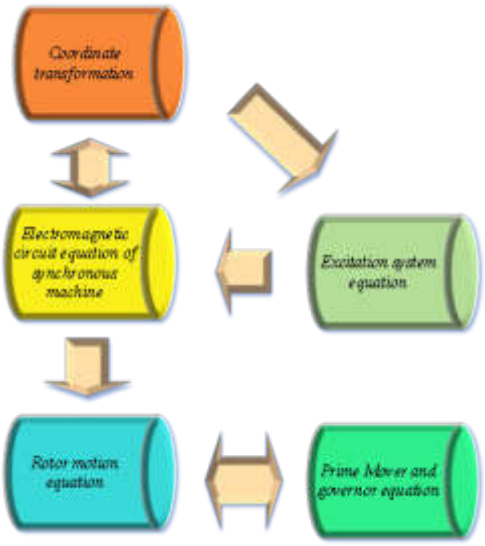

Fig. 2.2: Basic components of the generator set

network and the local communication network. The remote communication network communicates data between the edge computing center and the edge network intelligent terminal. The local communication network provides a data communication channel between the edge network and the edge server. The data processing and the perception platform realize full data collection, perception, and control through data exchange and real-time full duplex interaction with the edge computing center to complete the efficient and stable operation of the entire IoT system. The sensing and execution platform is responsible for providing the overall operation status of the distribution network, application equipment status, and other basic data, executing decision commands, and realizing control functions.

2.2. Time domain equivalent dynamic model of generator set. Because the generator set is a differential equation in the electromechanical transient simulation process of the power system, the interface processing with the network algebraic equation is more complex. Therefore, according to the practical model of the generator set, the mathematical model of the synchronous generator set is transformed, and the discrete-time domain equivalent model of the generator set suitable for transient electromechanical simulation is established. The generator set mainly comprises a synchronous generator, excitation regulation system, prime mover, and speed regulation system. Its typical structure is shown in Figure 2.2 [14].

In Figure 2.2, the excitation system equation affects the synchronous generator magnetic circuit equation. The synchronous generator magnetic circuit equation affects the rotor motion equation and the rotor motion equation. The kinematic equations of the rotor, prime mover, and governor affect each other. The state equation of the generator set is expressed in matrix form as shown in Eq. 2.1-2.3 [15,16].

$$\dot{a}(t') = Qa(t') + P_p a_p(t') + P_G G(t') \tag{2.1}$$

$$b(t') = Wa(t') \tag{2.2}$$

$$a(O') = a(kT) \tag{2.3}$$

In Eq. 2.1-2.3, $0' \leqslant t' \leqslant T$, 0' corresponds to the initial time of the network $T_0 = kT$. Q, P_p, P_G and W are the constant coefficient matrix of the subsystem state equation. a is the internal state vector of the generator

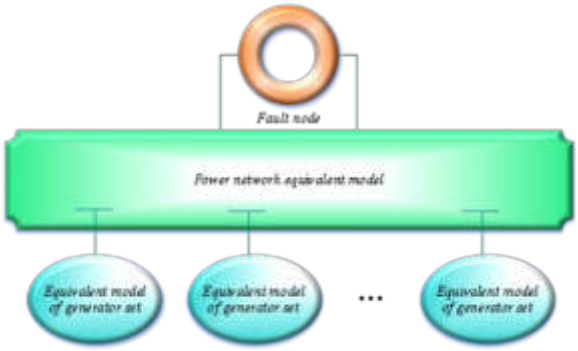

Fig. 2.3: Schematic Diagram of Power Network Division

set subsystem determined by the used model of generator, excitation system, and prime mover. The calculation method is shown in Eq. 2.4.

$$a = [\Delta\varepsilon\omega H_j' H_j" H_i''' \varphi P_m u_R u_q H_g u_g]^T \tag{2.4}$$

a_p is the current parameters I_i and I_j in the i-j coordinate system. The voltage amplitude V_t at the end of the generator and the output active power P_f constitute the input vector of the network side subsystem. The calculation method is shown in Eq. 2.5.

$$a_p = [I_i I_j V_t P_f]^T \tag{2.5}$$

G is the endogenous excitation vector of the generator set subsystem, which includes the reference value of speed ε_0 of prime mover and governor system, the reference value of voltage V_0 of excitation system, and the unit value of synchronous speed ε_p. The calculation method is shown in Eq. 2.6.

$$G = [\varepsilon_0 V_0 \varepsilon_p H_{gi}]^T \tag{2.6}$$

b is the output vector of the generator set subsystem, including the internal generator potential related to the generator stator voltage equation as well as the work angle ω. Its specific form is determined by the generator model adopted and the demand at the grid side. Its calculation method is shown in Eq. 2.7.

$$b = [H_j" H_i" \omega]^T \tag{2.7}$$

2.3. Electromechanical transient simulation program based on generator unit equivalent model. In the transient electromechanical process of the power system, the differential equation of the generator set and the linear equation on the grid side are usually calculated simultaneously. Then, during the electromechanical transient simulation, the generator set can be separated from the power system. The power network can be divided into interconnections between multiple generator set subsystems and the network [17]. This method of machine network division is conducive to the equivalence of the generator network and simplified calculation, as shown in Figure 2.3 [18].

In Figure 2.3, the fault nodes are separated in the power network for separate processing, which can reduce the amount of simulation calculation. After the fault node is separated and treated separately, the network side equation can be expressed as an equivalent model. The network side equation does not need to be calculated repeatedly in the simulation process. Additionally, the power system is decomposed into multiple generators set subsystems and electrical network subsystems by cutting branch current method. According to the generator equivalent model, the electromechanical transient simulation program is designed, as shown in Figure 2.4.

Fig. 2.4: Simulation program based on the equivalent model of generator set

In Figure 2.4, the electromechanical transient simulation calculation process is to calculate the equivalent admittance and current source of the generator unit at the current time according to the generator equivalent model. According to the network's equivalent admittance, the interconnected system variables are calculated. The amount of input at the next moment in the equation of state of the generator set is calculated. Whether the current split-suture period is over is judged. If it is not finished, the program returns to calculate the equivalent admittance and equivalent current source of the generator set the next time, and the calculation is in sequence. If it ends, the program calculates the initial value of the generator set state variable at the next split-suture time. Whether the simulation is over is judged; if not, the program returns to split the network again and continues the calculation.

3. Simulation experiment design.

3.1. Simulation experiment environment. The Western System Coordinating Council (WSCC) 3-machine and 9-node are examples of simulation analysis. Its machine network segmentation method and equivalent model are shown in Figure 3.1 [19].

The condition settings of the two faults are as follows: in condition 1, the fault type is set as a three-phase short circuit of No. 2 generator, the fault time is 1s, and the removal time is 1.1s. In condition 2, the fault type is set as 50% of the whole network load removal, the fault time as 1s, and the fault removal time as the simulation end time.

3.2. Simulation experiment analysis under fault condition 1. Under fault simulation condition 1, the generator terminal voltage change is shown in Figure 3.2.

In Figure 3.2, the dotted line results from the PSASP analysis. In Figure 3.2(a), the terminal voltage change of the No. 1 generator through generator equivalent model simulation is very similar to the changing

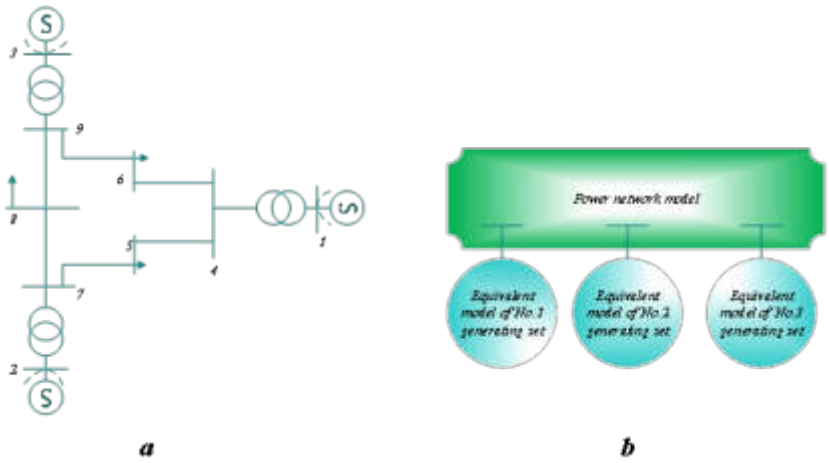

Fig. 3.1: Schematic diagram of WSCC3 machine 9-node machine network segmentation method and equivalent results (a is WSCC3 machine 9-node machine network segmentation method. b is WSCC3 machine 9-node generator equivalent model)

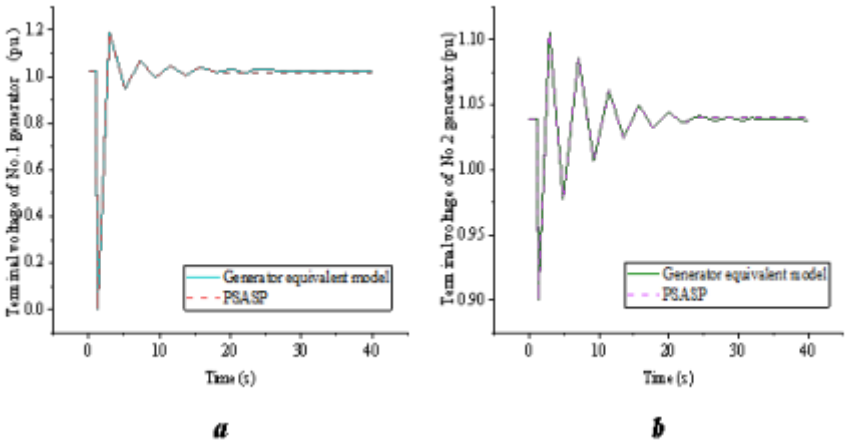

Fig. 3.2: Voltage change at generator terminal (a is the voltage change at generator terminal 1. b is the voltage change at generator terminal 2)

trend of PSASP software results. The terminal voltage change trend is that after fluctuating up and down, it tends to be stable in about 18s. Finally, it is stable at 1.02pu. In Figure 3.2(b), the changing trend of the terminal voltage of the No. 2 generator simulated by the generator equivalent model is very similar to that of PSASP software results. The terminal voltage changes are stable in about 24s after sharp fluctuation. PSASP results are finally stable at 1.04pu. The generator equivalent model simulation results fluctuate up and down at 1.04pu, but the fluctuation value is small. The data shows that the model simulation results are valid. Based on the power angle of the No. 1 generator, the relative power angle of the No. 2 and No. 3 generators is shown in Figure 3.3.

In Figure 3.3(a), the relative power angle change of the No. 2 generator simulated by the generator equivalent model is very similar to the changing trend of PSASP software results. The relative power angle of

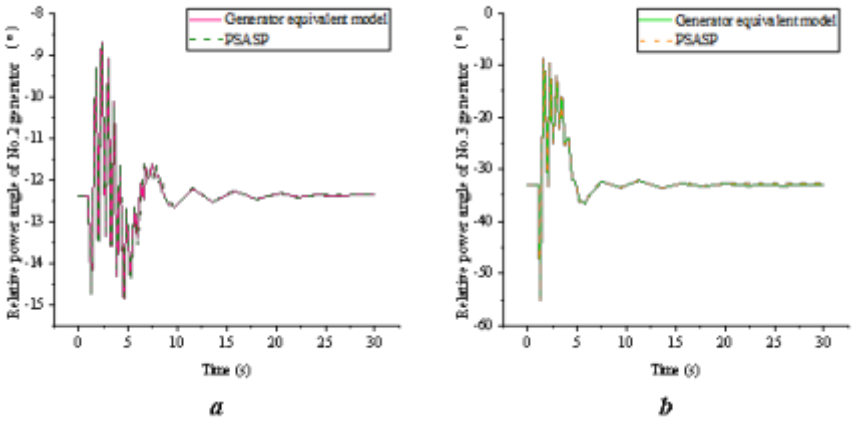

Fig. 3.3: Relative power angle change of generator (a is the relative power angle change of No. 2 generator; b is the relative power angle change of No. 3 generator)

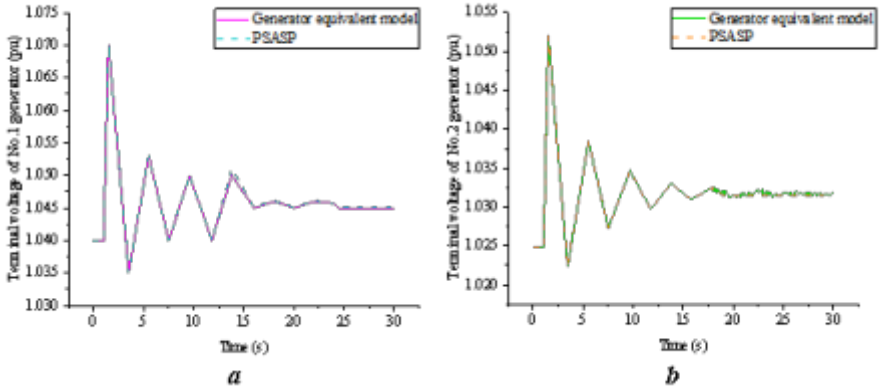

Fig. 4.1: Voltage change at generator terminal (a is the voltage change at generator terminal 1; b is the voltage change at generator terminal 2)

the No. 2 generator fluctuates first and then stabilizes. After severe fluctuations, it tends to be stable from about 20s to about -12.35°. The result of PSASP software is stable at -12.35 °. In Figure 3.3(b), the changing trend of the relative power angle of the No. 3 generator simulated by the generator equivalent model is very similar to that of the PSASP software. The changing trend of the relative power angle of the No. 3 generator is generally upward and stable. After fluctuation, it tends to be stable from about 15s to about -32.8°. The result of PSASP software is stable at -32.8°. The data shows that the simulation result of the generator equivalent model is effective.

4. Simulation experiment analysis under fault condition 2. Under fault simulation condition 2, the generator terminal voltage change is shown in Figure 4.1.

In Figure 4.1(a), the terminal voltage change of the No. 1 generator simulated by the generator equivalent model is like the changing trend of PSASP software results. The terminal voltage change trend is that the terminal voltage tends to be stable at about 25s after sharp fluctuation, and finally, it is stable at 1.045pu. In Figure 4.1(b), the changing trend of the terminal voltage of the No. 2 generator simulated by the generator

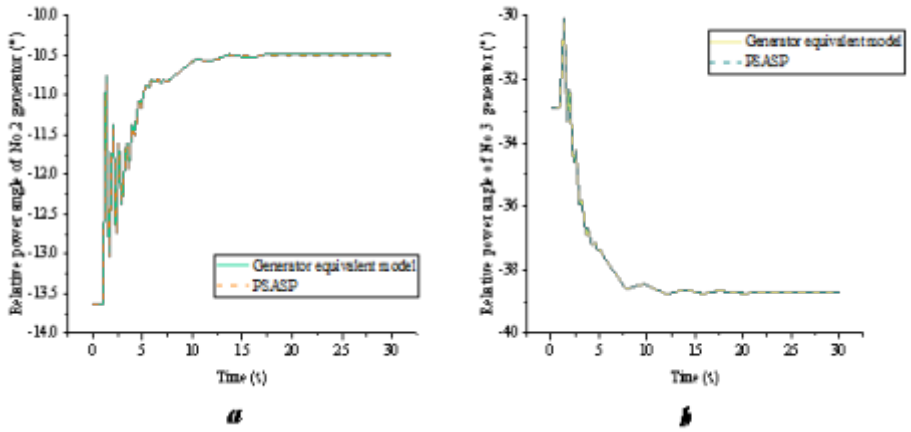

Fig. 4.2: Change of relative power angle of the generator (a is the change of relative power angle of No. 2 generator; b is the change of relative power angle of No. 3 generator)

equivalent model is very similar to that of PSASP software results. The terminal voltage changes are stable in about 18s after sharp fluctuation. PSASP results are finally stable at 1.0315pu. The generator equivalent model simulation results fluctuate up and down at 1.0315pu, but the fluctuation value is small. The data shows that the model simulation results are valid. Based on the power angle of the No. 1 generator, the relative power angle of the No. 2 and No. 3 generators is shown in Figure 4.2.

In Figure 4.2(a), the relative power angle change of the No. 2 generator simulated by the generator equivalent model is very similar to the changing trend of PSASP software results. The changing trend of the relative power angle of the No. 2 generator is rising first and then stable. After severe fluctuations, it tends to be stable from about 10s to about -10.5°. The result of PSASP software is finally stable at -10.5°. In Figure 4.2(b), the changing trend of the relative power angle of the No. 3 generator simulated by the generator equivalent model is very similar to that of the PSASP software. The changing trend of the relative power angle of the No. 3 generator is generally downward and then stable. After fluctuation, it tends to be stable from about 15s to about -38.7°. The result of PSASP software is finally stable at - 38.7 °. It shows that the simulation result of the generator equivalent model is effective.

5. Conclusion. In order to explore the online monitoring system for electromechanical transient simulation data of distribution network, based on the equivalent generator set model, this paper designs the power distribution IoT from the relevant theoretical knowledge of edge computing and introduces the network architecture of power distribution IoT. Secondly, according to the practical generator set model, the mathematical model of the synchronous generator set is equivalently transformed. The discrete-time domain equivalent model of the generator set suitable for transient electromechanical simulation is established. Finally, based on the discrete-time domain equivalent model of the generator, the electromechanical transient simulation system of the distribution network is constructed by introducing the machine network division of the power network. The model's effectiveness is verified by the network segmentation of the WSCC3 machine and nine nodes and the simulation experiment of the equivalent model under two fault simulation conditions.

The following conclusions are found: (1) under the condition that the fault type is set as a three-phase short circuit of No. 2 generator, the fault time is 1s, and the clearing time is 1.1s. The generator terminal voltage change and the generator relative power angle change have little difference between the results of the generator equivalent model simulation and the results of PSASP software. The data shows that the simulation results are valid. (2) Under the condition that the fault type is set to cut off 50% of the whole network load, the fault removal time is 1s. The fault removal time is the simulation end time, and the results of generator terminal voltage change and generator relative power angle change in the generator equivalent model simulation

and PSASP software simulation are similar—the data indicating that the simulation results are effective. (3) The changing trend of generator equivalent model simulation and PSASP results is similar and stable. After PSASP results are stabilized at a value, the simulation results fluctuate with a minimum fluctuation above and below the value. However, there are still some deficiencies in this paper. In the process of research and simulation, the nonlinearity of generator equations and constant power load in the network is not considered. In the following research, the electromechanical transient simulation system of the distribution network can be discussed based on the nonlinear equations of generator sets.

THE DEFECT IDENTIFICATION SYSTEM OF ELECTROMECHANICAL EQUIPMENT ON THE EDGE SIDE OF THE POWER GRID UNDER EDGE COMPUTING

HAIAN HAN*AND FAN HU†

Abstract. With the development of the industrial Internet of Things, modern industrial systems have developed towards intelligence. Electromechanical Equipment (EE) is essential, and its defect identification is fundamental. Firstly, this research introduces the basic content of Gated Recurrent Unit (GRU), Variational Auto-Encoder (VAE) in Deep Learning (DL), and Edge Computing (EC) to explore the construction of a defect identification system for EE on the edge side of the power grid. Secondly, combined with the advantages of GRU and VAE, a GRU-VAE defect recognition model is proposed. Then, the EC architecture is introduced, and the EE defect identification system based on the GRU-VAE algorithm is constructed. The EC intelligent EE defect identification service system is designed with this as the core. Finally, simulation experiments are carried out using different data sets to verify the performance of the GRU-VAE model. The results show that the GRU-VAE model has higher precision and recall than the separate GRU model and VAE model, and the corresponding F1 value is also higher. The F1 value can reach 0.997 on aperiodic data and 0.966 on periodic data. In addition, the optimal thresholds of different datasets are analyzed, and the relationship between the length of the time window and the model's performance is studied. When the time window length is 15, the model performance is optimal. This research on the defect identification system of EE on the edge side of the power grid based on EC and DL can provide a new path and inject new vitality into the defect detection of EE.

Key words: maintenance of the electromechanical equipment, edge computing, gated recurrent unit, variational auto-encoder, defect detection

1. Introduction. Electromechanical Equipment (EE) is an integral part of Industrial Internet of Things (IIoT) production activities. With the development of the IIoT, the development of EE also tends to be intelligent. Transportation, intelligent appliances, and computers have become indispensable EE products in people's lives. EE is widely used in intelligent manufacturing, transportation, smart city, and other fields [1]. However, failures due to long-term operation and lack of maintenance of EE often occur. Therefore, people pay more and more attention to the defect identification of EE. However, the complexity of electromechanical systems makes maintenance increasingly expensive. Machine Operation and Maintenance (O&M) gradually shifts from manual O&M to intelligent O&M [2]. Currently, most O&M data relies on Cloud Computing (CLO) platforms. In the IIoT, intelligent terminal application scenarios pay more attention to real-time service feedback. CLO has gradually exposed the shortcomings of high data transmission delay, untimely processing, and data privacy leakage. Then, Edge Computing (EC) emerged.

The combination of IIoT and intelligent O&M has become a development trend. Scholars have done much research in this regard. Based on the fifth-generation communication technology analysis and IoT technology, Liu et al. (2020) proposed the reference architecture of smart factories and its application path for traditional manufacturing enterprises in China. They combined the IoT with big data and EC to design a real-time tracking and monitoring system for intelligent workshop products [3]. Pivoto et al. (2021) investigated the major cyber-physical system architecture models available in industrial settings, highlighting their key features, technologies, and correlations. They pointed out the goals, advantages, and contributions of introducing IIoT in Industry 4.0 and identified the leading technologies adopted in current state-of-the-art cyber-physical systems and IIoT technologies [4]. Zhu et al. (2020) introduced the automation transformation of a sewage treatment plant based on practical engineering experience. They built a remote measurement and control system for sewage treatment based on the IIoT to realize wide-area monitoring and control of sewage treatment [5]. These studies combine IIoT with different modern technologies to explore the advantages and intelligence of IIoT from

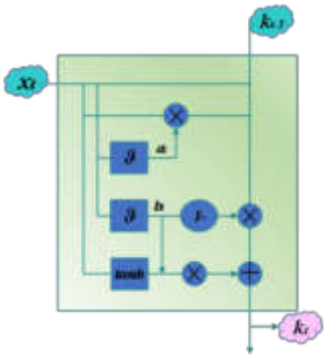

Fig. 2.1: GRU structure

different perspectives, but few studies consider defect and fault identification of EE.

Based on the above background, starting from the theoretical knowledge of Deep Learning (DL) and EC, the structure and workflow of Gated Recurrent Unit (GRU) and Variational Auto-Encoder (VAE) and the basic content of EC are briefly introduced. The GRU and VAE are fused. The EC architecture is introduced to build a defect detection algorithm model. The defect identification system of EC intelligent EE is designed, taking the defect detection model of GRU-VAE as the core. Meanwhile, the architecture of the system and its core part, the EE defect detection service system, are introduced. This research can provide ideas for establishing a defect identification system for EE on the edge side of the power grid.

2. EC EE defect detection system.

2.1. Theoretical basis of DL and EC. DL models often consist of artificial neural networks known as Deep Neural Networks (DNNs). It can simulate complex functions, learn the underlying laws of data through network structure, and achieve excellent performance in image classification, natural language processing, face recognition, and other fields [6]. Common DNNs include Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and generative neural networks. RNNs have the problem of gradient vanishing and explosions. Scholars optimized it and proposed the GRU to solve this problem [7]. GRU is a variant of RNN, a gating mechanism unit. Its structure is shown in Figure 2.1 [8].

In Figure 2.1, GRU mainly comprises update and reset gates. The update gate controls the effect of the previous moment state information on the current moment state, and the reset gate controls the degree of ignoring the previous moment state information to obtain a long time memory capability. The reset gate vector can be calculated according to Eqaution 2.1.

$$a_t = \theta(Q_a x_t + W_a k_{t-1} + \beta_a) \tag{2.1}$$

In Equation 2.1, x_t is the input data at time t, a_t represents the reset gate vector. k_{t-1} represents state information at the previous moment of time t. θ stands for sigmoid function, whose output value is between zero and one, which is used to choose how much information is left. Q and W are the weight matrices, and β_a is the reset gate parameters. The calculation process of the update gate vector is similar to that of the reset gate, as expressed in Eqaution 2.2.

$$b_t = \theta(Q_b x_t + W_b k_{t-1} + \beta_b) \tag{2.2}$$

In Eqaution 2.2, b_t is the update gate vector, and β_b is the update gate parameter. The updated value $\widetilde{k_t}$ is jointly determined by the reset gate vector a_t, the output k_{t-1} at the previous moment, and the input x_t at that moment, as given in Eqaution 2.3.

$$\widetilde{k_t} = tanh[Qx_t, W(a_t \cdot k_{t-1})] \tag{2.3}$$

The final output at the current moment is determined by the updated value $\widetilde{k_t}$, the update gate b_t, and the previous moment's input k_{t-1} together, as shown in Eqaution 2.4.

$$k_t = b_t \cdot k_{t-1} + (1 - b_t) \cdot \widetilde{k_t} \tag{2.4}$$

In generative neural networks, VAE is a generative model based on an encoder-decoder framework [9]. The encoder effectively encodes the input data and obtains the characteristics of the input data. The decoder is connected to the encoder, and the data encoded by the encoder is restored to new data similar to the input data after the encoder. The encoder-decoder performs lossy compression and decompression of the data, which has the role of noise reduction and extraction features. The encoding process of VAE mainly models the structure of existing data sets. It captures the relationships between different dimensions of time series data and learns the distribution of low-dimensional hidden variables. The decoding process of VAE generates new data that conforms to the input data distribution by adding white noise [10].

EC is relative to CLO. CLO is a virtual and manageable computing and storage capacity driven by economies of scale. It is also a large-scale distributed computing model delivered to external users through the Internet according to user needs [11]. CLO can provide services to users anytime, anywhere, using resources such as shared computing facilities and applications on demand. However, the upper-layer computing applications of EE are more demanding to run. CLO can no longer meet the requirements of faster real-time and higher interactivity of new services. To solve this problem, scholars have proposed EC. The main computing nodes and applications of EC are distributed in data centers close to terminals, which makes service response performance and reliability higher than the traditional centralized CLO concept. The act of collecting and analyzing data occurs in local devices and networks close to where the data is generated, without having to transfer the data to the cloud, where computing resources are centralized for processing [12]. Different application scenarios subdivide EC into mobile EC, micro CLO, and fog computing [13]. When EC is interactively fused with Artificial Intelligence (AI), the AI frontier is pushed to the edge of the network to unlock the potential of big data at the edge. Intelligent decision-making capabilities are provided to end devices at the data source, resulting in intelligence at the edge [14]. Edge intelligence can empower edge devices with environmental awareness and data analysis, thereby improving the service quality of EC.

2.2. Defect detection algorithm based on GRU-VAE. GRU and VAE were used to integrate the two to construct a defect detection model of EE based on GRU-VAE. Therefore, the GRU-VAE model has not only the noise reduction and defect detection functions of the VAE model but also the long-term correlation of the GRU model to capture EE data. The role of long-term prediction of time series data can solve the problems of spatial dimension and time dimension of EE data. Its structure is demonstrated in Figure 2.2.

Figure 2.2(a) shows that the GRU-VAE defect detection model is divided into three parts: VAE encoder based on the CNN network layer, prediction module based on GRU, and VAE decoder based on the CNN network layer. The GRU module is embedded between the encoder and decoder of the VAE model. The preprocessed time series data X_t is fed into the VAE encoder, which is transformed into a low-dimensional hidden variable h_t. The GRU prediction module learns the transformation trend of time series data and predicts the hidden variable $\hat{h}_{t+1}$ of the next time series. The hidden predicted variable $\hat{h}_{t+1}$ is connected to the VAE decoder, and the new $\hat{x_{t+1}}$ data is obtained by decoding the predicted hidden variable $\hat{h}_{t+1}$. Finally, the defect detection of EE is realized by calculating the reconstruction error. The detailed process is as follows.

First, the dataset $X_t = \{x_{t-l-1}, x_{t-l}, \cdots, x_t\}$ represents the window vector of l consecutive time series data in front of the t moment, and X_t is the input of the VAE encoder. X_t passes through the convolution layer of the VAE encoder and performs vector operations with the convolution kernel to complete the sampling and feature extraction of the X_t window vector. The encoder encodes X_t into the hidden variable h_t in the potential space by Equation 2.5.

$$h_t = encoder(X_t) \tag{2.5}$$

The hidden variable is connected with the GRU time series hidden variable prediction model. The structure of the GRU time series hidden variable prediction model is shown in Figure 2.2(b) [15]. The hidden variable h_t is used as input to the GRU module, and GRU predicts the final output $\hat{h}_{t+1}$, as shown in Eq. 2.6-Eq. 2.7.

$$k_t = GRU(h_t) \tag{2.6}$$

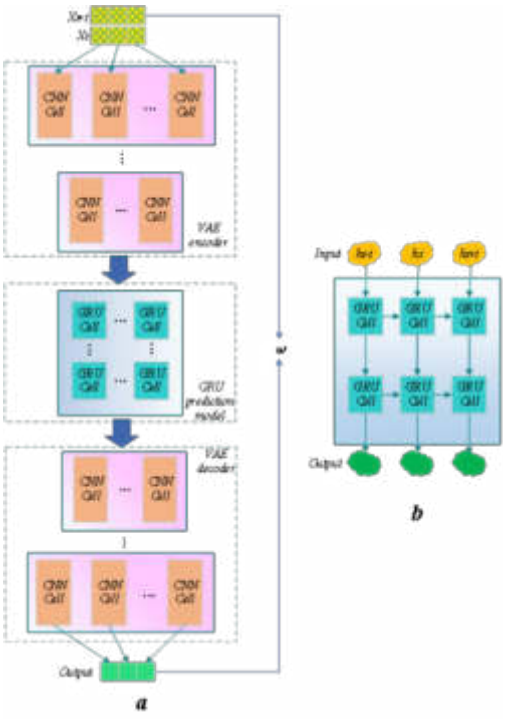

Fig. 2.2: GRU-VAE defect detection model (a is the GRU-VAE defect detection model; b is a GRU-based time series hidden variable prediction model)

$$\hat{h}_{t+1} = k_t \tag{2.7}$$

The predicted hidden variable $\hat{h}_{t+1}$ is reconstructed by the VAE decoder into the time series window $\hat{X_{t+1}}$ at the next moment. Window $\hat{X}_{t+1}$ of the VAE model reconstruction does not contain defect data and noise. The location of the window defect is determined by calculating the reconstruction error ω_{t+1} with the real-time series window X_{t+1}, as shown in Eq. 2.8-Eq. 2.9.

$$\hat{X}_{t+1} = decoder(\hat{h}_{t+1}) \tag{2.8}$$

$$\omega_{t+1} = ||\hat{X}_{t+1} - X_{t+1}||_2 \tag{2.9}$$

2.3. EC EE defect detection service system architecture. The IoT and intelligent monitoring technology of EE are combined, and the design concept of EC architecture is introduced to build a defect detection service system for EE based on EC. The computing and storage capabilities of the cloud center are deployed to edge nodes. The EE defect detection model based on DL is directly deployed at the edge node, which can realize real-time processing and rapid response to defect detection and provide edge intelligent services. The overall architecture of the EE defect detection service system based on edge intelligence is displayed in Figure 2.3.

From Figure 2.3, the EC intelligent EE defect detection service platform is divided into the terminal device layer, edge node layer, and cloud center layer. The terminal device layer is responsible for sensing EE data in the EC intelligent platform and transmitting data through the network. Meanwhile, the terminal device receives and executes the control command from the edge node to control the EE in real-time. As an extension of the cloud hub on the data source side, the edge node has the cloud center's computing, storage, and communication capabilities. It also has functions such as protocol conversion, data collection, data storage, data transmission,

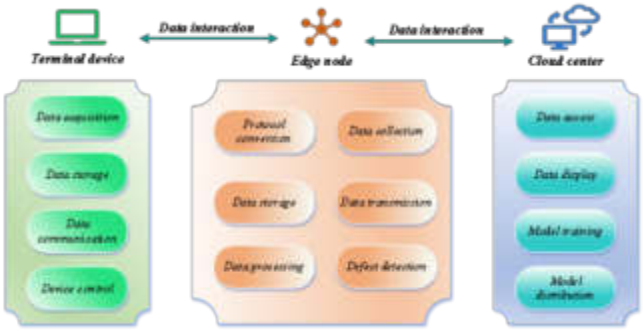

Fig. 2.3: EC EE defect detection service system architecture

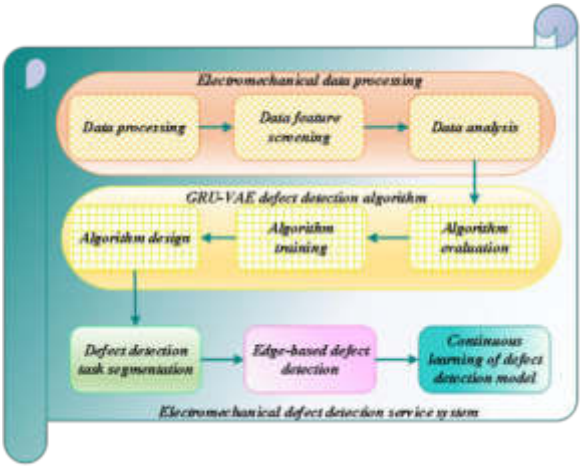

Fig. 2.4: EE defect detection service system

data processing, and defect detection. In addition, the edge node is the bridge of the EC intelligence platform. The edge node parses the EE data collected by the terminal device, obtains the original data of the EE and transmits it to the cloud center, and establishes a database to store the original data. Edge nodes receive real-time data from EE and merge them with historical data. After data processing, the DL defect detection model is used to monitor the EE in real-time. The cloud center layer has the functions of data access and storage of EE. It analyzes and mines EE data with powerful computing power. The cloud center builds an intelligent O&M system for EE. According to the geographical location, monitoring status, historical status, and other factors of the EE, the functions of data monitoring, equipment management, data analysis, and other functions are uniformly managed.

The core of the intelligent EE defect detection service platform based on EC is the EE defect detection service. The EC intelligent platform provides data collection, interaction, storage, and edge device access functions for EE defect detection. It combines EC, CLO, and DL-based defect detection, trains the GRU-VAE EE defect detection model with the powerful computing resources of the cloud center, and deploys the GRU-VAE defect detection model trained by the cloud center on edge nodes. The EE defect detection service system is built. Figure 2.4 displays its structure.

From Figure 2.4, the EE defect detection service system is divided into five parts: EE data processing, GRU-VAE defect detection algorithm, defect detection task segmentation, edge-based defect detection, and continuous learning of the defect detection model. EE data processing is divided into three sub-parts: data

analysis, feature screening, and data processing. They are mainly used for analyzing EE data to discover specific data patterns, mine the potential value of data, screen features to extract dimensional features related to EE defects, process and delete redundant data, fill in missing data, and standardize data. The GRU-VAE defect detection algorithm is the core of the entire EE defect detection service system. The standard data after the data processing of EE is divided into the training set, verification set, and test set. The training set enters the GRU-VAE defect detection model with a fixed window length and continuously trains and updates the GRU-VAE model parameters. After model training and verification, the GRU-VAE model detects the test set of EE data and evaluates the defect detection performance of the model. Defect detection task segmentation uses EC to fuse with the GRU-VAE model to segment the inspection task. GRU-VAE model training is placed in the cloud center, and GRU-VAE model inference is placed in edge nodes. Edge-based defect detection refers to cloud center training models and delivering model files to edge nodes. Edge nodes detect EE data in real-time close to the data source. The continuous learning of the defect detection model is aimed at the actual use scenarios of EE, prevents the static model phenomenon of the GRU-VAE model, and continuously learns the model regularly to improve the model detection performance.

2.4. GRU-VAE model evaluation method. The performance of the GRU-VAE model is verified using precision, recall, and harmonic mean F1 values [16]. Precision indicates the proportion of true defect samples to total defect samples in defect detection. It is obtained according to Eq. 2.10.

$$Pre = \frac{TP}{TP + FP} \tag{2.10}$$

In Eq. 2.10, TP means that the true value of the sample is positive, the model's predicted value is also positive, and the correct sample is judged. FP means that the true value of the sample is negative, the model's predicted value is positive, and the correct sample is wrong. The recall rate represents the proportion of true defect samples to true samples in the detection, calculated as shown in Eq. 2.11.

$$Rec = \frac{TP}{TP + FN} \tag{2.11}$$

In Eq. 2.11, FN means that the true value of the sample is negative, the model's predicted value is positive, and the correct sample is wrong. The F1 value is the harmonic mean of recall and precision, which is the final evaluation term of the experiment, and the performance of the model detection is comprehensively evaluated with the F1 value. F1 value can be calculated according to Eq. 2.12.

$$F1 = \frac{2 * Pre * Rec}{Pre + Rec} \tag{2.12}$$

In the calculation of F1 values, precision and recall are weighted equally.

3. Simulation of experimental design.

3.1. Simulation experiment environment and data set. This simulation experiment is based on a server with a high-performance graphics processor. The Central Processing Unit (CPU) is Inter(R) Core(TM) i7-8700K CPU@3.70GHz. The graphics processor is the NVIDIA GeFoece RTX 2080. Table 3.1 demonstrates the parameters of the GRU-VAE model.

In this simulation experiment, an EE data set of the highway power grid is collected. Two public datasets are collected: Machine Internal Temperature (MT) data set and the Electrocardiogram (ECG) data set. The data set is divided into the training set, validation set, and test set according to the ratio of 5:1:4. The training and validation sets include only normal data. The test set includes normal data and defect data The EE dataset is divided into two dimensions: current I and temperature T. The current data set EE-I is aperiodic, and the temperature data set EE-T is periodic. Among the two public datasets, the MT dataset is aperiodic, and the ECG dataset is periodic.

Table 3.1: GRU-VAE model parameters

Time window size		14
Batch size	GRU	32
	VAE	32
Number of training	GRU	55
	VAE	55
Learning rate	GRU	0.0003
	VAE	0.0005

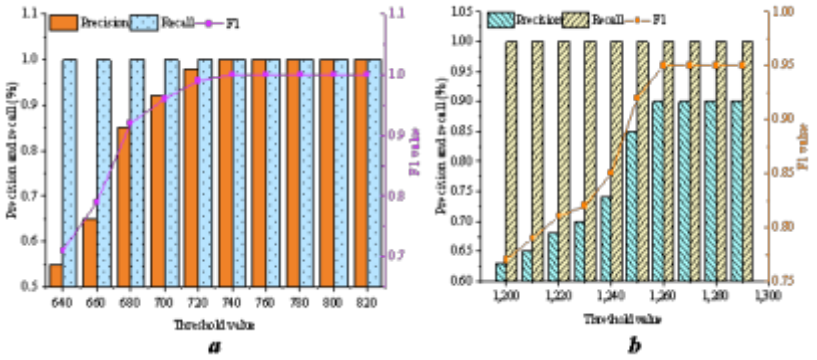

Fig. 3.1: Defect detection performance of EE in EE data sets under different thresholds (a is the defect detection performance of EE under EE-I data sets; b is the defect detection performance of EE under EE-T dataset)

3.2. Dynamic threshold selection model performance simulation experimental analysis. The GRU-VAE defect detection algorithm detects defects in EE data through reconstruction error. The standard for defect definition is that the reconstruction error is not less than the threshold ω. The current data is marked as defective, and the opposite is normal. If the threshold is too small, the GRU-VAE model is more sensitive to defect data, and some normal data are mistakenly detected as defect data. If the threshold is too large, the model appears less sensitive. Defective data is misdetected as normal data, and the model's usefulness is reduced. The dynamic threshold selection algorithm is used to select the threshold of four sets of data sets, EE-I, EE-T, MT, and ECG. The defect detection performance of EE of EE data under different thresholds is shown in Figure 3.1.

From Figure 3.1(a), the F1 value of the EE-I dataset increases with the increase of the threshold and reaches stability at the threshold of 740, which is 1. So, the optimal threshold of the EE-I dataset is 740. From Figure 3.1(b), the F1 value of the EE-T dataset increases with the increase of the threshold and reaches a stable level of 0.95 when the threshold is 1,260. So, the optimal threshold of the EE-T dataset is 1,260. The defect detection performance of EE under different thresholds of MT and ECG data sets is shown in Figure 3.2.

From Figure 3.2(a), the F1 value of the MT dataset decreases with the increase of the threshold and peaks at 0.96 at the threshold of 6,400. Then, the F1 value decreases significantly. So, the optimal threshold of the MT dataset is 6,400. From Figure 3.2(b), the F1 value of the ECG dataset decreases with increasing threshold, peaking at 460 at 0.93. After that, the F1 value decreases significantly. Therefore, the optimal threshold of the ECG dataset is 460.

3.3. Time series window performance simulation experimental analysis. This simulation experiment analyzes the relationship between the time series window size of the GRU prediction module and the performance of GRU-VAE defect detection to verify the influence of time window length on local defects and time-dependent defects. Besides, 15 data lengths are a time window, and the number of time windows is entered

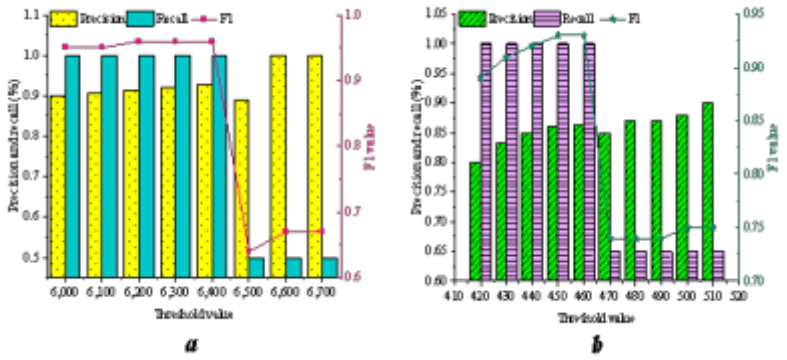

Fig. 3.2: Defect detection performance of EE in MT and ECG datasets under different thresholds (a is the defect detection performance of EE under the MT dataset; b is the defect detection performance of EE under the ECG dataset)

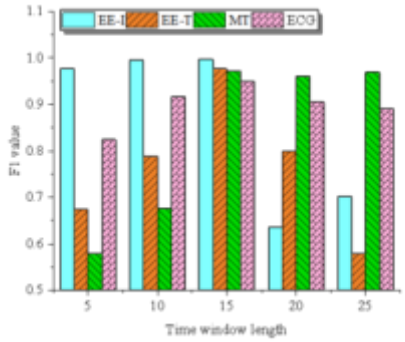

Fig. 3.3: Time series window performance experiment

into the GRU model with different time windows. The influence of 5 to 25-time window lengths on the F1 value of GRU-VAE is evaluated. Figure 3.3 reveals the results.

From Figure 3.3, with the increase of the length of the time window, the F1 value on the four datasets first increases, peaks when the time window length is 15, and begins to gradually decrease after reaching the peak. The time window length directly affects the correlation before and after the time series data. It determines the input time window length of the GRU prediction module to predict the next time window. When the length of the time window is too small, the GRU prediction module is not enough to obtain the distribution law of the time series of the time window. It is difficult to support the time series data for long-term prediction, so the F1 value of the model is low. When the time window is too large, defect data is diluted, resulting in degraded model performance. Therefore, when the other experimental conditions are unchanged, the time window length is 15, the GRU-VAE model fits the time series data best.

3.4. EE defect detection model performance simulation experimental analysis. When performing model performance comparison experiments, the dataset is experimented with in batches according to periodic and aperiodic periods. Both the separate GRU and VAE models are compared. The performance test results of the aperiodic data are provided in Figure 3.4.

From Figure 3.4, in aperiodic data detection, the GRU-VAE model has a higher F1 value than both the

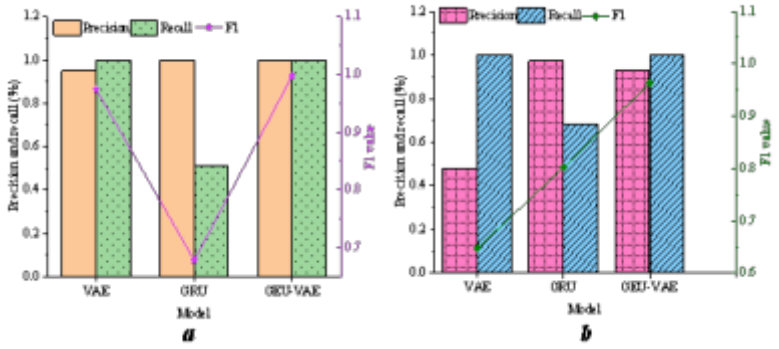

Fig. 3.4: Comparative experimental results of aperiodic data defect detection (a is the comparison result of the EE-I dataset; b is the comparison result of the MT dataset)

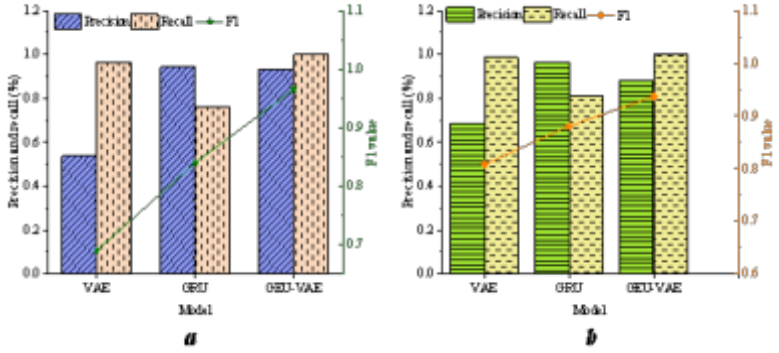

Fig. 3.5: Periodic data defect detection comparison experimental results (a is the comparison result of the EE-T dataset; b is the comparison result of the ECG dataset)

VAE and GRU models alone, and the precision and recall are also higher. In Figure 3.4(a), the F1 value of the EE-I dataset in the GRU-VAE model is 0.997, nearly 1. However, the GRU model alone performs poorly in the recall, indicating that the GRU model can recognize normal data but cannot detect defective data well. In Figure 3.4(b), the F1 value for the MT dataset in the GRU-VAE model is 0.963. The VAE model alone only has a higher recall, and the GRU model has a higher accuracy. Therefore, the F1 value of both is lower than that of the GRU-VAE model.

The detection results of periodic data are presented in Figure 3.5.

From Figure 3.5, in periodic data detection, although the recall rate of the VAE model is high, the accuracy is very low, indicating that the VAE model can detect the defect data of EE well during periodic data detection. Still, there is a defect detection error, and the defect data will be recognized as normal data. The GRU model has high precision but relatively low recall, indicating that the GRU model misses defect data when inspecting. The GRU-VAE model combines the high precision of GRU and the high recall of VAE. The F1 value is optimal compared to GRU and VAE alone, with 0.966 on the EE-T and 0.937 on the ECG datasets.

4. Conclusion. This research builds a GRU-VAE defect recognition algorithm model based on the VAE and GRU models in DL. It combines the advantages of both to study the defect identification of EE on the edge side of the power grid. Based on this, the EC architecture is introduced, and the EC intelligent EE defect identification system with the GRU-VAE model as the core is designed. Simulation experiments verify the

effectiveness of the model. It is found that the following conclusions: (1) The time window length is too large or too small will affect the model's performance. When the time window length is 15, the performance of the GRU-VAE model is optimal. (2) For periodic data, the recall rate of the VAE model alone is higher, and the precision of the GRU model is higher. The GRU-VAE model combines the advantages of both, with high precision and recall, and excellent F1 values up to 0.966. (3) For aperiodic data, the precision and recall of VAE on the EE-I dataset are relatively good, but there is still a certain gap compared with the GRU-VAE model. On the MT dataset, the precision of VAE and the recall of GRU are less than ideal. Therefore, the performance of the GRU-VAE model is better, and the F1 value can reach up to 0.997. However, there are some shortcomings. Only the GRU and VAE models are compared. No other DL models are compared. As a result, more models will be used in experiments to compare and find the shortcomings of the GRU-VAE model.

NETWORK DATA INTRUSION DETECTION AND DATA FEATURE EXTRACTION OF ELECTROMECHANICAL FACILITIES FROM MACHINE LEARNING

TING XU*, LIJUN WANG†, YANHONG HU‡ AND XUMING TONG§

Abstract. With the rapid development of Internet technology, network security issues have become more complex and changeable. Various intrusion methods threaten the information network environment in the Electromechanical Facility (EF) system. This paper focuses on EF to study the relevant detection methods and data feature extraction in complex network intrusions. Firstly, four common machine learning algorithms are used to calculate the data set. The advantages and disadvantages of each algorithm are analyzed after tuning and comparison. Secondly, a network intrusion detection algorithm is proposed based on Recursive Feature Elimination (RFE) principal component analysis. It uses RFE to reduce the number of features and improve the elimination judgment index to align with the detection requirements of information network datasets. Finally, a fault diagnosis method is proposed based on empirical pattern decomposition and support vector machine under Renyi entropy complexity measurement. This method trains and identifies the Renyi entropy of several basic pattern components obtained by decomposing empirical patterns as feature vectors. The results show that the RFE method judged by random forest removes irrelevant features, and the evaluation index is improved to align with the network dataset's detection requirements. It reduces the data dimension, reduces the operation time, and improves the accuracy of a few attack types. The comprehensive final detection effect is better than other algorithms. Additionally, the embedded operating system construction method based on the protection mechanism realizes the separate storage of the operating system and key data. Also, it can prevent the network system from being maliciously invaded, ensuring the stability of the instrument operation under harsh working conditions.

Key words: Machine learning, electromechanical facility, network data intrusion, data feature extraction, detection algorithm

1. Introduction.

With the rapid development of mobile Internet information technology such as cloud computing, big data, the Internet of Things, and artificial intelligence, traditional industries have been transformed into digitalization. The information network has achieved full coverage, popularization, and application in various fields and industries. The resulting information data has also grown exponentially. Big data has become an emerging resource [1]. Data growth can also bring some problems. In the Electromechanical Facility (EF) system, the information and control system are installed between each facility, which integrates computing, communication, and electromechanical systems to form a highly interconnected intelligent network information system. However, human factors attack the EF network, and the information system of the electromechanical enterprise is destroyed. Physical attacks can arbitrarily rewrite web pages and delete information data, which will seriously affect the integrity of information networks. In addition, various intrusion and cyber-attack tools and methods also exist in information system networks. Virus Trojan implants, Distributed Denial of Service attacks, phishing, and vulnerability attacks in the network all threaten the system's network security. Cybersecurity issues are also on the rise [2]. Based on this, this paper introduces the research results of Machine Learning (ML) in big data into intrusion detection for the network intrusion of EF. Various ML algorithms include Random Forest (RF), Gradient Boosting Decision Tree (GBDT), Adaptive Boosting (AdaBoost), and eXtreme Gradient Boosting (XGBoost). Among them, the Decision Tree (DT) is easy to understand and interpret, can be visualized and analyzed, and can easily extract rules. RF is used to classify and predict using multiple tree classifiers. Meanwhile, it can process high-dimensional datasets and solve nonlinear problems. The neural network has high classification accuracy, strong learning ability, and robustness and fault tolerance to noisy data, which provides good help for the research of network security intrusion detection.

2. Literature Review. Kobayashi wrote a technical report called "Computer Security Threat Monitoring and Surveillance," which first coined the term "threat." It is similar to the meaning of intrusion anomaly, indicating potentially unauthorized access to the system, resulting in a vulnerability of the entire system [3]. Thirimanne combined both statistical and rule-based techniques to design a new system. The system model can cope with real-time intrusion detection to become a new network defense measure. This system has a great effect on intrusion detection research [4]. Then, Moustafa wrote a paper titled "A Network Security Monitor." Network flows were used directly as a data source for the first time. Monitors were used to obtain the Transmission Control Protocol/Internet Protocol Address packets. The system could also be detected when the data is not converted into a uniform format. From this, network intrusion detection began to derive [5].

Shen used binarization techniques to decompose the original dataset into subsets of binary classes. Then, the Synthetic Minority Oversampling Technique (SMOTE) algorithm was applied to each subset of the unbalanced binary class to obtain balanced data. Finally, an RF classifier was used to achieve the classification goal [6]. Zhang proposed a Copy/Paste Detector-SMOTE algorithm. The neighbor set with high correlation was determined from the characteristics of the small sample and the surrounding sample distribution of the training set. The neighbor set was expanded into a new sample set by the SMOTE algorithm, which had a good effect on processing the unbalanced dataset [7]. Jahangir combined the Principal Component Analysis (PCA) algorithm and the SMOTE algorithm to denoise and reduce the dimensionality of the data set before interpolating the data. Modeling with the RF algorithm could improve the classification performance of unbalanced datasets [8]. Tong further distinguished boundary samples by Borderline-smote, generating different numbers of synthetic samples for different boundary samples, further improving Borderline-smote [9]. Wang proposed an upsampling method for secondary synthesis. The first synthesis was performed on samples that contained important information in the support selection of minority samples. Then, according to how the centroid of minority samples was distributed on samples in the neighborhood, the synthesis range of the second sample was optimized to form a secondary synthesis [10].

The innovations in this paper are as follows. First, the network data intrusion detection of EF is studied. Besides, various algorithms are applied for comparative experiments. In terms of accuracy, the advantages and disadvantages of each algorithm in the attack detection effect in the data set are analyzed. Second, in terms of running time, each algorithm's calculation and running time are counted. The two are combined to evaluate, and the algorithm with the better experimental effect is selected as the basic algorithm. Third, data feature extraction based on network intrusion detection can prevent the network system from being maliciously intruded on and ensure the stability of instrument operation under harsh working conditions.

3. Establishment of optimization model of construction parameters.

3.1. Algorithms related to network data intrusion of EF.

3.1.1. RF algorithm. RF uses resampling technology. There are put back from the training set repeated random selection of some data to form a new data set. DT is used for training, and a certain number of DT is used to form an RF. The final result is determined by the number of votes cast in the DT [11]. The essence is to improve the algorithm for DT conduct. Multiple DTs are combined from a single DT. Each tree is independent of the other. A DT is built according to the different samples taken. So, a single tree may not be very effective in classification. Still, the test of the sample by the forest formed by multiple trees will result in a more accurate classification after statistics.

The total number of training sets of the RF algorithm is N. A single DT is to randomly take n training samples from the training set, and bootstrap has a putback sample. When the input feature of the training sample is M, M is much greater than m. Each DT splits according to characteristics. m features are randomly selected out of M. If the Gini coefficient is used as the basis for division, one of the characteristic attributes is selected to split until all the characteristic attributes have been used.

When using Gini index splitting, if there are m samples of different classes in the training sample set T, the Gini index of the sample set is:

$$gini(T) = 1 - \sum_{i=1}^{m} p_i^2 \# \tag{3.1}$$

In Equation 3.1, p_i is the probability of the type i sample. For sample T contains l sample subsets $T_1, T_2, ..., T_l$, the subset contains a sample number of $N_1, N_2, ..., N_l$, respectively. The splitting Gini coefficient is:

$$gini_{spht}(T) = \frac{N_1}{N} gini(T_1) + \frac{N_2}{N} gini(T_2)\# + \cdots + \frac{N_1}{N} gini(T_1)\# \tag{3.2}$$

3.1.2. GBDT algorithm. GBDT is also a type of ensemble learning. Compared with the traditional AdaBoost algorithm, it is different from iterating again and again by updating the weight of the error rate of the previous weak learner. GBDT uses a forward distribution algorithm. The weak learner regression tree model is used, and the iterative method is also different from AdaBoost [12].

When using an iteration of GBDT, if the strong learner obtained by the previous iteration is $f_{t-1}(x)$, the loss function is:

$$L(y, f_{t-1}(x)) = L(y, f_{t-1}(x) + h_t(x))\# \tag{3.3}$$

Each round of iteration will find the weak learner $h_t(x)$ on the CART regression tree model to minimize the loss function each time. The resulting DT should minimize sample loss.

The multivariate GBDT classification algorithm code is as follows.

If there are K classes, the log-likelihood loss function is:

$$L(y, f(x)) = -\sum_{k=1}^{K} y_k log p_k(x)\# \tag{3.4}$$

Suppose there are k sample output categories, = 1. The expression for the k-type probability $p_k(x)$ is:

$$p_k(x) = \frac{exp(f_k(x))}{\sum_{k=1}^{K} exp(f_l(x))}\# \tag{3.5}$$

From the above two equations, it can be concluded that the negative gradient error of the class l corresponding to the ith sample of round t is:

$$r_{til} = -[\frac{\partial L(y_i, f(x_i))}{\partial f(x_i)}]_{f_k(x)=f_{l,t-1}(x_i)}\# = y_{il} - p_{l,t-1}(x_i)\# \tag{3.6}$$

In Equation 3.6, the error on the sample is the probability that sample i is the true l-category minus the probability of prediction at round t-1. The optimal negative gradient fit value for each leaf node in the resulting DT is:

$$c_{tjl} = argmin \sum_{i=1}^{m} \sum_{k=1}^{K} L(y_k, f_{l,t-1}(x_i)) + \sum_{j=1}^{J} c_{tjl}(x_i \in R_{tjl})\#\#\# \tag{3.7}$$

Since the above equation is difficult to optimize, it is generally used as an approximation. Then, Equation 3.8 is obtained.

$$c_{tjl} = \frac{K+1}{K} \frac{\sum_{x_i \in R_{til}} r_{til}}{\sum_{x_i \in R_{til}} |r_{til}|(1 - |r_{til}|)}\# \tag{3.8}$$

In calculating negative gradient and the best negative gradient fitting of leaf nodes, the operations of multi-classification, binary classification, and regression algorithms are similar.

3.1.3. AdaBoost algorithm. The AdaBoost algorithm adaptively enhances the error samples of the previous basic classifier and retrains the next basic classifier with weighted samples. Additionally, the latest weak path is added to each operation. The operation is stopped when a pre-specified range of error rates is met, or the maximum iteration value has been run [13].

The AdaBoost classification algorithm process is as follows.

The input is the sample set $T = \{(x_1, y_1), (x_2, y_2), ..., (x_m, y_m)\}$. The output is {-1,1}. Then, it is a weak classifier algorithm, and the number of weak classifier iterations is K. The output is the final strong classifier.

(1) The initialized sample set weights are as follows.

$$D(1) = (\omega_{11}, \omega_{12}, \cdots, \omega_{1m}); \omega_{1i} = \frac{1}{m}; i = 1, 2, \cdots, m\# \tag{3.9}$$

(2) When k = 1, 2,...,K,

(a) For the dataset adding the weight D_k, the generated weak classifier is $D_k(x)$.

(b) The classification error rate of $D_k(x)$ is:

$$C_k = P(G_k(x_i) \neq y_i) = \sum_{i=1}^{m} w_{ki} I(G_k(x_i) \neq y_i) \tag{3.10}$$

(c) The coefficients of the weak classifier are calculated as:

$$\beta_k = \frac{1}{2} log \frac{1 - C_k}{C_k} + log(R - 1) \tag{3.11}$$

In Equation 3.11, R is the number of categories. From the above equation, if it is a binary classification, R=2. If it is a quintuple classification, R=5.

(d) The weight distribution of the updated sample set is:

$$w_{k+1,i} = \frac{w_{ki}}{Z_k} \beta xp(-C_k y_i G_k(x_i))\# \tag{3.12}$$

Here, Z_k is the normalization factor, as shown in the following equation.

(3) The final classifier is constructed as:

$$f(x) = sign \sum_{k=1}^{K} \beta_k G_k(x)\# \tag{3.13}$$

3.1.4. XGBoost algorithm. XGBoost is an open-source ML project. It is one of the boosting algorithms, a good classifier that integrates many tree models. Algorithms and engineering improvements are carried out efficiently based on GBDT to make it more powerful and suitable for a larger range to improve the tree model [14].

The main flow of the XGBoost algorithm is as follows.

The input is the sample set $T = \{(x_1, y_1), (x_2, y_2), \cdots, (x_m, y_m)\}$. The maximum number of iterations is K, the loss function is L, and the regularization coefficient is λ, γ.

The output is the strong learner f(x).

For the number of iteration rounds k = 1,2,..., k, there are:

(1) The first-order derivative g_{ki} of the loss function L based on $f_{k-1}(x_i)$ and the second-order derivative h_{ki} are calculated for the ith sample in the current round. Besides, $i = 1, 2, \cdots, m$. All samples contain first-order derivatives and $G_i = \sum_{i=1}^{m} g_{ki}$ and second-order derivatives and $H_i = \sum_{i=1}^{m} h_{ki}$.

(2) When splitting is attempted on a node, the default fraction equals zero. G and H are the sums of the first and second-order derivatives of the node to be split. For the feature sequence number, q=1,2,..., Q.

(a)$G_L = 0, H_L = 0$;

Table 3.1: Dataset distribution

Data set	U2R	R2L	DOS	Detect attacks	Normal attack
Training set	48	1263	38729	4519	98371
Percentage of training sets	0.02%	0.31%	81.32%	0.91%	21.69%
Test set	265	17651	235916	4476	62098
Percentage of the test set	0.08%	6.21%	71.79%	2.65%	22.95%

(Note: DOS: Disk Operating System; R2L: Remote-to-Login; U2R: User-To-Root)

(b.1) The k features are arranged sequentially, and the ith sample is called in order. After the output samples are placed into the left subtree, the first and second-order derivatives of the left and right subtrees are summed, as shown in the following equation.

$$\begin{aligned} G_L &= G + g_{ki}\# \\ G_R &= G + G_L \\ H_L &= H + h_{ki} \\ H_R &= H + H_L\# \end{aligned} \tag{3.14}$$

(b.2) Try to update the maximum score, as shown in Equation 3.15.

$$score = max(score, \frac{1}{2}\frac{G_L^2}{H_L + \lambda} + \frac{1}{2}\frac{G_R^2}{H_R + \lambda} - \frac{1}{2}\frac{(G_L + G_R)^2}{H_L + H_R + \lambda} - \gamma) \tag{3.15}$$

(3) The feature and eigenvalue split subtrees are divided according to the best results.
(4) If the maximum score is zero, the DT creation is finished. All the leaf regions w_{kj} are calculated, and the weak learner $h_k(x)$ can be obtained. The strong learner $f_k(x)$ is adjusted. Then, the next weak learner is calculated iteratively. If it is not zero, then step two is continued to try to branch the DT again.

3.2. Data sources and features. Marker datasets are necessary to train and evaluate anomaly-based network intrusion detection systems. Knowledge of the underlying packet- and stream-based network data is required. The Data Mining and Knowledge Discovery 1999 (KDD 99) sample set contains five million data, but the dataset provides 10% of the training and testing subsets. Here, 10% of the training set in the KDD dataset is used as an experimental study [15]. Its sample category distribution table is shown in Table 3.1.

In the experiments, the categories of each type of attack are correspondingly labeled for the convenience of calculation. The attack categories in the network dataset can be divided into five major categories, subdivided into 42 attack types. There are 21 types in the training set. The new 18 types of attacks that do not appear are displayed in the test set. This allows for testing the model's adaptability to the experiment's new environment. Whether the designed model can accurately identify the type of attack when a new attack appears in the outside world is an important indicator to evaluate the system's capability.

3.3. Recursive Feature Elimination (RFE) cross-validation. The main idea of RFE is to build models repeatedly. After each round of model construction, the first n features with the least correlation are eliminated, and the subsequent features are re-screened to obtain the feature importance ranking. After traversing all the features, the optimal feature set is selected. This process is the process of eliminating the features in turn [16]. Figure 3.1 shows the schematic of ten cross-validations.

In the experiment, ten cross-validations will be used to ensure the stability of the experimental effect. The dataset is divided into ten copies, with only one as the test set and the remaining nine for training. Figure 3.2 demonstrates a schematic diagram of the One vs One (OVO) decomposition.

For unidentified samples, the OVO method trains the binary classifier with a classification algorithm to distinguish between paired classes. Reintegration confidence is the probability that the classifier will classify an

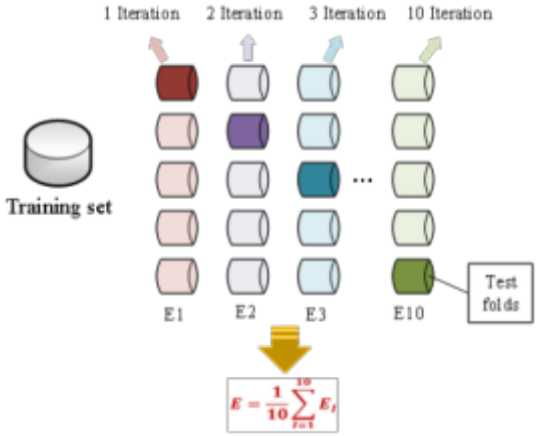

Fig. 3.1: Schematic of ten cross-validations

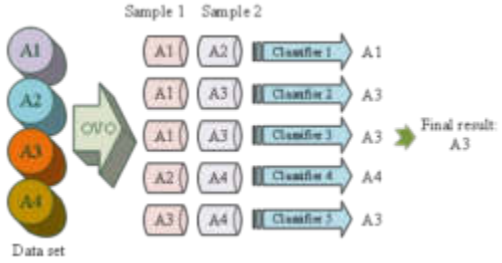

Fig. 3.2: Schematic diagram of the OVO decomposition

unknown sample that should be classified as j into i. Performing the above operation for each paired class will result in a complete score matrix [17]. Figure 3.3 presents the information network intrusion detection model of the OVO algorithm.

A K-means-based hybrid imbalance processing method is also used to deal with unbalanced data to improve the recall rate of network intrusion detection for minority attacks. The entire operation flow chart is shown in Figure 3.4.

The classification algorithm used in the model is the OVO intrusion detection model based on the REF Cross Validation-PCA proposed in the previous section. It has an attack imbalance characteristic for the selected dataset. Firstly, the data is preprocessed, the special symbols are numeric, and some data values are considered large for standardization. Then, the K-means-based hybrid imbalance processing method is used to sample the attack categories to obtain a balanced data set. The model proposed in the previous section is used to train this data set. Finally, the detection results of network intrusion attacks are obtained, which are compared with the unprocessed unbalanced data operation model [18].

3.4. Information analysis and feature parameter extraction technology. Given the current problems of facility condition monitoring and the lack of effective data communication between the facility condition monitoring and the facility management system itself and between them, the embedded condition monitoring and diagnosis system for facility management under the network architecture developed during the specific implementation of the project is shown in Figure 3.5.

The whole system is based on Client/Server (C/S) and Browser/Server hybrid architecture. According to the specific needs of the enterprise, the system provides a variety of commonly used network databases for

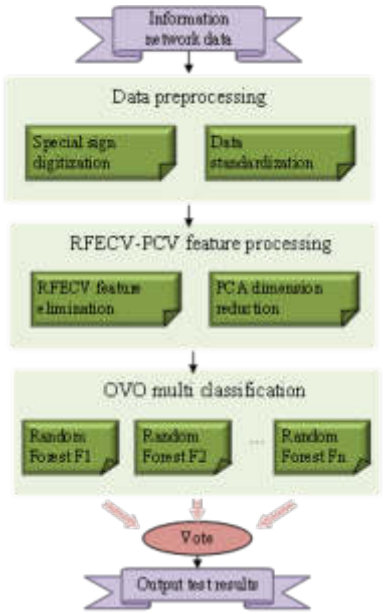

Fig. 3.3: RFECV-PCA-OVO algorithm-based intrusion detection model for information networks

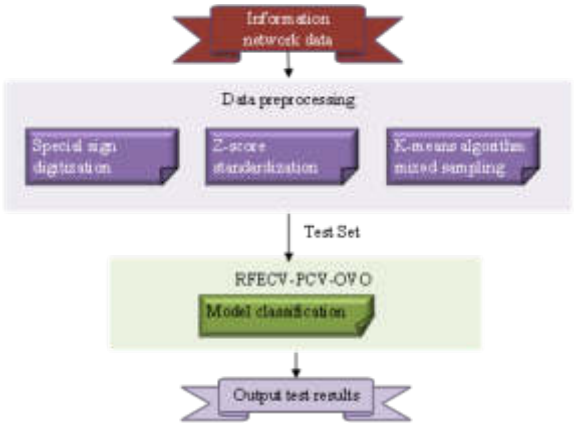

Fig. 3.4: Flow diagram of intrusion detection model based on K-means hybrid method

selection. The entire system framework can be divided into three networks as shown in the figure above. Figure 6 shows the workflow diagram of feature parameter extraction.

In the facility condition monitoring and diagnosis network in C/S mode, the facility monitor uses the embedded data acquisition analyzer to download the facility inspection path from the remote server, extracts the facility status data according to the downloaded path information, and saves it to the analyzer. At this time, the monitor can not only use the signal analysis method provided in the analyzer for on-site data analysis but also upload the collected data to the corresponding measurement point directory specified on the server [19]. The facility monitoring personnel or experts in the monitoring center can obtain the uploaded facility status data from the remote server as the client user of the system after permission verification. The method of signal analysis and diagnosis in the client intrusion software provided by the system on the computer is run. The health status of the facility is extracted and analyzed. If necessary, corresponding maintenance decisions

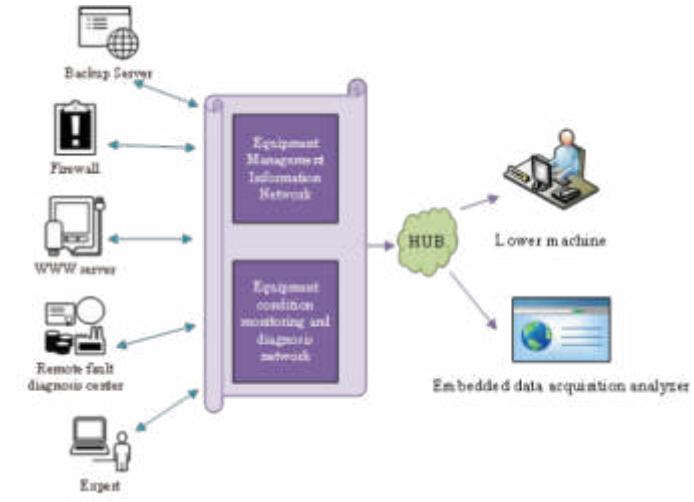

Fig. 3.5: Feature parameter extraction system framework

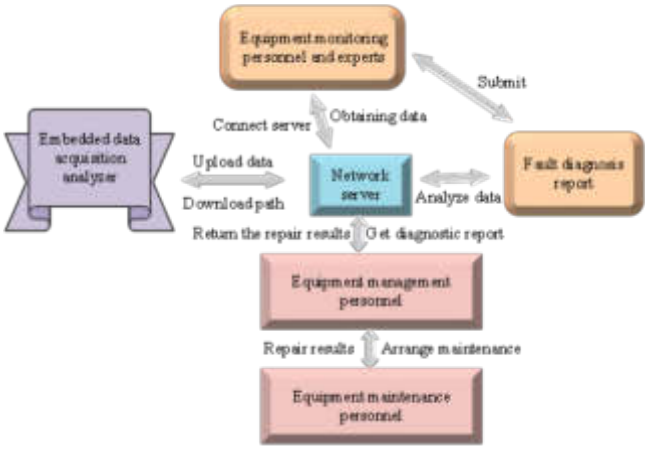

Fig. 3.6: System workflow

can be made, and facility maintenance plan reports can be submitted to the network database.

4. Test of construction parameter optimization model.

4.1. Comparison of network intrusion simulation results. The final result is parameter-dependent for the accuracy of various algorithms. Tuning is required to have a better model. The main parameters are the number of DT N_estimators, the maximum depth Max_depth, the minimum number of samples of leaf nodes Min_samples_leaf, and the minimum number of samples required for internal node subdivision Min_samples_split. The optimal values of the simulation parameters of the four algorithms are revealed in Figure 4.1.

The simulation test here is carried out in the Windows 10 environment, using the python programming language under Jupyter in Anaconda as a simulation experiment platform. The simulation environment for hardware conditions is Inter(R)Core(TM) i5-8500 CPU 3.00GHz, memory size 8.00GB, 64-bit operating system. After the parameter tuning of various algorithms, the running effects of various algorithms are compared. The advantages and disadvantages of each are analyzed, and the algorithms with a better effect on the network

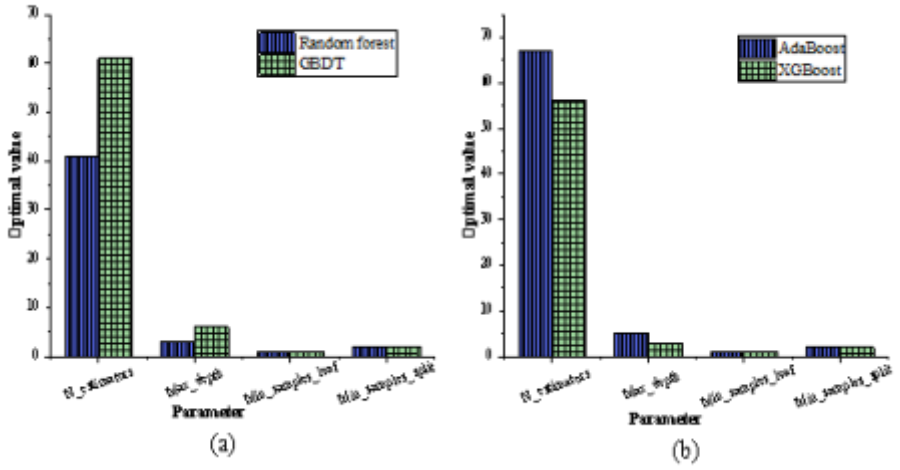

Fig. 4.1: Optimal number of main parameters of four types of algorithms

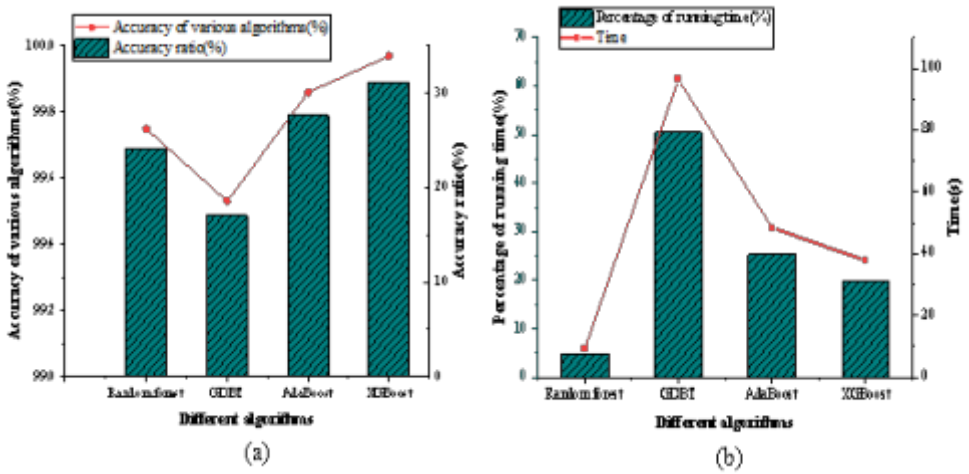

Fig. 4.2: Results from operation (a) are the accuracy of each type of algorithm; (b) is the algorithm running time

security dataset are screened out. After running, the result is shown in Figure 4.2.

Ten operation iterations are performed on the algorithm to prevent the chance of one operation. In Figure 4.3, the abscissa is the number of operations. It can be seen that although the accuracy results of each type of algorithm are a little biased, the detection rate is a very high value. In addition to accuracy, the efficiency of algorithm operation is also very important. As long as it is maintained in real-time, it can effectively block intrusion attacks and ensure the reliable operation of the system.

After one run and ten iterations, it is found that the RF has the least operation time, 9.19s. Several of the remaining algorithms are more than four times this time. Combined with the accuracy, it can be concluded that the RF algorithm has a better effect on the detection effect of network security datasets than other types of algorithms.

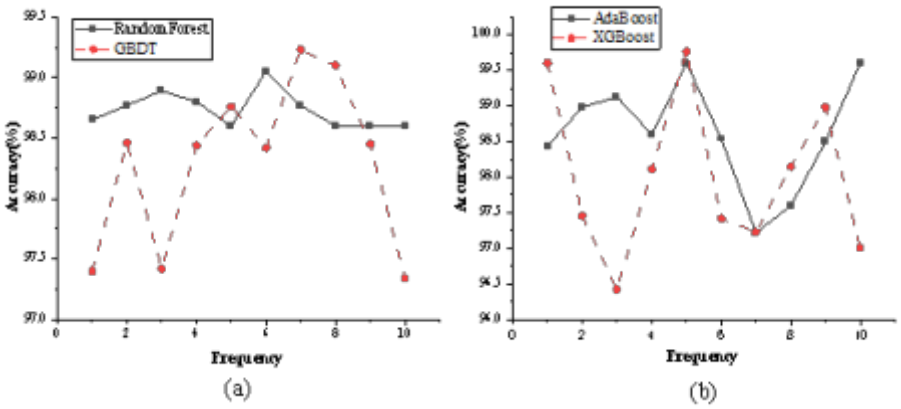

Fig. 4.3: Ten iterations of the operation (a) are RF and GDBT results; (b) are AdaBoost and XGBoost results

4.2. Comparison of network attack detection. After analyzing the entire dataset, it is found that DOS attacks account for a large proportion of the dataset, while U2R attacks account for a very small proportion. This can lead to an imbalance in the data set so that the data detection results are heavily biased towards the data type that accounts for many data types. Therefore, the final result is more one-sided. Therefore, when observing the application of each algorithm model on the dataset, it is necessary to view the accuracy and recall of various attack types to analyze the operation effect more comprehensively. A summary of the program output is shown in Figure 4.4.

The number of DOS attacks of the first category is relatively large in the dataset, about 80%. The various algorithms are not much different and work very well, staying at the same level. However, the GBDT algorithm has some shortcomings in terms of accuracy. The number of positive cases judged to be true accounts for a small proportion of all examples. The second NORMAL category is a more normal number of normal data in the data set, about 20%, similar to the DOS category of attacks. The RF, AdaBoost, and XGBoost algorithms work well, while the GBDT algorithm lacks recall. It indicates that the ratio of positive cases judged by the classifier to be true to the total positive cases is low, and the effect is not very good. The number of PROBE-type attacks in the third category is relatively small in the dataset, about 0.83%. The effect of each type of model is a little bit lower than the first two types of attacks, and the overall detection effect is quite good. The number of R2L attacks in the fourth category accounts for very little of the data set, holding only 0.23%. The algorithms in each category dropped to less than 80%. The number of U2R attacks in the fifth category is very small in the dataset, occupying only 0.01%. Models of all types are the least effective in detecting such attacks.

4.3. Network intrusion faults based on feature extraction analysis. According to a large number of experimental analyses and comparisons in previous studies, it is found that the first seven components after the decomposition of the original signal contain most of the information of the signal. Therefore, only the Renyi entropy of the first seven decomposition components is found to reflect the complexity of data feature extraction under different network intrusion states. The test results are given in Figure 4.5.

It can be seen that through this simple Renyi entropy measurement method, it is already possible to separate the three types of states. It can be seen from the analysis that under the normal working conditions of the network, the energy distribution of the intrusion signal in each frequency band is relatively uniform, the uncertainty and complexity of the energy distribution are large, and the Entropy of Renyi is also greater. For outer ring faults, the data will be more concentrated in the natural frequency band, with less relative uncertainty and less complexity. As a result, Renyi entropy is also smaller. The network shock caused by cage facility failure is less severe than the outer ring due to the small natural excitation frequency. The energy distribution is relatively divergent, and the uncertainty is relatively increased. Therefore, its Renyi entropy also increases accordingly. However, on the whole, the size of the Renyi entropy in the event of a facility failure

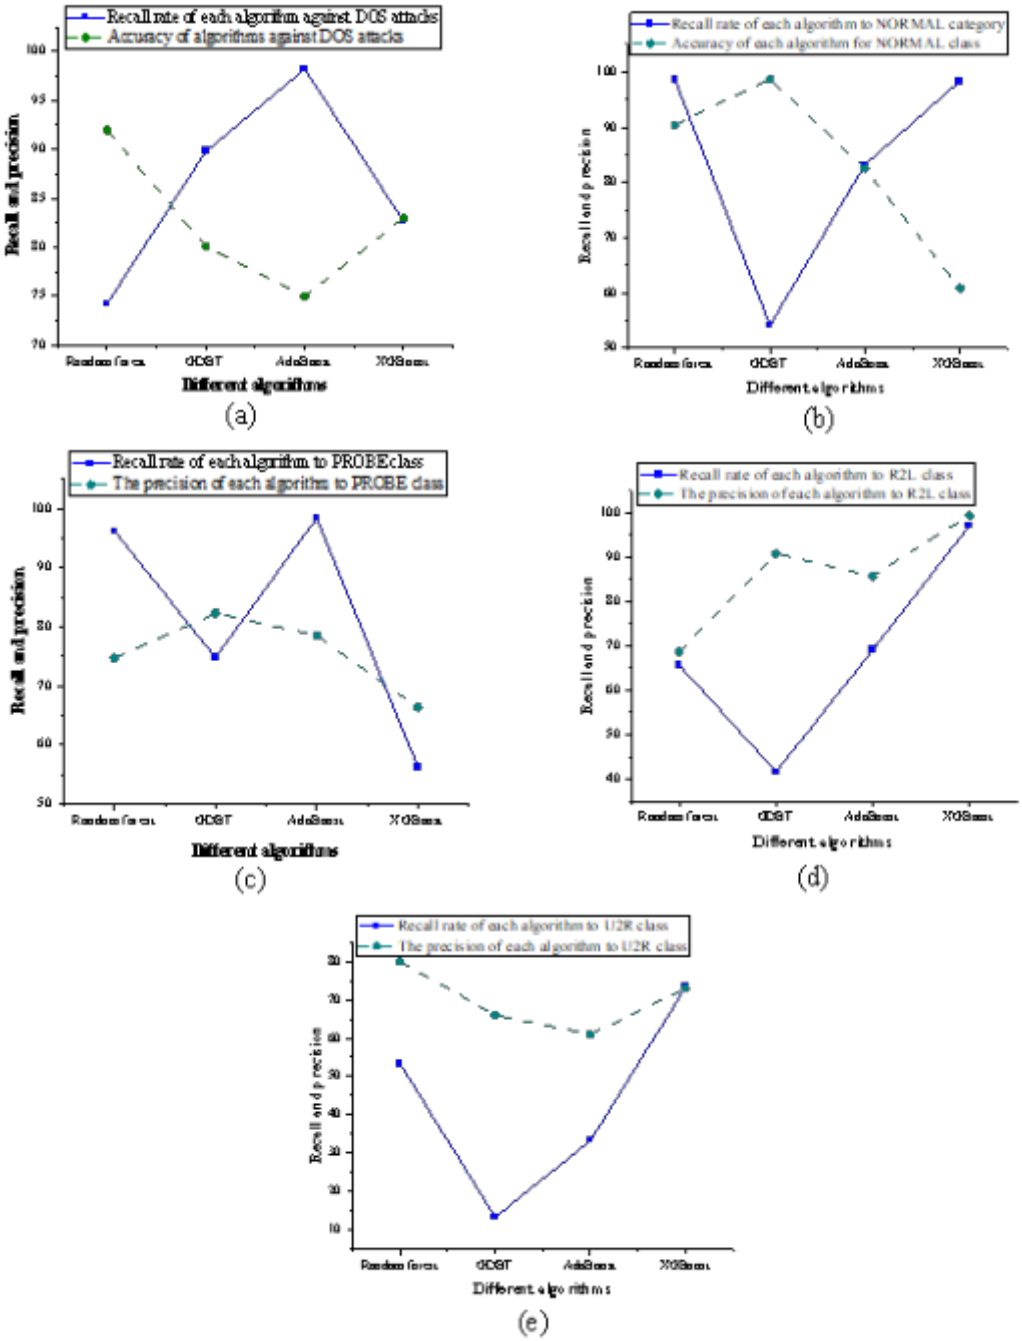

Fig. 4.4: Detection results of various algorithmic attacks

should be between normal and outer ring failure. The Renyi entropy in different states is obtained by adding the Renyi entropy of each energy distribution. Although the above three states can be distinguished, this distinction is not very obvious. The difference in Renyi entropy between different states is not very large.

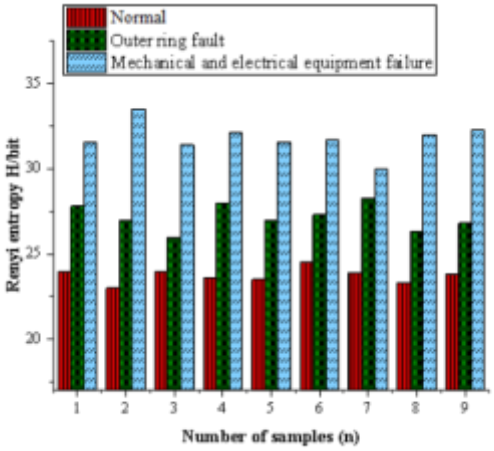

Fig. 4.5: Feature extraction detection results

5. Conclusion. Traditional EF network intrusion detection technology and means have become ineffective with the increase in data volume. Various attack techniques are constantly optimized, and the attack methods are changeable. It is easy to have problems such as false positive rates and false negative rates during analysis. ML methods in big data can be better applied to network security intrusion detection. It can make up for the detection deficiency of traditional information networks and extract data characteristics for facility failure problems to analyze fault problems. This paper mainly focuses on the problems of insufficient recall and accuracy in detecting a small number of attack data in the network data of EF. The following conclusions are drawn: (1) The operation time of the RF is 9.19s. Among the four algorithms, the running time is the least to reduce the data dimension and operation time. Furthermore, the accuracy rate of a few attack types has been improved, which is more in line with the detection requirements of network datasets. (2) Among the five types of network attacks, the number of extractions of DOS attacks is the best, accounting for a relatively large proportion of the dataset, about 80%. The various algorithms are not much different and work well. (3) Renyi entropy can vary depending on the complexity of network intrusions. The embedded operation of the protection mechanism effectively resists different degrees of external intrusion, realizes the separate storage of the operating system and key data, and ensures the stability of the operation of the EF. The disadvantage is that real EF network data cannot be obtained due to the limitations of the experimental environment of the facility. The selected data set is the KDD 99 data set. Although good classification effects have been achieved, it has not been verified whether other EF system data sets can also achieve these effects. Subsequent work will attempt to obtain real data so that the model can be applied to actual information network intrusion detection.

MATHEMATICAL NONLINEAR GRAPH THEORY TOPOLOGY LAYER MODEL FOR PHOTOELECTRIC TRACKING SYSTEM

JING LI* AND YUNPENG SHANG†

Abstract. The performance of the photoelectric tracking system mainly depends on the tracking accuracy. In order to achieve the purpose of high precision tracking, controlling the power dragging device, the main component of the photoelectric tracking system, is the main means to achieve this purpose. In order to improve the tracking speed and accuracy of photoelectric tracking systems, the author proposed a mathematical nonlinear graph theory topology layer model for photoelectric tracking systems. The topology layer model and the motion node servo mechanism model of the photoelectric tracking system are studied, and the two-stage disturbance sources that affect the tracking stability are analyzed. The results show that the interference estimation error range designed by the author reaches 3×10^{-3} through comparison, it can be seen that the estimation error designed by the author is significantly smaller than the ESO estimation error, and the buffeting is small. Through comparison, it can be concluded that the estimation error of the algorithm and the disturbance observer designed by the author are significantly smaller than the estimation error of ESO, and the buffeting is small, and they have strong compensation ability for the disturbance of different frequencies. The interference observer can quickly and accurately estimate the interference and prove its stability. The effectiveness of the proposed observer and disturbance observer is fully demonstrated. The finite time integrated site selection mode disturbance observer (F-ISMDOB) is designed to quickly estimate and compensate for equivalent interference, and effectively improves the anti-interference performance of the system structure layer.

1. Introduction. Photoelectric tracking system is a high-precision acquisition and tracking equipment with multi-disciplinary integration, such as optics, mechanical design, power electronics, signal processing, etc, it is commonly used in range measurement, spacecraft orbit determination, laser communication and target tracking and other applications. Photoelectric tracking servo control system mainly includes: photoelectric detection, signal processing, intelligent control and mechanical device and other parts. Its main function is to control the motor drive tracking axis according to the target position deviation signal, to achieve real-time, high-precision tracking of the target, which has been widely used in both military and civilian fields. In order to achieve high-precision tracking of the target, the traditional photoelectric tracking system generally adopts the composite axis control technology, including two tracking units of rack and precision tracking platform[1]. The rack system drives the actuator of the rack according to the tracking error of the coarse detector with large field of view and low resolution to complete the primary coarse tracking; Because the classical control method cannot accurately calculate the actual operation trajectory of the target, some new intelligent control methods and the hybrid control formed by mutual fusion are applied, which improves the stability of the target tracking. Examples are multi-mirror systems and systems. The high-resolution precision detector detects the residual error of the first-level tracking, and uses the precision tracking platform to complete the real-time tracking of the target to obtain the final tracking accuracy of the photoelectric tracking system. With the continuous expansion of the application field of photoelectric tracking system, photoelectric tracking systems with different mechanical structures are gradually emerging[2].

Composite axis tracking control is an effective means to improve the tracking accuracy of the photoelectric tracking system at present, and its core is the collaborative work of two levels of coarse and fine tracking. Photoelectric capture and tracking devices are often equipped with astronomical telescopes, weapon control

†School of Computer Engineering, Guangzhou City University of Technology, Guangzhou, Guangdong, 510800, China (YunpengShang6@163.com)

systems and other photoelectric measurement equipment, in order to quickly achieve the purpose of discovery and accurate tracking targets. The servo tracking system is mainly to quickly capture and continuously track the identified target, or to guide the target into the capture field of view. On the basis of the precise positioning of the rack servo system, the primary coarse tracking ensures that the tracking residual is within the compensation range of the secondary fine tracking according to the close-loop of the coarse TV miss distance, so as to achieve the final desired tracking accuracy. Generally, the control loop of the rack positioning link in the primary coarse tracking consists of three closed loops, namely, current-inertia-positioning[3]. The current control circuit determines the action torque when the frame rotates, and its performance is determined by many aspects, such as motor selection, control algorithm design and hardware matching; The inertial loop uses inertial sensors, such as speed measuring gyroscope and accelerometer, in order to make the actuator stable relative to the inertial space, so as to achieve the effect of resisting disturbance; The photoelectric tracking servo system processes the instructions, state and error signals from the image processing computer, main control computer, gyroscope, rotating transformer and other components, and processed through the digital signal processor to rotate the motor of the drive turntable to realize the stable and accurate tracking of the photoelectric tracker. Generally, a multi-closed-loop cascade composite control structure, including current loop, rate loop and position loop, is used to meet the needs of the system for fast response, high-precision tracking and reliability control. The positioning loop designs the controller according to the positioning residual to ensure that the positioning residual is small enough to complete the secondary precision tracking. Similarly, the precision tracking platform matched with the secondary precision tracking is also composed of a current-velocity-tracking three-loop control circuit, the motors of the precision tracking platform are generally piezoelectric ceramics, voice coil motor and giant magnetostrictive actuator; Inertia loop is used for anti-interference; The key of secondary precision tracking is the control algorithm design of the tracking loop, which determines the final pointing accuracy of the photoelectric tracking system[4]. Conventional control technology is widely used in practical industrial activities because of its simple principle and good stability. However, the conventional time-varying and non-linear system cannot achieve the purpose of precise control, so it is difficult to maximize its role. It is a new stage to solve the control problem of complex system, realize rapid response and smooth transition and other advantages of the development of intelligent control.

2. Literature review. Because of its unique strategic significance in military field, photoelectric tracking system has always been a hot research topic at home and abroad. In 1915, the aerial camera was first used in aerial reconnaissance, opening the application of airborne camera. The research status of optoelectronic tracking platform system and optoelectronic tracking and stabilization platform system LOS stability control are introduced respectively. The original photoelectric tracking platform was designed to be used as the eyes of aircraft for military reconnaissance. Later, due to the lack of real-time aerial cameras, which can not meet the needs of the battlefield, the development of new photoelectric platforms has become a research hotspot in various countries. The fuzzy controller is used to reason about the controlled object, and the dynamic characteristics and performance indexes of the controlled object are described by fuzzy language and rules, so as to realize the method of controlling the system is called fuzzy control. Fuzzy control system is a control process that simulates human reasoning and decision-making based on fuzzy control theory and taking empirical knowledge and expert control as the control rules. Fuzzy control uses fuzzy logic reasoning, fuzzy set theory and fuzzy language variables, and it is an intelligent control system that replaces human operation through computer control technology. At the same time, optics, electronics, automatic control technology and computer technology have also developed vigorously. In recent years, countries around the world have taken the research of optoelectronic stabilization platform as an important research content, and constantly seek new control technologies to improve scientific research capabilities, the United States, Israel and other countries have made many research achievements and developed relatively rapidly[5]. At the beginning of the 1970s, the photoelectric imaging equipment developed by Israel sent the images on the UAV back to the ground for the first time, opening the precedent of the research on the photoelectric stabilization platform. The stabilized platform can keep the optical equipment on it relatively stable, and is widely used in the optoelectronic pod system. The photoelectric pod is the most important part of the photoelectric tracking system, the photoelectric pod carried on the UAV can replace people to carry out reconnaissance tasks, improving human security. The photoelectric pod can be widely used in land, sea, air and space reconnaissance, and its carrier is vehicles, ships,

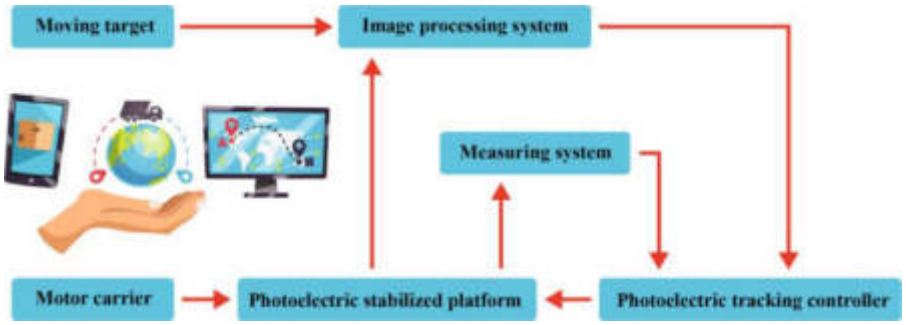

Fig. 3.1: Schematic diagram of photoelectric tracking imaging system

aircraft and satellites. Tong, W proposed two non-single interval type 2 fuzzy PID (NIT2F-PID) controllers for high-precision photoelectric tracking system (ETS) to improve its anti-interference ability [6]. Bao, G studied the latest progress of cooperative control of constrained heterogeneous multi-agent systems [7]. Ziquan, Y. introduced the latest development of fault-tolerant cooperative control (FTCC) for multiple unmanned aerial vehicles (UAVs)[8].

To improve the tracking speed and accuracy of the photoelectric tracking system. The author aims at the problem that the distributed cooperative control system does not measure the speed and has interference. First, combined with the advantages of the super-spiral anti-buffeting, a finite-time super-twisting observer (F-SO) is proposed to estimate the state information of the system structure layer quickly and accurately; Secondly, the Finite-time Integral Siting Mode Disturbance Observer (F-ISMDOB) is designed to quickly estimate and compensate the equivalent interference, thus effectively improving the anti-interference performance of the system structure layer. The results show that the interference estimation error range designed by the author reaches 3×10-3 through comparison, it can be seen that the estimation error designed by the author is significantly smaller than the ESO estimation error, and the buffeting is small.

3. Research methods.

3.1. Structure of photoelectric tracking system. The platform structure of the photoelectric tracking system is composed of the pitch axis, the azimuth axis, the gyroscope, the drive motor and the relevant optical equipment. The basic principle of the photoelectric tracking system is: to calculate and process the position deviation signal of the target and send it to the loop control unit to control the motor drive turntable, so that the photoelectric sensor can realize automatic tracking. The system can also turn the turntable according to the predetermined requirements. Due to the mobility performance of the target and the stability and tracking requirements of photoelectric tracking, the power drag control technology of servo turntable has become the key technology of the system. The so-called electric drag control, namely for the speed control of the motor and mechanical equipment, so that the rotation speed can be freely adjusted. In order to ensure the normal operation of the system, it is necessary to understand the mechanical characteristics and process characteristics of the motor and load equipment. Based on the brief introduction of the system stability control method, as shown in Figure 3.1, the photoelectric tracking imaging system. When the system is working, the miss distance information is calculated by the computer, the data is detected in real time by the sensor, and the input and output deviation error is obtained, and then the unified cooperative control algorithm is used to track it in real time, while weakening and isolating all kinds of interference received by the system, so as to make the optical equipment stable imaging [9].

From the above analysis of optoelectronic equipment structure and imaging mechanism, the optoelectronic tracking system is composed of several typical servo mechanisms. Field of view of moving target CCD camera, through the image processing system, the target miss distance information is sent to the servo control mechanism of the pitch and azimuth axes, which drives the frame to move, and then makes the LOS close to the target point; At the same time, the image processing system transmits the detected miss distance difference information

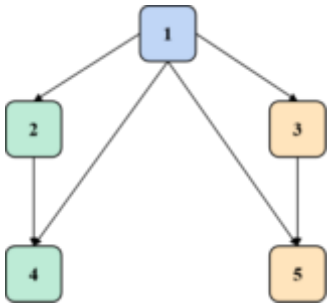

Fig. 3.2: Topological structure

to the servo actuator of the fast mirror, which includes the pitch and azimuth two axis structure, the fast mirror realizes the purpose of fast tracking and understanding the target through the compensation of tracking deviation; The measuring equipment further corrects the system control error by measuring the output value as the system feedback [10].

3.2. Modeling of photoelectric tracking system network structure.

3.2.1. System network structure modeling. The photoelectric tracking system is mainly used to complete the target search and automatic or automatic (semi-automatic) tracking functions, and accurately points to the target for the carrying task equipment. Through the feedback of Angle measuring elements and infrared tracker, and the rotation Angle of the azimuth axis and pitch axis is controlled, so as to complete the real-time tracking of the moving target. From the perspective of the overall structure of the photoelectric tracking system, according to the actual situation of the connection and communication mode of each actuator of the system and the tracking, the overall structure model and kinematics model of the photoelectric tracking system are established by using topological structure, algebraic graph theory and matrix; Taking the expected acceleration as the bridge connecting the whole structure and the actuators, the kinematic model of the actuator with moving nodes is established [11].

In the topological network structure model of the system, the nodes in the figure represent the moving target and each actuator of the photoelectric tracking system (the azimuth and pitch axes of the execution frame, the azimuth and pitch axes of the fast mirror), the edge in the figure represents the information transmission and connection mode between various actuators, and the direction of the edge represents the logic or information transmission direction.

As shown in Figure 3.2, the topological structure of the photoelectric tracking system with two axes and two frames, node 1 represents the moving target, and nodes 2 and 3 represent the pitch axis and azimuth axis of the photoelectric tracking system respectively, the target is directly tracked, nodes 4 and 5 represent the pitch axis and azimuth axis of the fast mirror, respectively, and track the residual error of the tracking moving target quickly [12].

According to the matrix theory, the topological structure of the system is transformed into a matrix, and the network structure of the photoelectric tracking system is expressed in the form of matrix, such as adjacency matrix, penetration matrix, Laplace matrix, etc.

$$\text{Adjacency matrix: } A = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \end{bmatrix}$$

Penetration matrix (diagonal matrix): $D = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 0 & 2 \end{bmatrix}$

Laplacian matrix: $L = D - A = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 & 0 \\ -1 & 0 & 1 & 0 & 0 \\ -1 & -1 & 0 & 2 & 0 \\ -1 & -1 & 0 & 0 & 2 \end{bmatrix}$

The first-order kinematics model of each node including the moving target point is described as follows 3.1:

$$\dot{x}_i = u_i, i = 1, 2, \cdots, n \tag{3.1}$$

where $x_i \in R$ represents the position status of actuator i, and $u_i \in R$ represents the control input of actuator i.

Since the photoelectric tracking system and its tracking target point are second-order kinematics models, the structural kinematics model can be described as follows 3.2:

$$\dot{x}_i = u_i, i = 1, 2, \cdots, n \tag{3.2}$$

where x_i and v_i represent the position status and speed status of the actuator i, u_i represents the control input of the actuator, and d_i represents the interference of the actuator i.

The photoelectric tracking system is a cooperative control system including multiple actuators, the traditional control method is a control strategy designed for a single actuator, forming multiple closed-loop control systems. Due to the many coupling of each actuator, the working environment and physical model are different, and with the development of technology, the number of hardware on the device is also increasing, resulting in more coupling between the various systems, greater interference and low coordination and cooperation ability, and the improvement of tracking performance has limitations [13].

Combining the advantages of distributed cooperative control, the problem of LOS stability and target tracking to be solved by the photoelectric tracking system is equivalent to the problem of consistency and robustness of cooperative control. According to the actual situation of photoelectric tracking equipment tracking the moving target, by analyzing the state of the target point movement (including position, speed and acceleration information), all executing agencies can coordinate and cooperate with each other through commands to maintain the consistency of position and speed (position deviation and speed deviation are zero), that is, the system can achieve accurate tracking [14].

The consistency conditions of the system are as follows 3.3:

$$\begin{cases} \lim_{t \to +\infty} ||x_j - x_i|| = 0 \\ \lim_{t \to +\infty} ||v_j - v_i|| = 0 \end{cases} \tag{3.3}$$

where x_i, x_j and v_i, x_j represent the position and speed of different nodes.

If the following consistency control law is selected, the following formula 3.4:

$$u_i = \sum_{j \in N} a_{ij}[(x_j - x_i) + \eta(v_j - v_i)] \tag{3.4}$$

where η represents the controller parameter, the system state equation is as follows 3.5:

$$\begin{bmatrix} \dot{X} \\ \dot{V} \end{bmatrix} = \begin{bmatrix} 0_{n \times n} & I_n \\ -L & -\eta L \end{bmatrix} \begin{bmatrix} X \\ V \end{bmatrix} \tag{3.5}$$

where $X = [x_1, \cdots, x_n]^T \in R^N, V = [v_1, \cdots, v_n]^T \in R^N$ and L are the Laplace matrices of the topological structure diagram.

3.2.2. Modeling of network structure based on leader-following . When studying the group formation control method, the pilot-following idea is simple and practical, it is also an effective method to study the consistency of collaborative control. Generally, when a group conducts group behavior movement (gathering and formation), it takes an individual in the system or an individual with leadership behavior as a leader, and other individuals as followers, through the cooperative control strategy, the position deviation and speed deviation between individuals will eventually tend to zero, which is to achieve the goal of group consistency. Unlike formation control, the performance index of consistency is that the state error between nodes is close to zero, while the constraint condition of formation control requires that the position error be constant to meet the required formation requirements.

In the photoelectric tracking system, the moving target is regarded as the leader, and each executive servo mechanism is regarded as the follower, the corresponding topological network structure is established, and the cooperative control strategy based on leader-following is researched and designed to realize the stable tracking of the photoelectric tracking system [15].

According to the matrix theory, the topological structure of the system is transformed into a matrix, and the network structure of the photoelectric tracking system is expressed in the form of matrix, such as adjacency matrix, penetration matrix, Laplace matrix, leader B matrix, etc.

Adjacency matrix: $A = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$

Penetration matrix: $D = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$

Laplace matrix: $L = D - A = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{bmatrix}$

Leader B matrix (diagonal matrix): $B = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$

The tracker kinematics model is as follows:

$$\begin{cases} \dot{x}_i = v_i \\ \dot{v}_i = u_i + d_i \end{cases}, i = 1, 2, \cdots, n \tag{3.6}$$

Where, x_i and v_i represent the position and speed of the ith follower respectively, and d_i represents the disturbance to the ith follower.

The navigator kinematics model is as follows:

$$\begin{cases} \dot{x}_l = v_l \\ \dot{v}_l = u_l \end{cases} \tag{3.7}$$

The consistency performance index of the second-order collaborative control system is as follows:

$$\begin{cases} \lim_{t \to +\infty} ||x_i - x_L|| = 0 \\ \lim_{t \to +\infty} ||v_i - v_L|| = 0 \end{cases} \tag{3.8}$$

where, x_i, x_j and v_i, v_j represent the position and speed of different nodes.

If the following traditional consistency control law is selected, the following formula 3.9:

$$u_i = \sum a_{ij}[(x_j - x_i) + \eta(v_j - v_i)] + b_{ii}[(x_L - x_i) + \eta(v_L - v_i)] \tag{3.9}$$

where η represents the adjustment parameter and the element in the leader B matrix, then the closed-loop dynamic equation of the system is:

$$\begin{bmatrix} \dot{X} \\ \dot{V} \end{bmatrix} = \begin{bmatrix} 0_{n\times n} & I_n \\ -(L+B) & -\eta(L+B) \end{bmatrix} \begin{bmatrix} X \\ V \end{bmatrix} + \begin{bmatrix} 0_{n\times n} & 0_{n\times n} \\ B & \eta B \end{bmatrix} \begin{bmatrix} X_L \\ V_L \end{bmatrix} \tag{3.10}$$

where $X = [x_1, \cdots, x_n]^T \in R^N, V = [v_1, \cdots, v_n]^T \in R^N$ and L are Laplace matrices and B is leaderB matrices.

3.2.3. Consistency tracking control of finite time convergence. In the distributed cooperative control system of photoelectric tracking, fast, stable and accurate are the requirements for the stable operation of the photoelectric tracking cooperative control system. Therefore, convergence speed and accuracy can be used as performance indicators of tracking control method. Since most control algorithms are asymptotically convergent, the convergence time is particularly important for practical control systems, especially for systems requiring high control accuracy.

In order to improve the stability speed of the system, for the control strategy designed in the cooperative control system, all node states need to reach the same or the given accuracy in a limited time. Therefore, it is of great significance to study the finite-time cooperative control of photoelectric tracking system [16].

For nonlinear systems, the following formula 3.11:

$$\widehat{x} = f(x,t), f(0,t) = 0, x \in R^n \tag{3.11}$$

Considering the above nonlinear system, it is assumed that there is a C^1 smooth function $V(x)$ defined on the neighborhood $\widehat{U} \subset U_0 \subset R^n$ of the origin, and there are real numbers c>0 and 0<a<1, so that $V(x)$ is positive definite on $\widehat{U}$, $\dot{V}(x) + cV^{\alpha}(x) < 0$, then the origin of the system is stable in finite time, and its upper bound is the following formula 3.12:

$$T(x_0) \leqslant \frac{V^{1-\alpha}(x_0)}{c(1-\alpha)} \tag{3.12}$$

The real finite-time consistency convergence of the collaborative control system needs to meet the conditions, as shown in the following formula 3.13:

$$\begin{cases} \lim_{t\to T_0} ||x_i - x_L|| = 0 \\ \lim_{t\to T_0} ||v_i - v_L|| = 0 \end{cases} \tag{3.13}$$

where x_i, x_j and v_i, v_j represent the position and speed of different nodes, and T_0 is the convergence time.

The pilot-following second-order multi-agent system gives a consistent tracking control protocol based on one leader and n followers, as shown in the following formula 3.14:

$$\begin{aligned} u_i = &- [\sum a_{ij} aig^{\alpha_1}(x_i - x_j) + b_i sig^{\alpha_1}(x_i - x_l)] \\ &- [\sum a_{ij} sig^{\alpha_2}(v_i - v_j) + b_i sig^{\alpha_2}(v_i - v_l)] \end{aligned} \tag{3.14}$$

where $0 < \alpha_1 < 1, \alpha_2 = \frac{2\alpha_1}{\alpha_1+1}$.

The finite-time consistency tracking control protocol based on leadership acceleration is as follows:

$$\begin{aligned} u_i = &u_l - k_1 sig^{\alpha_1}(\sum a_{ij}(x_i - x_j) + b_i(x_i - x_l)) \\ &- k_2 sig^{\alpha_2}(\sum a_{ij}(v_i - v_j) + b_i(v_i - v_l)) \end{aligned} \tag{3.15}$$

where $0 < \alpha_1 < 1, \alpha_2 = \frac{2\alpha_1}{\alpha_1+1}. k_1 > 0, k_2 > 0.$

3.3. Finite Time Hyperspiral State Observer. The essence of the state observer is to estimate / observe variables that cannot be directly measured through the fusion of different types of information. As a virtual sensor, it provides state information feedback in real time and ensures the performance of the closed-loop control algorithm. In the actual system, because the speed information is not measurable, the system speed information can be effectively observed by designing a state observer. Considering the system (Formula 3.6) and (Formula 3.7), the following observer is defined as follows:

$$\begin{cases} \dot{\widehat{x}}_i = \widehat{v}_i + \lambda_1 sig^{\frac{1}{2}}(\widetilde{x}_i) + \lambda_2 \widetilde{x}_i \\ \dot{\widehat{v}}_i = u_i + \lambda_3 \widetilde{x}_i + \lambda_4 sgn(\widetilde{x}_i) + \widehat{d}_i \end{cases}, i = 1, 2, \cdots, n, l \tag{3.16}$$

where $\widehat{x}_i$ and $\widehat{v}_i$ are state observations and $\widehat{d}_i$ are interference estimates. Observation error $\widetilde{x}_i = x_i - \widehat{x}_i$, $\widetilde{v}_i = v_i - \widehat{v}_i$, $\widetilde{d}_i = d_i - \widehat{d}_i$. The following formula 3.17:

$$\begin{cases} \dot{\widetilde{x}}_i = \widetilde{v}_i - \lambda_1 sig^{\frac{1}{2}}(\widetilde{x}_i) - \lambda_2 \widetilde{x}_i \\ \dot{\widetilde{v}}_i = \widetilde{d}_i - \lambda_3 \widetilde{x}_i - \lambda_4 sgn(\widetilde{x}_i) \end{cases}, i = 1, 2, \cdots, n \tag{3.17}$$

Assume that the interference observation error is differentiable and bounded, that is, the following formula 3.18:

$$|\widetilde{d}_i| \leqslant \delta and |\dot{\widehat{d}}_i \leqslant \overline{\delta} \tag{3.18}$$

where $\delta > 0$, $\overline{\delta > 0}$and $\lambda_4 > \delta$. Formula 3.18 is the following formula 3.19:

$$\begin{cases} \dot{\widetilde{x}}_i = \widetilde{v}_i - \lambda_1 sig^{\frac{1}{2}}(\widetilde{x}_i) - \lambda_2 \widetilde{x}_i \\ \dot{\widetilde{v}}_i = -\lambda_3 \widetilde{x}_i - \lambda_5 sgn(\widetilde{x}_i) \end{cases}, i = 1, 2, \cdots, n \tag{3.19}$$

Among them $\lambda_5 = \lambda_4 - \delta$.

If there is real number $x_1, x_2, \cdots, x_n$ and 0<a<1, then there is: $(\sum_{i=1}^{n} |x_i|)^{\alpha} \leqslant \sum_{i=1}^{n} |x_i|^{\alpha}$.

Consider the system (equation 3.6), (equation 3.7) and observer (equation 3.16). If the assumption is true, the parameters meet the following equation 3.20:

$$\begin{aligned} \lambda_1 > 0, \lambda_2 > 2, \lambda_3 > max(o, \beta_1), \lambda_5 > max(\beta_2, \beta_3) \\ \beta_1 = \frac{9\alpha_1^2}{16\alpha_2(\alpha_2 - 2)} + \frac{\alpha_1^2 - 2\alpha_1^2\alpha_2}{2(\alpha_2 - 2)} \\ \beta_2 = \frac{9\alpha_1^2\alpha_2^2}{4\alpha_3} + 2\alpha_2^2 + 1.5\alpha_2 \\ \beta_3 = \frac{\frac{9}{16}\alpha_1^2(\alpha_2 + 0.5)^2/\alpha_2^2}{(\alpha_2(\alpha_3 + 2\alpha_1^2) - (2\alpha_3 + 0.5\alpha_1^2) - \frac{9\alpha_1^2}{16\alpha_2})(\alpha_2 - 2)} + \frac{2\alpha_2(\alpha_2 + 1)}{4(\alpha_2 - 2)} \end{aligned} \tag{3.20}$$

The system (Equation 3.17) converges to the origin in a finite time.

Proof: Order $X = [X_1, \cdots, X_n], sig^{\frac{1}{2}}(\widetilde{x}) = [sig^{\frac{1}{2}}(\widetilde{x}_1), \cdots, sig^{\frac{1}{2}}(\widetilde{x}_n)], \widetilde{v} = [\widetilde{v}_1, \cdots, \widetilde{v}_n]^T$. Consider the following Lyapunov function, as follows 3.21:

$$\begin{aligned} V_T =& \frac{1}{2} X^T X + \frac{1}{2} \widetilde{v}^T \widetilde{v} + 2\eta_3 (sig^{\frac{1}{2}}(\widetilde{x}))^T sig^{\frac{1}{2}}(\widetilde{x}) + \eta_5 x^T x \\ =& \frac{1}{2} \sum x_i^2 + \frac{1}{2} \sum \widetilde{v}_i^2 + 2\eta_3 \sum |\widetilde{x}_i| + \eta_5 \sum \widetilde{x}_i^2 \\ =& \frac{1}{2} \sum v_{ti}^2 \end{aligned} \tag{3.21}$$

where, $V_{Ti}=\frac{1}{2}X_i^2+\frac{1}{2}\widetilde{v}_i^2+2\eta_3|\widetilde{x}_i|+\eta_5\widetilde{x}_i^2=\xi_i^TP\xi_i, x_i=-\eta_1 sig^{\frac{1}{2}}(\widetilde{x}_i)-\eta_2\widehat{x}_1+\widetilde{v}_i, \xi_i=[sig^{\frac{1}{2}}(\widetilde{x}_i)\widetilde{x}_i\widetilde{v}_i]^r$, positive definite matrix is as follows 3.22:

$$P=\begin{bmatrix} 2\eta_3+\frac{\eta_1^2}{2} & \frac{\eta_1\eta_2}{2} & -\frac{\eta_1}{2} \\ \frac{\eta_1\eta_2}{2} & \frac{\eta_2^2}{2}+\eta_5 & -\frac{\eta_2}{2} \\ -\frac{\eta_1}{2} & -\frac{\eta_2}{2} & 1 \end{bmatrix} \tag{3.22}$$

The derivative of V_T is given by the following formula 3.23:

$$\begin{aligned} \dot{V}_T &= \sum \dot{V}_{Ti}=\sum \dot{\xi}_i^TP\xi_i \\ &= \sum((2\eta_3+\frac{\eta_1^2}{2})sgn(\widetilde{x}_i)\dot{\widetilde{x}}_i+2(\eta_1^2+\eta_4 s_{ti})\dot{\widetilde{x}}_i \\ &+2\dot{v}_i\dot{v}_i+1.5\eta_1\eta_2|\widetilde{x}_i|^{-\frac{1}{2}}\dot{\widetilde{x}}_i-\eta_2(\dot{\widetilde{x}}_iv_i+\widetilde{x}_i\dot{v}_i) \\ &+\eta_1(|\widetilde{x}_i|^{\frac{1}{2}}sgn(\widetilde{x}_i)\widetilde{x}_iv_i\dot{v}_i-|\widetilde{x}_i|^{-\frac{1}{2}}\dot{\widetilde{x}}_iv_i)) \\ &\leqslant \sum(-|\widetilde{x}_i|^{-\frac{1}{2}}\xi_i^TQ\xi_i+\xi_i^TM\xi_i)^{-1} \end{aligned} \tag{3.23}$$

Wherein, formula 3.24 is as follows:

$$\begin{aligned} Q=\begin{bmatrix} Q_{11} & Q_{12} & Q_{13} \\ Q_{21} & Q_{22} & Q_{23} \\ Q_{31} & Q_{32} & Q_{33} \end{bmatrix}, M=\begin{bmatrix} M_{11} & M_{12} & M_{13} \\ M_{21} & M_{22} & M_{23} \\ M_{31} & M_{32} & M_{33} \end{bmatrix} \\ Q_{11}=0.5\eta_1^3+\eta_1\eta_3, Q_{12}=Q_{21}=0, Q_{13}=Q_{31}=-0.5\eta_1^2, \\ Q_{22}=2.5\eta_2^2\eta_1-1.5\eta_1\eta_2+Q_{23}=Q_{32}=-1.5\eta_1\eta_2, Q_{33}=0.5\eta_1; \\ M_{11}=-0.5\eta_1+2\eta_1^2\alpha_2+\eta_2\eta_3-2\eta_3, \\ M_{12}=M_2M_{13}=M_{31}=-0.75\eta_1, M_{22}=\eta_2^3-\eta_2^2+\eta_2\alpha_4-2\eta_4, M_{33}=\eta_2 \end{aligned} \tag{3.24}$$

Since the matrices Q and M are positive definite, the following formula 3.25:

$$\dot{V}_{Ti}\leqslant -|\widetilde{x}_i|^{-\frac{1}{2}}\xi_i^TQ\xi_i\leqslant -|\widetilde{x}_i|^{-\frac{1}{2}}\lambda_{min}(Q)||\xi_i||^2\leqslant -\lambda_{min}(Q)||\xi_i||<0 \tag{3.25}$$

It can be seen that the following formula 3.26:

$$\dot{V}_T\leqslant \sum \dot{V}_{Ti}\leqslant -\gamma_t\sum V_{Ti}^{\frac{1}{2}} \tag{3.26}$$

where $\gamma_t\frac{\lambda_{min}(Q)}{\lambda_{max}(P)}$. Combining with lemma, the system (equation 3.2) converges to the origin in finite time, and the convergence time is as follows 3.27:

$$t_1=\frac{2V_T^{\frac{1}{2}}(\widetilde{x}(0),\widetilde{v}(0))}{\gamma_t} \tag{3.27}$$

3.4. Finite-time integral sliding mode disturbance observer. In the actual second-order cooperative control system, the dynamic performance and stability accuracy of the system are affected by the uncertain interference such as communication interference, input error and external environment. A sliding mode disturbance observer is designed to compensate the influence of disturbance on the system control effect.

The integral sliding surface is defined as follows 3.28:

$$S_{ti}=\dot{\widetilde{v}}_i+\widetilde{v}_i+\int(m_1\dot{\widetilde{v}}_i+m_2\widetilde{v}_i)d\tau \tag{3.28}$$

The interference observer is designed as follows 3.29:

$$\dot{\widehat{d}}_i=(m_1+1)\dot{\widetilde{v}}_i+m_2\widetilde{v}_i+m_3sgn(s_{ti})+m_4s_{ti}^{\omega_1}+m_5s_{ti}^{\omega_2} \tag{3.29}$$

where $m_1, m_2, m_3, m_4$and m_5 are positive real numbers. Considering the system (Equation 3.6), (Equation 3.7) and the state observer (Equation 3.16), assuming that 4.1 is true and the disturbance observer is selected (Equation 3.25), the sliding mode surface (Equation 3.24) is guaranteed to converge to zero in a finite time [17].

Proof: Order $S_T = [s_{t1}, \cdots, s_{tn}]^T, V_T = [v_{t1}, \cdots, v_{tn}]^T$. Let Lyapunov function be the following formula 3.30:

$$V_T = \frac{1}{2} S_T^T S_T = \frac{1}{2} \sum s_{ti}^2 = \sum v_{ti} \tag{3.30}$$

Take the derivative of and get the following formula 3.31:

$$\begin{aligned} \dot{V}_T = S_T^T \dot{S_T} = \sum s_{ti} \dot{s_{ti}} \\ = \sum s_{ti} (\ddot{\widetilde{v}}_i + (m_1 + 1) \dot{\widetilde{v}}_i + m_2 \widetilde{v}_i) \\ = \sum s_{ti} (\dot{d}_i - \dot{\widehat{d}}_i + (m_1 + 1) \dot{\widetilde{v}}_i + m_2 \widetilde{v}_i) \end{aligned} \tag{3.31}$$

Substitute formula 3.25 into the above formula to obtain the following formula 3.32:

$$\begin{aligned} \dot{V}_T = \sum s_i (\dot{d}_i - m_3 sgn(s_{ti}) + m_4 s_{ti}^{\omega_1} + m_5 s_{ti}^{\omega_2}) \\ \leqslant \sum (\dot{\delta} s_{ti} - m_3 |s_{ti}| - m_4 s_{ti}^{\omega_1 + 1} - m_5 s_{ti}^{\omega_2 + 1}) \\ \leqslant \sum (-(m_3 - \dot{\delta}) |s_{ti}| - m_4 |s_{ti}|^{\omega_1 + 1} - m_5 |s_{ti}|^{\omega_2 + 1}) \end{aligned} \tag{3.32}$$

When $m_3 - \dot{\delta}$, so $\dot{V} < 0$. Let $m_3 - \dot{\delta} = \phi$, formula 3.27 be the following formula 3.33:

$$\dot{V}_T \leqslant \sum (-m_3 |s_{it}|^2 - \phi |s_{ti}|) \leqslant -\phi \sum s_{ii} = -\sqrt{2} \phi (v_{ti})^{1/2} \tag{3.33}$$

Further, $\dot{V}_T \leqslant -\sqrt{2} \phi V_T^{1/2 \leqslant 0}$; Combined with Lemma 3.2, the sliding surface S_T quickly converges to zero, and the convergence time is as follows 3.34:

$$t_2 \leqslant \frac{\sqrt{2} V_T^{\frac{1}{2}} (S_{T0})}{\phi} \tag{3.34}$$

The author gives a finite-time integral sliding mode disturbance observer, which can effectively weaken the chattering and enhance the robustness of the system, so as to realize fast and accurate compensation for the overall structural disturbance of the system.

4. Result analysis. In order to verify the effectiveness of the design algorithm, the finite-time super-helix state observer, disturbance observer (Equation 3.24) and (Equation 3.23) proposed by the author are simulated and compared with ESO. The following formula 4.1:

$$\begin{cases} \dot{\widehat{x}}_i = \widehat{v}_i + \lambda_5 sig^{\omega_3} (\widetilde{x}_i) \\ \dot{\widehat{v}}_i = u_i + \lambda_6 sgn^{\omega_4} (\widetilde{x}_i) + \widehat{d}_i \\ \dot{\widehat{d}}_i = \lambda_7 sig^{\omega_5} (\widetilde{x}_i) \end{cases} , i = 1, 2, \cdots, n \tag{4.1}$$

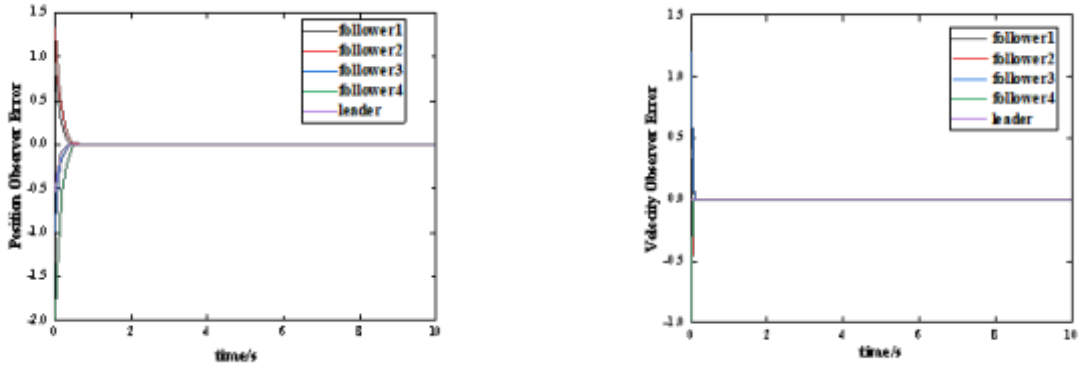
The equivalent disturbance signal is $D = [0.5sin(2t), cos(5t), -0.6sin(20t), -0.5cos(10t)]^T$, the controller is selected (Formula 3.14), and the node level disturbance signal is $D = 0.5sin(6t)$.

Parameter design of (equation 3.16): $\lambda_1 = 3, \lambda_2 = 3, \lambda_3 = 5, \lambda_4 = 17 m_1 = 3$.

Parameter design of (equation 3.25): $m_2 = 1, m_3 = 5, m_4 = 10, m_5 = 5, \omega_1 = 0.5, \omega_2 = 1.5$.

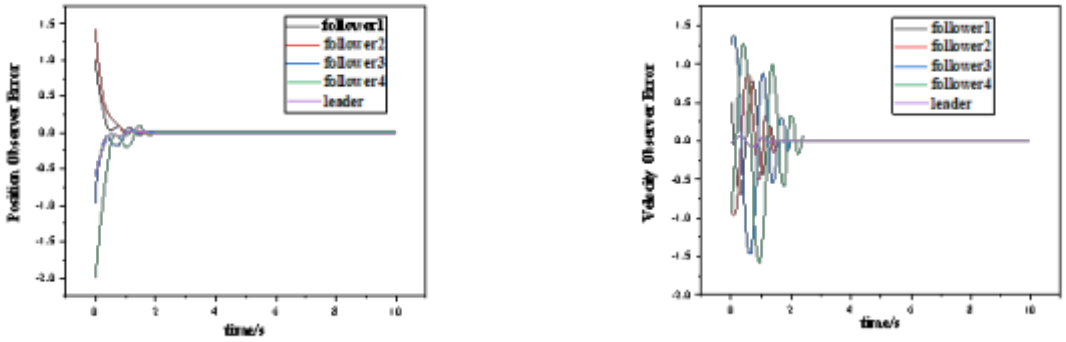
Parameter design of (Equation 3.22) and (Equation 3.23): $c_1 = 5, c_2 = 2, \alpha_1 = 0.5, \alpha_2 = 2.5, \eta_1 = 8, \eta_2 = 3$.

The estimated error curves of the algorithm (Equation 3.16) and the interference observer (Equation 24) proposed by the author are shown in Figures 4.1 and 4.3. The ESO estimation error curve of the comparison method is shown in Figure 4.2 and Figure 4.4.



(a) Position estimation error diagram (b) Speed estimation error diagram

Fig. 4.1: State estimation error curve (Equation 3.16)



(a) ESO position estimation error (b) ESO speed estimation error

Fig. 4.2: ESO state estimation error curve

It can be seen from Figure 4.1 that the error accuracy of the system state estimation value reaches 1×10^{-8},5×10^{-6}. Estimation error range of interference observer (Equation 3.24) 5×10^{-4}. As can be seen from Figure 4.3, the position, velocity and interference estimation error accuracy of ESO respectively reach $2 \times 10^{-7}, 210^{-4}, 110^{-2}$. Through comparison, it can be concluded that the estimation error of the algorithm (formula 3.16) and the disturbance observer (formula 3.24) designed by the author are significantly smaller than the estimation error of ESO, and the buffeting is small, and they have strong compensation ability for the disturbance of different frequencies[18]. The interference estimation error range of ESO (equation 3.20) is 0.03; The interference estimation error range of (formula 3.23) designed by the author reaches 3×10^{-3}. Through comparison, it can be seen that the estimation error of (formula 3.23) designed by the author is significantly smaller than that of ESO, and the buffeting is small[19,20]. The author aims at the problem that the distributed cooperative control system does not measure the speed and has interference. First, combined with the advantages of the super-spiral anti-buffeting, a finite-time super-twisting observer (F-SO) is proposed to estimate the state information of the system structure layer quickly and accurately; Secondly, the Finite-time

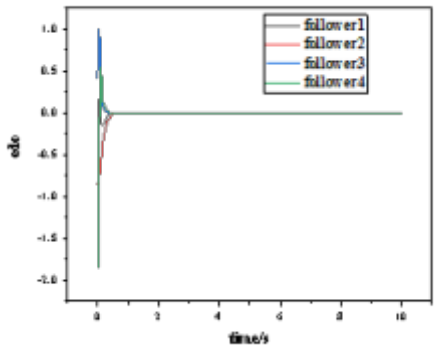


Fig. 4.3: Interference estimation error (Equation 3.16)

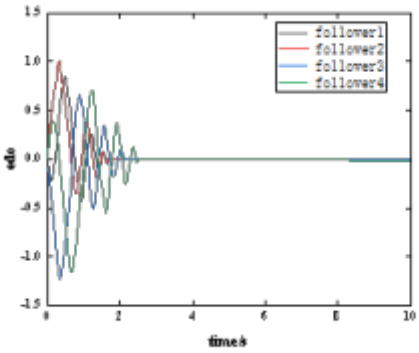

Fig. 4.4: ESO interference estimation error

Integral Siting Mode Disturbance Observer (F-ISMDOB) is designed to quickly estimate and compensate the equivalent interference, thus effectively improving the anti-interference performance of the system structure layer.

5. Conclusion. With the development of modern power electronics technology, the mobility of tracking target is enhanced, and the requirements for response speed and tracking accuracy of photoelectric tracking system are also increasing. In the industrial field, many occasions need to control the speed of electric motors. It is difficult to obtain a complex control system with multivariable and strong combination, and it is difficult to obtain good control performance. So a good control scheme is the focus of the discussion.

Aiming at the problem of obtaining unknown velocity information, the author designed a finite-time super-helix observer, which effectively estimated the system state information, and proved its stability using Lyapunov function; Aiming at the influence of system interference on system stability, the author proposes an interference observer based on integral sliding mode, estimates the interference quickly and accurately, and proves its stability.

The interference estimation error range of ESO (equation 20) is 0.03; The interference estimation error range of (formula 23) designed by the author reaches 3 × 10-3. Through comparison, it can be seen that the estimation error of (formula 23) designed by the author is significantly smaller than that of ESO, and the buffeting is small.

The author has carried out simulation analysis and compared with ESO, which fully proves the effectiveness of the observer and disturbance observer proposed by the author.

In the future, based on optoelectronics, we uses optics, precision machinery, electronics and computer technology to solve various engineering application topics. Its information carrier is being expanded from electromagnetic wave segment to optical wave segment, so that the application of photoelectric science and opto-mechanical integration technology is extended to the research direction of electrical information industry of optical information acquisition, transmission, processing, green storage, display and sensor.

Authors' contributions. The authors have made important personal contributions to this manuscript. Jing Li: writing and performing surgeries; Yunpeng Shang: data analysis and performing surgeries; article review and intellectual concept of the article.

DESIGN AND SIMULATION ANALYSIS OF BRIDGE ANTI-COLLISION STRUCTURE BASED ON NONLINEAR NUMERICAL SIMULATION

RUIFANG CHEN* AND YANXIN ZHANG†

Abstract. In order to solve the dynamic nonlinear problem of bridge loads and responses during ship collisions, a design method for bridge anti-collision structures based on nonlinear numerical simulation was proposed. The author describes in detail the entire process of collision force evolution, energy conversion, and plastic deformation of the anti-collision energy dissipator, and conducts a comprehensive simulation of it. The experimental results show that when a ship with a mass of 1000 tons collides forward at speeds of 1, 3, and 5 meters per second, the collision depth is 0.23, 1.46, and 3.95 meters, respectively, less than the maximum allowable collision depth of 4.3 meters, and the collision energy dissipator is still in the protective working state for the bridge pier. When a ship with a mass of 3000 tons collides with the collision avoidance energy dissipator at a speed of 3 or 5 meters per second, the collision depth exceeds the maximum allowable collision depth, and the collision avoidance energy dissipator fails, the ship will directly collide with the wharf. The plastic deformation of the anti-collision energy dissipator provided has important reference value for design.

Key words: Ship-bridge collision, Nonlinear finite element, Anti-collision energy dissipator, Plastic deformation

1. Introduction. In recent years, with the rapid development of China's national economy, a large number of bridges across major rivers and seas are being planned, constructed or put into use. The piers of these large bridges may be accidentally hit by ships of tens of thousands of tons. The impact load is one of the important control data for bridge design. At present, there are quite a number of empirical formulas that can be used to estimate the collision force of a certain tonnage ship against the pier, but their parameters are simple and cannot describe the details of the bow structure. Unlike other engineering structural problems, the ship-bridge collision force can hardly be obtained through the scale model test, because the dynamic plastic deformation of the bow structure occurs during the collision, and the similarity law cannot be established for this strong nonlinear mechanical process at present. Therefore, using modern nonlinear finite element technology and software, through the numerical simulation of the collision process, is the best and most accurate method to obtain the ship-bridge collision load at present [1,2].

Ship-bridge collision is a different process involving non-uniformity, geometric nonlinearity, contact nonlinearity and other phenomena, so it is difficult to conduct theoretical research on it. However, the cost of comprehensive research is very high, and research conclusions are limited by experimental technology; It is difficult to accommodate many nonlinear factors in a measurement system. Existing research on ship-bridge collisions is mainly based on experimental methods, focusing on the effects of ship-bridge collision forces, flow process corrections, and basic structures of collision structures.

With the rapid development of water transportation in China, the number of newly-built bridges has gradually increased, but the ship-bridge collision accidents have also become more frequent, resulting in major losses such as bridge damage and collapse, channel obstruction, threat to people's lives and property, and environmental pollution. Therefore, the study of ship collision force of bridges is particularly important [3,4], as shown in Figure 1.1.

2. Literature review. The existing research shows that when the bow collides with the pier of a large bridge, the pier stiffness is far greater than the structural stiffness of the bow. The main aspect of damage is the bow. The collision force and its time history are mainly determined by the collapse strength of the bow structure. When the bow strikes the plane part of a large pier, the pier can be simplified as a rigid plane wall.

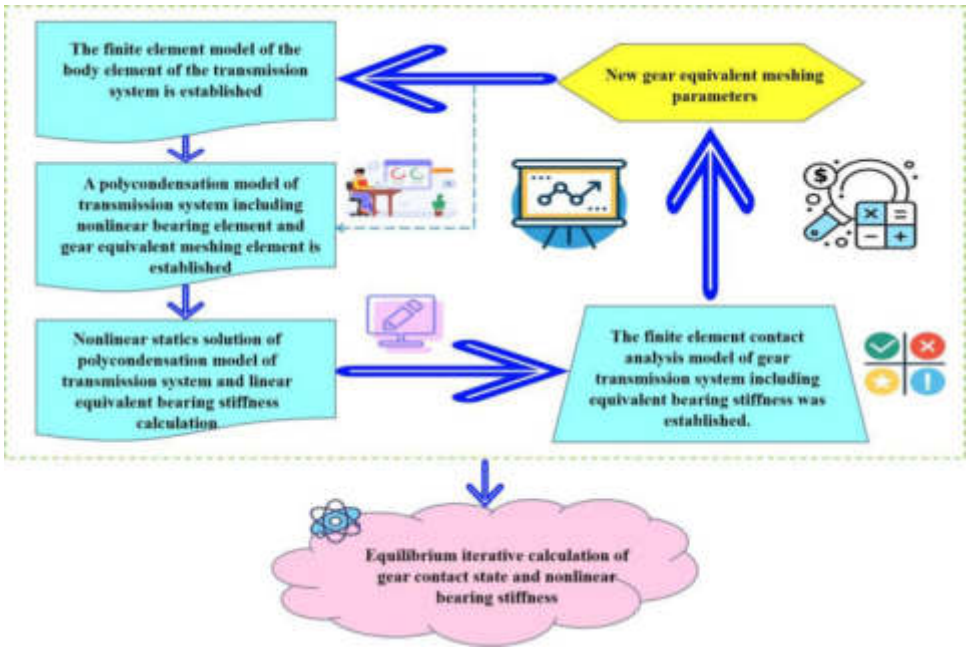

Fig. 1.1: Bridge anti-collision structure of nonlinear numerical simulation

Based on this, we can calculate the collision force of bow and rigid wall of various tonnage ships in advance, which is very close to the collision force of real ship and real bridge, for reference of bridge design. However, for different ships of the same tonnage, the rigidity of the bow structure is not the same, so the collision force of the ship bridge is also different, but generally in a close range [5,6].

Minorsky theory, Hans Drucher theory and simplified analytical method are the basis of commonly used methods for analyzing ship-bridge collision problems nowadays, but the above theories are based on quasi-static simulation analysis of collision. However, ship-bridge collision is a complex nonlinear dynamic response process of bridge structure and hull structure under huge impact load in a short time. It has very obvious dynamic characteristics, and the components in the collision zone generally need to quickly surpass the elastic stage and enter the plastic stage, and may have various forms of damage such as tearing and buckling, so it is not accurate to analyze the ship-bridge collision with the existing ship-bridge collision theory [7].

With the increasing progress and maturity of nonlinear finite element technology, it is widely used in the numerical simulation of structural impact, making the finite element numerical simulation technology can better solve the ship-bridge collision problem. Based on the basic theory and key technology of collision simulation, this paper numerically simulates the forward collision process of a ship's anti-collision energy dissipator on the main bridge pier of a bridge. We also describe and analyze the collision force evolution, collision energy conversion and collision avoidance capability (i.e. maximum absorbed energy) of collision energy dissipator during the collision process, and study the inherent regularity of collision phenomenon. It shows the advantages and prospects of the application of collision numerical simulation analysis.

3. Methods.

3.1. Nonlinear finite element control equation. The equation of motion of the ship-bridge collision problem can be generally expressed as

$$[M]\{\ddot{d}\} + [C]\{\dot{d}\} + [K]\{d\} = \{F^{ex}\} \tag{3.1}$$

where $[M]$ is the bridge mass matrix; $[C]$ is the damping matrix; $[K]$ is the stiffness matrix; $\{\ddot{d}\}$ is the acceleration vector; $\{d\}$ is the velocity vector; $\{d\}$ is the displacement vector; $\{F^{ex}\}$ is the external force vector. The

collision force is output in the form of contact force by defining the ship/collision avoidance system as the contact surface[8,9].

The explicit direct time domain integration method is suitable for the transient dynamic problems formed after the finite element discretization. By automatically controlling the time step, we can obtain a stable solution and ensure the accuracy of time integration. In practice, the minimum time step is defined by dividing the characteristic length of the minimum finite element mesh by the stress wave velocity:

$$\Delta t \leqslant \Delta t_{cr} = min(L^e/C) \tag{3.2}$$

3.2. Contact algorithm in collision. Collision-style (or composite) interaction is performed by the contact algorithm. A master-slave contact surface is defined between two contacting surfaces. Check if the slave has access to the main interface at any point in the resolve. Otherwise, the calculation will continue; Otherwise, a shearing force is applied to the base face to prevent the slave from further penetrating, and this force is the contact force [10].

The calculation in this paper is completed with the help of the powerful nonlinear finite element software LS-DYNA.

3.3. Project overview of collision simulation calculation model between ship and anti-collision energy dissipator. A bridge is a PC continuous rigid frame bridge. The main pier is a double-thin-walled pier. The size of the foundation cap is 18.6mx12.6mx5m. The design requires navigation of ships with a full load of 1000t. The main pier of the bridge is equipped with anti-collision energy dissipator in the form of angle steel supporting steel pipe frame. The material is Q235 steel, the diameter of steel pipe is 800 mm, the thickness is 10 mm, the model of support angle steel is 100 mm x 100 mm x 10 mm, and the thickness of node steel plate is 10 mm except for 1 6, which is 20 mm [11].

3.4. Strain rate sensitivity analysis of materials. At the same time, most of the anti-collision bridges are made of low carbon. The plastic material of the steel material is sensitive to the filter value, and its strength increases with the filter value. Therefore, the effect of different costs of intervention should be included in the model used to determine the difference in the problem. Among the constitutive equations that understand the components, the Cowper-Symonds constitutive equation is the most widely accepted.

$$\sigma_0'/\sigma_0 = 1 + (\varepsilon'/D)^{1/q} \tag{3.3}$$

where σ_0' is the dynamic yield stress at plastic strain rate ε'; σ_0 is the corresponding static yield stress; D and q are the strain rate parameters of the material. For mild steel, D=40.4, q=5.

For the steel used for anti-collision device, the contribution of isotropic strengthening and follow-up strengthening to the material needs to be included in the strengthening parameter β. $\beta = 0$ for follow-up strengthening and $\beta = 1$ for isotropic strengthening. Therefore, the improved Cowper-Symonds constitutive equation is adopted for the anti-collision device in the analysis of ship collision bridge problems

$$\sigma_0' = [1 + (\varepsilon'/D)^{1/q}](\sigma_0 + \beta E_p \varepsilon_p^{eff}) \tag{3.4}$$

where E_p is the plastic strengthening modulus; ε_p^{eff} is the effective plastic strain.

3.5. Establishment of finite element model for numerical simulation analysis. The collision process of ships and bridge structures is highly dependent on environmental conditions (wind, waves, weather, water, etc.) and ship characteristics (ship type, size, speed, load, bow force, stiffness). is complicated., hull and deck house, etc.), bridge characteristics (size, shape, material, quality, bridge characteristics, etc.) and steering response time. Due to the complexity of the ship-bridge collision process, it needs to be simplified in numerical simulation analysis. In the study of ship bridge collisions, the ship's rotational forces and the relationship between the ship's bridge and the bridge structure are important [12,13,14].

The key to study the anti-collision energy dissipation effect of the anti-collision energy dissipator of bridge structure is to obtain the impact force between ships and bridges and the energy absorption of the anti-collision energy dissipator during the impact process. Therefore, the finite element model of the anti-collision energy dissipator is only established when studying the anti-collision energy dissipator. Since the dynamic response of

the upper and lower structures of the bridge has little impact on the energy transfer and absorption, it can be ignored [15].

The water medium around the hull moves with the hull and participates in the absorption of collision energy. Since the hull is mainly rigidly displaced longitudinally in the collision when the ship collides with the anti-collision structure, the impact of the water medium around it is relatively small. The impact of water can be fairly accurately expressed by using an additional water mass 0.04 times the total mass of the hull.

In the study of collision between ships and anti-collision structures, it is very important to establish an effective finite element model in numerical simulation. When establishing the finite element model of anti-collision structure, because the joint steel plates between angle steel and angle steel and between angle steel and steel pipe are relatively rigid, rigid joints are used in the finite element model, and fixed bearings are used at the connection of angle steel support and foundation bearing platform; Since the deformation energy absorption capacity of anti-collision energy dissipator is mainly studied during the collision process, it is reasonable to use beam element to simulate steel pipe and angle steel support in DY-NA program. The section of steel pipe beam element and angle steel beam element are hollow steel pipe section and angle steel section respectively, and the finite element model of anti-collision energy dissipator.

When a ship collides with an anti-collision structure, the energy in the collision process mainly comes from the rotational forces of the ship. After the collision, the anti-collision force will absorb most of the energy, and the body will undergo some deformation to absorb some of the energy. In finite element modeling of the ship, shell material (THIN SHELL163 element) is used for the contact between the ship collision and the damage of the anti-collision structure to simulate the deformation of the ship during the collision. e.g. bow), stabilizers are used to change the accuracy of the ship (including additional water) and to ensure that the ship's torque during collisions is consistent with the truth. Deformation of the ship affects only the deformation of the hull falling on the bow [16].

Based on the above discussion, the LS-DYNA nonlinear finite element program is used to establish the finite element model of the anti-collision energy dissipator and the ship of a bridge, and the forward collision process between the ship and the anti-collision energy dissipator is numerically simulated, and the dynamic performance of the anti-collision energy dissipator during the collision process is studied. In the numerical simulation analysis, the beam element (BEAM161) is used to simulate the anti-collision structure. The ship uses two types of shell element (SHELL163) and solid element (SOL-ID164). In the whole finite element model, there are 16240 beam elements, 25000 shell elements and 500 solid elements.

For marine low-carbon steel and anti-collision structural low-carbon steel, the material has entered the nonlinear stage during the collision. The bilinear strengthening elastoplastic constitutive relation is adopted for low-carbon steel materials, and the improved Cowper-Symonds constitutive equation is adopted for material properties. In the material, only the contribution of follow-up strengthening to low carbon steel is considered. The values of parameters in the calculation model are as follows: material density $\rho = 7.85 \times 10^3 kg/m^3$, elastic modulus $E = 2.1 \times 10^{11} N/m^2$, hardening modulus $E_h = 1.18 \times 10^9 N/m^2$, yield stress $\sigma_0 = 2.35 \times 10^8 N/m^2$, Poisson's ratio $v = 0.3$, strain rate parameter D=40.4, strain rate parameter q=5, hardening parameter $\beta = 0$, maximum failure and other effects $\varepsilon_{failure} = 0.34$.

4. Results and discussion.

4.1. Collision force analysis between ship and anti-collision structure. The collision force between the ship and the anti-collision structure refers to the interaction force (i.e. the contact force between the two) when they collide. The size of the collision force represents the degree of damage of the ship to the anti-collision structure.

Figure 4.1 shows the time-history curve of the collision force between the ship and the anti-collision structure during the forward collision of a 1000t ship with the anti-collision energy dissipator at a speed of 3 m/s. It can be seen from the figure that the impact force curve has nonlinear wave characteristics. At different stages of the collision process, the collision force jumps to different degrees. Each jump increase of the collision force indicates that the propagation of the stress wave makes some components in the anti-collision structure effectively participate in the anti-collision work; The jump reduction of each collision force indicates the failure or failure of some components. In this example, the drop of impact force is mainly caused by the dynamic buckling of some angle steel supporting frame structures [17,18].

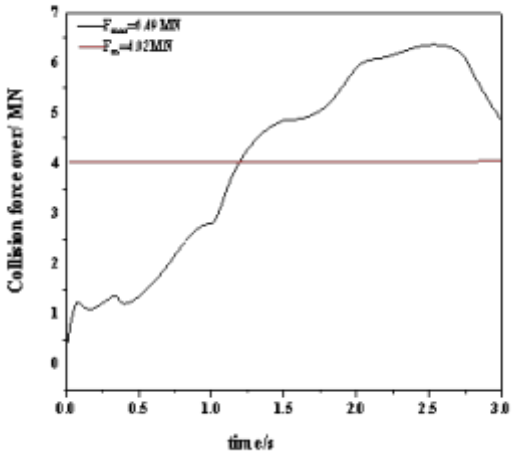

Fig. 4.1: Time history curve of impact force

In Figure 4.1, $F_{max} = 6.49MN$ represents the maximum collision force in the collision process, and represents the average collision force in the collision process. It can be seen from the figure that at the beginning, the collision force gradually increases with the increase of time (that is, the increase of impact depth). When the maximum collision force occurs, the collision force curve starts to slide (that is, the last section of the collision force curve). This is due to the rebound of the ship after the collision with the anti-collision structure. The above calculation results are basically consistent with the existing research results.

Table 4.1 lists collisions between 1000t and 3000t ships in head-on collisions with anti-collision energy dissipators at speeds of 1, 3, and 5 m/s. During a collision, the maximum force of the collision is very large, but the duration is short, so the damage to the structure is very small. Therefore, the collision damage of ships and anti-collision energy emitters of bridge structures are mainly determined by the size of the middle part of the collision force of the connection, that is, the greater the average collision force during the collision, the greater the energy emitter from the collision damage to prevent the collision. As the table shows, the force of the boat increases at the beginning of the turn, and the average collision force also increases. It can be concluded that the greater the ship's turning force, the greater the average collision force and the greater the effect of the collision force dissipator. From the ratio of the average collision force to the maximum collision force, it is not difficult to see that the average collision force is about half of the maximum collision force, which is consistent with the conclusion that the maximum collision force is twice the average. The force of the collision as demonstrated by the results of the Warsing experiment [19].

4.2. Energy conversion during collision. During the collision, the initial collision kinetic energy of the ship (including the kinetic energy provided by the additional water mass) will be converted into the following energy: the elastic-plastic deformation energy and the residual kinetic energy of the collision ship; Elastoplastic deformation energy and kinetic energy of anti-collision structure; Thermal damage caused by friction between components. In addition, the volume element and shell element in DY-NA program have only one integral point (located at the centroid of the element). Some deformation modes of the element do not have stiffness, resulting in the hourglass phenomenon and causing certain energy loss. The energy loss caused by the hourglass can be controlled to a small amount by adding viscous damping coefficient and reasonably dividing the grid. The calculation results show that the energy loss caused by friction is very small in the above energy. Therefore, the initial kinetic energy of the ship is mainly converted into the deformation energy and kinetic energy of the anti-collision structure, and the deformation energy and residual kinetic energy of the collision ship.

Figure 4.2 shows the energy conversion and energy time history curves for collision avoidance, and the

Table 4.1: Comparison of collision forces when ships with different initial kinetic energy collide with anti-collision energy dissipators in the forward direction

Ship mass/t	Initial velocity of collision/(m/s)	Collision initial Kinetic energy/MJ	Maximum impact force (F_{max})/MN	Average collision force (F_m)/MN	$\eta = F_m/F_{max}/\%$
1000	1	0.5	3.23	1.82	56.3
	3	4.5	6.49	4.02	61.9
	5	12.5	8.35	5.02	60.1
3000	1	1.5	4.54	2.43	53.5
	3	13.5	9.67	5.90	61.0
	5	37.5	11.35	6.53	57.5

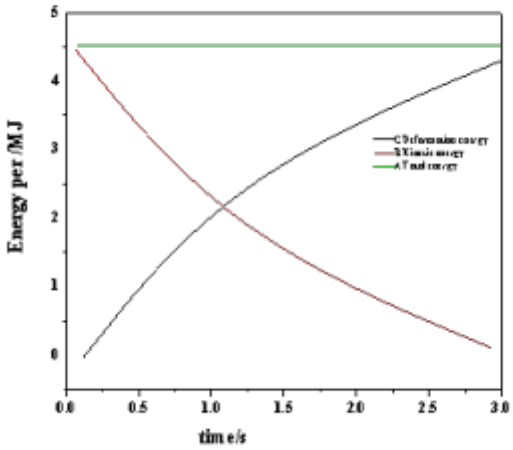

Fig. 4.2: Energy time-history curve

electrical energy of a 1000-ton ship when the next ship collides with a speed of 3 m/s. Line A represents the total energy of the entire system, while lines B and C represent the rotational energy and deformation energy of the entire system (rotational energy and deformation energy of the entire system, including the collision avoidance installation and the ship). As you can see from the figure, the bending force of the whole system (line B) is gradually decreasing, while the deformation energy of the whole system (line C) is gradually increasing, so yes, the rotational energy of the system is changing. the deformation energy of the system, but the total energy of the whole system (line A) remains unchanged (line A is horizontal), - this only shows that the transformation of energy in the collision process is consistent with the law of conservation of energy.

4.3. Damage and deformation analysis of anti-collision energy dissipator. Under the impact of ships with different initial kinetic energy, the size of the plastic deformation of the anti-collision energy dissipator of the pier is different. When its plastic deformation is greater than the safe design distance (i.e. the maximum allowable impact depth), the anti-collision energy dissipator will fail and the ship will directly impact the pier. Therefore, in the numerical simulation analysis, it is specified that when the ship directly collides and contacts the pier surface, the anti-collision energy dissipator will exit the protective working state. The maximum allowable impact depth of anti-collision energy dissipator is 4.3m[20].

Table 4.2 lists the deformation energy and impact depth of 1000t and 3000t ships when they collide with the anti-collision energy dissipator at the speed of 1, 3 and 5 m/s. It can be seen from the table that when the

Table 4.2: Deformation energy and impact depth of anti-collision energy dissipator under forward collision of ships with different initial kinetic energy

Ship mass /t	Initial velocity of collision /(m/s)	Initial kinetic energy of collision /MJ	Kinetic energy at the end of collision /MJ	Deformation energy of anti-collision energy dissipator /MJ	Impact depth /m	Whether the anti-collision energy dissipator fails
1000	1	0.5	0.12	0.30	0.23	No
	3	4.5	0.78	3.49	1.46	No
	5	12.5	0.71	11.45	3.95	No
3000	1	1.5	0.33	1.05	0.72	No
	3	13.5	0.37	12.77	4.30	Yes
	5	37.5	24.10	13.03	4.30	Yes

ship collides with the anti-collision energy dissipator, most of the dissipated kinetic energy is converted into the deformation energy of the anti-collision energy dissipator (that is, absorbed by the anti-collision structure). As the initial kinetic energy of the ship increases, the impact depth of the anti-collision energy dissipator also increases. When a ship with a mass of 1000 tons collides with the anti-collision energy dissipator in the forward direction at the speed of 1, 3 and 5 m/s, the impact depth is 0.23, 1.46 and 3.95 m respectively, which are less than the maximum allowable impact depth of 4.3 m, and the anti-collision energy dissipator is still in the protective working state for the pier.

When a ship with a mass of 3000t collides with the anti-collision energy dissipator in the forward direction at a speed of 3 or 5m/s, the impact depth exceeds the maximum allowable impact depth, the anti-collision energy dissipator has failed, and the ship will directly hit the pier. It is not difficult to find from the table that the anti-collision capacity (i.e. the maximum absorbed energy) of the anti-collision energy dissipator is only related to its own structure and material properties, but not to the initial kinetic energy of the collision ship.

5. Conclusion. This paper presents the design and simulation analysis of bridge anti-collision structure based on nonlinear numerical simulation. This method uses explicit transient nonlinear finite element analysis technology to successfully simulate the collision process of ship and bridge structure anti-collision energy dissipator. The results of numerical simulation analysis can reflect the general phenomena and basic laws in the collision process, and can more accurately reproduce the dynamic process inside the structure. The simulation analysis results can also simulate and reproduce the whole time course of collision force evolution, energy conversion and plastic deformation of anti-collision structure in the process of collision between ships and anti-collision energy dissipators.

RESEARCH ON THE MARKOV-CHAIN STATE INTERVAL DIVISION BASED ON PREDICTED DATA CORRECTION

LIXIN PENG[*], XIN ZHANG[†], JUNJIE LI[‡], WU BO[§], FUHAO YANG[¶], AND XU GONG[‖]

Abstract. By 2022, the total length of roads in Tibet Autonomous Region reached 121,447 kilometers. Due to the unique geological conditions in Tibet, various natural disasters such as earthquakes, mudslides, landslides, avalanches, and strong winds frequently occur. Along the Sichuan-Tibet Highway alone, over 300 disasters happen each year, significantly impacting the region's economic development. This study focuses on the complexity and randomness of natural disaster mechanisms and combines Markov chain theory to improve the accuracy of prediction data for mudslides, landslides, and earth subsidence etc. The main method is to modify the state interval of the prediction model parameter-Markov chain based on the distribution of discrete points on the number axis.

The following state interval division methods are proposed:(1) If the relative error of the predicted value exceeds 50%, adjust the prediction model. (2) Obtain the lower bound of state E1 by taking the floor value downward. (3) The width of each interval does not need to be uniform. (4) Arrange continuous, dense, and close points on the number line in the same side in batches, and represent a state continuously, dividing it into one suitable interval or batches. Using this method, an improved RMSE of 0.28mm and MAPE of 0.87% were obtained for engineering examples, outperforming other models such as GM(1,1), Verhulst, DGM(2,1) with corresponding RMSE values of 0.86 mm, 0.69 mm, and 1.38 mm, and MAPE values of 2.75%, 2.53%, and 5.99%. The combined prediction results for five sets of data yielded an RMSE of 0.14 mm and MAPE of 0.56%, which are quite close to the results obtained using Markov selection correction with an RMSE of 0.37 mm and MAPE of 1.01%. Furthermore, comparing the four sets of case, the average reduction in RMSE and MAPE is 3.56mm and 1.72%, respectively, demonstrating that this method can further improve the performance of Markov chain prediction.

Key words: Markov Chain, State Interval, Prediction, Correction

1. Introduction and examples. Forecasting, forecasting and early warning of natural disasters are important tools for disaster prevention and mitigation agencies and university researchers to combat natural disasters in a scientific, economic and rational way. The allocation of protection works in the coming years, the rational arrangement and use of human and material resources, and the promotion of economic development are of great importance to relevant departments. The prediction of natural disasters in the short and medium term involves numerous and complex factors, so the lack of a reasonable and scientific correction model can be fatal to such predictions [1, 2].

There are various prediction models involved in slope displacement prediction, ground settlement prediction, road disease prediction, rainfall prediction and lake area prediction, such as GM (1,1) [3, 4], deep learning [5, 6, 7, 8, 9], and neural network [10, 11, 12, 13], which all have their own advantages. GM(1,1) is more effective for predicting structured sample with less data. Deep learning is more prominent for predicting unstructured data. Neural network has outstanding regression prediction ability for structured data. For prediction models, there are advantages and disadvantages, and different models are selected according to different needs. However, for correction models, it is particularly important to study the commonalities among them [18, 19, 20].

This research employs statistical concepts.Statistical analysis is a crucial step in the five stages of statistical work: statistical design, data collection, sorting and summarization, statistical analysis, and information feedback.The use of statistical analysis methods in research is a high-level investigative requirement. The application of statistical analysis methods in scientific research has the following basic characteristics.

1. Scientific. They are based on mathematics and have a strict structure. Specific procedures and specifications must be followed, from confirming topic selection and proposing hypotheses to sampling, specific implementation, analyzing, and interpreting data. Specific procedures and specifications must be followed, from confirming topic selection and proposing hypotheses to sampling, specific implementation, analyzing, and interpreting data. Specific procedures and specifications must be followed, from confirming topic selection and proposing hypotheses to sampling, specific implementation, analyzing, and interpreting data. The conclusions drawn must meet certain requirements of logic and standards.

2. Appreciation. It is important to appreciate that the real world is complex and diverse, and its essence and laws are difficult to grasp directly. Statistical analysis methods are used to collect data from real scenes and quantify them through steps, frequencies, and concise chart representations. Processing this data allows for research and exploration of the world, leading to insights into the inherent laws of the real world.

3. Repeatability. Reproducibility is a measurement index of the quality and level of current research. Research conducted using statistical analysis methods is reproducible. All aspects of the research, from the number of topics to the design of pollutants, as well as the collection and processing of data, can be repeated under the same conditions, allowing for verification of the research results.

The fundamental concept of statistics is to solve practical problems by:

1. Identifying practical issues related to statistics; this article addresses the issue of designing reasonable state interval division standards.
2. Establishing an effective index system; this article uses MAPE and RMSE as evaluation indicators.
3. Collecting data; this article presents 4 representative cases.
4. Selecting or creating effective statistical methods to process and display the characteristics of the collected data; this article lists them.
5. Make reasonable inferences about the overall characteristics based on the collected data, combined with qualitative and quantitative knowledge. Provide suggestions for better decision-making based on these inferences. This article presents a solution based on this approach.This is an idea. There are multiple ways to approach it. This process is typically referred to as the hypothesis testing method when added to a hypothetical solution [21-34].

2. Methods.

2.1. A.Principle of Markov Model. Markov forecasting approach, proposed by Russian mathematician Markov in 1907, regards time series as a random process, in which the probability of a given event occurring is determined by the previous event, so as to determine the development of future states. If the event has K states $E_1 \sim E_k$, only one state can exist at a time, and each state can have K transition directions. The upper and lower bounds, $E_i \in [a_{1i}, a_{2i}], i = 1, 2, 3, \ldots, k$, are determined by relative error for each state.

$$a_i = (Y(i) - \hat{Y}(i))(Y(i))^{-1} * 100\%, \tag{2.1}$$

$Y(i)$ is the ith monitoring data, and $\hat{Y}(i)$ is the ith predicted data. a_i represents the relative error corresponding to the ith data.

Let $P_{ij} = m_{ij}{M_i}^{-1}$, indicating the probability of the state E_i transitioned to the state E_j by one step, where m_{ij} represents the number of times for the state E_i transitioned to the state E_j by one step, and M_i represents the number of the E_i occurrences. The matrix P composed of all one-step transition probabilities is called the state transition matrix, as follows:

$$P = \begin{pmatrix} P_{11} & \cdots & P_{1k} \\ \vdots & \ddots & \vdots \\ P_{k1} & \cdots & P_{kk} \end{pmatrix}. \tag{2.2}$$

2.2. Markov-Chain Improvement Model Steps. To begin with, the initial step is to identify the randomness between the predicted and measured values of the model. It is assumed that these values follow a random process. The relative error states are then divided through the Markov chain. Based on the theory, the probability of a given event occurring is determined from the previous event, allowing for the prediction

of similar states. Corrections are made accordingly to obtain the latest corrected value. The specific steps involved in this process are as follows:

1. The prediction model is used to get the corresponding predicted value $\hat{Y}(i)$.
2. The state interval E_i is determined based on the magnitude of the predicted relative error.
3. The next state is predicted from the latest state. If there is a non-unique maximum probability value, a two-step transition or an n-step transition is performed until a unique state is predicted according to the maximum probability criterion.
4. According to the state interval, the predicted value is corrected using equation 2.3.

$$Y(t) = \hat{Y}(t)[1 + 0.005(a_{1i} + a_{2i})]. \tag{2.3}$$

In this equation, $Y(t)$ represents the corrected predicted value, while $\hat{Y}(t)$ represents the predicted value. Additionally, a_{1i} and a_{2i} represent the lower and upper bounds of the predicted value, respectively.

5. The data prediction correction process involves replacing the latest predicted data with the set of data farthest from the predicted data, and then repeating steps $1 \sim 4$ until the correction is completed [14].
(1) Some formulas are:

$$B_i(t) = \frac{1}{2}(\overline{\otimes_{1i}} + \overline{\otimes_{2i}}) - \hat{y}(t) = \frac{1}{2}(C_{iup} + C_{idown}). \tag{2.4}$$

The horse chain characteristics prediction curve is based on a prediction value of $\hat{y}(t) = \hat{x}^0(t)$. The upper and lower sides of the curve define the state, with each adjacent pair of curves representing the state. The prediction sequence is divided into intervals and denoted as $\otimes_1, \otimes_{2i}, \otimes_m$. Based on the determination of the transition state of system , the predicted value of the future moment random $B_i(t)$ is most likely taken at the midpoint of the interval $(\overline{\otimes_{1i}}, \overline{\otimes_{2i}})$ [35].
The method's disadvantage is that it evenly divides the state, which is excellent but requires a significant amount of computation. In some cases, this level of accuracy may not be necessary. Proportional revisions are more aligned with the general public.
(2) Some formulas are:

$$\hat{x}^0(k) = \hat{y}(k) + \frac{A_i + B_i}{2}. \tag{2.5}$$

The system is in state K, where the original state is $(\otimes_{1i}, \otimes_{2i})$,$\otimes_{1i} = \hat{y}(k) + A_i$,$\otimes_{2i} = \hat{y}(k) + B_i$ and A_i, B_i changes with k.
The addition of the corresponding error mean directly is a simple and crude method. However, it is important to note that this approach may not be sufficient to meet the logical evaluation criteria.
The $Y(t) = \hat{Y}(t)[1 + 0.005(a_{1i} + a_{2i})]$ It is scientific, rational, and objective in its value.

2.3. State Interval Division Conjecture. The effectiveness of state intervals is determined by their reasonable and scientific division. To achieve this, the following hypothesis is proposed: the final correction effect is dependent on the division of state intervals.

1. According to equation 2.1, the model should be reconsidered if 100 a_i exceeds 50.
2. If the relative errors are similar, they can be expressed as a range.
3. According to equation 2.3, it is recommended to place the upper and lower bounds of the same interval on the same side of the number axis, and subdivide them as much as possible.
4. According to our criteria, a prediction is considered accurate if the relative error is within 1%. In cases where at least 50% of the data has a relative error of 1%, we define an interval of [-1%, 1%].
5. The lower bound of the initial state is determined based on the relative error of the corresponding predicted value. The lower bound is selected using the down-integer operation.
6. The appropriate interval length is determined starting from the lower bound and increasing upwards. This ensures that there is at least one data point in all state intervals, without the requirement of a consistent interval width.

Convert to Mathematical Language:
If $\exists\{[Y(i) - \hat{Y}(i)](Y(i))^{-1}\} \in E_i[a_{1i}, a_{2i}]$ and $\lim_{n \to i}(\hat{Y}(n) - Y(i)) \sim 0$
If and only if $\{[Y(i) - \hat{Y}(i)](a_{1i} + a_{2i})\} \geq 0$

Original paper [14] data.

3. Accuracy Evaluation Method. The evaluation of prediction accuracy cannot be solely based on a single predicted value. This study employs root mean square error (RMSE/mm) and mean absolute percentage error (MAPE/%) as metrics to assess the accuracy.

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(Y(i) - \hat{Y}(i))^2}{n-1}} \tag{3.1}$$

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}|\frac{Y(i) - \hat{Y}(i)}{Y(i)}| \tag{3.2}$$

The variable $Y(i)$ represents the measured value, while $\hat{Y}(t)$ represents the corrected predicted value.

4. Experimental. The literature [14] divides the state intervals into $E_1[-23\%, -5\%]$, $E_2[-5\%, 0\%]$, $E_3[0\%, 10\%]$ and $E_4[10\%, 40\%]$ as shown in Table 4.1 and Table 4.2.

Based on the conjecture presented above, the state intervals have been redivided into $E1[-23\%, -16\%)$, $E2[-16\%, -8\%), E3[-8\%, 0), E4[0, 10\%)$, and $E5[10\%, 37\%]$. The initial state transfer matrix P is shown

below:

$$P = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{5} & \frac{2}{5} & \frac{1}{5} & \frac{1}{5} \\ 0 & 0 & \frac{1}{5} & \frac{4}{5} & 0 \\ 0 & 0 & \frac{1}{5} & 0 & \frac{4}{5} \end{pmatrix}. \tag{4.1}$$

The $18th$ phase data is predicted from the $17th$ phase data. The state of the $17th$ phase is corrected to $E3$ and the matrix for the $18th$ phase data is calculated as $[0, \frac{1}{5}, \frac{2}{5}, \frac{1}{5}, \frac{1}{5}]$. According to the maximum likelihood criterion, the corrected value of the 18_{th} phase data is $849.899 * (1+0.005(-8+0)) = 815.903$, and the predicted relative error is -0.63%. The data from phases $2nd$ to $18th$ are added to the original data to reset the state transition matrix P:

$$P = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{6} & \frac{3}{6} & \frac{1}{6} & \frac{1}{6} \\ 0 & 0 & \frac{1}{5} & \frac{4}{5} & 0 \\ 0 & 0 & \frac{1}{4} & 0 & \frac{3}{4} \end{pmatrix}. \tag{4.2}$$

The process of calculating the $18th$ phase data is repeated. According to the maximum probability criterion, the state of the $19th$ phase data is obtained as $E3$, with the corrected value $880.739*(1+0.005(-8+0)) = 845.509$ and the predicted relative error -1.8%. The relative error is predicted using the $3rd$ to 19th phase data to calculate the state transition matrix P:

$$P = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{7} & \frac{4}{7} & \frac{1}{7} & \frac{1}{7} \\ 0 & 0 & \frac{1}{5} & \frac{4}{5} & 0 \\ 0 & 0 & \frac{1}{3} & 0 & \frac{2}{3} \end{pmatrix}. \tag{4.3}$$

The data for the $20th$ phase is $907.595 * (1 + 0.005 * (-8 + 0)) = 871.291$, with a predicted relative error of -3.7%. Similarly, the state transition matrix P for the data from the $4th$ to $20th$ phases is shown below:

$$P = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{8} & \frac{5}{8} & \frac{1}{8} & \frac{1}{8} \\ 0 & 0 & \frac{1}{5} & \frac{4}{5} & 0 \\ 0 & 0 & \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix}. \tag{4.4}$$

In Table 4.3, the corrected data for the $21st$ phase in state $E3$ is $931.051 * (1 + 0.005(-8 + 0)) = 893.809$, with a predicted relative error of -6.1%.

The state intervals, including $E1[-10\%, -5\%), E2[-5\%, 0), E3[0.5\%)$ and $E4[5\%, 10\%)$, have been divided in the literature [15]. Since the relative error equation a_i in the literature [15] and the relative error equation 2.1 defined in this paper are inverse to each other, the opposite number replacement operation is carried out to replace it with the format in this paper. The revised equation recalculates the $9th$ phase data according to 2.3, and the state is predicted as $E1$ after four transition steps, with the corrected value $14.95*[1+0.005(-10-5)] = 13.83$ and the relative error 5.47%. The $10th$ phase state is predicted as E1 after two transition steps, with a corrected value of $16.22 * [1 + 0.005(-10 - 5)] = 15.0$ and a relative error of -1.01%. The $11th$ phase state is predicted as $E4$ after two transition steps, with a corrected value of $17.63 * [1 + 0.005(10 + 5)] = 18.95$ and a relative error of -26.76%. The original data are shown in Table 4.4 and Table 4.5.

According to the given conjecture, the state intervals have been redivided into $E1[-10\%, -0.1\%]$ and $E2[-0.1\%, 10\%]$. The corresponding state transition matrix P, as per the theory, is as follows:

$$P = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}. \tag{4.5}$$

Table 4.3: Comparison of models and their relative errors.

Observed Phase	Value1 /mm	Value2 /mm	Relative Error	Value 3	Relative Error	Value 4	Relative Error
18	810.8	849.889	-4.82	828.642	-2.20	815.903	-0.63

RMSE/mm		74.119		40.204		35.936	
MAPE/%		7.360		3.968		3.068	

Corrected Predicted Value.
Value1, 2, 3, 4 refers to Measured Value, MFF Fitted Value, Markov Improved MFF Predicted Value and Corrected Predicted Value of State Redivision, respectively.

Table 4.4: Case 2 Original data.

No.	Measured Value/mm	Predicted Value/mm	Relative Error/%	State
1	6.33	6.33	0	3
2	8.31	8.35	-0.48	2
3	8.56	9.07	-5.96	1
4	10.95	9.86	9.95	4
5	10.72	10.71	0.09	3
6	10.67	11.64	-9.09	1
7	13.02	13.05	-0.23	2
8	13.74	13.75	-0.07	2

Table 4.5: Comparison between the measured values and the predicted values.

No.	Measured Value/mm	Predicted Value/mm	Corrected Value/mm	Relative Error/%
9	14.63	14.95	13.83	5.47
10	14.85	16.22	15.00	-1.01
11	14.95	17.63	18.95	-26.76

According to the $8th$ phase data, the initial vector $\varepsilon_0 = [0, 1]$, the product of the initial vector and the two-step state transition matrix for the $9th$ phase data is $\varepsilon_0 = [1, 0]$. The $9th$ phase state is predicted as $E1$, with the corrected data $14.95 * [1 + 0.005(-10 - 0.1)] = 14.20$ and the relative error 2.94%. Then, we remove the $1st$ phase data, and bring the $9th$ phase state $E2$ into the $2nd - 9th$ phases for predicting the state of the $10th$ phase data. The state transition matrix remains P. After two steps of transition, the state transition matrix is P_1:

$$P_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \tag{4.6}$$

Therefore, in Table 4.6, the $10th$ phase is in state $E1$ with corrected data of 15.4 (-3.7% relative error) and the $11th$ phase data is revised to 16.74 (-11.97% relative error) by repeating the above steps.

Figure4.1 displays the scatter distribution of relative errors calculated based on the original model. The red scatter points represent the same distribution of relative errors as the original model. The blue horizontal line represents the new interval selected according to the state interval division standard proposed in this article, and the green horizontal line represents the state interval divided in the original model. Two adjacent lines of the same color represent a state interval, while the blue-green dotted line represents a common interval. The upper and lower limits of the respective status intervals can be found on the left.

Table 4.6: Comparison between the original prediction model and the state interval redivision.

No.	Measured Value/mm	Corrected Value/mm	Relative Error/%	Corrected Value of Redivision/mm	RE[1]/%
9	14.63	13.83	5.47	14.20	2.94

represents the new interval selected according to the state interval division standard proposed in this article, and the green horizontal line represents the state interval divided in the original model. Two adjacent lines of the same color represent a state interval, while the blue-green dotted line represents a common interval. The upper and lower limits of the respective status intervals can be found on the left.Figure4.3 and Figure4.4 convey the same meaning, but with different cases and models.

Based on the above two examples, a preliminary conclusion of conjecture 2 and 3 (as described in Section 2.3) is as follows: If the upper and lower bounds of the same interval are continuously dense and close on the same side of the number axis, they can be included in a suitable interval or batch, and the continuously dense and close relative error values can be represented as a continuous state as much as possible, for example Table 4.7.

According to the data provided in literature [16], Table 4.8 shows Case 3 data.

The above GM(1,1) data is corrected on the basis of the Markov-chain improvement steps. According to Figure 4.3 and Table 4.9, the theoretically reasonable state intervals are $E1[-1\%, 0], E2[0, 2\%), E3[2\%, 4\%)$, and $E4[4\%, 9\%]$.

MAPE/%	2.75	2.53	5.99	0.56	0.87	1.01

The predicted data is revised according to 2.3, with the results as follows Table 4.10.

It can be seen from Table 4.11 that the accuracy of the Markov correction model is higher than that of other models, indicating that the division of state intervals is very reasonable and successful.

According to the data provided in reference [17] Table 4.12.

According to the division of state intervals conjecture, the original state interval $E1[-14.242\%, -8.323\%), E2[-8.323\%, -2$ is divided into $E1[-15\%, -5\%), E2[-5\%, -3\%), E3[-3\%, 0\%), E4[0\%, 1\%), E5[1\%, 4\%]$ As shown in the following picture Figure 4.4.

According to the hypothesis, the state interval is divided, and the initial state transition matrix from 2011

Table 4.12: Case 4 Original data.

Year	Actual Value	Estimated Value	Residual	Relative Residual
2011	80.2	80.2	0	0
2012	103.9	118.6985	-14.7985	-0.14243022
2013	135.2	138.4021	-3.2021	-0.02368417
2014	159.1	165.8975	-6.7975	-0.04272470
2015	198.4	194.3022	4.0978	0.02065423
2016	229.4	232.1136	-2.7136	-0.01182911
2017	280.2	274.1254	6.0746	0.02167951
2018	336.4	324.5689	11.8311	0.035169738
2019	387.5	384.2121	3.2879	0.008484903
2020	436.6	452.5011	-15.9011	-0.03642029

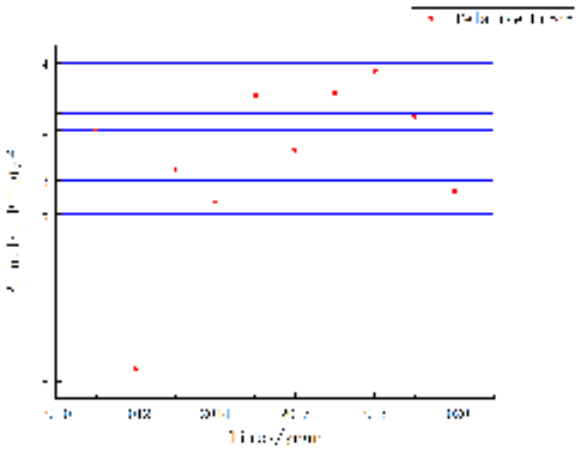

Fig. 4.4: Relative phase distribution scatter diagram and state interval distribution diagram for case 4.

to 2020 is recalculated according to the revised model:

$$P = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} \\ 0 & \frac{1}{2} & 0 & 0 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix}. \tag{4.7}$$

In 2020, the state is classified as $E2$, with $\varepsilon_0 = (0, 1, 0, 0, 0)$. After one transition step, multiplied by the initial state transition matrix P, it becomes $\varepsilon_1 = (0, 0, 0, 0.5, 0.5)$. According to the maximum probability criterion, it is impossible to determine the state in 2021. However, after analyzing and multiplying with the ten-step state transition matrix, it can be determined that the state in 2021 is $E2$, with $\varepsilon_9 = (0, 1, 0, 0, 0)$ Therefore, the predicted correction value for 2021 is $Y(t) = 536.7538 * [1 + 0.005(-5 - 3)] = 515.2836$. Using the 'equal innovations' model and excluding 2011, re-modeling from 2012 to 2021 yields a predicted value of 622.2154 for 2022. The product of the two-step state transition matrix and the initial state matrix was recalculated to obtain the 2022 status, which is $E3$. The corrected value is $Y(t) = 622.2154 * [1 + 0.005(-3 - 0)] = 612.8822$.The comparison results are shown in Table 4.13.

Table 4.13: Case 4 Data comparison.

Years	Actual Value	The optimal estimated value of the original model	Re-estimation of the estimated value.
2021	503.5	525.5426	515.2836
2022	576.4	617.5202	612.8822
RMSE/mm		46.6556	38.3380
MAPE/%		5.76	4.33

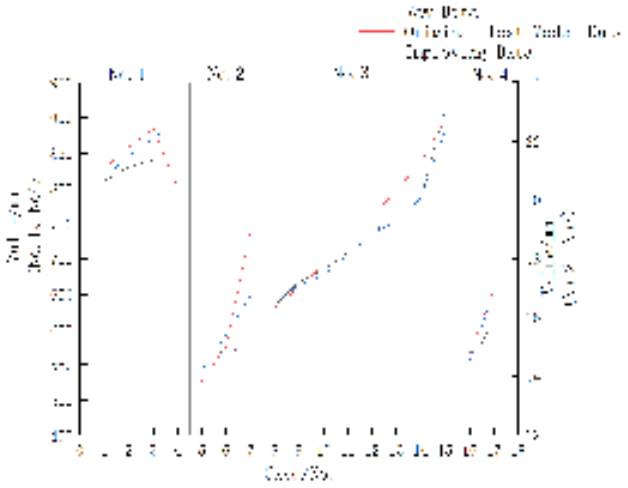

Fig. 5.1: Comparison of Numerical Fitting in Different Cases.

5. Discussion. In comparing the above tests to the original optimization model, the MAPE and RMSE indicators, as well as the level of fitting curves, have all significantly improved. This paper's rules were used to classify the results. Researchers in the fields of landslide displacement prediction and ground subsidence prediction can use this method to divide the state intervals of Markov chains. See Figure 5.1 for a visual representation. Figure 5.1 displays four distinct case models, each separated by a vertical black line and labeled with its corresponding case number. The black curve represents the original data, the red curve represents the curve of the original model data fitting, and the blue curve represents optimization. The final curve should be as close as possible to the black curve for better prediction accuracy. In the figure, the blue curve closely resembles the black curve, indicating a good fitting effect. This suggests that the state interval division method used in this paper is both superior and more scientific.The values of Case 2 and Case 3 correspond to the right coordinate value, while the values of Case 1 and Case 4 correspond to the left coordinate axis value.

6. Conclusions and Results. This paper addresses the scientific division of Markov chain state intervals using the hypothesis testing method. In the geological prediction problem, the MAPE and RMSE indicators are used as references, and this study has significantly optimized the data for these two indicators.

The RMSE for the Markov-MFF model has decreased by 4.268mm, and the MAPE has reduced by 0.9%. RMSE for the Grey-Markov model has decreased by 1.778 mm, and the MAPE has reduced by 4.877%. RMSE for the GNN model has decreased by -0.14 mm, and the MAPE has reduced by -0. 31%. RMSE for the GMM has decreased by 8.3176 mm, and the MAPE has reduced by 1.43%.

No previous scholarly research has been conducted on the reasonable division of state intervals. This article establishes the foundation for such research and provides the possibility for improved data optimization. However, the processing of complex relative error scatter distributions for large sample data is time-consuming, which presents a significant challenge. The future of this study will likely involve a discussion on the appropriate

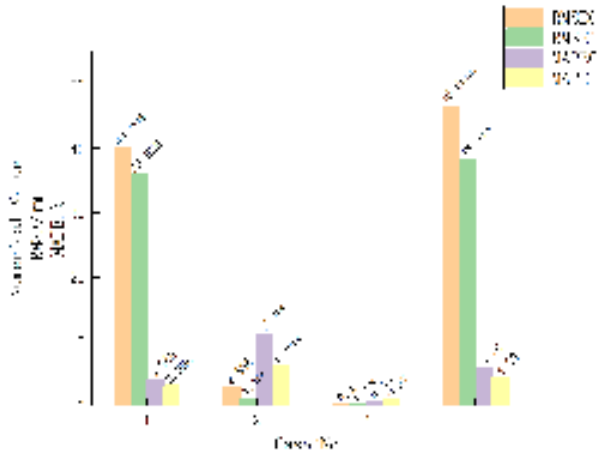

Fig. 6.1: Comparison of RMSE and MAPE optimization index results.

mathematical model for solving the problem of scatter distribution classification. The rules presented in this paper for the division of Markov chain state intervals are adequate. Figure 6.1 displays the results of the case comparison. Figure 6.1 compares the RMSE and MAPE indicators of four different models before and after improvement. Smaller values are better for both indicators. In Case1, RMSE0 represents the original model's RMSE index, while RMSE1 represents the improved index based on the rules proposed in this paper. Similarly, MAPE0 represents the original model's MAPE index, while MAPE1 represents the index after applying the improved rules proposed in this paper. The remaining values are analogous. Figure 6.1 shows that the method proposed in this article has significant optimization effects.

INTELLIGENT POSITIONING ALGORITHM FOR URBAN SUBSTATION PERSONNEL BASED ON WIRELESS SENSOR NETWORKS

LISHUO ZHANG[*], ZHUXIN MA[†], ZHE KANG [‡], XIAOGUANG LI [§] AND YONGZHAO LIU[¶]

Abstract. In order to solve the problem of accurate and low-cost location of substation personnel in digital cities, a substation personnel location system based on wireless sensor cloud computing network is proposed. ZigBee wireless sensor cloud computing network is introduced into the substation to improve the direct location algorithm of substation personnel, and a fuzzy reasoning algorithm is proposed. The algorithm takes the signal strength received by each reference node and the relative distance between the reference nodes as input. After fuzzy, fuzzy reasoning and deblurring, the reliability of the received signal strength of each reference node is obtained, and then three reference nodes with high reliability are selected for trilateral positioning calculation. The experimental results show that the positioning error after improvement is more stable than that before improvement, and the maximum error before improvement is 1.4115m. Practice has proved that the algorithm can significantly improve the positioning accuracy of substation personnel without adding any hardware and using fewer nodes.

Key words: wireless sensor network, Substation, Fuzzy inference, Signal strength, positioning accuracy

1. Introduction. As the "intelligent information sensing terminal", the Internet of things, with its unique advantages, can meet the needs of real-time, accuracy and comprehensiveness of smart grid information acquisition in many occasions, and play a great advantage in the generation, transmission, transformation, distribution, use and dispatching of smart grid [1].Wireless sensor network (WSN) technology is one of the core technologies of the Internet of things, as shown in Figure 1.1.

Wireless sensor network is a network composed of a large number of wireless sensor nodes, which is used to monitor, collect and transmit information in the physical environment, such as temperature, humidity, light, sound, pressure, and so on. These nodes can collaborate autonomously to achieve task allocation and data sharing, in order to execute tasks more effectively. As a new technology, wireless sensor network integrates sensor technology, self-organizing network technology, data fusion technology, target positioning technology, etc., effectively realizing the highly intelligent data collection, transmission and processing.

As a new technology means, wireless sensor network integrates sensor technology, self-organizing network technology, data fusion technology, target positioning technology, etc., and effectively realizes the high intelligence of data collection, transmission and processing. Wireless sensor network (WSN) is a multi hop, self-organized network system formed by wireless communication and composed of a large number of inexpensive micro sensor nodes deployed in the monitoring area. It can be widely used in environmental monitoring, border protection, space detection, target tracking and other fields [2]. With the occurrence of various disasters and accidents and the further improvement of people's requirements for safety protection, there is an urgent need for more timely and accurate field data to strengthen management. Similarly, in some production management links, in order to further improve production efficiency and strengthen safety supervision, it is also necessary to timely feed back various personnel information on the site, understand the basic situation of the site, and conduct accurate guidance and control [3].The substation is a high-risk operation environment, and illegal operations such as entering the interval by mistake and patrol inspection are not in place occur from time to time. The substation personnel positioning and tracking system can locate the current position of the operators in real time, track their movement track in the station, automatically sense the behaviors such as

entering the work area by mistake, automatically record the patrol track of the inspectors, effectively monitor the illegal operation behaviors such as insufficient patrol, missing patrol or even non patrol, and remind the operators by mistake in the form of sound and light alarm. At the same time of the on-site alarm, the relevant information is transmitted to the monitoring center. The background management department can take corresponding measures to prevent accidents.

The substation personnel positioning system based on wireless sensor network is a real-time positioning and monitoring system for substation personnel using wireless sensor network technology. The basic principle of this system is to arrange multiple wireless sensor nodes inside the substation, which transmit data to the central node through wireless communication protocols. The central node processes and analyzes the transmitted data to determine the location information of personnel inside the substation.

2. Literature review. With the expansion of power grid scale and the increase of equipment, the complexity of substation operation increases. In order to standardize and simplify the work of substation staff and improve their enthusiasm, a personnel positioning system is required to be applied to the substation [4]. Introducing automation technology, strengthening training and skill enhancement, establishing standardized workflow, and strengthening team collaboration and communication can help standardize and simplify the work of substation staff, increase their enthusiasm, and improve the efficiency and reliability of substation operation.

At present, ultra wideband (UWB) positioning method is used for personnel positioning in digital substation, which has the advantages of low power consumption, good anti multipath effect and high positioning accuracy [5]. However, due to its high cost, it is not suitable for promotion and use, so it is urgent to find a new positioning method. Among them, the personnel positioning technology based on ZigBee wireless sensor network has attracted wide attention in the world because of its low complexity, low power consumption and low cost [6]. In the wireless positioning technology based on ZigBee, the received signal strength indication (RSSI) positioning principle is applied to the wireless communication network. However, the RSSI direct ranging algorithm adopted at present is easily affected by the environment, with large error, unstable error and low positioning accuracy. Zahedmanesh, A. et al. Proposed several positioning methods for obstacles, but there is still little research on the precise positioning method of ZigBee positioning system based on RSSI in the space with large obstacles such as substation. It can provide real-time and accurate personnel positioning information for the above occasions, provide guarantee for various safety, and further improve production efficiency [7].In order to realize real-time and accurate personnel positioning, the whole positioning system can adjust the placement position of anchor nodes at any time according to the needs; The background map can be changed in time with the change of the site; Edit and manage the personnel information to be located; Personnel can be associated with mobile nodes; The current positions of all mobile nodes and the names of associated personnel can be marked in real time through the map displayed on the screen. And the positioning system can also provide a systematic environment for the positioning algorithm, routing mechanism, network survival time, personnel positioning accuracy, distribution of anchor nodes, wireless network security and related research and application of wireless sensor networks [8]. The implementation of the positioning system has strong expansibility with the hardware

and database used. In this, a positioning method of ZigBee system based on fuzzy inference is proposed with reference to the location parameters of obstacle free space [9]. In this method, the reference node with the largest RSSI value is taken as the control. Firstly, the RSSI value of the reference node adjacent to the reference node and the relative distance between the reference node and the adjacent reference node are taken as the input. Then, after fuzzification, fuzzy reasoning and defuzzification, the RSSI credibility of each adjacent reference node is obtained. Finally, the reference nodes corresponding to the two RSSI values with the highest reliability were selected, and the trilateral positioning calculation was carried out together with the reference node with the largest RSSI to obtain the location information of the station staff. The positioning method of ZigBee system based on fuzzy inference effectively avoids the ranging error of directly taking three maximum RSSI, and can accurately locate the mobile personnel in the substation with large obstacles. Moreover, it does not need to do a lot of experiments like deterministic positioning, and only needs to obtain appropriate positioning parameters in the space without obstacles through a few experiments. However, it is more accurate than the traditional empirical positioning method [10].

3. Methods.

3.1. ZigBee positioning system structure. Zigbee is based on IEEE standard 802.15.4 wireless standard research and development. ZigBee positioning system is a visual wireless positioning monitoring system composed of positioning monitoring center and wireless sensor network. The wireless positioning network system is mainly composed of ZigBee gateway, reference node and positioning node [11]. In order to ensure the accuracy and reliability of the positioning system, it is necessary to design and optimize the layout of sensor nodes and signal acquisition. At the same time, it is also necessary to consider factors such as the security and real-time performance of data transmission. This system can provide important support for safety management and emergency rescue work in substations, effectively improving the operational efficiency and safety of substations.

Since each positioning node in the network (i.e. the staff in the station) has its own network address, the ZigBee positioning system can achieve multi-person positioning without interference at the same time.

ZigBee Gateway: Network coordinator of wireless positioning system, consisting of a HFZ-CC2430EM module and HFZ-SmartrF07EB, connected to PC through RS232 serial extension cable. It plays a vital role in the whole system. First, it needs to receive the configuration data of each reference node and positioning node provided by the monitoring software and send it to the corresponding node. Secondly, the effective data (such as coordinates Bx and By of positioning nodes) fed back By each node should be received and transmitted to the monitoring software [12].

Reference node (Rn): a static node with known coordinates in the wireless positioning system, which is a router in ZigBee network and consists of a panel and a CC2430 module. This node must be correctly configured in the location region. Its task is to provide a packet containing its coordinate position Rx, Ry and RSSI values to the locating node. Such nodes are fixed on the support of the substation.

Positioning node (B): mobile node in the wireless positioning system, which is composed of a panel and a CC2431 module [13]. It calculates its coordinates by processing information packets sent by reference nodes, and is a router in ZigBee network. The positioning node can communicate with the reference node, collect the coordinate Rx, Ry and RSSI values of the reference node, calculate its own coordinate information based on these information and input parameters A and N, and then send its own position information Bx and By to the gateway, and finally to the positioning monitoring center through RS232[14]. This node is installed on the safety hat of the mobile personnel in the substation. Therefore, when substation workers wearing such helmets enter the substation, the monitoring center can monitor their real-time location in the station.

3.2. Fuzzy inference algorithm for ZigBee system positioning. The positioning principle of ZigBee positioning system is to select the first three largest RSSI from the information packet sent to the positioning node by the reference node, and then calculate the distance from the corresponding reference node to the positioning node, and then calculate the position coordinates of the positioning node by the three-sided positioning method. Specifically, the ZigBee positioning system first needs to deploy some wireless sensor nodes indoors, which can communicate with each other through the ZigBee wireless network and broadcast signals regularly.

When it is necessary to locate an object or person, the ZigBee device on the object or person can be used as the positioning target to send a request signal to the surrounding ZigBee nodes. Once the surrounding ZigBee nodes receive a request signal, they will reply with a response signal and send back the RSSI value of the response signal. Due to the influence of indoor environment on the propagation of wireless signals, the signal strength received by different nodes may vary. By using these different RSSI values, the distance difference between the positioning target and different nodes can be calculated, thus achieving triangular positioning. However, in the substation, due to the existence of obstacles, the obtained RSSI values of reference nodes are not all credible, so positioning errors may occur [15]. In order to overcome the defect of direct ranging algorithm, a ZigBee positioning method based on fuzzy inference algorithm is proposed in this . The working mechanism of the fuzzy inference system is as follows: Firstly, the input exact quantity is fuzzified by the fuzzification module and converted into the fuzzy set in the given domain. Then the corresponding fuzzy rules in the rule base are activated, the appropriate fuzzy inference method is selected, and the inference result is obtained according to the known fuzzy facts. Finally, the fuzzy result is defuzzified to get the final accurate output.

Fuzzy algorithm used in ZigBee system positioning can be divided into the following steps:

1. The reference node waits for the positioning node to send signals.
2. The positioning node sends signals to the reference node.
3. The reference node obtains RSSI and sends it to the positioning node together with its own position information [16].
4. The positioning node receives the information packet sent by the reference node, and then executes the fuzzy operation. Finally, according to the output of the fuzzy operation, the positioning calculation is carried out by the three-sided method.
5. The positioning node sends its position information to the gateway, and then the gateway sends it to the monitoring software of the monitoring center to monitor the position of the staff in the station in real time [17].

Fuzzy inference algorithms can be used for the localization of ZigBee systems, which can improve the accuracy and robustness of localization. Specifically, in ZigBee system positioning, the triangulation method is usually used, which calculates the position of nodes by measuring the time of arrival (TOA) of the signal.

3.2.1. Fuzzy system input. Due to the complex working environment of the substation, in order to ensure the reliability of RSSI value of each reference node, in this , 8 RSSI values of each reference node are averaged as its RSSI value. For all the RSSI values after taking the mean value, the one with the largest RSSI value is extracted as the reference of credibility, and the corresponding reference node is called the trust node. The RSSI value of the neighboring reference nodes around the fetching node and the relative distance from each neighboring node to the signal node are used as input. The two inputs are fuzzified by setting membership functions.

As shown in Figure 3.1, the fuzzy distribution of low RSSI is trapezoidal. When the RSSI value of the neighboring reference node is the smallest among all the neighboring reference nodes ($RSSI_{min}$), the membership degree is the largest. With the increase of RSSI, the membership degree linearly decreases until it becomes 0 when the RSSI is the median RSSI ($RSSI_{med}$). In, the fuzzy distribution of RSSI is triangular; The fuzzy distribution of high RSSI is trapezoidal, and the membership degree reaches the maximum when the RSSI reaches the RSSI($RSSI_{max}$) of the signal node[18]. For example, when $RSSI_{min}$ is -65dbm, $RSSI_{med}$ is -63dbm and $RSSI_{max}$ is -57dbm, and if the input RSSI is -62dbm, the membership calculated by the membership function is 0.167, 0.833 and 0 respectively in the fuzzy distribution of high, medium and low RSSI.

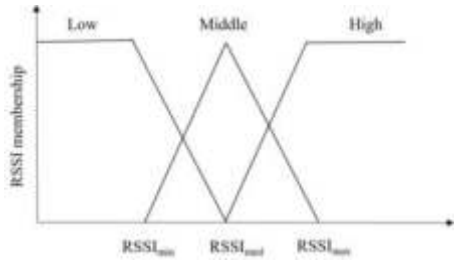

Fig. 3.1: RSSI distribution

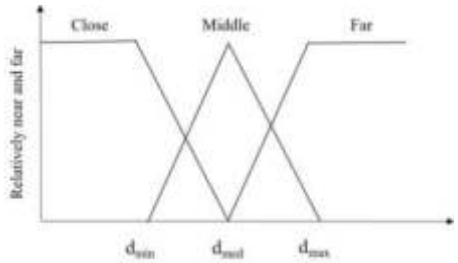

Fig. 3.2: Relative distance distribution

As shown in Figure 3.2, the fuzzy distribution of near-relative distance is trapezoidal. When the reference node is the shortest distance from the signal node (d_{min}), the membership degree is the maximum. With the increase of relative distance, the membership degree linearly decreases until it becomes 0 when the relative distance is the median (d_{med}). The fuzzy distribution of relative distance is triangle. The distant relative distance fuzzy distribution is trapezoidal, and the membership degree is maximum when the reference node is farthest from the signal node (d_{max}). For example, when Dmin is 2m, DMED is 4M and DMAX is 5m, if the input D is 3m, the membership degree calculated by the membership function is 0, 0.5 and 0.5 respectively in the fuzzy distribution of far, middle and near distance.

By setting the two input membership functions in this way, the membership functions can be modified online according to the actual situation of the RSSI of the reference node and the relative distance between the information node and its neighboring nodes to adapt to positioning in different environments.

3.2.2. Fuzzy inference. The fuzzy inference system in this adopts Mamdani inference method to carry out fuzzy inference [19].The signal node is set as high RSSI, and the membership degree is 1. According to the signal propagation theory: the farther away from the transmitting point, the weaker the signal strength received by the receiving point. Since the RSSI of the signal node is the largest, it is the closest to the transmitting point. The formulation of fuzzy rules is shown in Table 3.1.

The examples in Section 3.2.1 are used to blur the data. The fuzzy input activates rules ①,②,④ and ⑤ in the fuzzy rule base. Inactive rule confidence output is 0. The fuzzy inference process is shown in Figure 3.3. Take AND operation on the two inputs according to each rule, and then perform OR operation on the output result of each rule to obtain the credibility of each rule.

3.2.3. Fuzzy system output. The output of a fuzzy system is a specific numerical value or set of numerical values obtained through fuzzy reasoning and fuzzy processing, which represents the degree of influence of input variables on output variables. In fuzzy systems, the output is usually expressed in the form of fuzzy set, that is, the value of the output variable is divided into multiple fuzzy set with non-zero membership, and each fuzzy set represents a possible value of the output variable. In order to get a certain output value, these fuzzy set need to be de blurred and transformed into a specific value or a group of values. After the central method is used to defuzzification, the fuzzy system will output a value for each neighboring reference node,

Table 3.1: Fuzzy inference rules

Neighboring node RSSI		Relative distance	Confidence of output
High	①	Close	High
	②	Middle	Middle
	③	Far	Low
Middle	④	Close	Middle
	⑤	Middle	High
	⑥	Far	Middle
Low	⑦	Close	Low
	⑧	Middle	Middle
	⑨	Far	High

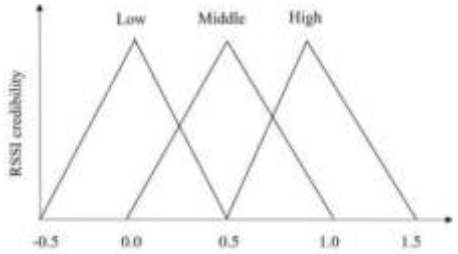

Fig. 3.3: RSSI reliability distribution

which represents the RSSI credibility of the reference node. The value ranges from 0,1. The closer it is to 1, the more trusted the RSSI is, that is, the more suitable the corresponding reference node is for positioning calculation. As shown in Figure 3.3, the low, medium and high trust degrees are all triangular distribution, with the midpoints 0, 0.5 and 1, respectively.

The central method defuzzification is shown in Equation 3.1.

$$y^* = \frac{\sum_{i=1}^{N}(y_i \mu_{max}^i(y))}{\sum_{i=1}^{N} \mu_{max}^i(y)} \tag{3.1}$$

where: N is the number of elements in the domain, namely the number of rules in the rule base; y_i refers to the fuzzy value of the ith central point in the theoretical domain, that is, the output central point obtained by operation according to the ith rule; $\mu_{max}^i(y)$ is the maximum membership degree obtained by the ith rule operation.

According to Equation 3.1, the examples in Section 3.2.2 are defuzzified

$$y^* = \frac{0.75 \times 0.167 + 0.5 \times 0.167 + 0.5 \times 0.5 + 0.75 \times 0.5}{0.167 + 0.167 + 0.5 + 0.5} = 0.625 \tag{3.2}$$

That is, when the RSSI of the neighboring reference node is -62dbm and it is 3m away from the information node, the output reliability is 0.625 after defuzzification.

3.2.4. Positioning Calculation. According to the three-side localization method, at least three reference nodes are needed for localization calculation. Therefore, firstly, according to the RSSI reliability of all neighboring nodes output by the fuzzy system, the reference nodes corresponding to the two RSSI values with the highest reliability are selected, and together with the information nodes, the three reference nodes required for positioning are composed. Then, the distance d between the three reference nodes and the positioning node can be calculated according to Equation 3.3. Finally, according to the position information of the three reference nodes, the coordinates of the positioning nodes are obtained by the three-sided positioning method, namely

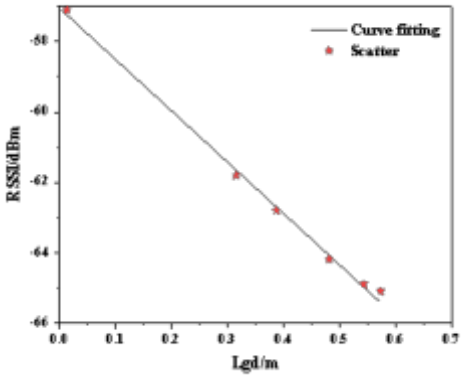

Fig. 3.4: Fitting curve of barrier-free space

Equation 3.4 [20].

$$d = 10^{\frac{A+RSSI}{-10N}} \tag{3.3}$$

where: A and N are positioning parameters, which are related to the actual environment such as weather. According to the barrier-free space experiment, different A and N are measured under different weather conditions. In actual positioning, parameters A and N are input according to the weather conditions. d is the distance from the reference node to the positioning node (unit: m); RSSI unit in dBm.

$$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 2(x_1 - x_3) & 2(y_1 - y_3) \\ 2(x_2 - x_3) & 2(y_2 - y_3) \end{bmatrix}^{-1} \cdot \begin{bmatrix} x_1^2 - x_3^2 + y_1^2 - y_3^2 + d_3^2 - d_1^2 \\ x_2^2 - x_3^2 + y_2^2 - y_3^2 + d_3^2 - d_2^2 \end{bmatrix} \tag{3.4}$$

where: x is the abscissa of the positioning node; y is the ordinate of the positioning node. $x_1, x_2, x_3, y_1, y_2, y_3$ are the position coordinates of the selected three reference nodes; d_1, d_2 and d_3 are the distances from the positioning nodes calculated by the RSSI of the selected three reference nodes.

3.3. The simulation positioning. According to Equation 3.3, if the distance between the reference node and the positioning node is to be determined, the values of the positioning parameters A and N must be known. Therefore, this first carries out simulation operation on the barrier-free space. Firstly, a positioning node is fixed, and then six reference nodes with different distances from the positioning node are randomly selected to obtain its RSSI by simulation, and the distance d from each reference node to the positioning node is calculated, so a set of data (RSSI, lgd) can be obtained for each reference node. 6 groups of data (RSSI, lgd) were fitted according to Equation (5), and A=57, N=1.47 were obtained. This is shown in Figure 3.4.

$$RSSI = -(A + 10 \times N \times lg(d)) \tag{3.5}$$

Then, the area where the six towers are located in the substation is taken. Set the distance between the poles and towers of the substation as 2m. According to the fuzzy inference algorithm proposed in this , the personnel location in the substation is also simulated. Among them, the position of the staff can be arbitrarily changed. In this , four typical positions are selected for analysis.

To further ensure the accuracy of fuzzy operation, $RSSI_{med}$ is obtained by theoretical calculation. When the location of substation staff (positioning node) is in the middle of the whole positioning area, the distance d between the positioning node and reference node 1 is calculated, and then the $RSSI_{med}$ is calculated by Equation 3.3 according to the fitted function. The minimum RSSI value of all reference nodes is $RSSI_{min}$. There are 3 relative distances between the information node and its neighboring nodes, which are 2m, 4m and 4.472m respectively. The three distance values were set asd_{min},d_{med} and d_{max}.

Table 4.1: Positioning results

Locating Node Number	a	b	c	d	
	x/m	0	-0.5	0	0.5
Actual location	y/m	1.8	1.5	1	1
	x/m	-0.0053	-0.1255	0.076	0.4881
Fuzzy algorithm	y/m	1.7617	1.5199	1.007	1.0024
	x/m	0.0389	0.3755	0.076	0.0112
Direct ranging	y/m	0.8314	0.0838	1.4115	0.8069
algorithm	y/m	1.7616	1.5199	1.007	1.0025
	e/m	0.8323	0.5846	1.4113	0.3064

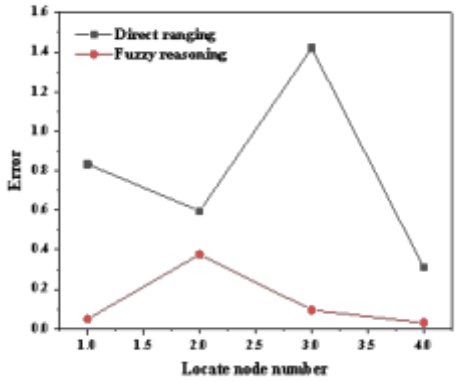

Fig. 4.1: Positioning error

4. Results and Discussion. In the simulation process of this paper, firstly, according to the fuzzy reasoning algorithm, the output credibility of all adjacent reference nodes is obtained. Then, two neighbor nodes with high reliability are extracted from each location node. Finally, the specific location of the staff in the substation is calculated by the trilateral method by combining the two adjacent reference nodes with high reliability with the signal nodes, as shown in Table 4.1. For comparison, for the direct ranging algorithm that directly selects the three largest RSSI values and their corresponding reference nodes for positioning, the trilateral method is also used to do the positioning calculation. The simulation results are shown in Table 4.1.

The positioning error is in formula 3.6

$$e = \sqrt{(x - x_0)^2 + (y - y_0)^2} \tag{4.1}$$

where: x,y is the staff coordinate obtained by simulation calculation; x_0,y_0 is the actual coordinate of the staff.

As can be seen from Table 4.1, the positioning accuracy after the algorithm improvement is significantly higher than that before the algorithm improvement. Fuzzy algorithm is an effective mathematical tool that can handle uncertainty and fuzziness problems in reality, and has advantages such as flexibility, adaptability, and interpretability. In addition, the improved positioning error is more stable than that before the algorithm is improved, and is stable within a small error range. As shown in Figure 4.1, the maximum is 0.3755m, and the maximum error before improvement is 1.4115m. It can be seen that compared with the positioning algorithm before the improvement, the improved positioning algorithm can locate substation personnel more accurately.

5. Conclusion. In this, the substation personnel location system based on wireless sensor network is proposed, and the substation personnel location method based on ZigBee wireless sensor network is adopted. Aiming at the shortcomings of low accuracy and unstable error of the direct ranging algorithm used in ZigBee, a

fuzzy inference algorithm is proposed. Through simulation, it can be known that the fuzzy inference algorithm has the following advantages for substation personnel location: (1) low cost. Using fewer nodes to locate the station staff; (2) High accuracy. Compared with the direct ranging algorithm, the positioning accuracy of the fuzzy inference algorithm is greatly improved; (3) Good positioning stability. Through the fuzzy inference algorithm, the error can be controlled within a small range. (4) It has wide applicability and can accurately locate mobile personnel in substations with large obstacles, which is expected to be popularized and used in various substations and even other positioning fields. (5) Handling ambiguity: There are various interference factors in the positioning of substation personnel, such as multipath effects of signals, changes in signal strength, and target movement. These factors can lead to errors and uncertainties in the positioning results, and fuzzy inference algorithms can handle these uncertainties, making the positioning results more accurate and reliable.

UPPER LIMB REHABILITATION ROBOTS TRAINING ANALYSIS BASED ON MULTI-SENSOR TRAJECTORY DATA AND HUMAN-COMPUTER INTERACTION

YANYU LIU* AND XIANQIAN LAO†

Abstract. Upper limb rehabilitation robots have important practical significance in helping patients recover their motor function, but traditional training methods often lack real-time and accurate evaluation of patient movement status and intention and have low interactive participation. Therefore, the study proposes a training system for upper limb rehabilitation robots based on multi-sensor trajectory data and human-computer interaction. The system is designed from three aspects: inertial sensor trajectory tracking, Kinect sensor image restoration, and interaction system design. A polynomial joint zero value constraint algorithm is introduced to correct errors, and variable parameter pixel filtering combined with a weighted average moving algorithm is used to improve image quality. The training results showed that the robot trajectory tracking accuracy significantly improved, and the improvement in motion trajectory error was greater than 20%. Compared with traditional training methods, interactive training had a recognition accuracy of over 85% in rehabilitation actions, and the system had better stability. This rehabilitation robot can effectively meet the feasibility and effectiveness of improving the interaction system, providing new technological means for intelligent medical services.

Key words: Inertial sensor; Trajectory data; Human computer interaction; Rehabilitation robots; Sports intention

1. Introduction. With the acceleration of social aging and the frequent occurrence of work-related accidents, the rehabilitation of upper limb motor dysfunction has received widespread attention from society. Among them, upper limb rehabilitation robots, as a new type of rehabilitation treatment method, aim to help patients recover their upper limb motor function through mechanical-assisted training. Moreover, early rehabilitation robots are mostly end traction type with a simple structure, resulting in lower control requirements and equipment costs. However, their guidance of joint strength is not precise enough, and their degree of freedom of movement and traction treatment safety are also low [1-2]. With the continuous development of control theory and artificial intelligence technology, rehabilitation therapy robots are also constantly improving in joint support, motion degrees of freedom, and other aspects based on the laws of human spontaneous movement. The acceleration of social aging and frequent accidents have led to an increasing demand for rehabilitation treatment. However, traditional rehabilitation methods have limited resources and are difficult to meet rehabilitation needs. Early rehabilitation robots have shortcomings in joint strength guidance, freedom of movement, and safety. Although traditional rehabilitation robot technology has made progress to some extent, they can accurately evaluate patient status in real-time There are still many challenges in adapting to personalized rehabilitation needs and improving patient engagement. Most existing rehabilitation robots often use a single sensor system, which limits their ability to capture complex upper limb activity dynamics, resulting in insufficient motion guidance and feedback. Therefore, to further promote the development of rehabilitation robot training technology, meet the growing rehabilitation needs, and promote the development of rehabilitation medical science, a training system based on sensor data and human-computer interaction is proposed. By capturing the patient's movement status and intention and applying interaction methods, the rehabilitation effect is improved.

Xiao W et al. developed a bilateral upper limb collaborative rehabilitation robot system based on mirror therapy and virtual stimulation. The affected limb can track healthy limbs for radial movement with the assistance of a robotic arm, and rehabilitation training based on neural networks and controllers can provide good visual stimulation. The results indicated that the system effectively completed rehabilitation training and improved patients' awareness of active rehabilitation [3]. Y Wang et al. achieved clinical rehabilitation

equipment design by segmenting and classifying the surface electromyographic signals of patients and processing them through signal encoding processing, transformation, and waveform classification comparison. The results showed that the signal classification had high accuracy [4]. Q Sun et al. believe that human-computer interaction can be achieved through rehabilitation training trajectories and simulation design can be carried out through the establishment of motion constraint equations and the acquisition of collaborative space. The results indicated that the designed indicators provided a good reference for the selection of training trajectories for rehabilitation robots [5]. Yousuf F H et al. designed an upper limb amputee rehabilitation system using SEMG sensors and stimulated hand movement using a robot simulator toolkit. The results indicated that the design approach had good effectiveness, but the sample size selected for testing was relatively small [6]. Chen X et al. developed a new type of soft and wearable upper limb rehabilitation robot, which can perform rehabilitation training for wrist and elbow joints. The results of wrist rehabilitation training indicated that this design approach effectively improved the flexibility, comfort, and safety of training [7]. Wu Q et al. proposed an adaptive neural collaborative control strategy to achieve intention-based human-machine collaborative rehabilitation training, and obtained muscle force data using surface electromyography signals and Kalman filtering. The results showed that this control strategy had good cooperation [8].

Whether it is using neural networks to design rehabilitation training systems, analyzing electromyographic signals, or introducing human-computer interaction to train robot trajectories, the essence lies in extracting information data related to patient movement. Therefore, the study utilizes multi-sensor trajectory data to achieve real-time and accurate acquisition of patient movement status and intention, and introduces the advantages of human-computer interaction into the design of training systems, to provide a more natural and comfortable user experience and improve the rehabilitation training effect of patients. Multi-sensor trajectory data can obtain real-time and accurate patient movement status and intention, while human-computer interaction technology can provide patients with a more natural and comfortable user experience during the use of robots, improving the rehabilitation training effect of patients. The research mainly demonstrates four aspects. The first part is a literature review of the current application technology of rehabilitation robots. The second part is the method design of inertial sensors, Kinect sensors, and human-computer interaction. The third part is the result verification of the training method proposed in the study. The last part is a summary of the entire article.

2. Related works. To meet the rehabilitation needs of stroke patients due to different disabilities, scholar X Li proposed an upper limb rehabilitation robot that can be used under hybrid control driven by flexible cables and designed different working modes to provide assistance to the subjects. The experimental results showed that this method adaptively adjusted the damping force and stiffness coefficient, adjusted the working mode according to the motion performance of the subjects, and had good application performance [9]. Q Meng et al. designed a lightweight upper limb rehabilitation robot with a spatial training function using a 4-degree-of-freedom end effector. The experimental results showed that the component had high flexibility (over 60%) and a large workspace, and passed joint training and drinking water trajectory planning experiments [10]. In response to the low participation problem of on-demand auxiliary controllers in robot-assisted rehabilitation, J Zhang et al. designed an adaptive controller by adjusting the trial-and-error participation estimation and energy information evaluation. The results indicated that this method effectively reduced the energy consumption of subjects (more than 30%), helping them improve the effectiveness of upper limb rehabilitation [11]. In response to the problem of parameter uncertainty in the dynamic modeling of upper limb rehabilitation robots, JL Wang et al. used a variable parameter particle swarm optimization algorithm for identification improvement. Simulation results showed that the algorithm improved identification accuracy and control effectiveness [12]. To solve the control problem of upper limb rehabilitation robots, N Mirrashid et al. proposed a fuzzy controller based on an ant colony optimization algorithm to achieve controller gain adjustment. The results indicated that the tracking error of the improved algorithm was much smaller than the original results [13]. To improve the effectiveness of rehabilitation treatment, scholar Q Wu proposed a control strategy combining adaptive neural collaboration and Gaussian radial basis function network to obtain human motion intention and muscle force data. The experimental results showed that this strategy had the potential to regulate interaction compliance and collaboration, demonstrating good accuracy and stability [14].

Traditional upper limb rehabilitation robots are unable to control patients based on their movement inten-

tions, resulting in low patient engagement. Therefore, scholar Q Meng proposed an upper limb rehabilitation robot based on electromyographic signal motion compensation control. The experiment verified that the control method demonstrated good performance in electromyographic compensation and trajectory execution [15]. C Rossa scholars proposed a robot-assisted model based on the eight degrees of freedom kinematics of the upper limbs to address the current situation of disability abilities. The results showed that the auxiliary robot effectively achieved spatial motion range matching, and the framework system was suitable for patient rehabilitation treatment [16]. J Zhou et al. proposed to improve the trajectory tracking performance of lower limb rehabilitation robots using a trajectory deformation algorithm and low-order proportional differentiation. The results showed that the robots designed by this method had good application potential in the field of assisted rehabilitation [17]. Scholar Li proposed a rehabilitation robot action recognition method based on multi-channel surface electromyography signals, which extracted motion features through bilateral mirror training and electromyography signal constraint processing. The results indicated that this method had faster convergence speed and better extraction accuracy [18]. S Cai scholars analyzed the feasibility of compensation for stroke patients based on pressure distribution data and support vector machine algorithm, and the results showed that this method had good classification performance in compensation analysis [19]. T Proietti proposed a multi-joint soft wearable robot based on textiles to assist upper limb rehabilitation training. The results showed that the robot achieved dynamic gravity compensation and joint trajectory tracking and demonstrated good performance and application potential in rehabilitation training [20].

Sensors can be combined with human motion to obtain motion information and estimate and track the wearer's posture and motion trajectory. Obtaining motion data information through sensors has become an important aspect of scientific research. Among them, Assad Uz Zaman M utilized Kinect V2 sensors to achieve motion tracking of robots, and based on sensor data, developed a solution that solved the inverse kinematics of upper limbs, which provided application ideas for remote rehabilitation treatment [21]. Azlan N Z et al. utilized an on-demand auxiliary control strategy to adjust sensor information in robot-assisted rehabilitation therapy. The results showed that the proposed control strategy effectively drove the upper limb rehabilitation robot to achieve zero steady-state error [22]. Tongtong Z et al. proposed a novel 7-degree-of-freedom upper limb exoskeleton robot, which replaced the grip of traditional exoskeletons with a new hand fixation device. The rationality of robot drive selection was verified through the model of this scheme [23]. Regarding the issue of poor compatibility of upper limb rehabilitation robots, Yan H et al. established an equivalent mechanical model of the human upper limb based on its anatomical structure. The configuration synthesis of upper limb rehabilitation institutions was carried out. The results indicated that the 5Ra1P configuration of the shoulder joint had better kinematic performance [24].

In summary, for rehabilitation robots, most scholars mainly focus on optimizing and improving their adaptability and patient engagement, including adaptive controller design, hybrid control, and other aspects. Methods such as motion compensation, degree of freedom kinematic models, and support vector machines have also been applied in research on motion intention control. Upper limb rehabilitation robots and their treatment methods are gradually developing towards human-machine interaction training. More and more scholars and teachers are researching various human-machine interaction methods such as patient motion intention detection and estimation, motion information capture, virtual reality, etc. This not only increases the fun of rehabilitation treatment but also improves rehabilitation motion intention. Whether it is the introduction of adaptive controller design, hybrid control, motion compensation, degrees of freedom kinematic models, etc., how to efficiently and accurately obtain patient motion intentions, limb end motion trajectories, and other information is gradually becoming a research focus. Previous studies have combined sensors with human motion, often based on motion data or trajectory tracking results for capture and analysis. However, they have overlooked the susceptibility of sensors to external acceleration, magnetic interference, and cumulative errors during use, making it difficult for a single sensor to achieve good motion trajectory data acquisition. Based on the advantages of sensors, this study proposes an improved rehabilitation training system based on multi-sensor and human-computer interaction, aiming to meet the upper limb movement needs of patients and provide technical means for rehabilitation medicine.

3. Design of robot training method based on multi-sensor trajectory data and human-computer interaction. Accelerating the exploration of human-machine rehabilitation interactive training methods can

Fig. 3.1: Performance parameters of the selected inertial sensor

improve patient motivation and participation. Therefore, in the design of rehabilitation robot training, it is necessary to accurately capture the patient's movement intention and trajectory information. Therefore, research is conducted on designing trajectory-tracking algorithms based on inertial sensors and Kinect sensors, and improvements are made in data fusion processing, tracking error correction, motion data acquisition, and other aspects. The joint design of multiple sensors and human-computer interaction can better improve the quality of rehabilitation training for patients.

3.1. Design of trajectory tracking algorithm based on inertial sensors. Considering the need to fix the sensor on the patient during rehabilitation exercise therapy, the study was conducted by selecting a nine-axis wireless inertial sensor, which can be used as a sensor for monitoring tilt, vibration, rotation, and multi-degree-of-freedom motion, and it can ensure a long time of stable operation and light weight. Figure 3.1 shows the performance parameters of the inertial sensor.

The sensor is equipped with its communication protocol, and motion data can be transmitted through Bluetooth through the sensor. The Bluetooth receiver can be connected to the upper computer system through a USB port. Inertial sensors often use their coordinate system to determine reference data in three-dimensional space, and the geographic coordinate system of the motion information of these objects is different. Therefore, coordinate conversion is necessary first. The coordinate transformation can be explained using equation (3.1).

$$\begin{bmatrix} Xb \\ Yb \\ Zb \end{bmatrix} = C \begin{bmatrix} Xe \\ Ye \\ Ze \end{bmatrix} \tag{3.1}$$

In equation (3.1), $[Xe \quad Ye \quad Ze]$ represents the geographic coordinate system, $[Xb \quad Yb \quad Zb]$ represents the sensor coordinate system, and C represents the rotation orthogonal matrix. When inertial sensors perform attitude calculation, they mainly include three parts: data processing, attitude calculation, and updating. However, due to the influence of component performance and usage environment, there is inevitably a noise problem when the sensor collects data. Therefore, research is conducted to calibrate the sensor error and obtain the output model, as shown in equation (3.2).

$$ai(t) = \hat{a}i(t) + gi(t) + ba, i(t) + \varepsilon a, i(t) \tag{3.2}$$

In equation (3.2), t is the moment, i is the axis direction, $ai(t)$ is the output value of the accelerometer, $\hat{a}i(t)$ is the acceleration component, $gi(t)$ is the gravitational acceleration component, $ba, i(t)$ is the zero bias error of the accelerometer device, and $\varepsilon a, i(t)$ is Gaussian white noise. By performing acceleration zero correction

on sensors placed in a horizontal plane, their zero bias error can be corrected. The output model of gyroscope $wi(t)$ and magnetometer h is equation (3.3).

$$\begin{cases} wi(t) = \hat{w}i(t) + ba, i'(t) + \varepsilon a, i'(t) \\ h = AH + B + \varepsilon \end{cases} \tag{3.3}$$

In equation (3.3), $\hat{w}i(t), ba, i'(t), \varepsilon a, i'(t)$ represent the angular velocity, bias error, and Gaussian white noise of the gyroscope motion. A, B are the soft and hard magnetic interferences of the magnetometer, ε is the Gaussian white noise of the magnetometer, and H is the height. To improve the accuracy of attitude calculation and reduce errors, research is conducted on the estimation error correction and compensation of accelerometers, gyroscopes, and magnetometers after the fusion processing of three types of information using a gradient descent method. Equation (3.4) is the error function of accelerometer and magnetometer information.

$$f = \begin{bmatrix} e(gs, as) \\ e(hs, ms) \end{bmatrix} \tag{3.4}$$

In equation (3.4), hs is the magnetic field strength, gs is the quaternion of gravitational acceleration, as is the quaternion of the accelerometer, and ms is the quaternion of the magnetometer. Equation (3.5) is the quaternion attitude update for the fusion information error function.

$$qt + 1 = qt + 0.5qtwt\Delta t - \beta \frac{\nabla f}{\|\nabla f\|}\Delta t \tag{3.5}$$

In equation (3.5), β is the weight of the correction function, wt is the angular velocity matrix, and $qt+1, qt$ is the quaternion of the attitude at the next and current moments. Subsequently, the motion trajectory of the sensor acceleration signal is extracted, and the gravity acceleration component is removed during the extraction process to obtain the true acceleration information. The tracking algorithm is designed based on frequency domain numerical integration. It should also be noted that since trajectory data is obtained through integration processing, cumulative errors such as sensor errors and random errors can also affect the trajectory data results, causing them to deviate from the true trajectory and, in severe cases, leading to trajectory distortion [25]. Therefore, the study proposes cumulative error correction based on polynomials. Considering the insufficient number of motion constraints, a first-order polynomial is used for fitting to obtain the displacement correction, as shown in equation (3.6).

$$xc(t) = xc(t) + \frac{1}{2T}[v(0) - v(T)]t^2 - v(0)t - x(0) \tag{3.6}$$

In equation (3.6), $xc(t)$ represents the corrected displacement, $xc(t)$ represents the uncorrected velocity after integration, $v(0)$ is the initial velocity, $v(T)$ is the final velocity, and $x(0)$ is the initial displacement. As time goes on. Relying solely on polynomial correction for error control makes it difficult to effectively solve the problem of integration error after data collection. Therefore, considering the intermittent characteristics of human upper limbs during movement, this study introduces zero-value constraints into polynomial error correction methods. By setting an acceleration data threshold to manually correct the theoretically zero data during the tracking process, the displacement value in the stationary state can be obtained, as shown in equation (3.7).

$$xcorrrcted = \begin{cases} xc(t-1), vc < v\lim it \cap ac < a\lim it \\ xc(t), vc \geq v\lim it \cup ac \geq a\lim it \end{cases} \tag{3.7}$$

In equation (3.7), $v\lim it$ is the velocity threshold, $a\lim it$ is the displacement threshold, and a is the acceleration.

3.2. Human upper limb motion trajectory tracking based on Kinect sensors. . The upper limb rehabilitation training techniques are mainly improved through hip joint rotation, elbow joint flexion and extension, and other methods. With the continuous development of modern medical technology, rehabilitation

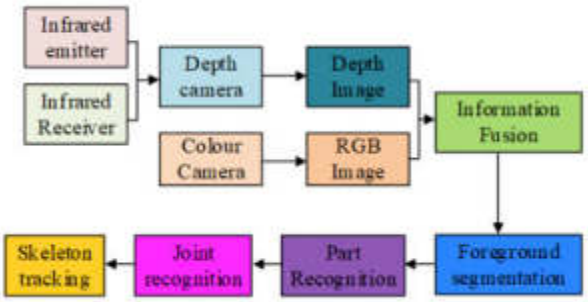

Fig. 3.2: Schematic diagram of Kinect sensor target tracking process

training systems based on intelligent sensors are receiving more and more attention [26]. Kinect sensor is a device based on visual and motion recognition technology launched by Microsoft, which can track the movement trajectory and posture of the human body in real-time, and collect depth data, bone data, and color data of the human body, with higher transmission rates [27]. In human upper limb rehabilitation exercise training, Kinect sensors can utilize their posture recognition function to assist rehabilitation patients in accurate and real-time motion monitoring and guidance and perform coordinate positioning and image processing based on the obtained data. Figure 3.2 shows the target tracking process of the sensor.

In Figure 3.2, the Kinect sensor utilizes depth images to track the skeleton framework. The grayscale values of each pixel in the image are the distance between a point in space and the camera. When the sensor tracks the target, it processes the obtained depth image information, performs foreground segmentation, identifies parts and joints, and constructs a three-dimensional coordinate system for the relevant nodes. Considering the possible deformation and distortion issues of the sensor camera lens during imaging, it is necessary to calibrate the camera. Research on reducing imaging interference during camera calibration by designing radial distortion coefficients. The distortion coefficient can be expressed as equation (3.8).

$$\begin{cases} Xa = Xb(1 + k1r^2 + k2r^4) \\ Ya = Yb(1 + k1r^2 + k2r^4) \end{cases} \tag{3.8}$$

In equation (3.8), Xb, Yb represent the coordinates before correction, Xa, Ya are the coordinates after correction, and $k1, k2$ are the distortion coefficients. The imaging information quality of Kinect sensors is closely related to the tracking function of the human skeletal framework, among which sensor performance limitations, surface material impact on reflectivity, environmental occlusion, etc. can all cause loss of depth image information. To reduce the loss of depth information caused by objective conditions, research proposes to repair depth images. Traditional filtering and denoising algorithms for images cannot effectively reduce the information loss areas in Kinect depth images, and to some extent, it will lead to changes in the depth values of the imaging areas. Therefore, the study proposes a repair algorithm based on variable parameter pixel filters to enhance the loss area. Figure 3.3 is a schematic diagram of the filter principle.

Pixel filters redefine the filtering area with candidate pixels as the center, set action thresholds for inner and outer filters, and compare and assign values to the number of pixels with the threshold. Due to the limited mobility of the target patients that the rehabilitation robot is facing, it mainly requires certain rehabilitation treatment in the upper limbs. Therefore, the study limited patients to engaging in activities within the range of Kinect sensor cameras. To achieve a balance between the image restoration effect and computational time, a certain area range was set for filter processing settings. The calculation equation for filter size and threshold is shown in equation (3.9).

$$\begin{aligned} Nineer &= \begin{cases} c1, u \in Z \cap v \in Z \\ c2, u \notin Z \cup v \notin Z \end{cases} \qquad Nouter = \begin{cases} c3, u \in Z \cap v \in Z \\ c4, u \notin Z \cup v \notin Z \end{cases} \\ Sineer &= \begin{cases} s1, u \in Z \cap v \in Z \\ s2, u \notin Z \cup v \notin Z \end{cases} \qquad Souter = \begin{cases} s3, u \in Z \cap v \in Z \\ s4, u \notin Z \cup v \notin Z \end{cases} \end{aligned} \tag{3.9}$$

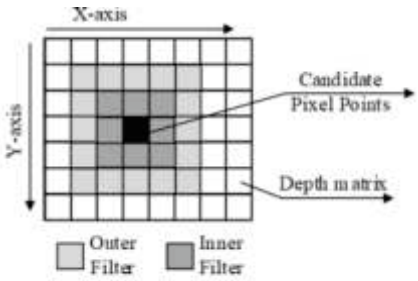

Fig. 3.3: Schematic diagram of filter principle

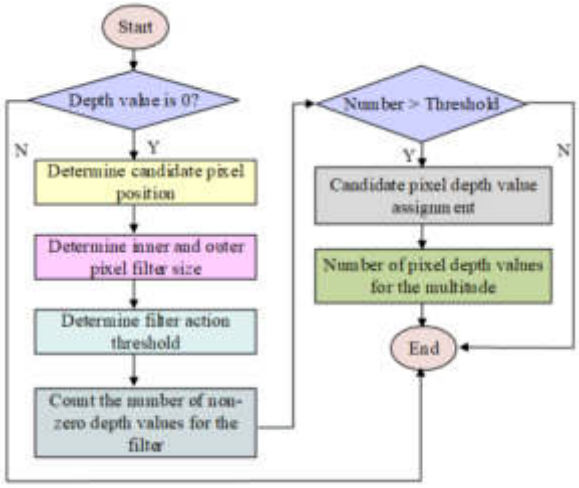

Fig. 3.4: Schematic diagram of the process of image restoration algorithm

In equation (3.9), Z represents the selected region range, $Nineer, Nouter$ represent the size of the inner and outer filters, and $Sineer, Souter$ represent the action threshold of the inner and outer filters. The flowchart of the image restoration algorithm is shown in Figure 2.4.

Variable parameter pixel filters can effectively reduce the number of information loss points and significantly improve the clarity of images. When Kinect sensors collect image information, there may also be random fluctuations in the depth values corresponding to the same pixel position. The study utilizes the weighted moving average algorithm to suppress random noise, and the algorithm process is shown in the figure. This algorithm assigns weights to the obtained depth frames and stores them in a queue data structure. It assigns larger values to depth frames that are closer in time, and the depth value weighting calculation method is shown in equation (3.10).

$$Snow = \frac{w1s1 + w2s2 + ...wnsn}{w1 + w2 + ...wn} \tag{3.10}$$

In equation (3.10), $Snow$ is the depth value matrix obtained by the sensor, $s1, s2, ..., sn$ is the depth value matrix of the previous depth frame, and $w1, w2, ..., wn$ is the weight value corresponding to the depth frame. At the same time, to improve the discrimination of image effects and reduce the subjectivity of contrast, Kinect sensors use classifiers to process depth information features and use these features to determine body parts.

The information features can be expressed as equation (3.11).

$$f\theta(I,x) = dI[x + \frac{u}{dI(x)}] - dI[x + \frac{v}{dI(x)}] \tag{3.11}$$

In equation (3.11), x is the value of the pixel position, dI is the depth value corresponding to the pixel value, $\frac{1}{dI(x)}$ is the offset normalization, and θ is the offset vector parameter.

3.3. Design of upper limb rehabilitation interaction based on multi-sensor fusion and interpersonal interaction. . The research designs the fusion of inertial sensors and Kinect sensors to achieve human motion trajectory tracking. Before data fusion, it is necessary to unify the coordinate systems of the two types of sensors. The study uses the geographic coordinate system as the intermediate coordinate system, and unifies the sensor coordinates into the intermediate coordinate system for coordinate conversion. The conversion method refers to the coordinate conversion method of inertial sensors. Subsequently, the sensor data is zero aligned, using the average output data of the two sensors as the data zero. Due to the different output frequencies of the two types of sensor data, the trajectory data calculated by the sensors is commented on and aligned before data fusion to ensure synchronization of data upload. The trajectory data for frequency alignment consists of the results of two inertial sensors and the Kinect sensor in the middle. Due to the small time interval, linear interpolation is used for data alignment to reduce system computational costs. The interpolated inertial sensor data at time $t2$ is expressed as equation (3.12).

$$x2 = x1\frac{t3 - t2}{t3 - t1} + x3\frac{t2 - t1}{t3 - t1} \tag{3.12}$$

In equation (3.12), $x1, x3$ represent the trajectory data of the inertial sensor at time $x1, x3$. Subsequently, considering that Kinect sensors are affected by occlusion during human motion trajectory tracking, resulting in data loss and jumps, it is necessary to process them. Research on the effectiveness judgment of sensor data based on confidence distance to improve the accuracy and stability of human upper limb motion trajectory tracking. The confidence distance measure can reflect the deviation between observed values, and its mathematical expression is shown in equation (3.13).

$$dij = 2\left|\int_{xi}^{xj} p(x\,|xi)dx\right| \tag{3.13}$$

In equation (3.13), xi, xj are the observed values of the trajectory data of the two sensors, and p is the trajectory data. The smaller the confidence distance measure, the closer the values are, and the calculated measure can form a confidence distance matrix. According to this matrix, a threshold conversion relationship is artificially set to verify the support between data, and the support value can be expressed as equation (3.14).

$$rij = \begin{cases} 0 & dij \geq \varepsilon 2 \\ 0.5 - 0.5(\frac{dij-\varepsilon}{\varepsilon 2-\varepsilon 1})^{0.5} & \varepsilon < dij < \varepsilon 2 \\ 0.5 & dij = \varepsilon \\ 0.5 + 0.5(\frac{\varepsilon-dij}{\varepsilon-\varepsilon 1})^{0.5} & \varepsilon 1 < dij < \varepsilon \\ 1 & dij \leq \varepsilon 1 \end{cases} \tag{3.14}$$

In equation (3.14), ε, $\varepsilon 1$, $\varepsilon 2$ represent the judgment threshold. The greater the support, the better the data compatibility between the two sensors. Subsequently, research was conducted on trajectory data fusion processing based on Bayesian estimation. Each dynamic verification process is a correction process of prior knowledge, and the conditional probability density function of the measured parameters can be expressed as equation (3.15).

$$p(\mu\,|x1, x2\,) = \frac{p(\mu, x1, x2)}{p(x1, x2)} \tag{3.15}$$

In equation (3.15), μ represents the measurement mean and follows a normal distribution, and $x1, x2$ represent the sensor trajectory data. The implementation of motion trajectory tracking in human-computer

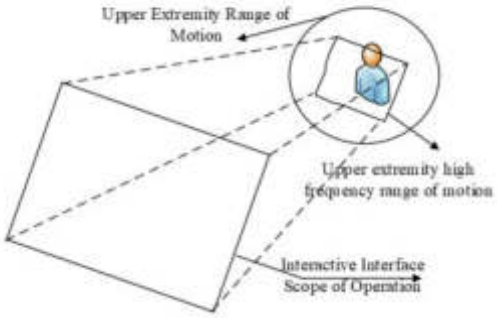

Fig. 3.5: Mapping relationship between upper limb movement range and interaction interface

interaction mainly relies on two interaction logics: "follow-up" and "instruction". The study analyzes the motion range of the Kinect sensor's two-dimensional plane in a "follow-up" interaction design, and maps the human motion range to the operating range of the interaction system, as shown in Figure 3.5.

After limiting the range of upper limb movement, the range of motion is approximately circular, and the study uses this range of motion for interactive mapping to expand the patient's motor ability. After setting the high-frequency range of upper limb movement, to ensure safety, it is necessary to reduce the proportion of this range by 10% as a safety margin, and any excess should also be treated according to the extreme value of the range boundary. When designing an interactive interface, calculate the aspect ratio of the interface and determine the maximum inscribed matrix within the high-frequency range of upper limb movement. The conversion coefficient can be expressed as equation (3.16).

$$\frac{u}{k} = \frac{v}{q'} = h \tag{3.16}$$

In equation (3.16), u, v represent the length and width of the inscribed rectangle, k, q' represent the length and width of the interactive interface, and h represents the conversion ratio coefficient. When using sensors for trajectory segmentation and feature matching, the "directive" interaction logic mainly relies on Kinect for Windows SDK2.0 tools for upper limb and hand state detection in human-machine interaction. Collect trajectory data by using hand stretching and curling as a sampling cycle, and then extract features from the trajectory information under time constraints, converting them into interactive interface instructions. The segmented trajectory data can obtain vector information and determine the direction of motion based on the starting point coordinates, and the azimuth of the vector coordinates can represent the vector orientation of the trajectory.

4. Training results analysis for upper limb rehabilitation robots. . The hardware part of the interaction system designed for research included a rehabilitation robot robotic arm, control cabinet, touch screen machine, display screen, inertial sensor, and Kinect sensor. The display screen was placed in front of the patient for data collection and rehabilitation exercise therapy. The study conducted tracking experiments using MATLAB attitude simulation tools and trajectory tracking experiments using the X-axis motion of an inertial sensor. The sensor accelerated and decelerated during the first and second half of its movement, and the obtained data was integrated to obtain its velocity and displacement change curves. The results are shown in Figure 3.1.

In Figure 4.1, there is a significant difference between the numerical values of the sensor data and the theoretical results after secondary integration processing, and during the sensor stop stage, the displacement data is still in a dynamic transformation state with time, and the error is constantly increasing. Subsequently, the tracking effect of the proposed error compensation algorithm was analyzed, and the results are shown in Figure 4.2.

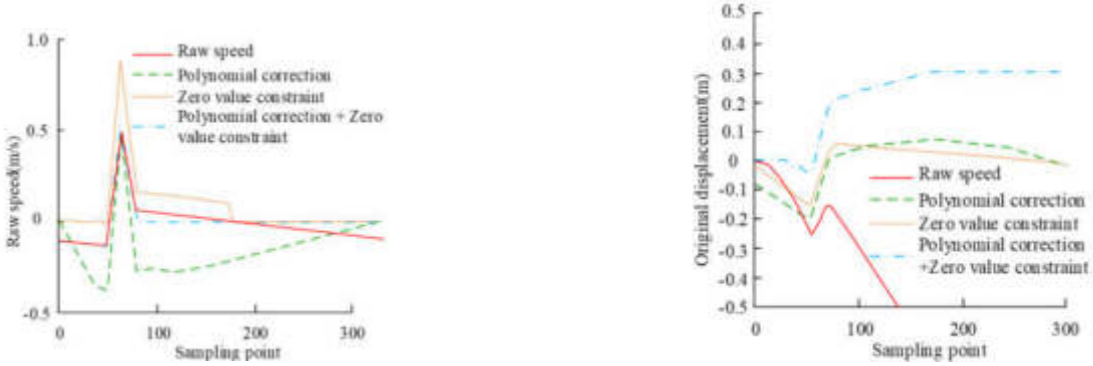
Fig. 4.1: Inertial sensor trajectory tracking results



(a) Cumulative error removal results for velocity values

(b) Accumulated error removal results for displacement values

Fig. 4.2: Cumulative Error Removal Effect

In Figure 4.2, after the error correction of the sensor, its initial motion speed and displacement are not zero. Among them, polynomial-based correction algorithms were more prone to increasing cumulative errors due to the increase of time product in abnormal data analysis, and their improvement effect was not the best. The cumulative error results of sensors under zero value constraints and polynomial correction were significant, and the trajectory tracking accuracy was significantly improved. In terms of numerical values, the displacement of the sensor's X-axis remained stable at around 304.6mm, which was close to the theoretical value. The training time of different algorithms was analyzed, and the results are shown in Figure 4.3.

In Figure 4.3, the overall average time consumption of the algorithm proposed in the study is less than 1.5 seconds, and its curve gradually tends to stabilize when the sample points are greater than 100. Its performance was significantly better than other comparative algorithms. Subsequently, the proposed image restoration and noise reduction effect was analyzed, with filter sizes of 5 and 7, and corresponding threshold sizes of 3.1 and 3.2. The results are shown in Table 4.1.

In Table 4.1, the maximum fluctuation extremum and fluctuation variance of image denoising before processing reached 2.5 million and 10 or more, and its pixel loss was significant, with a mean square error value exceeding 22. The image loss situation was alleviated only by pixel filtering and weighted moving processing, but its depth fluctuation variance and image mean square error were both greater than the fusion algorithm

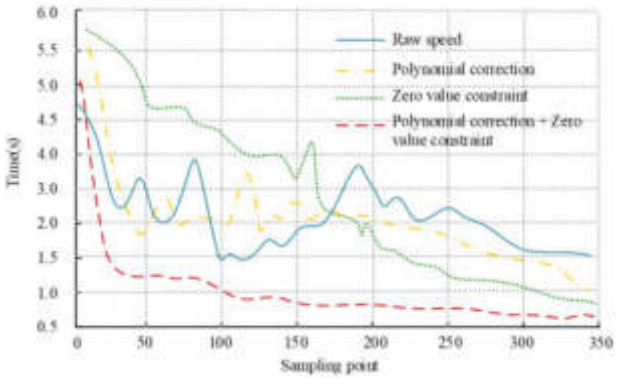


Fig. 4.3: Training time consumption situatione

Table 4.1: Evaluation Results of Image Restoration and Noise Reduction

Algorithms	Sum of fluctuating extremes(104)	Depth value fluctuation variance sum	Depth pixel loss points(104)	Image mean square error
Unused algorithms	255.17	12.45	3.19	22.67
Pixel Filter	188.41	8.59	1.55	3.06
Weighted Shift	173.98	9.36	2.58	13.70
Pixel filter + weighted shift	86.27	6.08	1.16	3.24

Fig. 4.4: Trajectory Data Results

proposed in the study. The image restoration effect of the proposed joint processing method was outstanding, with a loss value of 12000 pixels and a significant improvement in imaging quality. This study used the right hand as a reference to track the trajectory of upper limb movement, drove the arm with the right hand for rehabilitation spatial movement, and conducted experiments on the position coordinates of the wrist. The experimenter stood in front of the sensor and recorded motion tracking data. Figure 4.4 shows the trajectory results.

In Figure 4.4, the motion data of the original bone does not change steadily, with obvious fluctuations and some ”jumping” phenomenon in the data. After filtering the data, the processed three-dimensional spatial trajectory significantly improved its smoothness compared to the original data, with an error improvement of more than 20%. The instruction recognition results of the interactive system were analyzed and compared with traditional rehabilitation training methods. The results are shown in Figure 3.5.

Fig. 4.5: Instruction recognition results

Figure 4.5 shows the corresponding accuracy results of interaction instructions and robot actions. The results showed that the accuracy of interaction instructions and the four training actions of lifting, drooping, adduction, and abduction was 90.15%, 88.96%, 90.67%, and 92.12%, respectively, which were significantly higher than the traditional rehabilitation methods of 82.54%, 83.51%, 79.64%, and 78.33%. The rehabilitation actions of interactive training have good targeting and significant application effects.

5. Conclusion. This study analyzes an upper limb rehabilitation interaction system based on trajectory tracking and designs multiple sensors to track patient upper limb movement and trajectory data. The application results of the proposed interaction system in the study were analyzed, and the results showed that the error compensation algorithm can effectively improve the trajectory tracking accuracy. Compared with the cumulative error results of sensors under dual processing, the error was significantly reduced. The displacement of the sensor X-axis was stable at around 304.6mm, which was close to the theoretical value. The denoising processing of image data by sensors also effectively reduced information loss points (12000), and compared with the image fluctuation extreme value (>2.5 million) and fluctuation variance sum (>100000) before processing, the image quality improvement effect was significant. In the upper limb motion trajectory tracking results, the fluctuation of the filtered motion data was significantly reduced, and the error improvement was greater than 20%. Compared with traditional training methods, its accuracy in the four training actions of lifting, sagging, adduction, and abduction was 90.15%, 88.96%, 90.67%, and 92.12%, respectively, which was much higher than traditional rehabilitation results. Multi-sensor fusion and human-computer interaction can effectively improve the accuracy and stability of upper limb motion trajectory tracking. The proposed upper limb rehabilitation training system has improved the trajectory tracking of dry sensors and integrated multi-sensor data processing, which can effectively avoid the influence of accumulated errors on sensors, achieve higher accuracy in obtaining upper limb motion data, and achieve interaction with the rehabilitation training system. It has high stability and effectiveness. However, the shortcomings lie in the insufficient acquisition of dimensional information by sensors, and the scope of application verification scenarios still needs to be further expanded. In further research, it is necessary to consider and utilize data from different dimensions such as velocity and acceleration, and combine them with human upper limb kinematic models to provide more motion data for rehabilitation training. At the same time, machine learning technology can be used to automatically adjust the rehabilitation training plan based on the patient's rehabilitation progress and personal characteristics, provide remote rehabilitation support, and improve the convenience and accessibility of rehabilitation training. The proposed methods can be applied to more sensory games and virtual game designs, such as voice command control of the training process, or the use of VR technology to create immersive rehabilitation environments, to better improve the effectiveness and interactivity of rehabilitation training and treatment. Applying this method to healthcare and integrating it with other medical devices and health management systems, such as wearable health monitoring devices and electronic medical record systems, can achieve real-time monitoring of patient health status and provide more effective treatment plans for health management.

IMPLEMENTING A SECURE CLOUD-BASED SYSTEM TO SAFEGUARD SENSITIVE MEDICAL DATA FOR HEALTHCARE

NOOR ABDUL KHALEQ ZGHAIR *, AMEER MOSA AL-SADI †, AND ALI ABDUL RAZZAQ TARESH ‡

Abstract. In most developed countries, the medical healthcare system is experiencing rapid development from the stage of clinical information to the stage of information dissemination. In all of these countries, it is undeniable that the Internet of Medical Things (IoMT) technologies have contributed in order to develop information medical healthcare. In reality, the development of smart medical healthcare has been hindered by the protection of medical privacy, according to research and acceptance. This is especially true as telecommunications systems continue to expand and wireless sensor networks (WSN) develop, as well as ways to penetrate those checks that have become increasingly difficult. In the smart healthcare system, protecting users' information remains an outstanding issue. IoMT features and the protection of privacy and security have led to the development of an extended privacy homomorphism algorithm based on scrambling matrixes, an encryption algorithm enhanced by Modified RSA (mRSA), and a method of encrypted data compression that ensures data confidentiality. For the above purpose, we built a prototype system on a demo temporary domain using both hardware and software. According to the results, the proposed scheme protects E-healthcare from potential threats by providing stakeholders with a secure interface and preventing unauthorized users from accessing the mCloud, thus ensuring privacy. E-healthcare services based on cloud technology are protected by the proposed scheme because it is simple and robust.

Key words: Internet of Medical Things (IoMT); Modified RSA (mRSA); Discrete Wavelet Transform (DWT); Wireless Sensor Networks (WSN); Bit Error Ratio (BErR).

1. Introduction. Medical IoT technology has allowed privacy protection systems for medical data to be developed, including active surveillance, medical restrictions, smart healthcare, smart homes, and location-based services [1, 2]. A number of issues have arisen in sensing and obtaining medical data, such as how private and public information is collected, who asks for it, and who is responsible for overseeing or storing the data when that private data is leaked [3] Similarly, the rapid growth of populations in developed countries poses a number of challenges, including monitoring patients with chronic diseases, daily treatments, health care and rehabilitation, as well as medical restrictions imposed by the population and the methods of preserving and scheduling them, both of which form the basis of any society's health care system [4, 5]. In addition to keeping the privacy of elderly patients as much as possible, how to obtain their real-time physical information remains an unresolved issue. As a result, algorithms such as the K-Means clustering method and morphological operations such as erosion, dilation, and so on are used With the emergence of the IoT and traditional health care systems, this paper explores a privacy-protecting medical health care system based on IoM, ideally suited to the special demands of social aging management and care in developed countries [6]. The leading causes of mortality around the globe. It is critical to be able to identify the type of tumour as well as forecast patient clinical results. Lung cancer sufferers have a lower standard of living than the general population and patients with other cancers. If lung cancer is detected early, at least 50% of patients will still be alive 5 years later, free of recurrence.

Below is an organization of the rest of the paper. The literature related works are highlighted in the 2nd Section was organized. The 3rd Section describes the System Methodology. A detailed description about personal information protection is provided in the 4^{th} Section. Analyzing the security of mRSA cryptosystems was given in the 5^{th} Section. In the 6^{th} Section, a system model implementation was explained.

2. Literature Related Works. A review of some works on secure medical data sharing is presented in this section.

2.1. Data Sharing in a Secure Environment. Private cloud architectures are typically utilized in medical organizations to deploy IT infrastructure, which provides a trusted authority for secure medical data sharing [7]. The problem with this paradigm is that it requires a high level of computing and storage investment and is limited in terms of scaling. Collaboration outside the perimeter of the domain can be inconvenient for collaborators [8]. Data sharing that is flexible and fine-grained, however, is inefficient when using one-to-one encryption in a public environment. Multiple ciphertexts are generated in this case in order to encrypt medical data for each user, resulting in enormous computation and storage overheads.

As a control mechanism for outsourced medical data, Sahai and Waters [9] proposed attribute-based encryption. Users can specify access policies that determine what data they are allowed to read when utilizing key-policy attribute-based encryption (KP-ABE) [10]. According to the user's access policy, ciphertext can be decrypted using the key associated with it. Several studies have used attribute-based encryption primitives to address practical issues in secure medical data sharing [11], including multi authority [12], light-weighting [13], and anonymization [14]. In [15] presented a scalable Internet of Things device for heart disease diagnostics. The detected data from the Internet of Things device was processed using the logistic regression approach. The vast volume of data acquired from patients was stored and retrieved via cloud services. ROC analysis was used to assess the efficiency of the regression models in predicting heart disease, The issue of updating user privileges (revocation or extension) is also a popular research topic since it pertains to data sharing. It is still challenging to change user access rights without affecting others because attribute-based encryption attributes are shared.

2.2. The Revocation Process in Attribute-Based Encryption . Bethencourt et al. [15], explained revocation in their ciphertext-policy attribute based encryption scheme, in which each attribute is defined to expire after a certain period of time. The solution proposed by Piretti et al. [16], was improved by a single expiration time associated with each secret key. In these schemes, users are required to update their keys frequently, so revocation cannot be done in a timely manner. Rather than periodic revocation, Attrapadung et al. [17], proposed revocable attribute-based encryption that supported direct user revocation.

Secret keys are associated with attributes as well as identities in their scheme. An integrated revocation list protects the ciphertext encrypted under its attributes so that even users with credentials matching those in the list cannot decrypt it. In a paper published by Liang et al. [18], CP-attribute-based encryption-R schemes were proposed. During revocation, it uses binary tree and linear secret-sharing techniques to reduce communication and computation costs. Direct revocation, however, is limited by the predefined revocation list [19, 20, 21]. Revocation schemes that use indirect revocation [22, 23] propose updating the secret keys when revocation occurs to address this issue. A new encryption should be applied to the old ciphertext, so that revoked users are unable to read it. As a result, the data owner is burdened with a great deal of computation and communication costs. Yu et al. [24] introduced an honest proxy server into their revocable attribute-based encryption scheme, with the proxy server performing the bulk of the ciphertext and key update operations, allowing the authority to revoke any attribute of any user. Utilizing the second scheme [25], users' secret keys are outsourced to the cloud server, and an essential dummy attribute is added to ciphertexts and secret keys. Users' privacy is not compromised by the semi-honest cloud server updating ciphertext and secret keys. Encryption/decryption rely on the dummy attribute, so redundant computations and communications are necessary.

The majority of revocable schemes are concerned with the revocation of the identity of the user rather than the attributes of the user, so a user who is revoked cannot utilize any of his attributes. It is possible to decrypt ciphertext with an unrevoked user's secret key when only a portion of their attributes have been revoked, therefore the ciphertext can still be decrypted utilizing their secret key. Assigning users two access trees in KP-attribute-based encryption addresses the problem of single attribute revocation by utilizing two concrete constructions of attribute revocation. There can, however, only be one revoked attribute determined per encryption. CP-associate-based encryptions were implemented by Cui et al [27] using key separation and binary tree data structures to support selective revocation of attributes, and an untrusted server was introduced to reduce the workload of users during key updates. They do, however, realize attribute-level revocation only through a periodic key update phase, but not in a timely fashion.

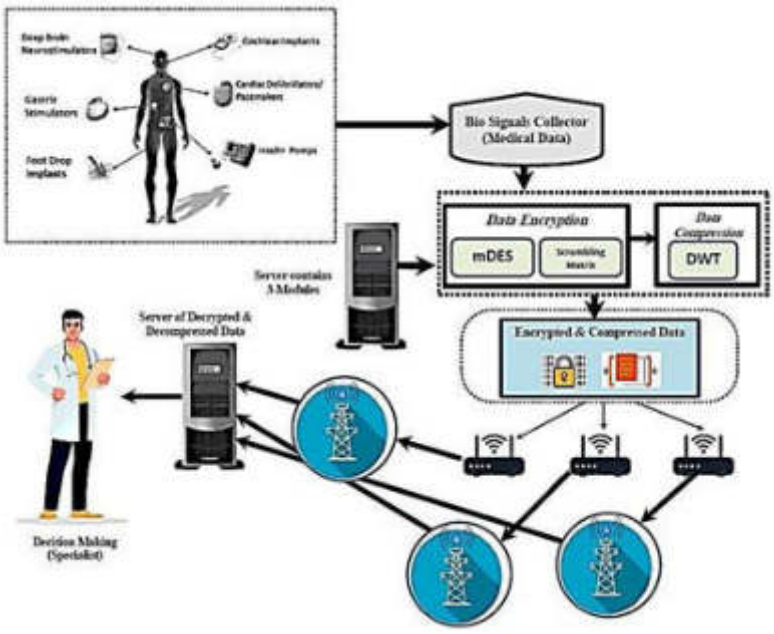

Fig. 3.1: Overall System Methodology

3. System Methodology. The wearable medical sensor nodes we deploy in nursing homes and communities for our intelligent medical applications provide benefits to the elderly. A network of gateway nodes will convert ZigBee signals to TCP/IP simultaneously in the community, and data will be transmitted to hospitals nearby via routers via distributed WSN. Hospitals can analyze and process feedback results from the web application, which allows users to measure physiological items (ECG, EEG, EOG, etc.). A diagram of the network topology can be found in Fig. 3.1. It is easy for attackers to intercept, modify, or alter physiological data transmitted online, such as eavesdropping, forgeries, etc. To protect and ensure the privacy and security of data sent between the source and recipient, three units are proposed:

Module 1: Data is disabled before a server session by creating a confusion matrix.

Module 2: Encryption is utilized for data transmission through WSN.

Module 3: Encrypt medical data sent so that it cannot be hacked, manipulated, or altered. The attacker cannot translate the compressed and incomprehensible plain text into clear text even if he obtains the encrypted data. As a result of the proposed algorithm, the feedback data from the server is guaranteed to be valid without requiring the algorithm to be realized or verified.

3.1. Algorithm of an Extended Privacy Homomorphism. The privacy homomorphism of Rivest in 1978 is a way to manipulate encrypted data directly. The main idea of the book can be summarized as follows.

Considering K_1 and K_2 as encryption and decryption keys respectively, E_{k1} and D_{k2} stand for encrypted and decrypted functions, and α and β are operations [28].

$$\alpha(E_{k1}(M_1), \alpha(E_{k1}(M_2), ..., \alpha(E_{k1}(M_n)) \text{ equal to } E_{k1}(\beta(M_1, M_2, ..., M_n))$$

and

$$D_{k2}(\alpha(E_{k1}(M_1), E_{k1}(M_2), ..., E_{k1}(M_n)) \text{ equal to } \beta(M_1, M_2, ..., M_n))$$

Hence, the algebraic system $(E_k, D_k, \alpha, \beta)$ satisfies the privacy homomorphism.

On integers, privacy homomorphism produces the best results with only two operations: addition and subtraction. Additionally, privacy homomorphism must be extended from integer to real number, and its operations must be expanded from addition to subtraction, multiplication, and division [29] [21].

In the first place, fmod stands for real mode operation:

$$fmod(r,i)\ equal\ to\ \begin{Bmatrix} mod(r,i), & if\ i \geq 0 \\ -mod(|r|,i), & if\ i \leq 0 \end{Bmatrix} \tag{3.1}$$

Function $fmod$'s first parameter r is a real number, while its second parameter i is an integer, and its mod is a normal mathematical mod function. The math.h head file must contain the $fmod$ function in $C++$ because it is utilized in real applications [21, 22].

3.2. Addition of Encrypted Real Numbers with Privacy Homomorphism. Homomorphism encryption need only discuss the addition operation since subtraction can be shown by addition. Following is the design of the detail encrypted algorithm:

Let a prime number p is equal to a prime number q meaning that n is the product of p and q, we get the plaintext space.

Z_p *equal to* $\{x|\ |x| \leq p_{max}\}$ is the set of the plaintext.

O_p *equal to* $\{+p, -p, xp, *p, /p\}$ is the operation set of the plain text, and system of algebra $(Z_p, plusp, minusp, *p, /p)$ is creates the plaintext space [25].

Likewise, Z_c *equal to* $\{x|\ |x| < c_{max}\}$ is the set of the ciphertext, the set of the operation of the ciphertext homomorphic.

O_c *equal to* $\{+c, -c, xc, /c\}$, and a system of algebra $(Z_c, plusc.minusc, xc, /c)$ contains the space of the ciphertext.

Develop the function of the homomorphic encryption $\forall x \in Z_p$, is the value of its encryption y *equal to* $E_{(x)}$ is computed by the below formula:

$$\begin{aligned} &y\ equal\ to\ E(x)\ equal\ to\ fmod \\ &\qquad ((x\ multiply\ sign(x)\ multiply\ rand()\ multiply\ p), n) \\ &\qquad srand((unsigned)time\ NULL)); \end{aligned} \tag{3.2}$$

A signed subsection is represented by sign in the formula above.

$$sign(x) = \begin{Bmatrix} One.....,\ & if\ x\ Greator\ than\ Zero \\ Zero....,\ & if\ x\ Equal\ to\ Zero \\ MinusOne....,\ & if\ x\ Less\ Than\ Zero) \end{Bmatrix} \tag{3.3}$$

$E(x)$ proves to be a monotonic, odd, and double-reflective homomorphic encrypted function. In addition to linear transformations and similar compounds, homomorphic functions can also be defined by linear transformations [24].

Generate Ciphertexts The Ciphertexts is generated by applying two steps. Beginning by converting the plaintexts into integers, and then adding the two real numbers x_1 and x_2. The mathematical representation of the above steps is shown below:

y_1 *equal to* $E(x_1), y_2$ *equal to* $E(x_2)$ by applying formula 3.2 [29].

Condition Checking If $|x_1|$ *minus* $p\{x_2| \geq 0$ | then it should ensure the $|y_1|$ *minus* $c|y2| \geq 0$ true, else, continue encrypting any real number until the condition is met by reversing the last step [26].

Sum Calculation Directly compute y *equal to* y_1 *plus* c *multiply* y_2, and automatically the result is also encrypted. In reverse, the algorithm of decrypted is easy: x *equal to* $D(y)$ *equal to* $fmod(y, p)$.

3.3. A Proposed Modified RSA (mRSA). A public key and a private key are both required in proposed mRSA cryptography because it makes use of asymmetric keys. A one-way system allows exclusive use of public/private keys for encryption/ decryption. As a result, cryptographic signing cannot be utilized for authentication. For the proposed mRSA cryptosystem, the following algorithm is utilized to generate keys [27, 18].

1. *Algorithm of Key Generation Phase*:

(a) Prime numbers are selected at random and independently p, q, r, and s should be made. All prime numbers should be equal in length.
(b) Calculate n *equal to* p *multiply* q, m *equal to* r *multiply* s,
ϕ *equal to* (p *minus* 1) *multiply* (q *minus* 1) and
λ *equal to* (r *minus* 1) *multiply* (s *minus* 1). Select e integer, when e greator than one and less than ϕ, $gcd(e, \phi)$ *equal to one*
(c) Calculate the exponent of the secret d, when d *greater than one* and less than $\phi, e\ x\ d\ mod\ \phi$ *equal to* 1.
(d) Choose g integer, wheng equal m *pluse one.*
(e) Calculate the inverse of the modular multiplicative: μ *equal to* λ^{-1} *mod* m.
(f) Key (encryption) for public utilize: (n, m, g, e).
(g) Key (decryption) for private utilize is (d, λ, μ) [9].

2. *Phase of Encryption*:
(a) Let m be a message to be encrypted where $mesg$ greator than $Zero$ and less than n.
(b) Choose a random r where r less then m.
(c) Calculate ciphertext as: c equal to $g^{(mesg^e mode\ n)}\ x\ r^m\ mod\ m^2$ [29].

3. *Phase of Decryption*:
(a) Calculate message:

$$m = ((\frac{c^\lambda\ mod\ m^2\ minus\ 1}{m})\ multiply\ \mu\ mod\ m)^d\ mod\ n \tag{3.4}$$

3.4. Discrete Wavelet Transform (DWT) for Data Compression. In order to overcome the weaknesses of Discrete Cosine Transform (DCT)-based techniques, DWT are utilized [21]. DWT is mostly related to 1D/2D DWT. In the first step, DWT can be implemented row-wise utilizing 1D-DWT). As a second option, 1D-DWT can provide four sub-bands such as Low Low (LL), Low High (LH), High Low (HL), and High High (HH) by applying it column-wise. There are four sub-bands within each of these four bands. A number of wavelet-based schemes have been proposed by researchers and are discussed below. Signal decomposition is studied with the DWT. Fast Fourier Transform (FFT) differs from this because it utilizes coefficients such as 'details' and 'approximation' [22]. A novel CAD method for early lung nodule detection. The volumetric variations in the detected lesion over time are used to calculate the growth rate of the identified lung nodule. Finding the threshold level that gives the best results requires a Graphical User Interface (GUI). Right now, the global threshold is being utilized instead of a threshold by level, which is the most accurate method. However, due to its complexity, the global threshold is being utilized for the time being. Signal types are chosen according to their complexity based on 1D data [23]. Hence, we will analyze which method works best with certain signals based on the criteria listed above. All the signals (length 1024) will be compared by the Mean Square Error (MSE), Root-Mean-Square Error (RMSE), and compression ratio. The complexity of 2D data will determine how many images are considered [24]. There is a fixed size (resolution) for all 2D data (image). Finally, real-life data (such as medical images) will be analyzed through a case study.

4. Personal Information Protection. Wireless sensor networks (WSNs) collect, aggregate and transport physical information. The purpose of this is to maintain data confidentiality and invisibility against hackers by utilizing privacy homeomorphisms and an mRSA-based lightweight encryption algorithm [25].

4.1. Algorithm Analysis. Compared to algorithms of a symmetric encryption RC5 and RC6, the proposed encryption algorithm is more efficient. The speed of the system is demonstrated through several experiments. The proposed algorithm, additionally RC6, and RC5, are utilized to encrypt 100 messages, and costs of their time are respectively [26]. The proposed algorithm is also resistant to a variety of attacks. Due to the ROL operation, linear and differential cryptanalysis are less effective than exhaustive attacks for our proposal. According to the proposed algorithm, RC5 and RC6 are no more secure than each other [27]. An exhaustive attack will be estimated in terms of computation costs. Cryptography algorithms RC5 and RC6 utilize 64-bit main keys. Hence, the key space consists of 264 elements. In practice, this is exaggerated, but

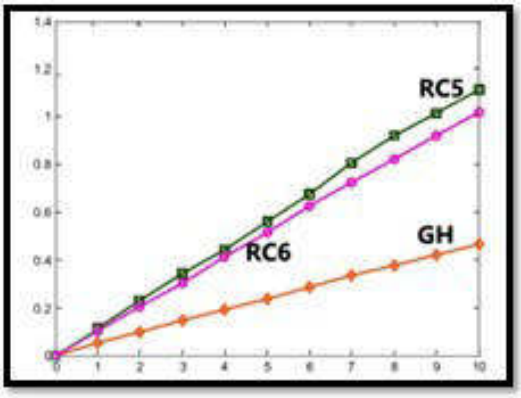

Fig. 4.1: Encryption Algorithm Comparisons

we can assume that the attackers' computer runs 109 instructions each minute. In other words, it will take 264/109/3600/365=14038 years to crack the plaintext of the message, exceeding the validity period of the data [23, 28].

5. A System Model Implementation. Nodes for medical sensors are deployed on multiple wearable devices for nursing home monitoring.

5.1. Medical Device Sensor Nodes. Sensors are used to collect patient information (ECG, EEG, pulse, blood oxygen levels, temperatures, etc.). Various types of medical sensors can be used for a variety of applications, as described below:
Temperature probes: Temperature measurement is performed using this device.
Force sensors: A kidney dialysis machine uses this material.
Airflow sensors: Laparoscopic systems, heat pumps, etc., operate on airflow.
Pressure sensors: Sleep apnea and infusion pumps use them. Embedded systems usually integrate pressure sensors.
Implantable pacemaker: Maintains proper cardiac rhythm with synchronized rhythmic electric pulses.
Oximeter: Measures the ratio of hemoglobin saturation to hemoglobin count.
Glucometer: Glucose concentration is approximated by this device.
Magnetometer: Determines the direction of the user by examining the earth's magnetic field.
Heart electrical activity: is measured by an electrocardiogram sensor. ECG sensors are used for ECGs.
Heart rate sensor: Minutely heartbeats are counted.
Electroencephalogram sensor: Measures brain activity.
Electromyogram sensor: Measures muscle electrical activity.
Respiration rate sensor: Measures the number of chest rises per minute.

5.2. Node for Gateways. The ZigBee signals are converted to TCP/IP at gateway nodes in the communication, and data is sent to nearby hospitals via routers [11].

5.3. A System Testing. Sensors such as blood oxygen sensors, pulse sensors with variable speed triggers, and temperature sensors are utilized to collect physiological data. Additionally, it ensures data transmission accuracy and reliability. Our sensor nodes were tested in a general environment in order to prove that they are capable of collecting accurate data. Temperature, oxygen saturation, and pulse are measured by sensor nodes. As a comparison, hospitals utilize standard instruments. The results of this study suggest that all sensors can be highly accurate. In order to get close to true value, we rely on a reliable data source.

Statistical analysis of the success rate and BErR of package transport is conducted in two more experiments. According to the proposed system's results, its success rate of transmissions (more than 0.899) and BErR (less than 0.049) are high. Communication with nodes and gateways ensures high reliability by conveying valid

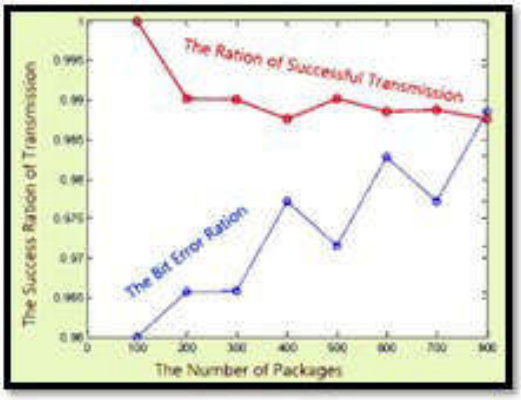

Fig. 5.1: BErR and Success Ration of Transmission Analysis

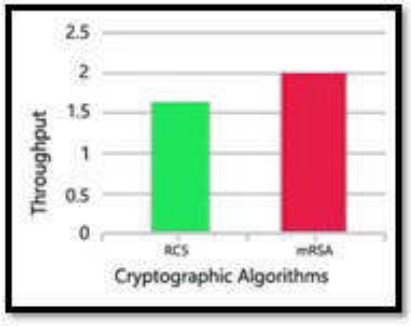

Fig. 5.2: Data Files Encryption Runtime

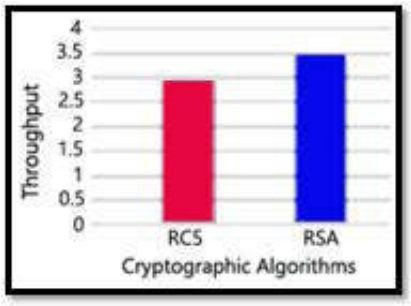

Fig. 5.3: Data Files Decryption Runtime

physiological data of patients. The sampled data were divided into sixty percent for training, twenty percent for validation, and twenty percent for testing, as shown in Figure 5.1.

By using our system interface, it is possible to compare both plaintext and ciphertext data. When an attacker eavesdrops on the information channel, he or she can only gain cipher information, unable to crack further due to the lack of a key. Obtaining the plaintext is possible if the attacker obtains the secret keys of decryption through accessing memory information. Homomorphic encryption prevents attackers from gaining any useful information about physiological data since they only obtain a confusing matrix.

Table 5.1: Encryption runtime of data files

File(MB)	RC5 (in sec)	RSA (in sec)
0.2	1.6	1.1
0.6	1.9	1.6
0.85	4.3	3.6
1.1	4.9	4.1
Average time	12.7	10.4
Throughput(MB/sec)	1.6	2

Table 5.2: Decryption runtime of data file

File(MB)	RC5 (in sec)	RSA (in sec)
0.2	1.6	1.1
0.6	2.1	1.6
0.85	2.6	2.1
1.1	3.6	3.1
Average time	9.9	7.9
Throughput(MB/sec)	1.6	2

Table 5.3: CR and PRD for 1D data and 2D data

Thresholding					
1D Data			2D Data		
CR			PRD		
1^st Tier	2^{nd} Tier	3^{rd} Tier	$1st$ Tier	2^{nd} Tier	3^{rd} Tier
10.87	52.27	79.42	1.576	3.11	16.45

Table 5.3 shows the CR and PRD for 1D data and 2D data.

6. Conclusion. Due to the rapid development of IoMT and WSNs, as well as our focus on privacy protection, we can expect that our medical healthcare scheme will have a wide scope of applications. A prototype system that proved it to be functional was created, where an encryption algorithm using a Modified RSA (mRSA), a compression technique using DWT, and a homomorphic strategy for data security and privacy protection have been proposed based on a scrambling matrix. Through values readings of compression ration and accuracy) (CR=79.42, and PRD=1.576) they are proving to be a more efficient algorithm. The proposed mRSA cannot be broken by guessing only the private key The LIDC dataset is obtained, pre-processed, and segmented to train and choose pre-trained deep learning models. As a result, we can conclude that mRSA is more secure in terms of brute force attacks, where the findings mention that the proposed mRSA algorithm becomes more secure against mathematical attacks due to improvements in security. Despite the abundance of sensor nodes, some problems remain unresolved, such as the lack of secure key management. These issues will be taken into consideration in the future.

A LONG SHORT TERM MEMORY MODEL FOR CHARACTER-BASED ANALYSIS OF DNS TUNNELING DETECTION

HUDA KADHIM TAYYEH *AND AHMED SABAH AHMED AL-JUMAILI †

Abstract. DNS tunneling is the attempt to create a hidden tunnel through a domain name service. Such a tunnel would jeopardize the targeted network and open the door for illegal access, control, and data exfiltration. The information security research community showed the variety of techniques that have been proposed to detect the tunnel. The majority of these efforts were relying on machine learning techniques where features of tunneling are considered such as length of DNS query, size, and entropy of the query. However, an additional analysis of the lexical information of the DNS query has been depicted recently and showed remarkable performance. This paper aims to examine the role of Long Short Term Memory (LSTM) model in terms of DNS lexical analysis. Two benchmark datasets related to DNS have been used. In addition, a character mapping mechanism has been used to replace every possible character with an integer number. Consequentially, the mapped representation has been fed into an LSTM model for DNS tunneling detection. Results showed that the proposed method was able to obtain a weighted average F1-score of 98% for both datasets respectively. Such results are competitive in the context of the state of the art and demonstrate the efficacy of the lexical analysis within the DNS tunneling detection task.

Key words: DNS Tunneling, Character-based Analysis, Long Short Term Memory.

1. Introduction and Preliminaries. TDomain Name Service (DNS) is a protocol that is used extensively within internet services to call an actual IP address of a location through an easy-to-call name. From the mechanism of calling the DNS, it is obvious that it is vulnerable to a wide range of threats. The common threat is through tunneling the DNS with another protocol known as DNS tunneling [1, 2, 3]. This tunneling is intended to perform various commands including control and data exfiltration. In this regard, DNS tunneling can be seen as a serious attack that could cause plenty of illegal access to protected networks and computers [4, 5]. With the dramatic developments of computer networking, ongoing development is also depicted by attackers and hackers by elevating their approaches in which the traditional firewalls could seem ineffective toward detecting such attempts of DNS tunneling [4, 6, 7]. Therefore, the research community tended to utilize much more sophisticated approaches such as machine learning techniques [8, 9, 10]. The key success behind machine learning techniques lies in the dynamic learning of changes that could occur within the DNS tunneling mechanisms. This can be done through training on simulated and actual traffic of tunneling attempts. Within this training, the machine learning techniques learn how to identify associated characteristics to the tunneling itself such as the length of the DNS query, size of the query and the entropy of the query [6].

The previous works in DNS tunneling detection were focusing on machine learning techniques where the aim was to utilize feature selection approaches for finding the most accurate subset of features that indicate the DNS tunneling. For example, Aiello et al. [11] used the K-Nearest Neighbor (KNN) classifier along with two statistical feature reduction approaches Principal Component Analysis (PCA) and Mutual Information (MI). Similarly, Davis & Foo [12] used a filtered classifier along with Information Gain (IG) as a statistical feature selection method for HTTP tunneling detection. The authors have concentrated on traffic features related to the DNS. Afterward, the researchers in DNS tunneling detection followed the same path by examining different machine learning classification methods along with a variety of feature selection approaches. The main focus was on DNS traffic features such as source, destination, information entropy and length of DNS query. For instance, Homem & Papapetrou [13] utilized the Artificial Neural Network (ANN), Support Vector

HTTPS	53
FTP	53
POP3	53
Total	212

Machine (SVM) and Decision Tree (DT) classifiers along with manual feature selection mechanism for DNS tunneling detection. Similarly, Shafieian et al. [14] used the KNN, ANN and Random Forest (RF) classifiers for DNS tunneling detection task. The authors utilized both PCA and IG as feature selection approaches. In the same regard, Yang et al. [15] utilized three classifiers composing of DT, SVM and KNN with a manual feature selection for the task of DNS tunneling detection task. On the other hand, Almusawi & Amintoosi [16] investigated the parameter tunning of the SVM classifier where multiple kernels have been addressed for the task of DNS tunneling. Lastly, Al-Ibraheemi et al. [17] examined the SVM classifier with Genetic Algorithm (GA) as a feature selection approach for DNS tunneling detection.

Meanwhile, another path has been depicted within the literature of DNS tunneling detection. Such a path was represented by the utilization of the lexical nature of the DNS encoding where the task turned into a text mining task. For example, Yu et al. [18] utilized the N-gram representation for the character-based of DNS encoding. The authors have used the ANN classifier to predict the occurrence of DNS. In addition, Palau et al. [19] have utilized the Convolutional Neural Network (CNN) through the exploitation of character-based features related to the DNS to predict the tunneling. Lastly, Luo et al. [20] utilized the classifier of Isolation Forest (IF) upon the character-based features related to the DNS to predict the occurrence of tunneling.
Although the exploitation of lexical or character-based features was promising yet, there is still an open door for improvement. Such an improvement can be seen by the utilization of the Long Short Term Memory (LSTM) model which has a remarkable performance in terms of handling sequential data [21, 22, 23]. Since the encoding of DNS is relying on sequences of characters, the use of LSTM can be seen as a potential.

This paper aims to propose an LSTM model along with character mapping for the purpose of DNS tunneling detection. Two benchmark datasets have been used within the experiments. In addition, different preprocessing tasks have been carried out to appropriate the specified task. Consequentially, the character mapping technique has been used to replace every possible character with an integer number. Hence, the integer mapped representation will be fed into an LSTM for the training and testing of predicting the DNS tunneling. The results acquired by the proposed method showed competitive performance against the state of the art.

The paper is organized as; Section 2 illustrates the proposed LSTM with character mapping, Section 2.1 highlights the results and provide a discussion where the comparison against the baseline study is given, Section 4 concludes the work.

2. Proposed LSTM. The framework of the proposed method starts with the datasets that have been used in the experiments. In particular, two benchmark datasets related to DNS have been used. After that, a preprocessing task will take a place in which the character-based features are being extracted from the two datasets. Consequentially, the character mapping process is conducted where each character will be mapped with an integer number. Hence, the mapped representation will be fed into an LSTM model for the DNS tunneling detection task. Lastly, the prediction of tunneling will be assessed using the common machine learning evaluation metrics. Fig. 2.1 shows the framework of the proposed method.

2.1. Dataset. In this study, two benchmark related to DNS have been used. The first dataset has been introduced by Homem et al. [24]. Such a dataset simulates the DNS traffic where multiple tunneling have been created including HTTP, HTTPS, FTP and POP3. Table 2.1 depicts the statistics of this dataset.

The second dataset is simulating the DNS protocol with normal and malicious attempts. This dataset has been introduced by Palau et al. [19]. Two threats have been simulated including Domain Generation

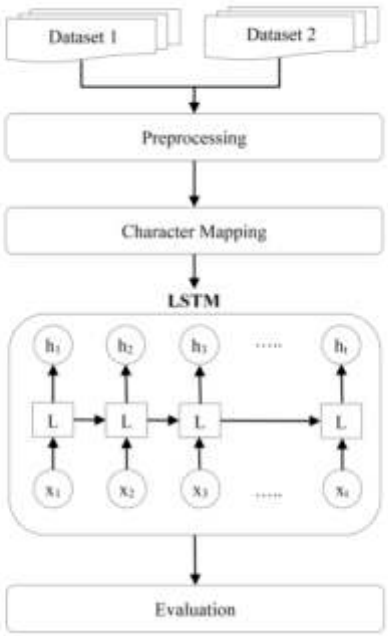

Fig. 2.1: Proposed LSTM's framework

Table 2.2: Details of Dataset 2

Class	Number of Samples
Normal	l 1,180,178
DGA	1,915,335
Tunneling	8,000
Total	3,103,513

Algorithms (DGA) and tunneling domain names. Table 2.2 depicts the statistics of this dataset.

2.2. Preprocessing. In the preprocessing phase, both datasets have undergone a preparation task where the character-based features are being extracted. For the first dataset, it contains six features, some are related to length of DNS request and IP request, the other is related to entropy of the DNS request with different sizes as shown in Table 2.3. However, there is a feature that is related to the hexadecimal encoding of the DNS request. This feature is containing both numeric and characters. Since this study aims at utilizing lexical or character-based features thus, only the hexadecimal encoding of the DNS request feature will be considered from Dataset 1 along with the class label.

The second dataset contains three attributes including the DNS request, label whether 0 or 1 that indicate normal or threat request, and finally the class of threat whether normal, DGA or tunneling as shown in Table 2.4. Basically, the first attribute which is considered the character-based feature and the class attribute will be considered within the experiments in this study.

2.3. Character Mapping. In this phase, the character-based features will be processed in which each character is replaced with an integer number. This task is important for the LSTM to turn the characters into sequential numeric data. For this purpose, two dictionaries have been created to correspond to each character occurrence within the two datasets. The first dictionary contains hexadecimal possible characters which include numbers from 0-9 and characters from a-f as shown in Table 2.5. Apparently, the dictionary size would be 16.

Table 2.3: Features of Dataset 1

Length of DNS Request	Length of IP request	Hexadecimal Encoding of DNS Request	DNS Request Entropy	DNS Request Entropy (50 bytes)	DNS Request Entropy (20 bytes)	Class
57	85	3832ca326862beee5	1.584	1.584	1.584	FTP

2	2
3	3
4	4
5	5
6	6
7	7
8	8
9	9
a	10
b	11
c	12
d	13
e	14
f	15

For the second dataset, the DNS request contains larger size of possible characters including numbers (i.e., 0-9), lower-case characters (i.e., a-z), upper-case characters (i.e., A-Z), and two special characters (i.e., '-' and '_') as shown in Table 2.6. Obviously, the dictionary size would be 64 characters.

After mapping each character with an index number, it is necessary to examine the length of longest possible combination of characters within the two characters. This is known as the maximum length which is important to be identified for the LSTM model. This due to the need of preparing a fixed length matrix of the input. Table 2.7 depicts the maximum length in the two datasets.

Once the maximum length is identified, all the instances will be supplemented with extra zeros equivalent to the length of maximum length.

2.4. LSTM. After mapping the characters and padding the length of instances within the two datasets, the resulted matrix will be fed into an LSTM. The input matrix's size will be equivalent to the maximum

Table 2.6: Dictionary of Dataset 2

Table 2.7: Maximum length within the two datasets

Dataset	Max Length
Dataset 1	448
Dataset 2	65

length of each dataset respectively. Therefore, both input shape and dictionary size have been brought from the previous section. However, for other hyperparameters of the LSTM such as dropout, activation function, and optimizer, the same parameter setting used in the baseline study of Palau et al. [19] who used a CNN model have been followed to facilitate the comparison. Table 2.8 depicts the parameter setting of the proposed LSTM.

2.5. Evaluation. The evaluation will take place based on the three metrics namely precision, recall and F1-score. Precision is intended to examine the number of DNS requests that have been successfully classified into their actual class in accordance to the total number of DNS requests, it can be calculated as follow [5, 25, 26]:

$$Precision = TruePositive/(TruePositives + FalsePositives) \tag{2.1}$$

Whereas, recall is intended to examine the number of DNS requests that have been successfully classified into their actual class in accordance to the total number of DNS class, it can be calculated as follow:

$$Recall = TruePositive/(TruePositives + TrueNegative) \tag{2.2}$$

Table 2.8: The proposed LSTM hyperparameters

Dataset 1	
Hyperparameters	Quantity
Input shape	448
Dictionary Size	16
Dropout	2 layers (0.5)

Optimizer	Adam
LSTM	256
Dataset 2	
Hyperparameters	Quantity
Input shape	65
Dictionary Size	64
Dropout	2 layers (0.5)
Activation layer	2 layers (ReLU) 1 layer (Softmax)
Optimizer	Adam
LSTM	256

Table 2.9: Results of Dataset 1

DNS Class	Precision	Recall	F1-score
POP3	0.8714	0.9901	0.9269
FTP	1.00	0.9901	0.9949
HTTPS	0.9812	0.9223	0.9508
HTTP	0.9901	0.9872	0.9886
Weighted Average	0.9866	0.9911	0.9884

Lastly, F1-score is the harmony between precision and recall, it can be calculated as follow:

$$F1 - score = 2PrecisionRecall/Precision + Recall \tag{2.3}$$

2.6. Results and discussion. In this section, the results of the proposed method is evaluated on two datasets. The evaluation is taking a place using precision, recall and F1-score. The splitting of data has been set into 80% training and 20% testing for the first dataset, meanwhile, 70% training and 20% testing for the second dataset. Table 2.9 depicts the results of the first dataset.

As shown in Table 2.9, the proposed method was able to acquire a precision of 0.8714, recall of 0.9901 and F1-score of 0.9269 for POP3 tunneling class label. In addition, precision, recall and F1-score of 1.0, 0.9901 and 0.9949 have been obtained for the FTP class label. For HTTPS class label, a precision of 0.9912, a recall of 0.98223 and F1-score of 0.9508 have been obtained. Lastly, for HTTP class label, the proposed method was able to score a 0.9901 for precision, 0.9872 for recall, and 0.9886 for F1-score. This has led to weighted average precision of 0.9866, recall of 0.9911 and F1-score of 0.9884. Table 2.10 depicts the results of the second dataset.

As shown in Table 2.10, the proposed method was able to acquire a precision of 0.9711, recall of 0.9921 and F1-score of 0.9814 for Normal class label. For DGA class label, a precision of 0.9901, a recall of 0.9851 and F1-score of 0.9875 have been obtained. Lastly, for Tunneling class label, the proposed method was able to score a 0.9931 for precision, 0.9182 for recall, and 0.9541 for F1-score. This has led to weighted average precision of 0.9805, recall of 0.9802 and F1-score of 0.9803. Table 2.11 depicts a comparison against the baseline studies.

As shown in Table 2.11, although the proposed method has obtained a relatively similar result of F1-score for the second dataset compared to the baseline of Palau et al. [19] (i.e., 98%). However, the proposed method

Table 2.10: Results of Dataset 2

DNS Class	Precision	Recall	F1-score
Normal	0.9711	0.9921	0.9814
DGA	0.9901	0.9851	0.9875
Tunneling	0.9931	0.9182	0.9541
Weighted Average	0.9805	0.9802	0.9803

Table 2.11: Comparison against baseline

DNS Class	Dataset 1 (F1-score)	Dataset 2 (F1-score)
Homem & Papapetrou (2017)	95%	-
Almusawi & Amintoosi (2018)	80%	-
Al-Ibraheemi et al. (2021)	94.6%	-
Palau et al. [19]	-	98%
Proposed method	98.84%	98.03%

showed a remarkable improvement in terms of the F1-score for the second dataset where it achieved 98.84% compared to 95% acquired by Homem & Papapetrou (2017), 80% acquired by Almusawi & Amintoosi (2018), and 94.6% acquired by Al-Ibraheemi et al. (2021). This demonstrates the efficacy of lexical or character-based analysis within the DNS tunneling detection task.

3. Conclusion. This paper has proposed an LSTM model for the DNS tunneling detection task. Two benchmark datasets related to DNS have been used. Experimental results showed a remarkable enhancement for the first dataset compared to the baseline studies. Whereas, the proposed method obtained relatively similar performance for the second dataset compared to the baseline. For future direction, the use of character embedding could be promising in terms of enhancing the detection accuracy.

CHARACTER-LEVEL EMBEDDING USING FASTTEXT AND LSTM FOR BIOMEDICAL NAMED ENTITY RECOGNITION

AHMED SABAH AHMED AL-JUMAILI *AND HUDA KADHIM TAYYEH †

Abstract. Extracting biomedical entities has caught many researchers' attention in which the recent technique of word embedding is employed for such a task. Yet, the traditional word embedding architectures of Word2vec or Glove are still suffering from the 'out-of-vocabulary' (OOV) problem. This problem occurs when an unseen term might be encountered during the testing which leads to absence of embedding vector. Hence, this study aims to propose a character-level embedding through FastText architecture. In fact, handling the character-level seems a promising solution for the OOV problem. To this end, the proposed FastText architecture has been used to generate embedding vectors for the possible N-gram combinations of each word. Consequentially, these vectors have been fed to a Long Short Term Memory (LSTM) architecture for classifying the words into its biomedical classes. Using two benchmark datasets of BioCreative-II and NCBI, the proposed method was able to produce an f-measure of 0.912 and 0.918 respectively. Comparing these results with the baseline studies demonstrates the superiority of the proposed character-level embedding of FastText in terms of Biomedical Named Entity Recognition (BNER) task.

Key words: Biomedical Named Entity Recognition, FastText, Long Short Term Memory, Character-level, Out of Vocabulary.

1. Introduction. The dramatic growth of biomedical and medical data represented by publications, books, blogs and others has demonstrated the need for detecting biomedical entities. Entities like disease names, drug names, symptoms and chemical compounds are frequently occurring in biomedical resources [1], [2]. The need of recognizing these entities lies in the benefits of determining side-effects, adverse drug reactions, drug-drug interactions and other valuable information that could be mentioned implicitly or explicitly through the text. Hence, theNamed Entity Recognition task in the biomedical domain (BNER) emerged to train the machine for identifying such entities [3], [4].

The earliest research efforts on BNER were relying on engineered features such as length, position, and frequency of the term along with dictionary-based approaches [5]. However, the emergence of new sophisticated techniques such as the Word Embedding has contributed toward improving the BNER task [[6]-[9]]. Word embedding is a technique that utilizes a Neural Network architecture to predict target term given its context terms or vice versa. The main goal of such a prediction is to learn distinctive embedding vectors of the terms where such a vector would represent the term in multi-dimensional space. In this regard, terms with similar context would have similar vector representation [10]. Yet, there are various issues have been encountered by the word embedding technique such as the amount of trainable text in which word embedding requires massive text for the training in order to produce accurate vector embedding [11]. In addition, the Out-of-Vocabulary (OOV) problem was the main challenge in which an unseen term within the training might occur during the testing where the word embedding model would have no embedding for such a term [12], [13]. These challenges come from the fact that the traditional word embedding approach is dealing with word-level. Therefore, this study aims to utilize a character-level embedding using FastText architecture in order to overcome the aforementioned drawbacks.

The paper is organized as; Section 2 provides the related work, Section 3 illustrates the proposed LSTM with character mapping, Section 4 highlights the results and provide a discussion where the comparison against the baseline study is occurred, Section 5 provides the final conclusion.

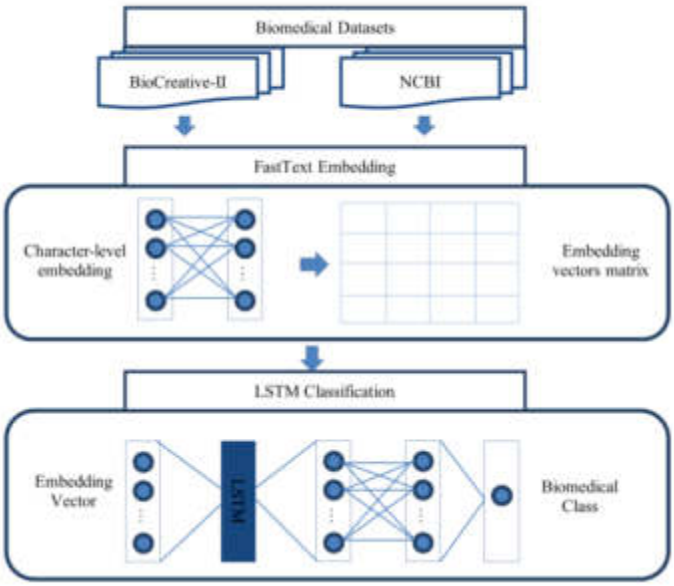

Fig. 2.1: Framework of the proposed method.

1.1. Related Work. The recent literature on BNER task has concentrated on word embedding techniques. For example, Gridach [14] have utilized a Word2Vec architecture to extract biomedical instances. Through a neural network architecture known as Long Short Term Memory (LSTM) with BioCreative-II dataset, the proposed method acquired 89.46% of f-measure. Similarly, Li and Jiang [15] have utilized the Word2Vec architecture for upon the same dataset with LSTM and got similar performance of f-measure (89.49%). Zhu et al. [16] utilized the Word2Vec with another neural network architecture known as Convolutional Neural Network (CNN) for BNER task. Based on the BioCreative-II and NCBI datasets, this study acquired an f-measure of 87.2% and 87.26% respectively. Cho and Lee [17] utilized another word embedding architecture known as Glove with LSTM for the BNER task. Using BioCreative-II and NCBI datasetsthe authors showed an f-measure of 81.44% and 85.68% respectively. Zhang and Wu [18] have proposed the Word2Vec architecture with LSTM for the BNER task. Using the BioCreative-II dataset, the proposed method obtained an f-measure of 89.94

2. Proposed Method. The proposed method of this study lies in the utilization of character-level embedding through FastText architecture. To this end, two benchmark biomedical datasets will be considered in this study including NCBI and BioCreative-II. Lastly, an LSTM architecture will process the embedding vectors generated from FastText to perform the classification of biomedical entities. Fig. 2.1 depicts these phases.

2.1. Dataset. In this study, two benchmark datasets of biomedical entities will be used. The first dataset is NCBI which introduced by Doğan et al. [19]. It concentrates on disease mentioning brought from one of the large medical sources of PubMed. The second dataset is BioCreative-II [20] consisting of genes and gene-related mentions. Table 2.1 shows the description of both datasets.

2.2. Character-level Embedding using FastText. The FastText architecture is very similar to the traditional Word2Vec in the context of examining part of text through a neural network architecture in order to predict specific target of the text. Yet, instead of handling the word-level like in Word2Vec, FastText handles the text as a character-level N-gram. In fact, handling the word-level showed various drawbacks such as the OOV problem which occurs due to the absence of vector embedding for unseen terms. Sometimes the OOV term would have derivational inflection matching within the embedding model but because the actual matching

Table 2.1: Dataset description

Dataset	Class	Description	Quantity
NCBI	UN	Disease name	8475
	O	Non-disease name	120,569
BioCreative-II	UN	Genes	15,700
	O	Non-gene	371,000

Table 2.2: One-hot encoding matrix for potential character n-gram of the 'cancers' term

	ca	an	nc	ce	er	rs
ca	1	0	0	0	0	0
an	0	1	0	0	0	0
nc	0	0	1	0	0	0
ce	0	0	0	1	0	0
er	0	0	0	0	1	0
rs	0	0	0	0	0	1

does not occur thus, no vector embedding can be brought. Assume a word embedding model that has been trained on a wide range of text contexts. Within such contexts, suppose the word 'cancer' has occurred without its derivational inflections such as 'cancers'. Handling such an inflection within the testing would lead to the OOV problem even though the model has seen similar term. Therefore, the FastText model has been emerged as a solution for this problem where the series of N-gram character of each word will be trained.
FastText architecture proposed by Facebook to process sequences of N-gram characters for every individual word and averaging the resulted vectors into a single embedding vector [21]. To illustrate the way of doing such an embedding, assume a term of 'cancers', FastText will produce a sparce matrix known as one-hot encoding matrix which is typical to the way Word2Vec works. Yet, rather than focusing on word-level contexts, FastText addresses the N-gram character sequence of the word. Table 2.2 shows an example using 'cancers' term.

Hence, the FastText architecture will process the potential character N-gram in order to predict specific N-gram characters. Like the Word2Vec, FastText will train the model and tune the weights in order to get matching between the prediction and the actual values. In this regard, the hidden neurons will articulate the embedding vector for the targeted N-gram characters. Fig. 2.2 represents a simple architecture of FastText where the N-gram character sequences of the word 'cancers' including 'ca', 'an', 'nc', 'ce', and 'er' are being processed in the input to predict the last N-gram sequence of 'rs'.

2.3. LSTM. Once the FastText model is being built and trained on the two corpora of NCBI and BioCreative, an LSTM architecture will be used to classify the words into its biomedical class label. LSTM is an architecture that has been built upon the Recurrent Neural Network (RNN) architecture which introduced the recurrent feedback connections [22]. Additionally, LSTM has extra components of memory and forget gate in which the contextual information is being saved and insignificant information is being forgotten [[23]-[25]]. LSTM has been widely used for sequence and time series data classification and prediction. Fig. 2.3 depicts the architecture of LSTM used in this study.

As shown in Fig. 2.3, the proposed LSTM will process the embedding vector of each word which has been generated by FastText. Apparently, the dimension of such a vector is 100. After that, an LSTM layer with a dimension of 32 will be utilized with a dropout in order to prevent overfitting. Consequentially, a dense layer or so-called a fully connected layer with a dimension of 64 will be utilized. Lastly, the output layer will be supplemented with a Softmax in order to articulate the biomedical class label of the word.

3. Results and discussion. Prior to show the experimental results, it is necessary to consider the experiment settings of both the FastText model and the LSTM architecture. Following subsections show the experiment settings and experiment results.

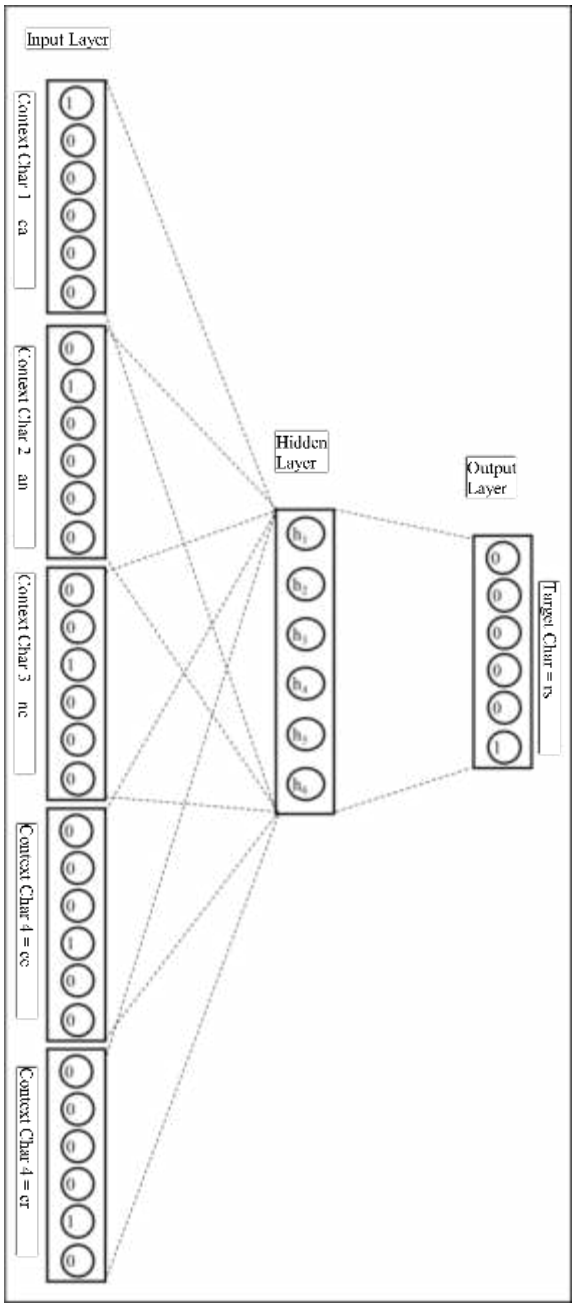

Fig. 2.2: Simple architecture of FastText.

3.1. Experiment Setting. Table 3.1 shows the hyperparameters of FastText model. Whereas Table 3.2 shows the hyperparameters of LSTM architecture.

3.2. Experiment Results. The results will be examined based on the three metrics of precision, recall and f-measure. Table 3.3 shows the results of applying FastText and LSTM for both datasets.

As shown in Table 3.3, the proposed method had the ability to identify BNEs within the NCBI dataset with a precision of 0.923, a recall of 0.901, and an f-measure of 0.911. Similarly, for the BioCreative-II dataset,

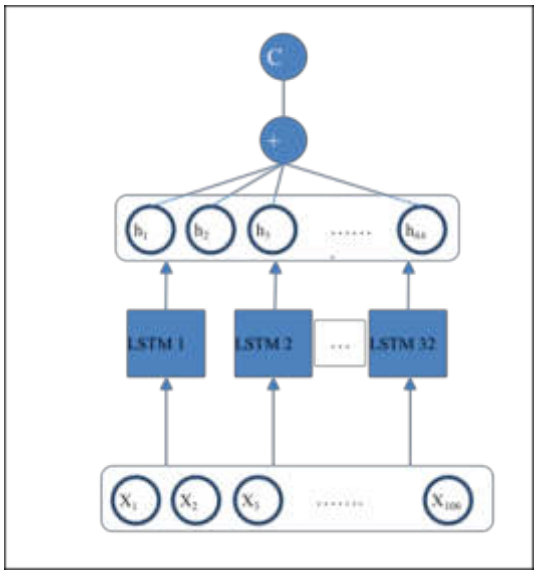

Fig. 2.3: LSTM architecture.

Table 3.1: Hyperparameter of FastText model

Hyperparameter	Description
Dimension	100
Window size	5
Number of epochs	10
Architecture	Skip-gram

Table 3.2: Hyperparameter of LSTM architecture

Hyperparameter	Description
Batch size	64
LSTM layer	32
Dropout	0.25
Dense layer	64
Number of epochs	100
Optimizer	Adam

Table 3.3: Results of BNER using FastText and LSTM

Dataset	Precision	Recall	F-measure
NCBI	0.92301	0.90105	0.91189
BioCreative-II	0.91929	0.90677	0.91298

the proposed method achieved 0.919, 0.906 and 0.912 for precision, recall and f-measure respectively.

3.3. Discussion. As depicted earlier, the proposed method has outperformed both studies of Gridach [14] and Li and Jiang [15] who used LSTM with Word2Vec upon the BioCreative-II dataset and obtained an f-measure of 0.894. On the other hand, the proposed method has superior performance of f-measure compared to

the study of Zhu et al. [16] who used CNN with Word2Vec on BioCreative-II and NCBI datasets and obtained 0.872 of f-measure respectively. Additionally, the study of Cho and Lee [17] who used LSTM and Glove for both BioCreative-II and NCBI datasets and achieved an f-measure of 0.814 and 0.856 respectively is still having lower performance compared to the proposed method. Lastly, the study of Zhang and Wu [18] who used LSTM with Word2Vec for BioCreative-II dataset and obtained 0.899 is still having lower f-measure compared to the proposed method. Generally, the proposed FastText embedding has contributed toward enhancing the recognition of BNEs. This is due to the character-level treatment that has reduce the OOV problem.

4. Conclusion. This paper has presented a character-level embedding approach using FastText. The embedding has utilized the N-gram character permutations in order to give a distinctive embedding vector for each combination. These vectors have processed through LSTM to classify the words into its biomedical classes. Experimental results demonstrated for the proposed method over the state-of-the-artin terms of f-measure using two well-known datasets. For future directions, utilizing a pretrained FastText embedding model might contribute toward enhancing the classification performance.

CONSTRUCTION OF CROSS ENERGY TYPE DATA MODEL BASED ON SPATIOTEMPORAL DATA MINING

BO PENG *, YAODONG LI†, XIANFU GONG‡, GANYANG JIAN §, AND GUO LI¶

Abstract. In order to ensure the accuracy of oilfield development dynamic data, the author starts from analyzing the characteristics of development dynamic data, and conducts in-depth research on the characteristics of development dynamic data, the algorithm set for accuracy detection of development dynamic data, and comprehensive analysis methods. Firstly, in response to the spatiotemporal heterogeneity in developing dynamic data, combined with the design concept of a multi detector combination algorithm based on spatiotemporal mixed patterns, the accuracy detection algorithm is evaluated and selected. Based on this, the author proposes a development dynamic data accuracy detection method that considers the influence of multiple factors (FAGTN); Secondly, ARIMA, MGLN, STGCN, and FAGTN algorithms were selected as the algorithm sets for developing dynamic data accuracy detection, in order to complete the data accuracy detection based on monthly oil well data as the research object; Then, a combined weighting based analysis method was proposed to comprehensively analyze the accuracy detection results of dynamic data development, and the results showed: The dynamic data accuracy detection method based on ARIMA has the worst performance, with detection accuracy below 70% in different detection attributes, which is relatively not high enough; The development of dynamic data accuracy detection method based on MGLN achieved an accuracy rate of 80.53% when detecting sleeve pressure, but the accuracy rate did not reach 80% when detecting oil pressure, dynamic liquid level, monthly oil and water production, and the detection effect was relatively unstable; The accuracy of developing dynamic data accuracy detection methods based on STGCN fluctuates around 80%; Realize comprehensive evaluation of detection results; Finally, the experiment and evaluation of the comprehensive detection method for developing dynamic data accuracy were completed using real sample data.

Key words: Spatiotemporal data mining, Cross energy types, Data model construction, Accuracy testing

1. Introduction. In the process of exploration and development, accuracy testing of the dynamic data of oilfield development that has undergone preliminary inspection is an important prerequisite for formulating oilfield development plans, in order to efficiently identify abnormal data [1]. In order to ensure the accuracy of dynamic data in oilfield development, researchers have become enthusiastic about researching methods for detecting the accuracy of dynamic data in development. At present, oilfield workers detect anomalies in dynamic oilfield development data by referring to historical data changes, making judgments based on manual experience, or using machine learning techniques. Due to the reliance on manual experience and lack of dynamism, this detection method has low detection efficiency and accuracy. The specific manifestation is that the professional knowledge and sensitivity to data of oilfield field workers vary, and the basic values for dividing the range of abnormal data based on expert knowledge are not precise enough, this will result in lower detection accuracy, and manual detection can only detect simple data filling errors and data format errors, while the detection ability for data with abnormal values is relatively weak. Therefore, relying on manual experience and expert knowledge to detect data accuracy has great limitations. Existing accuracy detection methods have not solved the applicability problem, and their intelligence is relatively weak when processing data with prominent spatiotemporal heterogeneity. At the same time, due to the influence of factors such as irregular spatial distribution of wells, complex connectivity between wells, well construction problems, changes in injection well indicators, and types of ternary composite flooding in the actual production process of developing dynamic data, existing accuracy detection methods lack applicability and dynamism, and there

may be misjudgments, which will further affect oilfield decision-making. With the update and development of modern technology, data with spatiotemporal characteristics has gradually become a typical data type in the era of big data. Compared to non spatiotemporal data, spatiotemporal data has more complex data dimensions, which leads to an increase in the workload required to process spatiotemporal data. Spatiotemporal data mining is the process of extracting intrinsic, uncertain, and interfering knowledge with important information from a dataset with spatiotemporal characteristics. Its purpose is to explore the spatiotemporal patterns, features, and laws that users are interested in. Currently, domestic and foreign scholars are enthusiastic about researching spatiotemporal data mining techniques and have achieved numerous research results in multiple fields such as data mining and deep learning. In addition, spatiotemporal data mining technology has also been widely applied in fields such as mobile e-commerce, digital urban management maps, air quality prediction, crime detection, traffic management, risk prediction, public health and medical health, human movement trajectory prediction, and oil and gas development.

Data accuracy detection is a branch of data quality detection, and as an important indicator of data quality evaluation, research on it is becoming more and more in-depth with the development of data quality evaluation. Early research on data accuracy detection mainly focused on building a data quality framework and completing data quality detection from multiple dimensions. The data quality framework designed based on this approach can effectively solve the conventional measurement problem of data accuracy, but the definition of data accuracy evaluation indicators is slightly weak. After a period of development, scholars have begun to establish a data accuracy evaluation index system from the perspectives of differential analysis of data accuracy measurement, data lifecycle, and data completion.

Based on the literature on the accuracy detection of dynamic data in oilfield development both domestically and internationally, this study focuses on two main topics: Data spatiotemporal feature mining and accuracy detection research. Currently, many scholars have conducted extensive research on spatiotemporal data mining, data spatiotemporal feature extraction, and accuracy detection, through a comprehensive analysis of the current research status on accuracy detection of dynamic data in oilfield development at home and abroad, the following conclusion can be drawn: Currently, there are few accuracy detection methods for oilfield data with spatiotemporal heterogeneity, which not only have simple rules and low detection accuracy, but also lack intelligence. The existing accuracy detection methods for oilfield data mostly rely on expert experience and obtain abnormal data detection results through knowledge base inference. This method ignores the spatiotemporal heterogeneity of the data, resulting in a lack of rationality and scientificity in the detection results [2]. Therefore, this study investigates the spatiotemporal characteristics of dynamic data in oilfield development, which helps to explore the spatiotemporal correlation between data and improve the efficiency of data accuracy detection.

The spatiotemporal data mining technology, with its excellent spatiotemporal feature extraction method and comprehensive spatiotemporal feature analysis process, can replace manual problem-solving in some aspects. Domestic and foreign scholars have achieved fruitful results in using spatiotemporal data mining techniques to solve anomaly detection problems. At present, some people have applied spatiotemporal data mining to reservoir data processing and proposed a knowledge discovery framework, but there is a lack of analysis in the spatiotemporal characteristics of the data. Therefore, based on spatiotemporal data mining techniques, the author constructs a spatiotemporal data analysis model to achieve accuracy detection of data. Through research, it has been found that designing an accuracy detection method for dynamic data in oilfield development based on spatiotemporal data mining has high effectiveness and application value [3,4].

2. Methods.

2.1. Analysis and selection of accuracy testing methods. In a spatiotemporal heterogeneous environment, there may be significant differences in the changes of various indicators for developing dynamic data. Therefore, using only one accuracy detection method to obtain detection results has significant limitations. It is necessary to fully consider multiple aspects and select multiple algorithms for comparative evaluation in order to obtain more reasonable accuracy detection results. By analyzing and summarizing the characteristics of developing dynamic data, a suitable set of accuracy detection algorithms for developing dynamic data is selected.

(1) Data characteristics. By analyzing the storage structure and spatial distribution of dynamic data, it is concluded that the development of dynamic data has the following characteristics:

The spatiotemporal heterogeneity is prominent. Developing dynamic data changes over time and space. In terms of space, the spatial position of each well is independent, and data indicators such as oil pressure and casing pressure have dynamic differences with changes in the spatial position of the well. In terms of time, the development of dynamic data has significant temporal characteristics. Taking monthly data of oil production wells as an example, there may be significant differences between data from different months.

Dynamic changes in spatiotemporal correlations. The difference in spatial location of wells leads to different spatial correlations between wells, specifically manifested as: The spatial correlation between connected wells is greater than that between adjacent wells, and the spatial correlation between adjacent wells is greater than that of the remaining wells. At the same time, the correlation between adjacent or similar data at time points is greater than that between data with longer distance from time points. That is, the closer two time periods are, the more significant the corresponding data correlation is. Conversely, the less significant the correlation is.

Multiple factors have a significant impact. The output environment for developing dynamic data is complex, and the data is easily influenced by various external factors. For example, indicators related to injection wells, types of ternary composite flooding, well construction issues, and equipment conditions can all have uncertain impacts on the output of development dynamic data [5].

(2) Selection ideas for accuracy detection methods. Selection idea: Developing accuracy detection for dynamic data requires addressing both temporal and spatial processing issues, and using only one intelligent detection method may result in biased results. The core idea for selecting and developing dynamic data accuracy detection methods is to break down the target problem into multiple sub problems and adopt the most appropriate intelligent detection technology to solve different problems by drawing on the idea of "divide and conquer, complement each other's advantages". The basic idea of divide and conquer is to decompose complex problems into relatively independent and easily solvable subproblems, until solutions to all subproblems are obtained, and then merge them into the original solution to the problem. For the accuracy detection problem of developing dynamic data, the process is phased and each stage is relatively independent, so a divide and conquer approach can be adopted to solve it. The complementary advantages are reflected in the selection of detection algorithms, which focus on analyzing the problem-solving ability of different detection methods, evaluating their advantages and disadvantages, using advantages to compensate for disadvantages, and integrating multiple technologies and methods to obtain the best solution to the problem. The selection process is shown in Figure 2.1.

Based on the idea of "divide and conquer, complement each other's advantages", consider from both spatial and temporal dimensions. Graph Convolutional Neural Networks (GCNs) are gradually gaining recognition in dealing with spatial structures based on graph models. In the processing of temporal data, Time Convolutional Networks (TCN), Convolutional Neural Networks (CNN), Recurrent Neural Networks (LSTM), and others are all popular methods. Multi detector combination based on spatiotemporal hybrid mode: The spatiotemporal hybrid mode is a hybrid mode framework that comprehensively considers business needs and satisfies the mining of spatiotemporal heterogeneous data patterns [6]. The spatiotemporal mixed pattern is divided into two parts: temporal pattern and spatial pattern, which represent different stages of pattern mining. It adds labels in the temporal and spatial dimensions, mainly explaining the changes of data objects in time and space. This classification method is not only applicable to the detection of dynamic data in oilfield development, but also to the quality inspection of other data. The difference lies in the differences in the quality inspection field and the difficulty of the business, as well as the different focuses and tendencies. A large number of examples and research results indicate that using "pattern analysis, individual detection, and merge analysis" for data detection in mixed mode is a good solution. Specific implementation methods include multi detector combination mode, tree pruning mode, etc. The detection mode that uses multiple detectors and scientifically combines them according to their respective applicable ranges is called the COMD combination mode (Combination of Multiple Detection). In the design of dynamic data accuracy detection methods, the COMD combination pattern is based on the expectation that "group capability is greater than member capability", and combines multiple detectors to form a comprehensive detection method to obtain the final detection results.

According to the data characteristics of developing dynamic data and the design concept of data accuracy

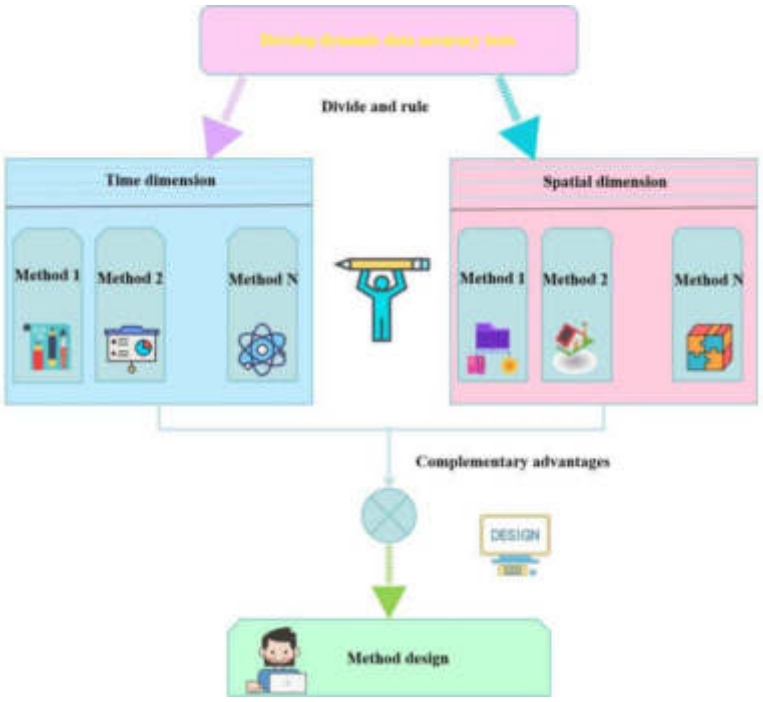

Fig. 2.1: Design ideas for developing dynamic data accuracy detection methods

detection methods, the spatiotemporal pattern mining process of developing dynamic data mainly includes two stages: Spatial feature mining based on well position coordinates and temporal feature mining based on monthly oil well data. Therefore, when testing the accuracy of dynamic data in development, different detection methods are used for different dimensions of data, and the detection results are ultimately combined for analysis.

(3) Development of Dynamic Data Accuracy Detection Algorithm Selection. After weighing various factors in the selection of accuracy detection algorithms for developing dynamic data, the author chose ARIMA, MGLN, and STGCN as the accuracy detection algorithms for developing dynamic data. In order to highlight the spatiotemporal heterogeneity of dynamic data development, the author selected the Autoregressive Mean Moving Model (ARIMA), which is mainly used for anomaly detection in time series data, as a single detection reference to compare with other methods that consider spatial factors. The reasons for selecting all methods are as follows:

The ARIMA model uses existing stable time series data to predict future values, that is, in order to obtain future data from existing stable time series data and complete data anomaly detection. The data form targeted by the model is similar to the indicator changes of development dynamic data, so the ARIMA model effectively utilizes the differences between development dynamic data of different time series lengths for detection [7].

The MGLN algorithm is based on the detection principle of mining the spatiotemporal correlation of data, extracting and analyzing features from both spatial and temporal dimensions. The spatial characteristics of developing dynamic data are reflected in the global or local correlation of data related indicators with changes in well spatial positions, and their temporal characteristics are reflected in the temporal nature of the data. The relationship between values in different time periods is complex. Therefore, the MGLN algorithm effectively utilizes the spatiotemporal heterogeneity of dynamic data development and has certain advantages in processing long time series data.

The implementation approach of the STGCN algorithm is similar to that of the MGLN algorithm, both analyzing from the dimensions of time and space. The difference lies in the different methods used by the algorithm to analyze the temporal features of the data. Therefore, the STGCN algorithm can also effectively

Table 2.1: Schematic diagram of well groups affected by water injection in some wells

...	...
G34-335	G23-S335,G23-S34,G24-S33,G24-S335

explore the spatiotemporal variation patterns of dynamic data in development, thereby completing accuracy detection tasks.

2.2. Improved Multi factor Development Dynamic Data Accuracy Detection Method.

(1) The overall design of the FAGTN method. This section introduces the overall structure of the Development Dynamic Data Accuracy Detection Method (FAGTN) based on GCN and TCN. Continuing from the data preprocessing methods in Chapter 3, the FAGTN method consists of two main parts: Data modeling and preprocessing, and method design and experimentation. In the data modeling and preprocessing section, unlike Chapter 2, this method requires processing of data related to injection well indicators, well construction issues, and types of ternary composite flooding to generate an external influencing factor matrix; In the network construction and experimental part, a dynamic data accuracy detection network model is constructed based on GCN and TCN. GCN is used for spatial feature mining of dynamic data, while TCN is used to discover the temporal correlation between dynamic data.

(2) Analysis of Factors Influencing the Development of Dynamic Data. The accuracy detection of dynamic data development is not only related to the spatiotemporal heterogeneity of the data itself, but also influenced by various external factors, such as inter well connectivity, injection well related indicators, ternary composite flooding types, well construction problems, etc. In the data preprocessing stage of this study, the inter well connectivity was transformed into a weight matrix through weight calculation, thereby enhancing the saliency of data space feature extraction. Therefore, this section analyzes and explains the impact of external factors from three aspects: injection well related indicators, well construction issues, and ternary composite flooding types.

Analysis of external influencing factors: injection well related indicators. Oilfield water injection plays a crucial role in the entire reservoir development process. Reasonable water injection can not only effectively maintain formation energy, but also improve the efficiency of oilfield development. In the actual process of oilfield water injection research, water injection utilization rate, water injection volume, water injection intensity, water drive index, underground deficit and other water injection related indicators are usually analyzed to evaluate the effectiveness of water injection development. The author uses injection well related indicators as external influencing factors for accuracy detection of development dynamic data, so only monthly injection water volume is selected as the representative influencing parameter of injection wells. Monthly water injection refers to the cumulative amount of water injected into the formation within each month, which can be expressed in cubic meters. It is an important indicator to characterize the water injection status of an oilfield. This study divides the range of water injection influence into well groups by analyzing the connectivity between oil wells and water wells. Table 2.1 shows a schematic diagram of the water injection impact range of some wells in the well group. (Note: The well numbers and other data in the following table have been processed accordingly).

There is a certain correlation between the changes in dynamic data of oilfield development and the monthly water injection volume of adjacent injection wells, and the correlation between the two is uncertain. This study is based on the grey correlation theory. By analyzing the correlation between the monthly water injection volume of injection wells and the monthly data of oil production wells, the impact coefficient of monthly water injection volume on the monthly data of oil production wells is calculated, and a reasonable evaluation of the impact of monthly water injection volume on development dynamic data is achieved. The grey correlation method analyzes whether the time-varying trends (such as direction, speed, and magnitude of changes) between data have similarities, in order to better explore the degree of correlation between each data. For example, for an injection well, there is a high similarity between the changes in the time series of the injection water volume

Table 2.2: Example of G34-32 Well Cluster Dataset

Well No.	Monthly water injection volume of injection well (m3)	Monthly water production of oil wells (m^3)			
time	G34-32	G23-32	G23-S325	G24-S315	G24-S32
T:l	1144	427	209	815	915
T:2	1190	329	393	543	879
T:3	1327	351	300	523	1024

T:12	1354	360	452	350	1175

Table 2.3: Calculation results of the correlation degree between injection wells and production wells

Water injection well	Production well	correlation
G34-32	G23-32	0.56
	G23-S325	0.701
	G24-S315	0.623
	G24-S32	0.905

and the monthly data time changes of a certain oil production well. The higher the coefficient of influence between the two, the greater the impact of the monthly output data of the oil production well on the injection well's monthly injection water volume, and vice versa. The specific calculation steps are as follows.

Step 1: Data preparation: As shown in Table 2.2, a dataset example of dynamic production data for G34-32 well group in a continuous time series is provided;

Step 2: Use the monthly injection water volume of the injection well as the parent sequence, and the monthly production water volume of the other wells as the subsequence;

Step 3: Use grey correlation analysis to calculate the correlation between this injection well and other production wells;

Step 4: Repeat Step 3 by sequentially taking the other parameters (oil pressure, casing pressure, dynamic liquid level, monthly oil production) of the remaining production wells in this group as subsequences;

Step 5: Calculate the mean correlation between this injection well and other wells. The larger the mean, the higher the correlation between the well and surrounding wells. According to the value of the influence coefficient, the correlation degree is divided into three levels: strong correlation (0.8-1.0), strong correlation (0.6-0.8), and weak correlation (0-0.6).

According to Table 2.2, the correlation degree between the injection wells and production wells in the well group is calculated as shown in Table 2.3.

The greater the correlation between water injection wells and oil production wells, the greater the impact of the monthly water injection volume of water injection wells on the monthly data of oil production wells. According to the calculation results shown in Table 3, G24-S32 is strongly correlated with G34-32 water injection wells, G23-S325, G24-S315 are relatively correlated with G34-32 water injection wells, and G23-32 is weakly correlated with G34-32 water injection wells.

The ternary composite oil recovery technology is an important means to further improve oil recovery in the later stage of high water cut oilfield. It can be divided into strong alkaline ternary composite flooding and weak alkaline ternary composite flooding according to the type of injected alkali. The use of different

types of ternary composite flooding will also have different effects on the monthly data of oil production wells. Compared with water flooding and polymer flooding, the cost of strong alkaline ternary composite flooding is higher, and scaling is also more severe; The scaling phenomenon of weak alkaline ternary composite flooding is slightly better than that of strong alkaline ternary composite flooding, mainly manifested in delayed scaling time and fewer scaling wells. However, the configuration process of weak alkaline ternary composite flooding is relatively complicated, and the quality of the configuration cannot be guaranteed. In the on-site application of ternary composite flooding, the staff matched the advantageous wells with the advantageous oil displacement technology, fully amplifying the advantages of the oil displacement technology and greatly improving the mining efficiency.

Construction of external influencing factor characteristic matrix. The author mainly considers three factors: injection well related indicators, well construction problems, and ternary composite flooding types. The monthly water injection volume is selected as the main influencing factor for the injection well related indicators, and a 3-digit independent heat vector is used for encoding, corresponding to three levels of correlation between oil and water wells. The first digit is 1, indicating a strong correlation between oil and water wells, the second digit is 1, indicating a strong correlation between oil and water wells, while the third digit is 1, indicating a weak correlation between oil and water wells. The well construction situation is encoded using a 3-digit independent heat vector, which represents three situations: well construction in the current month, no well construction in the current month, and well construction in the past three months; The type of ternary composite flooding is also encoded using a 3-digit unique heat vector, representing the use of strong alkaline ternary composite flooding, weak alkaline ternary composite flooding, and no ternary composite flooding, respectively.

(3) The loss function of FAGTN. The ultimate goal of training the FAGTN model is to continuously optimize data accuracy detection methods to adapt to the spatiotemporal heterogeneity of development dynamic data, even if the error between the actual values of various attributes of monthly oil well data and the detection values processed by the model is minimized. The loss function during model training is shown in equation 2.1.

$$Loss = ||X - \hat{X}||_2 + \lambda L_2 \tag{2.1}$$

Among them, $\hat{X}$ represents the actual values of various detection attributes in the monthly data of oil production wells, X represents the detection value of the model, and L_2 represents the regularization term of the model, which is used to avoid overfitting of the model, λ for hyperparameters.

3. Experimental Results and Analysis . This experiment compares multiple detection methods and comprehensively evaluates them to complete the accuracy detection of dynamic data development. The brief description of the experimental design is as follows [8]. Elaborate on experimental preparation work, including introducing the experimental environment, describing experimental data, and listing experimental evaluation indicators. Analyze the performance indicators of the FAGTN model proposed by the author and the other three models under various conditions to demonstrate the advantages of FAGtN in terms of detection speed, model accuracy, and stability in certain scenarios. Comparative analysis of the comprehensive analysis method based on combination weighting and the changes in various indicators of the four models, in order to demonstrate the rationality and credibility of using the comprehensive analysis method to detect the accuracy of development dynamic data.

3.1. Experimental preparation.

(1) Experimental environment. Simulate the subsystem of a data quality inspection system for a certain onshore oilfield. In a real environment, the control center is responsible for the unified intelligent scheduling of resources, the transfer platform is responsible for data detection tasks, the data center is responsible for providing data support, and the detection model is responsible for accuracy detection of data.

(2) Data Description. The dataset selected for this experiment is the development performance dataset of a certain oilfield described in Chapter 3. The dataset contains key attributes of monthly data on oil production wells, as well as basic information about the wells. Specifically, there are oil pressure, casing pressure, dynamic liquid level, monthly oil production, monthly water production, well location information, well connectivity information, and external influencing factors. The target detection oilfield consists of no less than 1700 wells. Provide the well distribution and partial well connectivity of the target oilfield.

The oilfield data is summarized once a month, and the experiment uses data from 2008 to 2018. According to specific experimental requirements, the training set, validation set, and test set are divided. This experiment represents multiple attribute parameters of monthly oil well data as different detection tasks.

(3) Evaluation indicators. When comparing the performance of FAGTN with ARIMA, MGLN, and STGCN models, this experiment uses three evaluation indicators: Root mean square error (RMSE), mean absolute error (MAE), and mean absolute percentage error (MAPE) to evaluate the performance of the four models. The specific calculation formula for indicators is shown below.

$$P_{RMSE} = \sqrt{\frac{1}{\gamma}\sum(\hat{X}_v^{t+1} - X_{v_i}^{t+1})^2} \tag{3.1}$$

$$P_{MSE} = \frac{1}{\gamma}\sum_{i=1}^{\gamma}|\hat{X}_{v_i}^{t+1} - X_{v_i}^{t+1}| \tag{3.2}$$

$$P_{MAPE} = \frac{1}{\gamma}\sum_{i=1}^{\gamma}\frac{|\hat{X}_{v_i}^{t+1} - X_{v_i}^{t+1}|}{X_{v_i}^{t+1}} \tag{3.3}$$

where $X_{v_i}^{t+1}$ and $\hat{X}_{v_i}^{t+1}$ respectively represent the next time point (t+1), the true and reference values of the attributes of well V, where V represents the number of wells. Both RMSE and MAE can reflect the error between the true value and the reference value, and the smaller the value of both, the higher the accuracy of the model. MAPE can reflect the ratio between error and true value.

The accuracy detection of developing dynamic data belongs to the binary classification problem, and the detection results only have two basic situations: accurate and inaccurate. Therefore, in the comprehensive evaluation experiment of the algorithm, the commonly used confusion matrix and its extended evaluation indicators for binary classification problems are selected, such as accuracy, recall, and fl_ Score and other criteria are used as evaluation criteria for the rationality of comprehensive evaluation methods. The abnormal data detected by the model is called a positive sample, and the normal data detected is called a negative sample. TP refers to positive samples that are correctly classified by the model, that is, real data is abnormal data, and the accuracy detection result is abnormal; FN refers to positive samples that have been misclassified by the model, where the true data is abnormal but the accuracy detection result is normal; FP refers to negative samples that have been misclassified by the model, where the true data is normal but the accuracy detection result is abnormal; TN refers to negative samples that are correctly classified by the model, meaning that the real data is normal and the accuracy test result is normal. Precision refers to the proportion of true data in a positive sample to a positive sample in the accuracy detection result. The higher the precision, the better the detection effect of the model. The calculation method is shown in equation 3.4. Recall rate refers to the proportion of correctly classified samples in real data samples, calculated as shown in equation 3.5. Fl score takes into account both accuracy and recall, and is an important criterion for measuring the accuracy of model detection. The calculation method is shown in equation 3.6 [9].

$$P = \frac{TP}{TP + FP} \tag{3.4}$$

$$R = \frac{TP}{TP + FN} \tag{3.5}$$

$$f1\_score = \frac{2 * P * R}{P + R} \tag{3.6}$$

Table 3.1: Comparison of experimental effects

Accuracy detection method	Serial Number	Detecting attributes	Accuracy (%)
ARIMA	1	oil pressure	66.46
	2	casing pressure	67.4
	3	dynamic liquid level	62.62
	4	monthly oil production	62.37
	5	Monthly water production	63.56
MGLN	1	oil pressure	79.38
	2	casing pressure	80.54
	3	dynamic liquid level	76.63
	4	monthly oil production	77.8
	5	Monthly water production	78.22
STGCN	1	oil pressure	75.33
	2	casing pressure	77.16
	3	dynamic liquid level	79. 98
	4	monthly oil production	81.15
	5	Monthly water production	81.12
FAGTN	1	oil pressure	80. 53
	2	casing pressure	79.74
	3	dynamic liquid level	81.76
	4	monthly oil production	79.22
	5	Monthly water production	82.16
A Comprehensive Analysis Method Based on Combination Weighting	1	oil pressure	83.28
	2	casing pressure	82. 47
	3	dynamic liquid level	84.56
	4	monthly oil production	81.29
	5	Monthly water production	83.62

3.2. Algorithm Comprehensive Evaluation Experiment . In order to solve the problems of weak credibility, large deviation, and insufficient support caused by using only one algorithm for dynamic data accuracy detection in development, the author proposes a comprehensive analysis method based on combination weighting. This experiment uses ARIMA for comparative analysis MGLN The results of using STGCN, FAGTN, and comprehensive analysis methods to detect the accuracy of development dynamic data verify that the comprehensive analysis method is more reliable and reasonable in solving the problem of accuracy detection of development dynamic data. The obtained experimental results are shown in Table 3.1.

The results in Table 3.1 indicate that the dynamic data accuracy detection method based on ARIMA has the worst performance, with detection accuracy below 70% in different detection attributes, which is relatively not high enough; The development of dynamic data accuracy detection method based on MGLN achieved an accuracy rate of 80.53% when detecting sleeve pressure, but the accuracy rate did not reach 80% when detecting oil pressure, dynamic liquid level, monthly oil and water production, and the detection effect was relatively unstable; The accuracy of developing dynamic data accuracy detection methods based on STGCN fluctuates around 80%; The accuracy of the dynamic data accuracy detection method based on FAGTN is higher than the previous models, with an accuracy rate of 82.15% when detecting monthly water production; The comprehensive analysis method based on combination weighting has an accuracy rate of over 80% in detecting the accuracy of five attributes, which is generally better than using any other algorithm alone. This indicates that the results of the comprehensive analysis method based on combination weighting have good credibility and applicability. In order to present the accuracy detection results more intuitively, as shown in Figure 3.1, a comprehensive analysis method was used to accurately detect the dynamic liquid level of a certain well over a period of time, and some abnormal points were marked.

According to the analysis rules of combination weighting, while determining outliers, the reference value

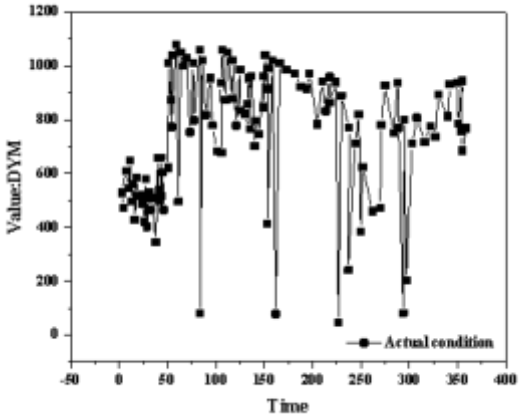

Fig. 3.1: Comprehensive analysis method detection results

Table 3.2: Comparison of reference value ranges

time	model	true value	reference value	confidence interval	Initial judgment	Final judgment	Reference range
44	MGLN	656.8	647.35	[517.88,776.82]	normal	abnormal	[434.72, 652.08]
	STGCN		505.92	[404.74,607.1]	abnormal		
	FAGTN		493.55	[394.84,592.26]	abnormal		
163	MGLN	77.7	85863	[686.9, 1030.35]	abnormal	abnormal	[680.05, 1020.07]
	STGCN		874.71	[699.77,1049.66]	abnormal		
	FAGTN		825.14	[660.11,990.17]	abnormal		

range of the model for determining outliers is also provided. Staff can refer to this range to complete data correction. Taking the data from the 44th and 163rd time points in the experimental area as an example, the reference value range is shown in Table 3.2 [10].

4. Conclusion. The author conducted in-depth research on the development of a comprehensive detection method for dynamic data accuracy, and designed a comprehensive analysis method for the results of dynamic data accuracy detection. Firstly, in response to the spatiotemporal heterogeneity in developing dynamic data, a multi detector combination algorithm selection concept based on spatiotemporal mixed patterns is adopted to complete the evaluation and selection of accuracy detection algorithms; Secondly, considering the various factors affecting the monthly data indicators of oil production wells, an improved accuracy detection method (FAGTN) is proposed by integrating GCN and TCN; Then, design and develop a comprehensive analysis method for the accuracy detection results of dynamic data, and complete the comprehensive evaluation of the accuracy detection results of dynamic data development; Finally, based on real data, experiments were conducted to compare the experimental results, proving the feasibility and effectiveness of this method in actual development of dynamic data accuracy detection.

E-COMMERCE AND MOBILE APPLICATION DEVELOPMENT IN THE SPORTS INDUSTRY

BIAO JIN*

Abstract. In order to achieve user recommendations that best match their current contextual needs, the author proposes a mobile service QoS (Quality of Service) hybrid recommendation model based on sports user situational awareness. Cluster the users and service items covered by mobile users based on their location contextual information according to the classification principle of autonomous systems, forming a collaborative filtering and recommendation mechanism for mobile user service items; In response to the cold start problem of new users and new projects in traditional QoS recommendation methods, prediction and recommendation of missing QoS attribute preference values are based on User based and Item based CF; In response to the problem of difficult determination of mixed recommendation weights caused by massive data and uneven distribution of service QoS attribute values in mobile network environments, MapReduce based ant colony neural network weight training is used for CF mixed recommendation. Experimental results have shown that the Hadoop sports industry has improved the operational efficiency of algorithms and reduced the time for global QoS preference prediction; And by comparing the operation results of the 10% and 100% sub datasets, it can also be seen that the acceleration ratio of the algorithm will continuously improve with the increase of data volume, thereby improving the operational efficiency of the recommendation algorithm. It has been proven that the MapReduce based ant colony neural network weight training method significantly reduces the global computation time of the algorithm and improves the operational efficiency of the recommendation system.

Key words: Sports industry, Situational awareness, QoS, Collaborative filtering and mixed recommendation, Ant colony neural network

1. Introduction. With the rapid development and increasing popularity of new generation information technologies such as the Internet of Things, computing, and mobile terminals, e-commerce, as a new business model, is accelerating its integration with the real economy and has become an important way to allocate resources under the conditions of informatization, networking, and marketization[1]. At the same time, this model has also expanded to the sports industry, deeply integrating with traditional formats, promoting the transformation and upgrading of the sports service industry, and giving birth to emerging formats. Sports e-commerce has not only become a new force in providing sports goods and services, a new driving force for the development of the sports industry, but also created new sports consumption demands, opened up new channels for employment and income growth, and provided new space for mass entrepreneurship and innovation.

According to the 51st Statistical Report on the Development of China's Internet released by the China Internet Network Information Center, as of December 2022, the number of internet users has reached 1.067 billion, and the internet penetration rate has reached 75.6%. In this context, information technology and digital means are gradually penetrating various fields of consumption. As of June 2022, the number of users who use the internet for shopping in China has reached 841 million, accounting for a relatively high proportion of 80% of the total number of netizens. However, in 2013, the number of users who use online shopping in China only accounted for 48.9% of the total number of netizens[2].

The rapid expansion of information in the e-commerce industry has led to a continuous increase in consumer demand for efficient product promotion. Faced with the complex and diverse information resources on e-commerce websites, efficient intelligent data processing technology has become the key to processing information. Traditional engine retrieval cannot provide differentiated results for personalized needs of different users and environments; Intelligent recommendation systems do not require users to describe their needs in detail, but instead explore their interests and preferences through historical data, filter personalized information for users, and provide feedback on the predicted results to users, effectively improving their shopping

experience and merchant sales efficiency. In e-commerce platforms, intelligent recommendation systems play an essential role. Domestic and foreign enterprises and scholars have conducted in-depth research on the intelligent recommendation problem used in e-commerce. Numerous personalized recommendation methods have emerged, which has also led to many application achievements in the recommendation field by Amazon, Ctrip, Alibaba, and others[3]. However, compared with foreign countries, China's research on e-commerce intelligent recommendation technology is still in a follower mode, and the compatibility between new ideas, methods, and technologies and e-commerce is still weak. For example, recommendation strategies are relatively simple, and the selection of recommendation methods does not change with environmental changes. Moreover, most domestic recommendation algorithms are used for customer push, while there is relatively little research on enterprise product and product evaluation recommendation algorithms.

In view of this, based on the integration of user interest and preference collaborative filtering and project scoring collaborative filtering methods, the author further introduces the perception attributes of mobile users and services in QoS location, proposes a sports user context aware mobile service QoS hybrid recommendation model, and integrates the contextual attributes of the autonomous system of mobile users and mobile services to predict missing QoS attribute values. At the same time, in response to the difficulty in determining mixed recommendation weights caused by massive data and uneven distribution of QoS attribute values in mobile network environments, the MapReduce ant colony neural network method is used to learn and train its weights. Finally, the MapReduce weights are inputted to calculate QoS preference attribute values and provide Top-N recommendation results. The QoS hybrid recommendation process for sports user context aware mobile services is shown in Figure 1.1.

2. Construction of QoS preference matrix for sports user context perception. In order to accurately predict the QoS preference attribute values perceived by sports users, this section effectively integrates mobile user location context, user based and item scoring based CF, and maximizes the exploration of user location context, user interests, and item scoring for collaborative filtering and recommendation.

2.1. User and Service Clustering Based on Location Context Perception. From the previous literature review, it can be seen that there is a high correlation between user QoS preferences and perceived geographic location attributes. Therefore, when constructing a QoS preference matrix for sports user context perception, the author clusters the target user, other users, and all services based on location context using an autonomous system AS (network connection combination controlled by one or more network operators) clustering, and based on this, prioritizes recommending relevant services to sports users within the same AS[4].

According to the composition of the Internet system, there are multiple autonomous system ASs in the Internet, each of which is connected to a LAN and the Internet. We can consider it as a small individual network structure unit, which also has a globally unique 16 bit code ASN, called the Autonomous System Number. In mobile networks, after a mobile node connects to a foreign link, it automatically configures and obtains the corresponding handover address through IPv6, thereby achieving "binding" between the mobile node and the handover address, and maintaining the association with the handover address through "binding confirmation".

For example, Apple Maps has reached a cooperation agreement with Planet Labs, a remote sensing satellite data company, to obtain global remote sensing satellite data support services through Planet Labs, achieving the "binding" of mobile nodes and forwarding addresses for Apple phone users, thereby providing location data update services for Apple phone users. When clustering users and services based on location-based situational awareness, the author divides mobile commerce users into decimal representations based on their mobile IPs, thus dividing them into different ASs. The specific method for converting the mobile IP addresses of mobile commerce users and services into decimal digits is shown in equation 2.1:

$$IP(A,B,C,D) = ((A \times 256 + B) \times 256 + C) \times 256 + D \tag{2.1}$$

By using the above equation, the decimal form of IP addresses for mobile commerce users and services can be obtained, and the corresponding AS self-made system can be identified by mapping the decimal IP addresses. Currently, mobile networks provide relevant AS measurement services, which can achieve mapping from decimal IP to AS.

2.2. User based QoS preference prediction. Assuming that the mobile user is u, CF recommendation is carried out based on the recommendation idea of User based CF, in order to predict the QoS attribute value of potential service p for the target user u.

Step 1: Convert the IP address of mobile user u to decimal representation according to equation 2.1, and find its corresponding AS through IP address mapping.

Step 2: Calculate the similarity between target user u and mobile user v using Pearson similarity formula 2.2, denoted as Sim (u, v), where Sim $(u, v) \in [-1, 1]$. Among them, the set of services that are jointly rated by the two is represented by p, and $r_{u,p}$ represents the QoS attribute value of user u calling service vp. The larger the predicted Sim (u, v) attribute value, the more similar the user u and v are.

$$Sim(u,v) = \frac{\sum_{p \in I(u) \cap I(v)} (r_{u,p} - \overline{r_u})(r_{v,p} - \overline{r_v})}{\sqrt{\sum_{p \in I(u) \cap I(v)} (r_{u,p} - \overline{r_u})^2} \sqrt{\sum_{p \in I(u) \cap I(v)} (r_{v,p} - \overline{r_v})^2}} \tag{2.2}$$

Step 3: According to Step 1, obtain Sim (u, v). When the number of users similar to the target user u in the same AS is greater than top-N, the operation enters Step 5.

Step 4: In the calculation process, if the user has called service p before, the predicted value can select the given by all previous users to service p[5].

Step 5: Predict the missing QoS attribute values according to formula 2.3.

$$P(r_{u,p}) = \overline{r_u} + \frac{\sum_{v \in Sim(u)} Sim(u,v) \times (r_{v,p} - \overline{r_v})}{\sum_{v \in Sim(u)} Sim(u,v)} \tag{2.3}$$

In the above equation, the $\overline{QoS}$ attribute value of u calling different services is denoted as $\overline{r_u}$,v, and the corresponding calling attribute value is denoted as $\overline{r_v}$. The predicted missing value is denoted as $P(r_{u,p})$.

2.3. Item based QoS preference prediction. The QoS preference calculation for mobile service projects in this section is based on the collaborative filtering idea based on projects for recommendation, in order to predict the QoS attribute values of potential service p for target user u. The method of calculating QoS preferences for mobile service projects is very similar to that of calculating QoS preferences for users. The difference is mainly reflected in the different objects for similarity calculation between the two, one is user similarity, and the other is project similarity. The specific calculation method includes the following steps:

Step 1: Convert the IP address of mobile service p to decimal representation according to equation 2.1, and find its corresponding AS through P address mapping.

Step 2: According to formula 2.4, calculate the similarity between service items similar to mobile service p, and its similarity is denoted as Sim(p,q),Sim(p,q)∈[-1,1]. Among them, the $\overline{QoS}$ called by different users for service item p is denoted as $\overline{r_p}$, the $\overline{r_q}$ called by service item q, and the set of users called by both

service items p and q is denoted as u. The larger the predicted Sim(p,q) attribute value, the more similar the service items p and q.

$$Sim(p,q) = \frac{\sum_{u \in U(p) \cap U(q)} (r_{u,p} - \overline{r_p})(r_{u,p} - \overline{r_q})}{\sqrt{\sum_{u \in U(p) \cap U(q)} (r_{u,p} - \overline{r_p})^2} \sqrt{\sum_{u \in U(p) \cap U(q)} (r_{u,q} - \overline{r_q})^2}} \tag{2.4}$$

Step 3: Based on Step 2, obtain Sim (p,q). When the number of service items similar to the target service p is greater than top-N, the operation enters Step 5.

Step 4: During the calculation process, if a service item has been called before, the predicted value can be selected from the $\overline{QoS}$ given by all previous users to the service item.

Step 5: Predict the missing QoS attribute values according to formula 2.4, and the predicted missing values are denoted as $P(r_{u,q})$.

$$P(r_{u,q}) = \overline{r_p} + \frac{\sum_{q \in Sim(p)} Sim(p,q) \times (r_{u,q} - \overline{r_q})}{\sum_{q \in Sim(p)} Sim(p,q)} \tag{2.5}$$

2.4. Construction of QoS preference matrix. In order to integrate mobile users' QoS preferences and mobile service items' QoS preferences to a greater extent, the author combines similarity weights to carry out collaborative filtering recommendations, that is, calculate the QoS attribute values of users who call common services in the same AS system, thus measuring the similarity between these users and service items, and finally giving recommendations.

Step 1: Improve the user based QoS preference similarity calculation method based on the similarity weight calculation method.

$$Sim'(u,v) = \frac{2 \times |I_u \cap I_v|}{|I_u| \cap |I_v|} Sim(u,v) \tag{2.6}$$

Among them, the number of services called by target user u is denoted as $|I_u|$, the number of services called by user v is denoted as $|I_v|$, and the number of services jointly called by u and v is denoted as $|I_u \cap I_v|$.

Step 2: Improve the project-based QoS preference similarity calculation method based on the similarity weight calculation method.

$$Sim'(p,q) = \frac{2 \times |U_p \cap U_q|}{|U_p| \cap |U_q|} Sim(p,q) \tag{2.7}$$

Among them, the number of users calling service p is recorded as U_p, the number of users calling service q is recorded as U_q, and the number of users calling p and q is recorded as $|U_p \cap U_q|$. The range of values for $Sim'(u,v)$ and $Sim'(p,q)$ obtained from formulas 2.6 and 2.7 is [-1,1].

Step 3: Calculate the missing QoS value according to equations 2.8 and 2.9. Among them, the missing value predicted based on user collaborative filtering is denoted as $(r_{u,q})_{user}$, and the missing value predicted based on project collaborative filtering is denoted as $P(r_{u,q})_{item}$. The calculation method for missing value $P(r_{u,q})_{user}$ is shown in 2.6, and the calculation method for missing value $P(r_{u,q})_{item}$ is shown in 2.7.

$$P(r_{u,q})_{user} = \overline{r_u} + \frac{\sum_{v \in Sim'(u)} Sim'(u,v) \times (r_{v,q} - \overline{r_v})}{\sum_{v \in Sim'(u)} Sim'(p,q)} \tag{2.8}$$

$$P(r_{u,q})_{item} = \overline{r_p} + \frac{\sum_{q \in Sim'(p)} Sim'(p,q) \times (r_{v,q} - \overline{r_q})}{\sum_{q \in Sim'(p)} Sim'(p,q)} \tag{2.9}$$

According to equation 2.10, the calculated $P(r_{u,p})_{user}$ and $P(r_{u,p})_{item}$ will form a collaborative filtering matrix P. Among them, $P(r_{u_m,p_n})_{user} \neq 0 \wedge P(r_{u_m,p_n}) \neq 0$.

$$P = \begin{bmatrix} P(r_{u,p})_{user} \\ P(r_{u,p})_{item} \end{bmatrix} = \begin{bmatrix} P(r_{u_1,p_1})_{user} & \cdots & P(r_{u_m,p_n})_{user} \\ P(r_{u_1,p_1})_{item} & \cdots & P(r_{u_m,p_n})_{item} \end{bmatrix} \tag{2.10}$$

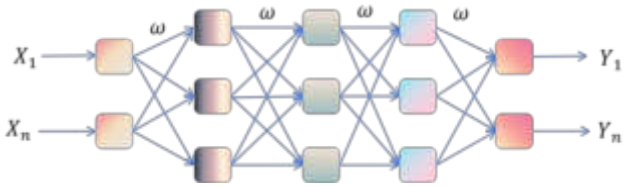

Fig. 3.1: Structural design of the ant colony neural network

3. Ant colony neural network hybrid recommendation for mobile service QoS preference prediction. The mixed recommendation method based on user location context, User based and Item based, can theoretically improve the accuracy of QoS prediction. However, how to discover the optimal weights of user based and Item based collaborative filtering methods in dynamic network environments and complete recommendations has become another key issue that needs to be addressed in research[6]. This section introduces the MapReduce based ant colony neural network method in the recommendation process to train the weights of two different CF methods for mixed recommendation, and ultimately recommend the top N items with better predictive attribute values to users.

3.1. Ant Colony Neural Network Weight Training Model . BP neural network is a data prediction method with strong convergence, which can be used to solve the optimal weight determination problem of User based and Item based mixed recommendations. The disadvantage of BP neural networks is that they face the problem of gradient descent, which means that when there are training errors with multiple peaks on the surface, it is easy to encounter the problem of local optimal training. Ant colony algorithm (ACO) has strong advantages in global optimization [7]. If it can be combined with BP neural network, it can overcome the local optimization problem during neural network training, and effectively solve the problem of long time consumption and low accuracy of a single training network. In view of this, the author proposes a hybrid recommendation weight training method based on ant colony neural networks.

3.2. Establishment of weight training model. The network structure of combining BP neural network and ant colony algorithm is shown in Figure 3.1, which consists of l layers and m nodes. In the figure is the weight, (x_k, y_k) is the M samples included in the structure (k=1, 2,..., m), and O_i is the output of node i after training, The input of the jth unit in the l-th layer of the neural network structure can be represented as $net^l_{jk} = \sum_j \omega^{i-1}_{jk}$, the output as $O^l_{jk} = f(net^l_{jk})$, and f(x) is a unipolar sigmoid function, $f(x) = \frac{1}{1+e^{-x}}$.

3.2.1. Model Establishment. The author's ant colony neural network weight training model first uses the ant colony ACO optimization algorithm for global optimization, providing a better initial weight combination for the BP neural network, which helps to solve the problem of traditional BP neural network operations easily falling into local optimal calculations; Secondly, based on the gradient descent principle of BP neural network, further training and testing were conducted on the weights of two different algorithms, user based and Item based, to ultimately provide the globally optimal weight combination strategy[8].

Before using the ACO optimization algorithm, the weight domain of the algorithm is delineated to obtain several weight sub regions, and the points at the boundaries of these regions form the candidate weights for each region. The number of pheromones at each point is the same at the initial time of t_0 in the ACO algorithm, and the specific pheromone values corresponding to each weight are shown in Table 3.1. Among them, a_i is the division scale value, τ_1 is the pheromone value corresponding to the i scale value ant. Ants pass through each combination of sub regions corresponding to the weights to obtain the weights that need to be trained through ant colony neural networks. After learning through neural networks, they can obtain error values that can provide a basis for updating ant pheromones.

Step 1: ACO initialization process. Firstly, evenly divide the weight interval $[\omega_{min}, \omega_{max}]$, and then establish corresponding pheromone tables for each parameter (see Table 3.1 for the method), set the initial value of pheromones to τ_0, set the volatility coefficient to σ , the intensity of pheromone increment is set to Q, and the maximum number of iterations for ACO is set to N_{AOC}, the learning rate and maximum

Table 3.1: The pheromone tables corresponding to the weights ω_i

	1	2	$\cdots$	M
Dividing scales	a_1	a_2	$\cdots$	a_m
Pheromone value	$\tau(t)$	$\tau(t)$	$\cdots$	$\tau(m)$

number of iterations of the neural network are η training error obtained from N_{BP} is E_0, and the number of optimal solutions is set to σ.

Step 2: Start the ant colony and release h ants. The probability of ant k transitioning from one path to another is $P_k = \frac{\tau(i)}{\sum_{1 \leqslant j \leqslant m} \tau(i)}$. Record all the paths traveled by h ants in tabuk, obtain the initial weight parameters, and use them as the initial parameters for training the neural network. After training, obtain the corresponding output and training error E.

Step 3: Compare the size of the minimum error E_{max} and E_0 after all training. If $E_{min}<E_0$, proceed to Step 7; otherwise, proceed to Step 4.

Step 4: Update pheromones according to equations 3.1 and 3.2 τ:

$$\tau(t+1) = \rho \cdot \tau(t) + \Delta\tau(t) \tag{3.1}$$

$$\Delta\tau(t) \begin{cases} \frac{Q}{E} & j \in \text{best solution} \\ 0 & otherwise \end{cases} \tag{3.2}$$

Step 5: Repeat steps 2 and 3 until the maximum number of iterations is met, then proceed to Step 6.

Step 6: Input the best weight obtained from ACO into the BP neural network and calculate the error $E_k = \frac{1}{2}\sum_j (y_{ik} - \overline{y_{ik}})^2$. Among them, $\overline{y_{ik}}$ represents the actual output value of unit j, and based on this, the total error $E = \frac{1}{2N}\sum_{k=1}^{N} E_k$ of ant colony neural network training is obtained.

Step 7: Weight test. If the error meets the operational requirements, the operation ends. Otherwise, it will proceed to Step 1.

3.3. Data normalization. In the verification of the author's mixed recommendation process for mobile service QoS based on user context awareness, experiments were conducted using the common RTT (round-trip response time) and Failure rate (service call failure rate) in mobile service QoS as examples. Given that the ant colony neural network model has high requirements for data input, and there is no clear pattern in the distribution of RTT and Failure rate tested by the author, it is necessary to normalize the original input data to make the input value $\in$ [0,1]. If the original value in the QoS preference matrix is $b_{i,j}$, the preprocessed value is $c_{i,j}$, and the maximum and minimum values in the matrix are represented by $minb_a$ and $maxb_a$, respectively, then equation 3.3 is used for linear normalization:

$$c_{i,j} = \begin{cases} \frac{(b_{i,j} - minb_a)}{maxb_a - minb_a} (When \quad maxb_a \neq minb_a) \\ 1 \quad (When \quad maxb_a = minb_a) \end{cases} \tag{3.3}$$

Among them, i=1,2,3,..., m+n, j=1,2,3,..., a. After normalization, all RTT and Failure rate inputs $\in$ [0,1].

3.4. MapReduce weight training. In order to reduce the computational complexity and weight training time of ACO and neural networks in large-scale sample data processing, the author adopts cloud computing MapReduce parallel processing technology for weight learning training. The specific running process includes two stages: Map and Reduce. In the Map phase, call the MapRe reduce Map() function to receive key value pairs (key, value) for calculating input and output, and calculate each ω weight change of backpropagation is determined by $\Delta\omega$, form intermediate key/value pairs (key = ω , value= $\Delta\omega$) and save the key value pairs output by each Map in the Hadoop system file $(\omega, \Delta\omega)$, enter key value pairs through the combine() function.

In the Reduce stage, call the Reduce() function according to equation 3.4 to $(\omega, \Delta\omega)$ normalize and use the output (key = ω, value = $\sum_{i=1}^{n} \Delta\omega/n$) as the final key value pair, using the job() function for each perform

batch updates and store the resulting weight matrix in Hadoop as preparation for subsequent MapReduce task iteration calls. When the weight error of the training is small enough to meet the specified requirements after multiple MapReduce treatments, the run ends. Otherwise, continue the iterative training of repeated weights.

$$\begin{cases} sum \leftarrow 0, count \leftarrow 0 \\ sum \leftarrow sum + value \\ count \leftarrow count + 1 \\ sum/count = \sum_{i=1}^{n} \Delta\omega/n \end{cases} \tag{3.4}$$

According to equation 3.5, the calculated $P(r_{u,p})_{user}$ and $P(r_{u,p})_{item}$ will form a collaborative filtering matrix P. Among them, $P(r_{u_m,p_n})_{user} \neq 0 \wedge P(r_{u_m,p_n})_{item} \neq 0$.

$$P = \begin{bmatrix} P(r_{u,p})_{user} \\ P(r_{u,p})_{item} \end{bmatrix} = \begin{bmatrix} P(r_{u_1,p_1})_{user} & \cdots & P(r_{u_m,p_n})_{user} \\ P(r_{u_1,p_1})_{item} & \cdots & P(r_{u_m,p_n})_{item} \end{bmatrix} \tag{3.5}$$

3.5. Final prediction of QoS preferences. Calculate the missing QoS values $P(r_{u,p})_{user}$ and $P(r_{u,p})_{item}$ for collaborative filtering recommendations according to equations 2.8 and 2.9, and calculate the final predicted value

$$P(u,p) = \frac{1}{(1+e)^{-(V\times(\frac{2}{1+e^{W\times P+B_1}}-1)+B_2)}}$$

of QoS preferences perceived by cloud computing users in context. Among them, $P(r_{u,p})$ is the final predicted value of collaborative filtering missing value $r_{u,p}$, P is the number of rows in matrix

$$P = \begin{bmatrix} P(r_{u,p})_{user} \\ P(r_{u,p})_{item} \end{bmatrix} = \begin{bmatrix} P(r_{u_1,p_1})_{user} & \cdots & P(r_{u_m,p_n})_{user} \\ P(r_{u_1,p_1})_{item} & \cdots & P(r_{u_m,p_n})_{item} \end{bmatrix}$$

j and P, and the weight matrix between input and hidden layers trained by ant colony neural network is W, the weight matrix between the hidden layer and the output layer is V, and B_1 and B_2 represent the offset matrices between the hidden layer and the output layer, respectively. Substitute the missing QoS attribute values $P(r_{u,p})_{user}$ and $P(r_{u,p})_{item}$, calculate $P(r_{u,p})$, and finally provide the optimal recommendation value for the target user based on the Top-N rule[9].

4. Algorithm validation.

4.1. Datasets. The author built the experimental cloud service MapReduce environment on a Hadoop platform with 9 servers, where the server where the system software was installed was NameNote (Lenovo server, 4GB memory, 1TB hard drive, 2.8G main frequency, named Hadoop), the remaining 8 servers are DataNote, named hadoop1, hadoop2,..., hadoop8, using Redhat5.5-x64 to install VMware virtual machine Linux system, and using Hadoop-0.21.0 version. The dataset used by the author for the experiment mainly consists of service QoS records stored on multiple mobile servers in different regions collected through Planet Lab. Each record includes two QoS values: failure rate and failure rate round-trip delay (RTT), which can be used to construct a QoS vector matrix for cloud computing services.

Location context-based user and service clustering methods, the IP addresses of mobile commerce users are mapped in decimal to obtain corresponding starting IP addresses, ending IP addresses, AS names, and AS numbers for mobile commerce users. By mapping the IP addresses of mobile commerce users, a total of 339 users were selected for this experiment to rate 5852 service items, with a rating range of 1-5 points for each user. Through sorting the dataset, it was found that 65.2% of user rating items are between 20 and 100, indicating that there are many missing values in each user's rating vector, therefore, user rating information is relatively sparse and can be used to detect the recommendation performance of the model in compensating for missing QoS values and alleviating cold start problems. The experimental dataset obtained by the author from Planet Lab includes the content shown in Table 4.1.

Table 4.1: Dataset Content Information

category	content
User List	339 user information
service list	5825 service information
RTT matrix	RTT records of 339 users calling 5825 services
TP matrix	339 users calling 5825 service TP records

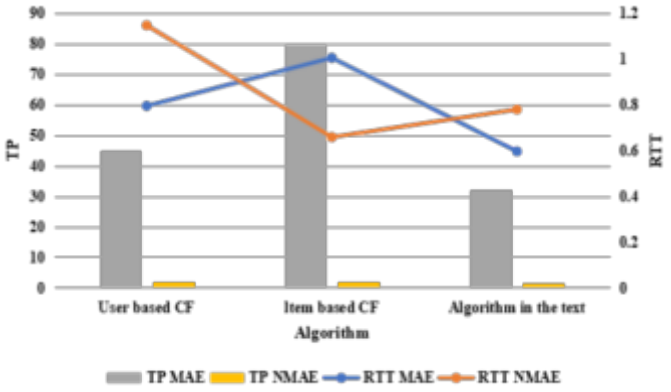

Fig. 4.1: Comparison of MAE and NMAE performance (Top k = 10)

4.2. Experimental Process and Result Analysis. In order to compare the prediction results of the author's algorithm with different algorithms, the author will compare the QoS prediction performance with User based and Item based algorithms respectively. The specific experimental process and results are as follows:

Step 1: As described in 4.2, the experimental data packet mainly considers the dynamic QoS attributes of failure rate and failure rate round-trip delay RTT when conducting neural network analysis. The trainLM function is used for network parameter training, the LEARNGDM function is used for adaptive learning, and the LOGSIG and MSE functions are used for activation and performance testing, respectively.

Step 2: Use MATLAB software to train the neural network with 300 sets of results obtained through cyclic calculation, set the global error index for ant colony neural network weight training to le-7 and the maximum training steps to 2000.

Step 3: Output the optimal weights trained by the ant colony neural network to predict QoS preferences for mobile commerce, and compare the recommendation performance of User based, Item based, and this method based on the output results.

The test experiment recommended a given cold start dataset and predicted its QoS attribute gap value. The recommendation results were compared using two scenarios, Top N=10 and Top N=5, respectively. The two most commonly used metrics in personalized recommendation research, MAE (absolute mean error) and NMAE (standardized absolute mean error), were used to compare the accuracy of different methods. The experimental results are shown in Figure 4.1 and Figure 4.2.

Comparing Figures 4.1 and 4.2, it can be seen that whether comparing the recommendation results of Top N=10 or Top N=5, the prediction accuracy of the sports user context aware mobile service QoS hybrid recommendation method is significantly higher than that of traditional user based and Item based recommendations. This indicates that the Failure rate and RTT with values ranging from [0,1] can obtain better mixed weights during the ant colony network training process, thereby improving the performance of QoS preference prediction. The experimental results of the two graphs further indicate that when using this algorithm for recommendation, selecting Top N=10 results in higher recommendation accuracy compared to Top N=5. This indicates that the sparser the ratings of

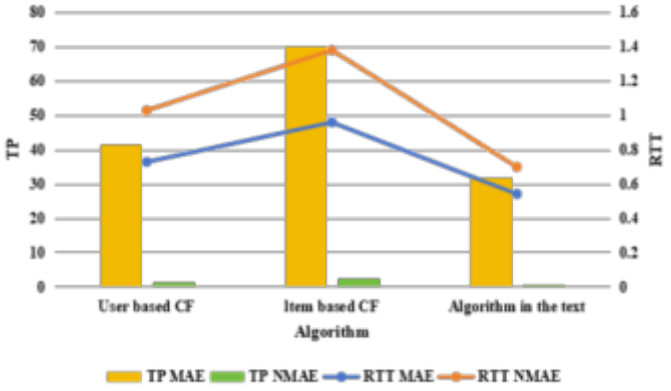

Fig. 4.2: Comparison of MAE and NMAE performance (Top-N=5)

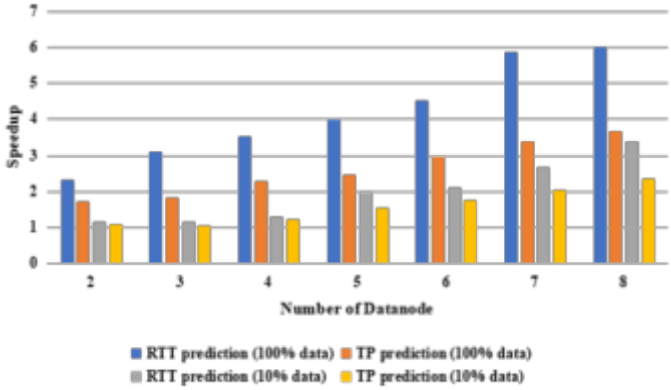

Fig. 4.3: The prediction time acceleration ratio in the Hadoop environment

cold start users or projects, the poorer the recommendation accuracy; The more ratings a cold start user or project receives, the higher the recommendation accuracy [10]. This also explains the normal phenomenon of the following: as the number of ratings increases, new projects and users lacking ratings begin to change their roles, evolving from the original new projects and users to general projects and users, basically no longer having the characteristics of missing ratings for new projects and new users. This reduces the missing values for cold start items, thereby improving the performance and accuracy of recommendation systems.

Step 4: Compare the parallel acceleration ratios of the algorithms. In order to accurately measure the efficiency of the algorithm, the calculation time required for single machine operation and parallel operation in the cloud environment was selected for comparison. The specific calculation formula is: S=T(1)/T(N), among them, T(1) is the single machine running time of the algorithm, T(N) is the consumption time of multi machine parallel processing in the sports industry, N=1,2,..., 9, and the ratio of the two is the author's measurement index acceleration ratio. Given that the data nodes of the Hadoop cloud platform in the author's experiment have different scenarios ranging from 1 to 8, the acceleration ratio index T (N) has N=1,2,..., 8.

The author divided the experimental dataset into 10% and 100% subsets for separate testing, and the final test results are shown in Figure 4.3. It can be seen that the acceleration ratio of the sports user context aware mobile service QoS hybrid recommendation method shows a linear growth trend during RTT and TP testing,

indicating that the Hadoop cloud environment improves the efficiency of the algorithm and reduces the time for QoS preference prediction on a global scale; And by comparing the operation results of the 10% and 100% sub datasets, it can also be seen that the acceleration ratio of the algorithm will continuously improve with the increase of data volume, thereby improving the operational efficiency of the recommendation algorithm.

5. Conclusion. In the context of massive mobile service resources, predicting QoS preferences for mobile services that fit user scenarios is a hot topic in the field of personalized research. The author incorporated sports user location contextual information into the User based and Item based recommendation mechanisms to create a hybrid model for mobile service QoS; At the same time, in response to the problem of difficult determination of mixed recommendation weights caused by massive data and uneven distribution of service QoS attribute values in mobile network environments, the MapReduce ant colony neural network method is used to learn and train its weights, and CF mixed recommendation is based on the trained weights. The experimental results have demonstrated that this method achieves lower MAE error values compared to traditional User based and Item based methods. The MapReduce based ant colony neural network weight training method also significantly reduces global computation time and improves the operational efficiency of recommendation systems; The user based and item based hybrid recommendation method that integrates situational awareness effectively compensates for missing QoS values and alleviates the problem of decreased recommendation accuracy caused by cold start in recommendation systems.

It should be pointed out that the author's proposed sports user context aware mobile service QoS hybrid recommendation model mainly focuses on the relatively single location context of mobile users for research, without introducing the idea of user context semantic logical reasoning for QoS recommendation. The author's subsequent research will take this as an opportunity to delve into the inference rules and recommendation methods of sports user context semantics, and achieve context sensitive mobile commerce QoS recommendation services.

EVALUATION OF ATHLETE PHYSICAL FITNESS BASED ON DEEP LEARNING

YOUYANG LV*

Abstract. In order to promote deep learning in physical education for students, guided by the concept of deep learning, the author integrates the concept of deep learning into flipped classrooms. The author proposes a flipped classroom design and classroom implementation process for promoting deep learning, and conducts a semester long experimental research based on basketball courses, continuously optimizing the design during this period.Through the analysis of various parameters appearing in the operation, the test results are satisfactory. The study found that students in three classes were physically trained by using the classroom teaching method of "deep learning". The classroom teaching mode based on deep learning achieved the best teaching results in the first stage. One habit that inspires real emotion in children is their pace: running in different directions. Classroom teaching based on deep learning can make students understand the importance of cross-movement. Thus, after experiment, there was no significant difference between the flipped classes and the traditional class teaching method in the cross run compared to before experiment. The effectiveness of flipped classroom design for promoting deep learning has been verified, achieving a promoting effect on students' deep learning. The flipped classroom designed by this research institute can effectively promote learners to achieve deep learning, specifically manifested as: The physical fitness level of students has improved, the level of cognitive structure has improved, and students are more able to learn independently. The goal of deep learning for students has been achieved.

Key words: Deep learning, Athlete physical fitness, Evaluation, Flipped Classroom

1. Introduction. At present, the quality of physical education teaching in many universities is worrying. On the one hand, the traditional concept of "valuing literature over martial arts" has deeply influenced us to this day. Both parents and children deeply believe that reading is the only way out in life [1]. On the other hand, teachers lack a sense of responsibility, without planning or organizing teaching. This leads to some students, after many years of physical education, ultimately unable to develop their own unique skills. Therefore, educators should continuously improve their own quality, theoretical level, and educational research ability, make good use of classroom time, and organize students to learn and practice diligently, so that students can truly learn sports techniques and exercise methods, increase their interest in sports, and enhance their physical and mental health.

At present, the state of college students is that on the one hand, their attitudes towards physical education classes are polarized. Some students love physical education classes very much, while others strongly reject them; On the other hand, the physical education learning ability of students needs to be improved [2,3]. In this trend, physical education learning ability becomes particularly important, as it not only reflects the speed of students learning skills, but also reflects changes in their thinking abilities. Deep learning aims to cultivate learners with unique insights and the ability to solve practical problems. From a technical perspective, immersive technology promotes effective learning with its advantages of low cost, high learning effectiveness, and repetitive experience. Wearable devices are gradually being applied in teaching courses due to their portability, user focus, intelligent interaction, augmented reality, and other characteristics. Mobile internet technology is combined with learning in different forms, artificial intelligence and big data technology provide technical and theoretical support for adaptive learning systems.

Educational practice research is aimed at helping students grow and develop better. In school, students not only need to learn knowledge, but also need to enhance the core competencies of physical education that are needed to adapt to our new era society. As young teachers of the new era, we should inject fresh blood into physical education teaching, use new teaching methods and means to comprehensively enhance students' core sports literacy, and enable students to play their main role in solving complex practical problems, truly

* School of Physical Education, Guizhou Normal University, Guiyang, Guizhou , 550025, China (13752719851@139.com)

improving their thinking ability, and providing some reference for physical education teaching reform.

Using the in-depth learning assessment model based on SOLO theory, analyze the changes of students' classroom comprehension to evaluate the effectiveness of classroom teaching.In- depth study initially has two meanings. The first layer is in the field of computer science. The construction and research of human brain neural networks have led to the exploration of deep learning strategies. It combines the finite element method and finally forms an abstract finite element model to find the distribution characteristics of the data for the representation.Another layer of meaning lies in the field of education. This concept is proposed based on the definition of shallow learning, which is classified according to Bloom's cognitive goals: memory, understanding, application, analysis, evaluation, and creation. Shallow learning includes the first two parts, while deep learning includes the last four parts. The so-called shallow learning refers to the learning form that is influenced by external factors and uses simple memory, repeated practice, and reinforcement memory to learn new knowledge. Shallow learning is when students can only develop shallow understanding within a limited time, resulting in teaching activities that become superficial, superficial, and performative. Deep learning is the exploration of a certain content or viewpoint, emphasizing critical understanding. What students learn can go beyond surface knowledge and achieve a deeper understanding of the knowledge. Compared to that, shallow learning is more about the mechanical accumulation of knowledge, and lacks emotional resonance among learners; Deep learning advocates learners to view learning materials with a critical and skeptical attitude, approach problems with a questioning and analytical attitude, establish connections between various viewpoints, and deepen their understanding of complex concepts. The author takes the flipped classroom teaching model based on deep learning, flipped classroom teaching model, and traditional classroom teaching model as the research objects in basketball teaching, focusing on the five physical qualities of students and their deep learning abilities [4].

2. Methods. The author focuses on the five physical qualities of students and their deep learning abilities in basketball teaching under three different teaching modes: flipped classroom teaching mode based on deep learning, flipped classroom teaching mode, and traditional classroom teaching mode.

2.1. Questionnaire survey method.

(1) Design of questionnaire. After soliciting opinions and suggestions from relevant experts multiple times, the questionnaire items were modified, added or deleted multiple times, and a survey questionnaire on students' deep learning ability was designed to ensure that all items can accurately express the research content, forming the final survey questionnaire. The completed questionnaire takes students from a university in A city, A province as a sample and conducts a survey. Through the distribution, collection, and organization of the questionnaire, the current situation of students' deep learning ability in physical education classrooms is understood, providing reference data for the author's research [5].

(2) Reliability and validity testing of the questionnaire. The Cronbach coefficient is a commonly used reliability evaluation tool. According to SPSS testing, the Cronbach coefficient value of the deep learning ability questionnaire is 0.916, indicating that the questions in the questionnaire have high internal consistency.

2.2. Teaching Experiment Method . After analyzing the situation of students' study and the characteristics of physical education, the physical education course reform teaching design system based on deep study was established. and the physical education course reform was designed. Experiment 1 used the classroom teaching model as the in- depth study, Experiment 2 used the classroom teaching model, and the traditional teaching model was used to control the classroom[6].

(1) Experimental hypothesis. The flipped classroom teaching model based on deep learning can better improve students' physical fitness and enhance their deep learning ability.

(2) Experimental subjects. A Normal University 2020 (undergraduate) students in the optional course of college sports basketball, including 32 students in Experiment 1 class, 30 students in Experiment 2 class, and 32 students in the control class.

(3) Experimental time and location. Experimental period: August 2021 to December 2022, with a total of 32 class hours and 16 week hours. Location: A Normal University West District Basketball Court.

(4) Teaching experiment process. Create an experiment class using Learningapp, where students can download instructional videos, materials, do tasks, and then log in to the classroom. Download videos and files

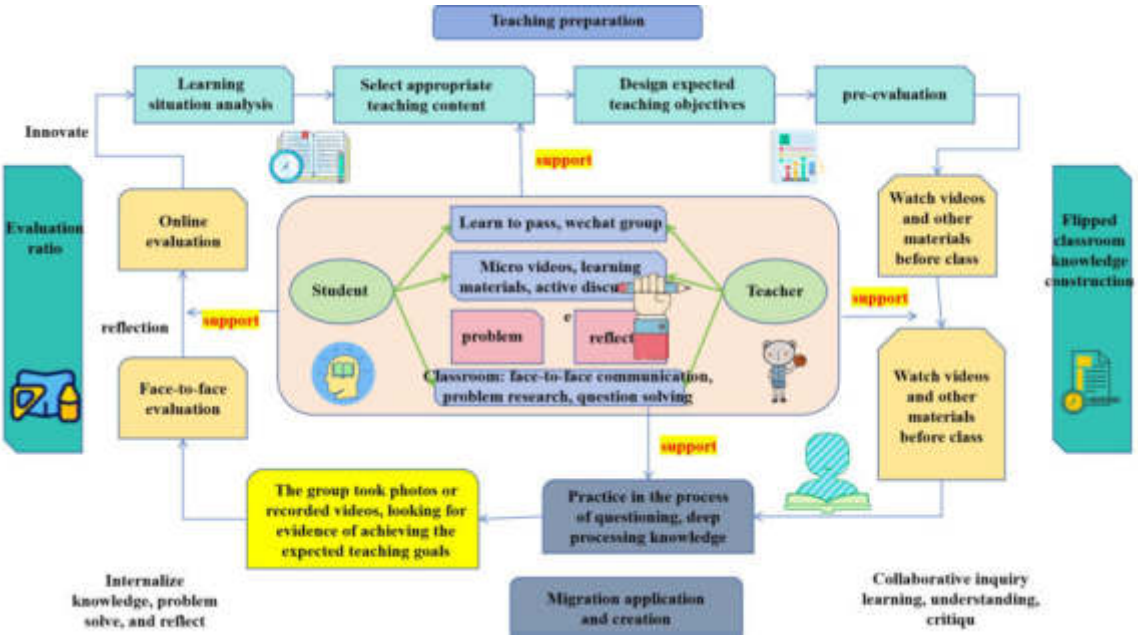

Fig. 2.1: Flipped classroom teaching mode based on deep learning

about basketball on the Internet, and use mobile phones, computers and other software to edit and edit the content to learn.

2.3. Experiment 1 Class Deep Learning Flipped Classroom Teaching Mode. *Before class:* Divide students into small groups based on their actual situation and set expected teaching dates for them. During the discussion, teachers use various kinds of "questions" and follow the principle of inquiry as teaching, allowing students to communicate online.During this period, the group leader collects and organizes key questions within the group, and focuses on explaining them in class. By questioning students in this way, it triggers their thinking and deepens their ability to learn independently, understand, and engage in deep learning. In class: After class, the sports committee will gather in a team, and the teacher will use the "Learning App" to publish check-in. Students will sign in. Teachers and students interact, and the teacher will announce the teaching content and objectives of this course and organize the interns. and Before class, teachers can check students' self-study by asking them to finish some questions or to ask questions about teaching. Our group of people raised issues and questions were discovered by their own group, and the teacher provided clear and concise advice on the issues of student cohesion.At the end of the course, the teacher prepares the students to practice or play games to help improve their physical fitness, such as running back, sitting, playing fast, etc., so as to improve their physical fitness. After exercise, relax and arrange some activities. Students and teachers will conclude classes together, assess whether the teaching objectives have been met according to the class situation, and improve the teaching prospects of the next class by making suggestions. Then, the class will be announced.

After class: The teacher thinks about the students and gives them a job opener (the job opener has no correct answer). For the assignment, students need to engage in independent and in-depth thinking, process newly learned knowledge, and combine it with the existing knowledge structure.

Through the above process, the author designed a flipped classroom process framework to promote deep learning, as shown in the figure. This framework presents the main teaching and learning activities of the flipped classroom before, during, and after class, aiming to gradually guide students to ultimately acquire higher-order thinking abilities. Figure 1 shows a flipped classroom teaching model based on deep learning.

2.4. The flipped classroom teaching method of Experiment 2. According to the teaching method, teaching videos (3-5 minute short films), pictures, PPT documents and textbooks are sent to the learning platform. Students are free to download what they learn and ask questions in the process, with the teacher giving answers.Some questions require students to have group conversations and let them engage in online communication.During this time, the group leader will collect and organize key questions within the group, and focus on explaining them in class.

In class: First, after the class bell rings, the sports team assembled the group. The teacher used the learning application to check later, and the students entered to use the notices received by their telephone. The teacher prepares the students to take part in the preparatory activities (including general and special activities related to volleyball skills), and then examines the students' self-study, expecting them to finish some tests or explain some comments about the teaching. Then each group sends representatives to explain the new content, other students evaluate it, and the teacher provides guidance. Then, the teacher needs to provide a unified summary, succinctly explain and demonstrate the key and difficult technical actions. In response to the questions raised by students, teachers should provide complete and detailed explanations and demonstrations of technical actions, and provide detailed explanations of key and difficult knowledge points. Then the students study in groups. Students use their phones to take photos or record videos with each other, in order to discover and correct mistakes, forming a good learning atmosphere of mutual assistance and learning. After the course, the teacher prepares the students to do exercises or activities which are beneficial to the improvement of their physique, such as turning, sitting, playing fast, etc., so as to improve their physique. After that, the teacher set the students to participate in the relaxation activities. After graduation, the students and the teachers summarized the course together and announced the end of the class.

After class: Learners independently carry out consolidation exercises to reinforce the knowledge they have learned, and then reflect and summarize the learning content and process to improve the effectiveness of their subsequent physical education course learning. Compared to the traditional classroom teaching mode of the control class: First, after the bell rings for class, the sports committee gathers in the team and reports the attendance situation to the teacher. After greeting each other, the teacher announced the teaching content and objectives of this lesson and arranged interns. Subsequently, organize students to carry out preparatory activities. The teacher provided a detailed explanation and demonstration of the teaching content for this lesson. Students listen attentively, study diligently, imitate the teacher for practice, and then practice together with their peers. During student practice, teachers need to provide tour guidance to understand their understanding and mastery of technical movements, point out errors and correct them on the spot, and provide students with reasonable suggestions. After the students practice separately, the teacher gathers them together and emphasizes the common problems that arise among the students. Then the students identify their own mistakes and correct them based on the problems pointed out by the teacher, in order to consolidate and strengthen their actions. Finally, at the end of the class, the teacher organizes students to practice in small groups and then allows them to relax. Then the teacher summarizes and evaluates the lesson, assigns homework, and announces the end of the class.

2.5. Mathematical Statistics. Classify and statistically analyze the relevant data of the experiment and the relevant questions in the collected valid questionnaires. Process various data using statistical theory and input them into a computer for data analysis using Microsoft Office 2016 and SPSS 17.0.

2.6. Teaching design strategies towards deep learning.

(1) The principles and design features of inquiry based teaching. The principle of inquiry based teaching is: Firstly, in order to guide students through inquiry, making their learning path clearer. Teachers should provide appropriate and timely guidance during the teaching process, allowing students to review and check previous knowledge points, thereby breaking through comprehension barriers and quickly solving problems. Secondly, concretize questioning to make students' thinking more complete. In physical education teaching, teachers can supplement and explain their own questions appropriately, making the problems more specific and allowing students to have a clearer understanding of the problems. Teachers should be able to publish their research questions to other sports activities or disciplines according to their study and content. This teaching method can guide students' thinking into deep learning, which is conducive to the development of their different thinking modes.

The characteristic of inquiry based teaching design: inquiry is to ask a certain question again after a question, relentlessly pursuing it, sometimes changing perspectives and proposing new questions, guiding students to think, abstract, and summarize, which is a form of deep learning. Through research, it has been found that the research on deep learning in the national education system is still relatively weak, and there are not many types of excellent courses, open courses, etc. carried out nationwide. In the new era, exploratory learning is advocated. For the teaching of technical or tactical essentials in new teaching, exploratory learning activities can be set up, through self-directed learning, flipping during class, and reflection after class, students are encouraged to engage in deep learning. The entire learning process cultivates their creativity, divergent thinking, and flexibility.

(2) Principles and features of reverse teaching design. The principle of reverse engineering teaching: 1. the principle of reverse engineering Starting from the needs of the students, it is the best choice to carry out sports teaching service quality education, and it is also necessary to cultivate and improve the students' personality. 2. His teaching is mainly focused on research as a subject. 3.

Different sports projects have different characteristics, and even different techniques and teaching forms in the same project have different effects, through summary, it is found that "reverse teaching" has appeared in the form of "teaching methods" in previous research on physical education teaching, but has not formed its fixed "mode". Perhaps because different sports have different characteristics, the same teaching model assumptions cannot be used when teaching different sports. This issue can be further explored as an extension. In this study, based on previous research findings and the characteristics of basketball, "reverse teaching" is defined as: understanding the basic situation of students, designing expected teaching goals that students can achieve, breaking the traditional teaching approach of simple to complex and easy to difficult without compromising completeness, and directly starting from the most important aspect of teaching as the entry point, then search for evidence in the classroom that students can achieve teaching objectives, and finally reflect at the end of the class.

(3) Other strategies to promote deep learning. Deep learning is the process of students participating in learning activities independently, constantly reflecting, exercising their thinking, and achieving creative learning. In physical education teaching activities, teachers should allow students to fully experience their true thinking state, achieve autonomous understanding of knowledge, actively think about problems, establish connections with learned knowledge, and answer suitable answers. The strategies to promote deep learning include inquiry based teaching, reverse teaching, and collaborative inquiry learning, among others.

2.7. Design of flipped classroom teaching process for college sports basketball elective course based on deep learning.

(1) Pre class self understanding and initial formation of understanding. The teaching of university courses cannot be limited to the transmission of knowledge in the classroom. It is necessary to change the traditional situation where teachers teach unilaterally and students learn unilaterally in the classroom [7]. Firstly, openness can promote students to have a deep understanding, mutual correlation, and clear and actionable expected teaching objectives; Second, in order to expand the depth and breadth of learning, we must choose those engaging learning materials that occupy the center of the topic. This feature of the curriculum is more likely to be expressed in the way of "problems",due to the particularity of physical education, the order of teaching content can be adjusted from easy to difficult in the past to difficult to easy, enabling students to actively think on the basis of problems and achieve the goal of deep learning; Finally, design questions for students, release specific learning tasks, guide the orderly development of pre class learning activities, and make full preparations for making full use of face-to-face teaching time for classroom learning.

(2) Sharing understanding in class and correcting cognitive biases. The so-called cognitive bias refers to the errors that occur when people form impressions of others in the process of mutual contact and interaction. Social cognition is the foundation of people's social behavior, so if there is cognitive bias, people's behavior will also make mistakes. In schools, the communication between physical education teachers and students is also influenced by the laws of social cognition.Subsequently, the teacher will answer questions and clarify doubts based on the actual situation, and practice skills after completing theoretical knowledge learning.

(3) After class reflection and understanding, training of metacognitive abilities. When students encounter conflicts between new and old cognition during the learning process, they will actively reflect, which can help

Table 3.1: Comparison and Analysis of Physical Fitness of Students in the Experimental Class and the Control Class before and after the Experiment (1)

index	group	Before the experiment	After the experiment	T	P
		Mean ± standard deviation	Mean ± standard deviation		
50 meters	Experiment Class 1	72.88±8.03	80.06±6.11	-8.888	0

	Experiment Class 2	75.63±8.58	75.80±7.71	-0.314	0.757
	Control class	73.59±8.03	74.06±7.48	-1.161	0.256

them become more open and willing to change their original cognition. Reflection after class is very important, it is a summary of learning activities before, during, and after class. On the one hand, students reflect on the thinking process of understanding a concept or problem through group learning activities, thereby achieving the goal of self-awareness. On the other hand, we should integrate classroom and learning resources, reflect on the new gains and other more beneficial information generated by teacher-student interaction, in order to achieve better teaching results.

3. Results and Analysis.

3.1. Comparative analysis of physical fitness between experimental and control class students before and after the experiment . Different types of physical activity before and after the experiment were evaluated by means of experiment and physical examination. On the basis of trial 1, Trial 2 and control group, the movements of the two groups were evaluated. Specific results are listed in Table 3.1, Table 3.2, and Figure 3.1 [8].

The results showed that the P value was less than 0.05 in 50 meters, sitting position, 800/1000 meters, turning and cross-country driving. In other words, in 1 and 1, the subjects showed significant differences in all five personality traits, and their average scores improved significantly.Students in Experiment 1 are able to do strenuous exercise in the last part of each level and have a clear understanding of the effects of exercise. They are able to prepare well before testing, so the overall health of Test 1 is best. Therefore, there are significant differences in physical exercise before and after the experiment of 50 meters, 10 meters, supine, 800/1000 meters, and bending forward. The average score is good, but there is no significant difference in cross-

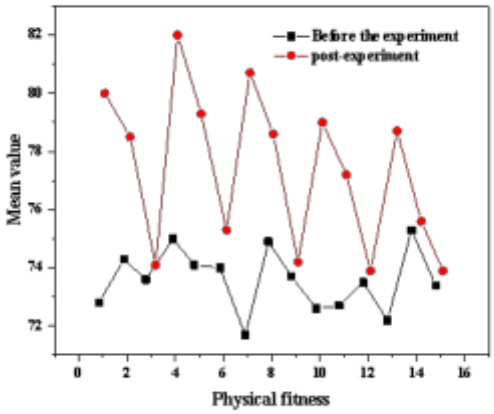

Fig. 3.1: Comparison and Analysis of Physical Fitness of Students in the Experimental Class and the Control Class before and after the Experiment

sectional work. The reason is that some students do not understand the law of the intersection and are prone to mistakes, resulting in a decline in the average number of students in the class. The P-values of each factor were significantly higher than 0.05 for 50 meters, sitting position, pulling, 800 meters, turning and intersection, respectively. The reason is that some students almost have no time to exercise except exercise for one time in the physical education class. In addition, students are not ready for games and exams, which makes some students not reach their best grades. Finally, there was no significant difference in five physical exercises before and after.

3.2. Comparative analysis of deep learning abilities between experimental and control class students before and after the experiment. Through experiment, conduct in-depth research on each class of students before and after experiment, and assess whether there are significant differences in the depth of study among students in Experiment 1, Experiment 2, and the control class before and after experiment. The specific results are shown in Table 3.3 and Figure 3.2.

In experiment 1 and experiment 2, the deep learning performance of the control class students before and after the experiment was tested by t test. According to the analysis results, the pre-test, single-stage setting, multi-stage setting, setting equilibrium and the degree of abstraction were all less than 0.05, indicating that there were significant differences between the two groups before and after the test. Through six months of study, through reverse teaching design and deep learning strategies such as questioning, students have more understanding of basketball, but also deepen their understanding of basketball knowledge, and promote their higher level of thinking. The final experiment showed that the students' cognitive ability improved in experiment 1 [9-10]. The P-values of Search 2 of the first sample level, single sample point, and multi-sample level are all less than 0.05, while the P-values of sample sample lead level and abstract level after all are more than 0. 05. This shows that there are differences among the pre-test level, single point model, and multi-level model of the students in Experiment 2, and there is no significant difference between the continuous model of the consecutive model and the abstract model level. The reason why after practicing flip course without in-depth study, students may have their own idea of grasping skills and ideas, but they still can't combine their present study with previous study and can't express themselves in their own language.As a result, students do not receive higher levels of education. The P values of the front and point levels of the model are < 0.05, while the P-values of multilayer model, sequence model and the next level model are all <0.05.This means that there is a significant difference between the students' management of the abstract continuity at three levels before and after the experiment at the model level before and one model point, while there is no significant

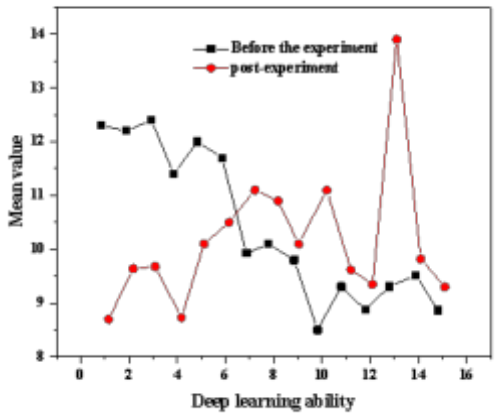

Fig. 3.2: Comparative analysis of deep learning abilities between experimental and control class students before and after the experiment

difference between the different model levels and the corresponding model levels. The Committee notes with appreciation, among other things, the efforts of the State party to ensure full commitment to the implementation of the Convention on Privileges and Immunities, as most students have a better understanding of the subject matter after receiving regular education.Therefore, traditional teaching can't let students take part in deep learning.

4. Conclusion. Using design strategies such as "reverse teaching design" and "inquiry based teaching", combined with pre class self understanding, in class sharing understanding, and post class reflection understanding, students are encouraged to think around inquiry questions, enhance their higher-order thinking abilities,

and achieve the goal of deep learning. Through teaching experiments, one-way ANOVA, multiple comparisons, and paired t-tests were conducted on the data of relevant indicators. The results show that there are significant differences in physical fitness between Experiment 1 and Experiment 2 before and after experiment, with significant differences in four aspects: 50 meters, supine/supine support, 800-1000 meters, and forward bending in sitting. There is no significant difference in horizontal run; There are no differences between the control groups; Experiment 1 shows the difference of the ability to learn deeply; At the levels of sample pretreatment, single point sampling and multiple samples, there were obvious differences in the sample pretreatment level of experiment 2, but there was little difference between the pretreatment level of continuous sample and that of continuous sample. However, there was no significant difference between the control group and the single mode group in the three periods of multi-mode, parallel mode and continuous mode. The traditional classroom teaching method can improve students' exercise ability, volleyball ability, comprehensive ability, and self-study ability, but the teaching method is not significant and can not reach the different level; The most important thing is the classroom teaching model based on deep education. Experiments show that this teaching model can improve students' physical quality, improve their basketball skills and use abilities; and so on. It can improve students' self-study motivation, improve their sense of belonging and level of understanding, and achieve the goal of promoting deep learning.

CONSTRUCTION METHOD OF INFORMATION SECURITY DETECTION BASED ON CLUSTERING ALGORITHM

SHAOBO CHEN*

Abstract. A method for K-prototype clustering, which can process mixed data types, is proposed first. An algorithm for information security evaluation of hybrid clusters based on K-prototypes was constructed. This method makes full use of the excellent global optimization performance of PSO and effectively solves the defect that the K-protection function quickly falls into local optimization. Simulation results show that the proposed method can effectively prevent local extreme values and improve overall performance.

Key words: Clustering; Information security; Safety evaluation; PSO algorithm; K-prototypes

1. Introduction. In enterprise information construction, various security devices will generate massive records. These log data are an essential source of threat information for information system security assessment. Therefore, it is a crucial issue in network security evaluation to quickly and effectively extract potential threats from extensive network data [1]. In recent years, more and more data mining methods have been applied to the security evaluation of information systems, and log-based cluster analysis has become a hot research direction. Cluster analysis is to classify something into one class according to the similarity of a particular class [2]. The similarity of the same class is high, and the similarity of different classes is low. Cluster analysis has been increasingly applied in data mining, pattern recognition, machine learning, image processing, etc. The existing clustering algorithms mainly include hierarchical clustering, partition clustering, density clustering and raster clustering.

K-means is a standard clustering algorithm based on blocks. The K-means algorithm transforms problems into multi-dimensional combinatorial optimal problems [3]. It groups a series of samples with several clusters and objective functions as constraints. So, you get the optimal solution. The classic K-Means method is fast and efficient. The disadvantage is that it only applies to numeric type data, is more sensitive to initial values, and only applies to spherical distribution data. Many improvements have been proposed to overcome some of K-Means' problems. Some scholars use genetic algorithms, particle swarm optimization, immune planning, ant colony, and other heuristic optimization algorithms to prevent algorithms from falling into the local optimal dilemma [4]. Algorithms such as K-modes and K-protection have been studied for the two types of mixed problems.

At present, the recorded data of security evaluation contains many characteristics of symbol type and number type, and some have strong characteristics of symbol type, such as network protocol type and network service type. They cannot be eliminated directly [5]. For this reason, the project intends to study a new way of clustering multi-source log data based on K-prototypes, combined with PSO's excellent global optimization performance, to solve the defects of the K-protection package algorithm that easily fall into local extreme values. Simulation results show that the proposed method can effectively prevent local extreme values, improve the overall convergence, and improve the accuracy and stability of the algorithm.

2. Clustering algorithm based on fuzzy K-prototypes. This paper introduces a fusion method of fuzzy K-means and fuzzy K-mode algorithms, which can effectively deal with data with different properties. Suppose $U = \{u_1, u_2, \cdots, u_n\}$ is a collection of data objects, and $u_i = \{E_{i1}, \cdots, E_{iq}, E_{i(q+1)}, \cdots, E_m\}$ represents that the data objects have m properties. The preceding q terms are continuous, and the $q+1$ through

*School of Mathematics and Computer Science, Shaanxi University of Technology. Hanzhong 723000, China (sxlgcsb@163.com)

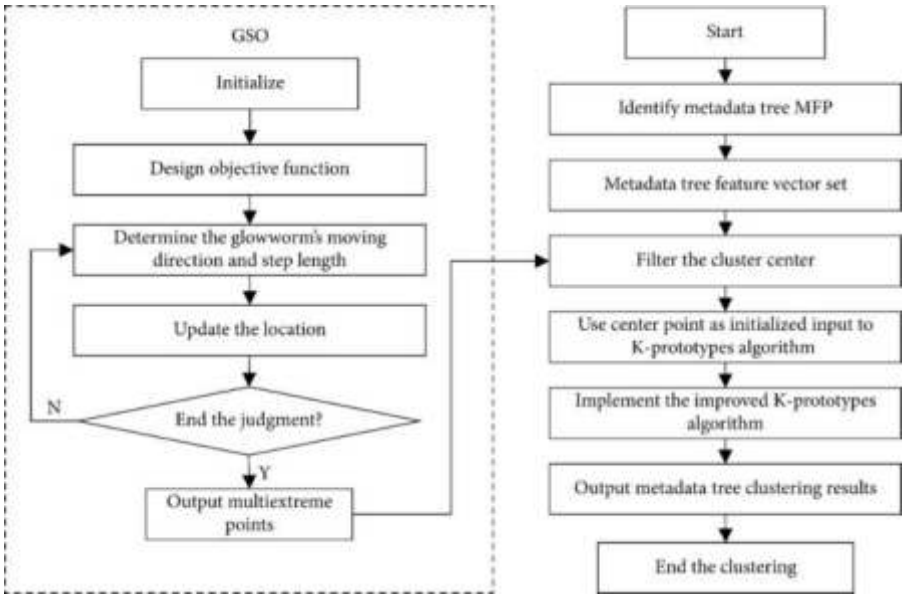

Fig. 2.1: *Flow of the clustering algorithm for fuzzy K-prototypes.*

m terms are categorical [6]. Therefore, the difference between data targets u_i and u_j can be obtained through calculation in formula (2.1). Figure 2.1 shows the process of the fuzzy K-prototypes clustering algorithm.

$$s\left(u_i, u_j\right) = \left[\sum_{h=1}^{q}\left(u_{ih} - u_{jh}\right)^2\right]^{1/2} + \mu \sum_{h=q+1}^{m} \gamma\left(u_{ih}, u_{jh}\right) \tag{2.1}$$

In (2.1), the former represents the difference in adjacent properties and the latter in class properties. μ is the weight used to adjust the degree of difference between two properties, called the "property ratio." The definition of $\gamma\left(u_{ih}, u_{jh}\right)$ is given in formula (2.2):

$$\gamma\left(u_{ih}, u_{jh}\right) = \begin{cases} 1, & u_{ih} \neq u_{jh} \\ 0, & u_{ih} = u_{jh} \end{cases} \tag{2.2}$$

The objective function of the fuzzy K-prototypes clustering algorithm is expressed in formula (2.3):

$$G(X, Y) = \sum_{k=1}^{z}\sum_{i=1}^{n}\left(x_{ki}\right)^{\partial} s\left(u_i, y_k\right) \tag{2.3}$$

$x_{ki} \in [0,1], \sum_{k=1}^{z} x_{ki} = 1, 0 < \sum_{i=1}^{n} x_{ki} < n; X$ is the dependency coefficient matrix of $n \times z.n$ is the number of data objects. Where z is the number of clusters. x_{ki} is the extent to which the i object belongs to the k cluster. Where Y is the cluster center of mass set, $Y = \{y_1, y_2, \cdots, y_z\}$. Where $\partial \in [1, \infty]$ is the fuzzy coefficient. In the fuzzy K-prototypes iterative method, membership x_{kj} is calculated in the following ways:

$$\underset{\substack{1 \leq k \leq z \\ 1 \leq i \leq n}}{\forall} x_{ki}\left(y_k, u_i\right) = \begin{cases} x_{ki} = 1, y_k = u_i \\ x_{ki} = 0, y_h = u_i, h \neq k \\ x_{ki} = \sum_{h=1}^{z}\left[\frac{s(y_k, u_i)}{s(y_h, u_i)}\right]^{-\frac{1}{(\partial - 1)}} \\ y_h \neq u_i, 1 \leq h \leq z \end{cases} \tag{2.4}$$

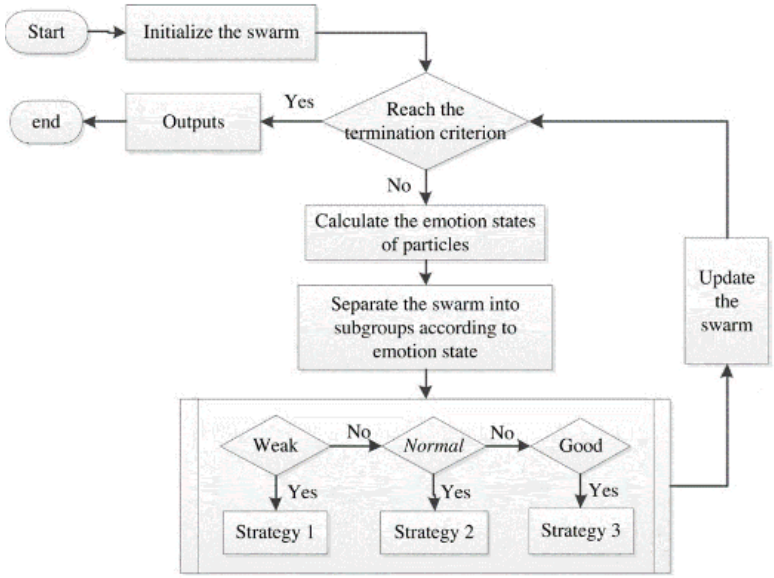

Fig. 3.1: *Flow of particle swarm optimization algorithm.*

In the iteration, $j(1 \leq j \leq q)$ adjacent properties E_{kj} of the cluster centroid y_k are computed by the following method:

$$E_{kj} = \frac{\sum_{i=1}^{n} (x_{ki})^{\partial} u_{ij}}{\sum_{i=1}^{n} (x_{ki})^{\partial}} \tag{2.5}$$

For feature $E_{kj} = e_j^{(c)} \in DOM(E_j)$ of category $j(q+1 \leq j \leq m), c$ must meet the following conditions.

$$\sum_{i=1}^{n} \left((x_{ki})^{\partial} \mid u_{ij} = e_j^{(c)} \geq \sum_{i=1}^{n} \left((x_{ki})^{\partial} \mid u_{ij} = e_j^{(t)} \right), 1 \leq c, t \leq n_j \right. \tag{2.6}$$

n_j is the number of numeric values of class property E_j.

3. Particle swarm optimization based on information security..

3.1. PSO algorithm. This project uses a binary particle swarm optimization algorithm to classify them. The group of particles is divided into N particles, and each particle is an active point in the discrete D-dimensional space [7]. At this time, the velocity of particle i at time t is $y_i(t), u_i(t), q_i(t)$, and the optimal position of the individual is $y_i(t)$, then the iterative formula of particle i velocity and position is as follows: Figure 3.1 shows the flow of the particle swarm optimization algorithm.

$$\begin{aligned} y_{is}(t+1) &= \varphi \cdot y_{is}(t) + z_1 c_1 \left(q_{is}(t) - u_{is}(t) \right) + z_2 c_2 \left(y_s(t) - u_{is}(t) \right) \\ u_{is}(t+1) &= \begin{cases} 1, & c_3 < \mathrm{Sig}\left(y_{is}(t+1) \right) \\ 0, & c_3 \geq \mathrm{Sig}\left(y_{is}(t+1) \right) \end{cases} \end{aligned} \tag{3.1}$$

$i = 1, \cdots, N$ (N is the size of the population, usually 20). $s = 1, \cdots, S$ (S stands for the dimensions of each component of the particle code given according to a particular problem). c_1, c_2, c_3 is any number in the interval

$(0,1)$. Where z_1 and z_2 are learning factors; It's generally thought that $z_1 = z_2 = 2; \varphi$ is not negative [8]. In this paper, it is called "inertia coefficient" or "inertia weighting". In the binary particle swarm optimization algorithm, $\varphi = 1$ is generally taken. $\mathrm{Sig}(\cdot)$ is the standard symbol, it's usually called $\mathrm{Sig}(u) = 1/(1+\exp(-u))$. 3.2 Fitness function. Label the category in the sample collection as $X = \{u_i \mid i = 1, 2, \cdots, N\}$. Where u_i is a vector in dimension S, then the class internalization of Xf_u is:

$$f_u = \sum_{i=1}^{N} \sum_{j=i}^{N} \|u_i, u_j\| \tag{3.2}$$

Cluster center X_z of X meets the following conditions:

$$X_z = \frac{1}{N} \sum_{i=1}^{N} u_i \tag{3.3}$$

Suppose the other categories of the sample collection represent $Y = \{y_i \mid i = 1, 2, \cdots, M\}$. Where y_i is a vector of S dimension, then the Euclidean distance between groups X and Y is their group interval $s(X, Y)$. The method synthesized the intra-group distance and interval, the intra-group aggregation degree and the inter-group dispersion degree and defined the adaptability value f. as the formula (3.5). The value of f' decreases with the decrease of the intra-group distance and the increase of the group distance [9]. The algorithm's convergence can be achieved by selecting the minimum fitness as the operating criterion.

$$f' = \frac{f_X + f_Y}{s(X, Y)} \tag{3.4}$$

4. Simulation experiment and result analysis.

4.1. Experimental data and parameter Settings. The experimental data used in this paper comes from the KDD99 intrusion detection system, which is highly similar to the real world and is widely used in intrusion detection systems. Each record has 42 characteristics, and an expert identifies the previous item as a regular link or an attack. Of the remaining forty-one attributes, nine are numbers, and thirty-two are numbers. Because many of the 41 experimental properties are useless, their appearance worsens the clustering result and the operation speed faster. Therefore, it is necessary to eliminate them when clustering them. This paper uses the attribute selection method proposed in the literature [10] to select 14 attributes, including four symbols and ten values. Because the data size of the complete knowledge discovery database is enormous, the paper selects some samples from the knowledge discovery database to carry out the algorithm test. In 10% of the training database, 55,555 samples were used as test data to ensure that the selected data matched the recorded data of the actual network [11]. There are 50,000 formally linked data; Of these, 5000 Dos attacks, 500 U2R attacks, 50 R2L attacks, and 5 Probe attacks. All test data are extracted from the 10% training library under the requirement of sampling quantity for each classification. First, the data should be normalized to prevent the impact of different dimensions on the data.

$$X_i = \frac{X_i - X_{\min}}{X_{\max} - X_{\min}} \tag{4.1}$$

X_i and X_i are the initial values and normalized values of each feature, respectively. $X_{\min}$ and $X_{\max}$ represent the maximum and minimum of this feature. The clustering results of this method are usually measured by three criteria: class target value, intra-cluster tightness and degree of separation between clusters. When the value of the cluster objective function is lower, the clustering results in the cluster are better [12]. With the decrease of the spacing between clusters, the clustering efficiency of clusters increases. As the distance between clusters increases, the clustering efficiency of clusters also increases. The number of particles in PSO-KP and the number of chromosomes in GA-KP were set to 20, and other regulation and control indicators were set in a general way. In the PSO-KP method, it is improved by taking $w_1 = 0.9, w_2 = 0.2$ as the initial value. $c_1 = c_2 = 2.0$ is used to express the acceleration coefficient. The maximum speed limit is denoted by $V_{\max} = 0.5$. The interaction possibility of the GA-KP method is expressed by $Pc = 0.6$, and the mutation possibility is expressed by $Pm = 0.05$.

Table 4.1: *Comparison of clustering results of various algorithms.*

Clustering algorithm	Evaluation criterion 1: Objective function value			
	Mean value	Standard variance	Minimum value	Maximum value
K-prototypes	0.7290	0.0824	0.6031	0.8965
GA-KP	0.5675	0.0221	0.5272	0.6168
PSO-KP	0.5225	0.0179	0.4926	0.5628
Clustering algorithm	Evaluation criterion 2: In-class distance			
	Mean value	Standard variance	Minimum value	Maximum value
K-prototypes	40488	5929	33486	50917
GA-KP	39696	1529	34623	41753
PSO-KP	40042	1401	37632	42252
Clustering algorithm	Evaluation criterion 3: Distance between classes			
	Mean value	Standard variance	Minimum value	Maximum value
K-prototypes	16.3921	2.2467	9.4027	19.4889
GA-KP	17.0264	1.3935	13.5611	20.1120
PSO-KP	20.0553	0.5652	17.9706	21.0883

4.2. Result Analysis. In the test, three algorithms for K-prototypes, GA-KP and PSO-KP, were executed 30 times and 100 times for each cycle, respectively. Table 4.1 shows the objective function values, in-class distance, standard deviation, and minimum and maximum values of the results of 30 operations.

It can be seen from Table 4.1 that the mean value and standard deviation of functions obtained by the K-prototypes algorithm were the worst. The GA-KP method gives the second-best value. The PSO-KP method is the best [13]. There is little difference between the three methods in the distance between classes. K-prototypes have the advantages of high mean value and low intra-class cohesion. GA-KP and PSO-KP methods have lower mean and mean square error and higher degrees of intra-class aggregation. GA-KP is slightly better than the K-prototypes method regarding distances within clusters, but it is better than GA-KP. Therefore, the PSO-KP method can ensure small coupling between clusters. In addition, the K-prototypes algorithm may also have local extreme values, and PSO can solve the problem of K-prototype's local extreme values in a certain sense, but it can better prevent falling into local extreme values. Compared with the K-prototypes strategy PSO-KP, which organically integrates the advantages of particle swarm optimization with K-prototypes, the particle swarm optimization has a robust global search performance, thus avoiding the defect of K-prototypes function quickly falling into local optimization [14]. For the generation of the next generation population, the idea of K-prototypes is adopted for genetic optimization of the particles, combined with K-prototypes' powerful global optimization ability and fast convergence characteristics to accelerate the search speed. Figure 4.1 shows the convergence rate of each method's optimal clustering objective function in 30 cycles. The convergence of the K-prototypes algorithm is the best, but its convergence function is too large. It is easy to fall into local extreme values [15]. The GA-KP method has a lower convergence rate, but its final function is smaller than the K-prototypes function. Compared with the K-prototypes method, the convergence rate of the PSO-KP method is slightly inferior to the K-prototypes function, but its convergence rate is higher, it can reach the optimal adaptation point, and its stability is better than that of standard genetic algorithms.

Because the selected test samples have specific classification and recognition, the cluster analysis method can be used to classify them. Table 4.2 shows the accuracy rates of the clustering results of the three algorithms. The accuracy of the method is only slightly higher than that of the K-prototypes method, while that of the PSO-KP method is higher than that of the other two methods, and the accuracy rate for each test is [83.24%, 88.96%], almost unchanged. The experimental results also prove that the PSO-KP method improves the clustering effect and stability.

5. Conclusion. A new hybrid clustering algorithm for prototypes was constructed by combining PSO with K-prototype functions. The advantages of the PSO and K-prototypes algorithm were organically integrated. This method can effectively solve the problems existing in the K protection method. The selection of the original cluster is too particular, and the local extreme value can quickly occur to improve its clustering ability

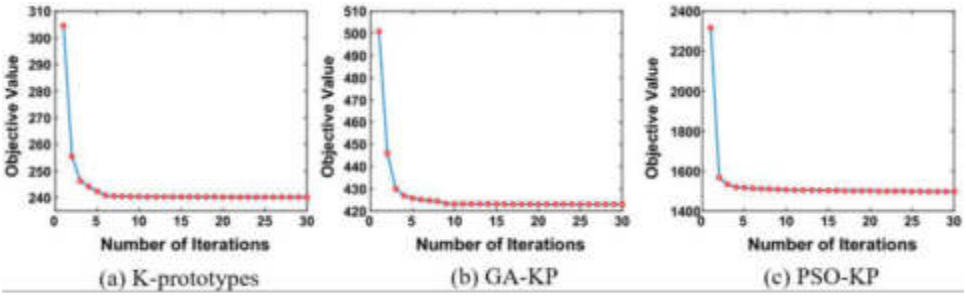

Fig. 4.1: *Convergence curves of optimal clustering objective functions for various algorithms.*

Table 4.2: *Clustering accuracy rate.*

Clustering algorithm	Accuracy rate of clustering results		
	Mean value	Minimum value	Maximum value
K-prototypes	51.90%	39.88%	71.45%
GA-KP	60.17%	50.49%	74.40%
PSO-KP	89.16%	86.40%	91.91%

and stability. Simulation results show the effectiveness of this method.

THE APPLICATION OF DEEP LEARNING IN SPORTS TRAINING

FANGLING YAN* AND QIUPING PENG†

Abstract. In response to the problems of overfitting, susceptibility to interference information, and insufficient feature expression ability in existing deep learning methods for sports action recognition, the author proposes a deep learning sports action recognition method that integrates attention mechanism. This method proposes a video data augmentation algorithm in data preprocessing to reduce the risk of model overfitting. Then, during the video frame sampling process, the existing sampling algorithms are improved to effectively suppress the influence of interference information. In the special section, the network residual consolidation is proposed to improve the feature extraction capacity of the structure. The Long Term Time Transform (LSTM) network is used to solve the problem of the global correlation of the spatial correlation, and the classification algorithm is achieved by Softmax. and the classification algorithm is proposed. The experimental results show that the recognition rates of this method on UCFYouTube, KTH, and HMDB-51 data are 96.73%, 98.07%, and 64.82%, respectively.

Key words: Deep learning, Sports training, Residual network, Attention mechanism, Long short-term memory network

1. Introduction. Identification and prediction of human body mass can provide useful supporting information for sports training [1]. By obtaining the relevant information of human movement and combining it with the data structure, adjusting the content of sports can improve their sports level. With the continuous development of computer technology, intelligence technology is also gradually growing.Deep neural networks (DNNs) can study data features to distinguish and distribute large-scale data, but the latest techniques still can not be directly used to capture human data. In order to capture human motion data, the resolution filters have to cover all human joints, so the resolution only occurs in the temporal direction [2,3]. DMP is a special hardware of IMU equipment which can calculate quaternion data by reading sensors. IMU directly receives the data from the auxiliary system, allowing the system design process to process the sensor data fusion without the interference of the system application process.

The purpose of the recognition algorithm is to determine the action taken by the human body in the video. Because of its application in intelligent building, intelligent security, human-computer interaction, video retrieval and so on, it is a very challenging research topic. In the field of behavior recognition, people have written a lot of textbooks, and carried out a lot of experiments on human contour, human node, space-time interest point and motion parameters. The traditional teaching material extraction method is too dependent on the content of the teaching material, and its anti-interference and generalization ability are not strong, so it is difficult to popularize. In contrast, deep learning can study individual personality traits more effectively. On this basis, a feature extraction method based on deep learning is proposed.

Sports is an activity with profound cultural heritage, which can not only exercise the body, but also improve the spiritual quality. The sports humanistic spirit is a kind of moral concept and humanistic spirit in sports, and it is an indispensable factor in sports. Among them, personality cultivation, as an important aspect of sports humanistic spirit, has a unique connotation and value.Personality cultivation refers to the behavior habits, ideas and moral level formed by an individual in social communication, which is the most important and basic quality in a person's life. In sports, personality cultivation is regarded as a value concept. In sports, justice is an indispensable value concept. In a competition, the referee needs to cut the result fairly, and the athletes need to follow the rules and respect the opponent. In training, honesty is even more important. Sports is a process of constantly challenging themselves. Athletes constantly transcend the limits and create new records.

*Dongchang College of Liaocheng University, Liaocheng, 252000, China
†School of Physical Education and Health Science, Guangxi Minzu University, Nanning, 530006, China (Corresponding author, pqp2022@126.com)

This spirit of challenging the limit not only exists in competitive sports, but can also be applied in daily life. Challenge their own limits, need to have a kind of indomitable spirit and perseverance.

Athletes need to work hard in every training and competition, and be indomitable in the face of difficulties. Only in this way can we go beyond our limits and achieve faster, higher and stronger goals. The spirit of breaking the limit is not only the essence of sports, but also an important spirit in life. In study, work and life, only by constantly challenging their own limits, can we make continuous progress and achieve the maximization of self-value. Therefore, the spirit of breaking through the limit occupies an important position in the humanistic spirit of sports.

Another connotation of sports humanistic spirit is team cooperation. In sports, whether it is team competition or individual competition, athletes need to cooperate and support each other. Only on the basis of team cooperation, can we achieve the best results and performance.Teamwork is not only in the competition, but also in the daily training. In the training, the team members need to cooperate with each other, encourage each other, help each other, to overcome difficulties, overcome their own weaknesses, and constantly progress. Teamwork is also a value and a spirit. Only on the basis of team cooperation, can we realize the maximization of self-value, and can better complete various tasks in work and life. In the team cooperation, everyone's contribution is indispensable, only everyone can do the best, can achieve the best results and achievements. Team work is an indispensable part of sports humanistic spirit, which emphasizes team spirit and cooperation ability, and is a positive, unity and cooperation spirit.

Sports training is the key link to cultivate athletes 'physical quality and competitive level, and also an important way to cultivate athletes' personality cultivation. In sports training, through participating in different forms of sports activities, athletes can learn and exercise their own conduct and moral character, and constantly improve their moral level and psychological quality. Through sports training, athletes have learned to make unremitting efforts, overcome difficulties and overcome themselves, as well as life attitudes and values such as compliance with rules, respect for opponents, discipline and civilized competition. At the same time, sports training can also cultivate athletes' tenacity, courage, confidence and perseverance, so that they are in the face of setbacks and difficulties, perseverance, do not give up the belief in the pursuit of success.The factors of cultivating athletes' personality cultivation can make athletes have more sense of responsibility and responsibility in daily life, and face various challenges in life more happily, confidently and openly. Therefore, sports training is not only to improve the sports level of the athletes, but also to cultivate the personality cultivation of the athletes, shape the healthy personality of the athletes, stimulate the athletes' sense of social responsibility and patriotism, and improve the spiritual civilization quality of the athletes. These factors can help the athletes to better integrate into the society and contribute to the development of the society.

Sports training can not only improve the physical quality and competitive ability of athletes, but also improve the income level of athletes, which is also the spiritual value and significance of sports humanities. Sports training can provide a platform for athletes to show off their competitive level, and participating in various competitions can allow athletes to receive prize money and awards. Athletes can get more income through their own efforts and performance, which can be used to create more wealth value and improve the living conditions of athletes. At the same time, successful athletes can get more business opportunities, such as signing sponsors, endorsing promotion products, so as to earn more income. The actual effect of this aspect can improve the income level of the athletes and make a greater contribution to the athletes' family and society. In addition, this can also promote social development and promote economic growth.Successful athletes can guide more people to participate in sports activities through the personal image and influence of the athletes, and increase the development and potential of the sports industry. At the same time, the beautiful image and sportsmanship of athletes can also bring more positive energy and positive influence to the society. In sports training, improving the income level of athletes can not only help athletes improve their living conditions, but also bring more positive social impact and promote the development of sports industry and social progress.

Sports training is not only to improve the competitive level of athletes, but also to establish a healthy training environment, to reflect and penetrate the value and significance of sports humanistic spirit.The establishment of a healthy training environment can promote the physical and mental health of athletes, and improve their comprehensive quality and competitive ability. A healthy training environment should include perfect training facilities and equipment, scientific training plans and methods, and reasonable diet and rest arrange-

ments. At the same time, the mutual trust and respect between trainers and athletes is also an important part of the healthy training environment. Establishing a healthy training environment can cultivate athletes' good qualities and behavior habits, such as respecting rules, observing discipline, overcoming setbacks, teamwork, professionalism, etc. These qualities and habits can not only be improved in sports training, but also be applied in daily life. This quality and habit can not only enable athletes to achieve better results and performance in their competitive career, but also make them become better citizens and make more contributions to the society.In addition, a healthy training environment can also enhance the athletes 'confidence, form a healthy interpersonal relationship, and improve the athletes' mental state and cultural quality. These improvements can not only promote individual growth and development, but also make more contributions to social development and progress. Establishing a healthy training environment can not only improve the competitive level and physical quality of athletes, but also promote the improvement of comprehensive quality, and form a healthy personality. This is also one of the values and significance of the sports humanistic spirit.

Sports training is not only to improve the sports quality and competitive ability of athletes, but also to inherit and carry forward the sports culture, and to reflect and permeate the value and significance of the sports humanistic spirit. Inheriting sports culture can enable athletes and the public to better understand and feel the cultural heritage of sports, and better understand the significance and value of sports. Through inheriting and carrying forward sports culture, more people can understand the spirit and value of sports, form a healthy lifestyle and a positive attitude towards life, and play a more active role in social life. Inheriting sports culture can also promote the interaction and integration between athletes and spectators, enhance mutual understanding, and improve sports cohesion. At the same time, it can also better promote and develop various sports, spread sports culture knowledge, and promote the development of collective and individual.Therefore, inheriting sports culture is a necessary way to improve the sports training system and improve the national quality. Inheriting sports culture can also carry forward and inherit the national cultural tradition and enhance national identity and pride. Integrating national cultural elements in sports and combining traditional culture with modern science and technology can promote the innovation and inheritance of traditional culture, and promote the transformation and development of cultural tradition to modernity. Inheriting sports culture in sports training not only helps to shape the cultural temperament and spiritual pursuit of athletes, but also can promote the development of cultural inheritance and enhance the national spirit. This is also one of the values and significance of the sports humanistic spirit.

Exercise can not only exercise the body, but also contribute to the balanced development of physical and mental health. Coaches should encourage athletes to pay attention to their physical and mental health, and guide athletes to achieve their inner balance and health through sports. Competition is only one aspect of sports, and sports itself can bring athletes a lot of competition, such as teamwork, self-monitoring, discipline and so on. The coach should emphasize the value outside of these games, so that the athletes realize that as an athlete, whether in training or competition, should have these spiritual characteristics.In sports, success is not always fixed, and in many cases, the outcome of a competition can be influenced by various factors. Coaches can guide athletes to better analyze, evaluate and summarize various problems in sports training through self-thinking, which can help athletes expand their vision, enhance their critical thinking ability, and thus enrich their spiritual life. Humanistic spirit can enrich the spiritual life of athletes in sports training, so that athletes can get inner satisfaction while exercising[4]. In addition, the current authentication system also faces the following problems: fewer animation instances in operation, overflow; There are a lot of redundant frames in the video that can be easily attached to the pattern[5]; The network structure is unable to extract the essential features, which affects the improvement of the recognition rate. The measures taken by the author to solve the above problems include: integrating data augmentation algorithms in data preprocessing to reduce overfitting caused by small sample size; and Reduce the impact of nonvolatile data by filtering low-level video data; By integrating the color module into the remaining network, the extraction of discrimination is improved [6,7].

2. Methods. In the process of recognizing video images, it is necessary to process them first, and then classify them. If each frame is processed according to the input data, the calculation result of this algorithm can be greatly improved. On this basis, this paper designs a face recognition method based on R3D network, which extracts 16 frames from each video and weights them. Finally, a soft classifier is used to classify behaviors. On this basis, a new method based on data processing, feature extraction and behavior classification is proposed,as

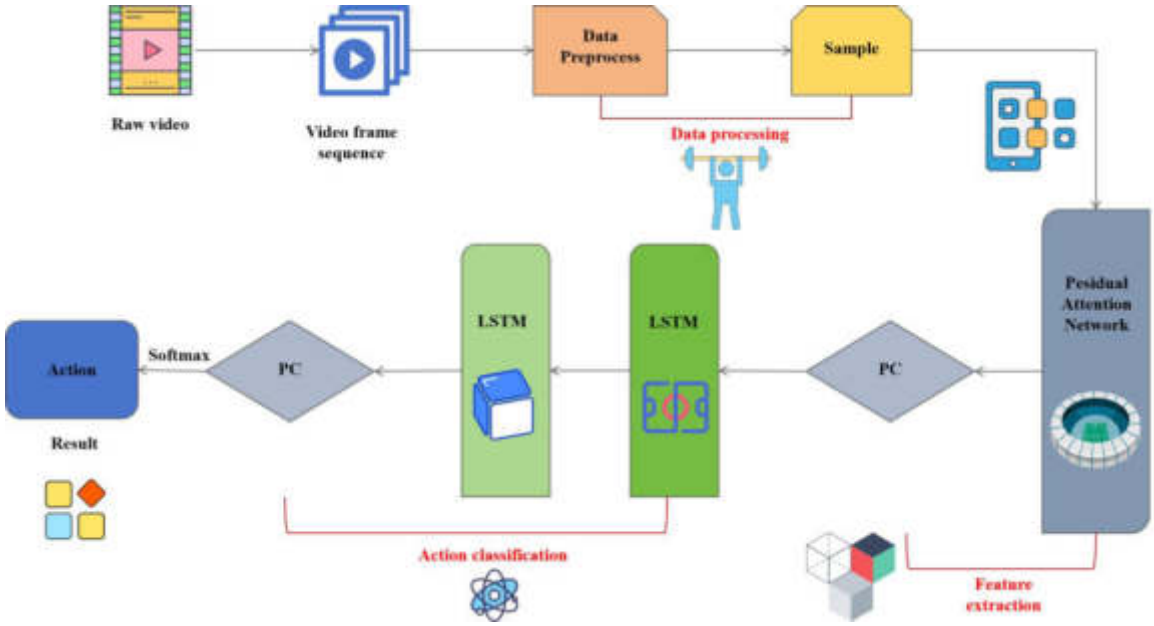

Fig. 2.1: Overall framework of the model

shown in Figure 2.1 [8].

2.1. Data processing.

(1) Data preprocessing. The traditional data pre-processing method is as follows: firstly, the fmeg module is used to sort the video into the system of video frame, and secondly, the first video frame is equal to the training requirement; and secondly, the first video frame is equal to the training requirement; Step three, focus on the cultivation and evaluation of video frames; Step four, convert the cropped video frame into a tensor form; Step five, tensor regular.

The algorithm has strong robustness, but it also faces two problems: first, the average confidence of the image in the image will cause the loss of the information boundary in the image; Secondly, the small number of action recognition samples of large samples leads to the phenomenon of overfitting during training.Therefore, in order to alleviate the above problems, the author proposes a data augmentation algorithm for videos (hereinafter referred to as Algorithm 1), in which, using a video frame sequence $\{f_1, f_2, ..., f_n\}$ to represent each action video V facilitates the indirect processing of video data using image processing methods [9]. If the video source has 50 frames and the output code range is (-6.6), after the data augmentation processing, the data can be expanded to 600 times. Meanwhile, the horizontal interpolation of video frames can also solve the problem of data edge loss by the average confidence. Therefore, the author incorporates data augmentation algorithms into data preprocessing, and the improved process of data preprocessing is as follows: firstly, data augmentation; and Step 2, scale; Step three, cut; Step four, alternating tensors; Step 5, regularly.

(2) Video frame sampling. The video frame structure mentioned in the human character recognition algorithm of R3D network is taken to measure the overall timing of the video frame system [10,11].

The specification is automatically generated with an L code of (0, R-16), where R is a video length parsed into a video frame; and Starting from frame L, select 16 frames of the sequence image as input to the model. Although this analytical method solves the computational cost problem caused by input in the network structure, it does not take into account the problem of data discrepancy in all the video frame sequences.If the initial output of the frame is in the low time frame data of the whole video, the input data obtained from the modeling process of R3D network human behavior recognition algorithm will be related to the model. Based on this, this paper proposes a human motion recognition method based on R3D network (hereinafter referred to as

"Algorithm 2"). In the algorithm 2, if the video frame rate is very low (n< 48), by using the index to ignore the effect of the frame parameter, the h number in the range of (0,n-16) is automatically generated, and 16 frames are selected from the h frame of the frame; In the case of high video frame rates, duplicate frames are removed in the start and end times and a random number h is generated in (n/3∼16,2 n/3∼16). Next, an image is selected from the 16th frame in the h frame of the text.

2.2. Feature extraction. Monitoring technology is to use neural networks to extract the information in the focus area, and to restrict other irrelevant information [12]. the Convolutional Attention Module (CBAM), as a lightweight module, has a rating of only 2.53×106, occupying very little expense. Therefore, in the special section, a subset of integrated circuit of CBAM is proposed.

(1) The basic structure of CBAM. CBAM includes two aspects: channel listening and spatial listening. Channel monitoring is an effective decision-making method, which assigns a higher weight to the channel with a large amount of information and uses it to study the source of the main message[13]. On this basis, this project proposes a method based on the maximum pool length and maximum pool length to compress the feature map F, and on this basis, the two feature fragments are introduced into the multi-layer perceptron (MLP), so as to reduce the coding and improve the performance. Finally, the MLP output signal is processed, and the channel density weight coefficient MC is obtained using the S-type function:

$$\begin{aligned} M_C =& \sigma(MLP(AvgPool(F))) + MLP(MaxPool(F)) \\ =& \sigma(W_1(W_0(F_{avg}^C)) + W_1(W_0(F_{max}^C))) \end{aligned} \tag{2.1}$$

CBAM multiplies the channel density weight factor MC by the input F, resulting in a new F'. Then, F 'is input into the airspace to obtain the spatial variation of the weight coefficient MS [14]. This paper presents a new algorithm. Finally, the F operation is performed on MS to obtain the final auditory feature F represented by formulas 2.2 and 2.3:

$$F' = M_C \bigotimes F \tag{2.2}$$

$$F" = M_S \bigotimes F' \tag{2.3}$$

(2) Improvement of CBAM. During training, each node in the network will dynamically adjust according to different inputs, which has a great impact on the subsequent characteristics. During collaborative learning, if the MLP weighs between the two groups of characteristics identical to the training, there will be a preceding problem. In order to solve this problem, improvements have been made to the channel monitoring system of CBAM. Firstly, concatenate and fuse the features after average pooling and maximum pooling, and then train the weights W_0' and W_1' through MLP, as shown in equation 2.4:

$$\begin{aligned} M_C =& \sigma(MLP([MaxPool(F); AvgPool(F)])) \\ =& \sigma(W_1'(W_0'([F_{max}^C; F_{avg}^C]))) \end{aligned} \tag{2.4}$$

In the formula, [MaxPool (F); AvgPool (F)] is the fused feature after concatenation. MLP consists of two FC layers, each with corresponding weights W_0' and W_1' [15]. After improving the channel attention module of CBAM, the parameter quantity of the weight W_0' obtained through training in the first FC layer of MLP is greater than the W0 before improvement. More, the performance of the model is stronger. Furthermore, although the improved W_1' has the same number of parameters as the pre improved W1, However,the development utilization of FC second layer in MLP can account for the maximum reservoirs and the average reservoirs,better the correlation between these two. For the sake of simplicity of description,an improved CBAM called C-CBAM,with only 2.99 units$\times 10^4$ buffer.

(3) Residual module. In the domain model, the network part uses the ResNet50 pattern and has sixteen sections.

To the right of the dotted box is a shorter connection that translates the input x directly into the output position. If the difference between x and F (x) is greater than 1. x changes in size; The difference in size. This

virtual block diagram represents the rest of the content, and it contains three levels, using 1 by 1. This project intends to use convolutional neural network to reduce the channel of input tensor, use 3x3 small convolution kernel to reduce the operational complexity, and then use 1xA convolution kernel and tensor channel to obtain F (x) output. Thus, the output value of the module as a whole is:

$$H(x) = F(x) + x \tag{2.5}$$

After F (x)=0, H (x)= x, this is the graph. Therefore, this project takes the residual probability F (x) as 0 to study the network part. In addition, it can be seen from formula (5) that the gradient loss and network problems caused by rules can be effectively avoided when the error reverse occurs in the residual network. Put 1 at x.

(4) Residual module integrated with G-CBAM. Put the rest of the pieces into GCBAM. Firstly, G-CBAM model is used to optimize the input features, and the optimal features are obtained. On this basis, according to the main information obtained, the depth feature of the original model is extracted. Finally, on this basis, the obtained results are further supplemented and integrated.

2.3. Action classification. Repetitive neural networks (RNNs) can handle timing problems well, but there are problems such as gradient loss when dealing with large-scale data[16]. To solve this problem, based on the specific structure of recurrent neural network, short-term memory model has the best performance in processing remote data. It inputs and outputs from the input gate, the forget gate, and the input gate.Among them, the input gate is located in the middle of the figure The layer, tanh layer, and a point by point multiplication "$\bigotimes$" determine how much input xt at the current time needs to be saved in the current unit state c_t; The recursive formula for updating LSTM is as follows:

$$f_t = \sigma(W_f h_{t-1} + U_f x_t + b_f) \tag{2.6}$$

$$i_t = \sigma(W_i h_{t-1} + U_i x_t + b_i) \tag{2.7}$$

$$\overline{c_t} = tanh(W_c h_{t-1} + U_c x_t + b_c) \tag{2.8}$$

$$c_t = f_t c_{t-1} + i_t \widetilde{c_t} \tag{2.9}$$

$$o_t = \sigma(W_o h_{t-1} + U_o x_t + b_o) \tag{2.10}$$

$$h_t = o_t \cdot tanh(c_t) \tag{2.11}$$

In the formula: W_f, W_i, W_c, W_o and U_f, U_i, U_c, U_o are the corresponding weight matrices, b_f, b_i, b_c, b_o is the corresponding bias, σ and tanh is the activation function.

3. Results and Analysis.

3.1. Experimental Environment. The author's test run environment is as follows: operating Ubuntu 16.04; Deep pytirch training 1.6.0%; Universal parallel computing architecture cuda10.2%; Deep neural network GPU fast cudnn7.6.5 library; GeForceRTX2080Ti graphics card with 11GB of memory; Picture card driving system nvidia450.80; 512GB Hard Disk [17].

3.2. Datasets. UCFYoutube.com has a total of 1,600 videos in 11 categories: shooting, swinging, swinging, cycling, horse riding, dog walking, diving, tennis, trampoline diving, volleyball. There are 25 different videos in each category, each with no less than four 320x240 pixel video clips. The KTH file contains 600 videos with a resolution of 160 px and 120 px. This case consists of 25 people who do 6 things in 4 different situations, including walking, jumping, speed, clapping, and swinging volleyball. HMDB51 materials consist of 6849 films, divided into 51 processing groups, with at least 101 films in each category and resolution of 320 pixels, × 240

Table 3.1: Experimental Parameters

parameter	numerical value

pixels. According to the category of actions, they can be divided into 5 types: facial acts, such as smiling and chewing; and A facial movement associated with surgery, such as smoking or eating; Physical exercise, such as shaking and walking; Interaction between bodies and objects, such as combing hair, dribbling balls, and drawing swords; Interactions between people, such as hugging and kissing. In this study, UCFYouTube and HMDB51 standards were used as 60 training topics, 20 were verified and 20 were tested. In terms of KTH data, because the sample number is relatively small, five different hybrid combinations are used in this method, 80% for training and 20% for testing.

3.3. Experimental Details. First, for UCFYouTube and HMDB51 data, their resolution is both 320 pixels×240 pixels, using it directly can increase the memory throughput due to excessive computation, need to be expanded, however, the KTH format is only 160x120 pixels, so the model can be imported directly. Secondly, in view of the high requirement of GPU computing power for video frequency recognition, this project intends to use transfer learning method to extract features from the model to improve training efficiency. That is, ResNet50, which retrains the web, has been ported to the ResNet standard adopted by the authors.Finally, in order to minimize the risk of network overfitting, each FC layer adopts Dropout technology to minimize the interference of nodes in FC layer with certain probability. The experimental results of the author are shown in Table 3.1.

3.4. Experimental process.

(1) The impact of attention modules on model performance. This project intends to make use of the accuracy and loss characteristics of YouTube (ResNetNetT), RLNetRLCBAM and RLNetG-CBAM modes (RLNetG-CBAM) (see Figure 3.1 and 3.2). All three models have large deviations in the initial learning stage, and tend to stabilize with the increase of the number of iterations. Compared with the traditional content-based network model, the combination of RLNet and content-based network model can effectively improve the classification effect of images, but the accuracy and loss rate of images will be greatly changed during training. The experimental results show that the combination of RLNet and G-CBAM has higher recognition rate and lower fall rate. The method has good stability because of its fast convergence speed, fast convergence speed and fast convergence speed. On this basis, a new method based on collaborative learning is proposed in this project. Through the correlation analysis of multiple elements, it can better deal with the correlation between multiple elements, reduce the impact of errors, reduce their importance, and enhance the stability and credibility of the model.

(2) Verification of the effectiveness of improvement measures. This project intends to use RLNet, RLNet1, RLnet2, 2 CBAM, 2G-CBAM and other models in UCFYouTube database to verify the above methods. The test results are shown in Table 3.2, where RLNet1 is the abbreviation of RLNetAlgol, and RLNet1 and 2 are the abbreviation of RLNetAlgolAlgo2 [18].

According to Table 3.2, various improvement measures have improved the recognition performance of the model by 1.57%, 1.17%, 1.89%, and 1.28%, respectively.

(3) Visualization of feature regions. Find out the implementation of the finite element method in the special section using Grade CAM technique. It can be clearly seen that the network extended with CBAM can not only locate the area where the main features reside, but also restrict other inefficient information.

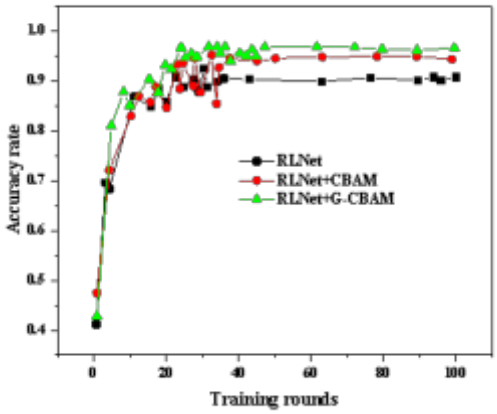

Fig. 3.1: Accuracy Curve

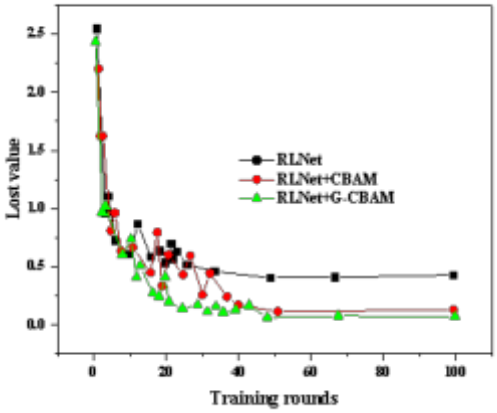

Fig. 3.2: Loss value curve

3.5. Experimental Results. In order to fully validate the method proposed in this article, experiments were conducted on three datasets: UCFYouTube, KTH, and HMDB51.

(1) Validation on UCFYouTube. After the training sample has been completed, the recognition rate of this sample on UCFYouTube data has reached 96.73%, which achieves better recognition than the existing recognition method, as shown in Table 3.3.

(2) Validation on KTH. The characteristics of KTH are that there are less information related to background, no interaction behavior, and the information is relatively simple. During the training process, the first 120 films in KTH are selected as the test samples, and the remainder is used as the training process, called the data, and then the first cross is validated. Similarly, a total of 5 cross-sectional trials were validated, and an average cost was taken as an experiment, as shown in Table 3.4 [19]. The The experimental results show that the recognition rate of RLNet1,2G-CBAM model of KTH reaches 98.06%.

Furthermore, as shown in Table 3.5, this method still has better recognition performance compared to other methods on the KTH dataset.

(3) Validation on HMDB51. 5151 chip data is mainly video, the data distribution is wide, the teaching content is complex. This project will use HMDB51 data collected by HMDB51 to test the recognition effect of RLNet1,2 GCBAM model in complex environment by comparing it with other algorithms. The results are shown in Table 3.6.

From Table 3.6, it can be seen that this method has some improvement compared to other motion recognition systems of HMDB51, but there is a significant difference in recognition accuracy compared to UCFYouTube and KTH [20]. It is shown that the method has a certain improvement in recognition accuracy. The main reason is that HMDB51 has higher video quality than other dual data rate, and has many disadvantages, such as camera motion, occlusion, background complexity, and changes in lighting quality, which leads to lower

Table 3.6: Comparison with other methods on HMDB51

Method	Accuracy/%

$RLNet_{1,2}$ +G-CBAM(This article)	64.82

recognition rate.

4. Conclusion. The author proposes an in- depth learning strategy that integrates human resource management process. This method reduces the risk of model overfitting by integrating data augmentation algorithms into data preprocessing. By filtering low data rate video frames, the influence of redundant data is reduced. By integrating the light weight of G-CBAM into the residual network, an improved performance is achieved with a small number of parameters. Ultimately, recognition rates of 96.73%, 98.07%, and 64.82% were achieved on the UCFYouTube, KTH, and HMDB-51 datasets, respectively. Through the simulation of HMDB51 data, it is proved that the accuracy of this algorithm in complex cases is very low. So, the next step is to focus on how to enhance the credibility of the model in many negative ways.

PERSONALIZED HEALTH MANAGEMENT STRATEGIES BASED ON DEEP REINFORCEMENT LEARNING IN THE NETWORK ENVIRONMENT

LILI WEI* AND JINDA WEI†

Abstract. In order to study the optimal personalized motion push target, the author proposes a personalized health management strategy based on deep reinforcement learning in the network environment. Firstly, the research problem is defined, and a real-time interactive personalized motion target decision-making model is constructed; Subsequently, in response to the uncertain characteristics of user behavior in the problem, a deep reinforcement learning algorithm was adopted, combined with the departure strategy temporal difference learning method and neural network nonlinear fitting method, in order to learn strategies from user historical data; Finally, the effectiveness of the proposed method was validated using a real dataset from Fitbit. The research results indicate that personalized motion goal push services based on deep reinforcement learning can help users cultivate a healthy lifestyle and improve their personal health management level by analyzing user behavior data in real-time, providing scientific guidance and timely incentives.

Key words: Mobile health information service management, Personalized sports goal optimization, Real time interaction model, Deep reinforcement learning

1. Introduction. The process of networking in modern society profoundly shapes the network characteristics of traditional culture, especially bringing tremendous changes to the lifestyle of young people [1]. The openness, dynamism, and virtuality of online cultural forms have expanded traditional receptive learning into experiential online learning, promoting active cognitive expansion; It also attracts students to stay away from classroom teaching, resulting in a weakening of the quality of formal learning and negative impacts on psychological, moral, and legal aspects. Combining the characteristics of the lifestyle of the network society in the era of information technology and knowledge economy, the author from the perspective of "online cultural education", links the prosperity and development of online culture with the healthy growth of young people through "education", and systematically examines and analyzes the healthy growth guidance strategies of young people towards "online cultural education".

The content construction and development of online culture have brought more diverse ways for young people to acquire knowledge, expanding their cognitive perspectives on nature, society, and thinking. The vast group of school students in their growth period, to a certain extent, suffer from lack of discernment and self-control leading to abnormal online behavior. Advocate for positive online cultural education among teenagers, establish a correct view of the internet, form a purified online environment and a good personal psychology, thereby cultivating a healthy online lifestyle. The following provides a method guide for the orderly development of online cultural education and the promotion of healthy growth of young people by exploring the connotation of the correct network view and the mechanism of educational innovation. Network culture originates from the spiritual reference of traditional culture and is also a physical reconstruction based on the network environment. The concept of network culture is the expression of the role of values in the field of network culture, which refers to people's overall understanding and basic views on network culture issues, including value goals, value evaluation, and value orientation. It reflects the attitudes of specific groups and individuals towards network culture, namely the cultural values, thinking patterns, and behavioral tendencies under the existing norms of the network society. Due to differences in ideological quality, moral cultivation, and other factors, teenagers inevitably exhibit different characteristics in their views on online culture [2,3].

*Department of Sports, Shangqiu Polytechnic, Shangqiu, 476000, China
†Legal Affairs Department, ZTE Corporation, Shenzhen, Guangdong, 518000, China (Corresponding author, Wei12345620240126.com)

The correct view of online culture should be to use online culture to enhance knowledge understanding, expand thinking horizons, promote social value convergence in learning progress and healthy growth. Therefore, establishing a correct view of online culture should adhere to traditional cultural values, pay attention to the harmonious atmosphere, moral standards, and legal compliance of online participation. The basic connotation of the healthy and upward network culture view is the overall understanding and external behavior of the network lifestyle in terms of culture, which conforms to the overall orientation of the socialist core value system. Require individuals and groups to reflect their beliefs, ideals, spirits, morals, and psychology in a rational adherence to social core values in their natural state, viewing the internet as an extension of the real society, and adhering to its essential constraints of technological tools, resource platforms, and knowledge education. The concept of online culture, as a cognitive view reflected in the perspective of online culture, requires young people to have "advanced culture, harmonious themes, scientific development, and key control", in order to form correct goals for group participation and individual intervention in online culture, establish scientific standards for measuring the value of online culture, and continuously regulate and guide the positive and innovative orientation of online culture education.

A healthy and upward view of online culture can help teenagers align their learning and growth goals, rely on online cultural education to focus on the main channel of knowledge learning, promote the improvement of thirst for knowledge and the cultivation of values.

Health management is an effective strategy in the context of industrialization, globalization, urbanization and aging, the implementation of hypertension, diabetes and other multiple diseases, is the internal requirements of the implementation of the healthy China strategy and the implementation of a new round of healthy Hubei national action. Health management is not only a technology, but also an integrated governance of the whole population, the whole life cycle and the whole society. Government leaders at all levels should take the lead in understanding the multi-level connotation of health management and guide the whole society to promote the deepening of health management reform. Health administrative departments at all levels should take the initiative to win the attention of the government and the support of various government departments, fully consider health factors in the economic and social development planning, integrate health into all policies, promote the connection between health management planning and macroeconomic policies and social policies, and create a good development environment for health management.

At present, with the development of artificial intelligence technology, mobile devices such as smartphones can collect health-related information and accumulate massive structured and unstructured health data, such as exercise steps, heart rate, etc. How to leverage advanced data analysis and machine learning methods to fully tap into the value of massive health data, guide users to participate in fitness activities more scientifically, and help users improve their personal health status is a hot topic of concern in today's management academia and related enterprises. On August 3, 2021, the State Council issued the "National Fitness Plan (2021-2025)", proposing to build a higher-level public service system for national fitness under the national strategy of national fitness, which can fully leverage the comprehensive value and diverse functions of national fitness in improving people's health levels [4]. The plan points out that improving the level of scientific and health guidance services is the main task that the country needs to complete at present. Mobile health information services refer to service providers providing health guidance services to users based on shared personal health data, promoting users to achieve health goals such as weight loss and body shaping. But users need to go through a period of exercise to experience the effects of health improvement. That is to say, the user's exercise behavior has delayed reward characteristics. Therefore, health information service providers usually provide guidance services for users on short-term goals to generate certain motivational effects, thereby helping users persist in exercising and achieve the ultimate goal of improving their health condition. Currently, most wearable device service providers encourage users to increase their exercise volume and improve their health by setting fixed exercise goals. For example, according to the recommendations of the Centers for Disease Control and Prevention in the United States, Fitbit bracelets set a target of 10000 steps for users to exercise. The 10000 step exercise goal is difficult to match the different health needs of different users. Therefore, it is particularly important for service providers to set targeted short-term goals based on the current state of users and maximize their exercise effectiveness.

On this basis, the author explores health information service providers providing users with sports goal push

Fig. 1.1: Health Information Service Artificial Intelligence System Framework

services in a way similar to virtual coaches. This type of intelligent information service based on sports big data is a new trend in the development of the health service industry. For example, the sports social app Gudong has laid out intelligent sports and proposed using AI technology to empower and promote the development strategy of "Fitness 3.0". The author combines the concept of "Fitness 3.0" with the basic model of behavioral theory, and applies artificial intelligence technology to the service of pushing sports goals. On the one hand, compared to fixed sports goal setting, it can continuously track the user's exercise progress and make adaptive adjustments to the exercise plan. On the other hand, compared to users setting their own exercise goals, this service can provide users with more scientific exercise plans, helping them improve their health level. The author's core is to design deep reinforcement learning algorithms to achieve the functions of traditional fitness coaches, providing users with interactive and targeted one-on-one scientific guidance services. The artificial intelligence system framework for intelligent health information services is shown in Figure 1.1. The artificial intelligence module relies on cutting-edge deep reinforcement learning algorithms to collect daily exercise and other physiological data tracked by wearable devices, and learn recommendation rules for developing personalized exercise plans for users. It is worth noting that health information services can only recommend suitable exercise goals for users and cannot directly control their exercise behavior. Therefore, artificial intelligence systems need to continuously interact with users, adaptively adjust recommendation strategies based on their historical exercise data, and improve the quality of health services.

2. Methods.

2.1. Problem Description. In real-time interactive mobile health information services, service providers learn service operation strategies from historical interactive data [5]. During each interaction cycle, service providers use wearable devices to monitor user data, including physiological status, exercise status, etc. Then, based on a decision rule and the monitoring results of the user's current state, select an appropriate motion target scheme for the user. After receiving the exercise target, the user responds and executes the exercise activity. Subsequently, the service provider collects feedback information on user behavior based on wearable devices and updates the decision rules for the next cycle. Due to the fact that service providers can only determine the exercise goals to be pushed to users, they are unable to control their behavior in executing exercise activities. Therefore, the problem that health information service providers need to solve is how to set personalized optimization exercise goals for users with the goal of maximizing their long-term utility in an environment of uncertain user behavior, and improve the quality of health information services.

2.2. Model construction.

(1) Personalized Sports Objective Optimization Decision Model. The author studies the problem of health information service providers pushing personalized exercise goals to users at each decision-making stage. The author is based on behavioral economics theory and considers the impact of exercise goal setting on user utility.

At time t, t=0, 1, T. The service provider observes the user's health status ot at time t-1 through wearable devices, including the amount of exercise and calorie consumption generated. Based on this information, the service provider pushes the exercise target gt for stage t to users, which is the amount of exercise that needs to be completed. After receiving the motion target gt, the user performs exercise and generates a new health state ot+1. In this process, the user's utility includes three parts: the health benefits brought by burning calories, the cost of exercise, and the motivational value of exercise goals. The decision-making goal of service providers is to maximize the total revenue of users during the service cycle.

(2) Optimal strategy. The goal of the Markov decision process constructed by the author is to find an optimal strategy π° [6]. From the decision-making process, it can be seen that when the system is at decision time t, the trajectory from time 0 to time t is a deterministic trajectory that has already occurred, denoted as $h_t = (o_0, g_0, o_1, g_1, \cdots, o_{t-1}, g_{t-1}, o_t), t < T$. The random event of user movement from time t to service termination time T did not occur, and the utility of users recommended based on motion targets is also random. Assuming that the motion target gt is selected at time t, a profit sequence of $R_{t+1}, R_{t+2}, \cdots, R_T$ is obtained in the subsequent interaction process. For the discounted return $Y_t = R_{t+1} + \delta R_{t+2} + \cdots + \delta^{T-t-1} R_T$ obtained by mobile health service providers, δ is the discount factor. In addition, the user's state changes follow Markov properties, and the random variables after time t are only related to t. Introduce the value function v_π and the state action function q_t^π to measure the total expected utility of the policy user from time t to time T.

2.3. Deep Reinforcement Learning Methods. Mobile health information service providers need to find the optimal strategy for personalized exercise goals. Due to the influence of many random factors on user behavior during exercise activities, service providers find it difficult to predict the impact of exercise goal decisions on user health benefits. That is to say, service providers are unable to obtain accurate information on the probability of user state transition for processing the state transition process. Furthermore, it is not possible to fully model the problem of personalized motion goal decision-making. The following adopts a data-driven approach to learn strategies from the real interactive environment of health services. The author used a neural network-based algorithm for temporal differential learning of derailment strategies to solve personalized motion target optimization problems. The departure strategy temporal differential learning method, also known as Q-learning algorithm. The Q-learning algorithm combines the sampling method of valuation updates with the Bellman optimal equation of the optimal strategy to solve personalized motion target decision-making problems. However, due to the large state space of users in personalized motion goal decision-making problems, each state action pair (o, g) corresponds to a value function q (o, g) that needs to be learned, so the process of estimating the state action value function is slow. It is very important to use neural network approximation to estimate the value function q (o, g). By approximating the function, a small number of parameters θ can be used to fit the state action value function, $\widetilde{q}(o, g; \theta) \approx q_\pi(o, g)$.

(1) Algorithm design ideas. The author adopted the prioritized replayDQN method, a neural network based on priority experience replay, for temporal differential learning of the derailment strategy. During sampling, the priority of the samples was taken into consideration, which resulted in faster convergence speed of the algorithm. Firstly, construct an experience pool with an accumulated binary tree structure to store sample data, which is the historical data of users used for learning by mobile health information service providers, and normalize the data. Then, using the target strategy $\pi(g|o)$ and the behavior strategy $\mu(g|o)$, the target network DQN1 and behavior network DQN2 neural network models are constructed for the two strategies, respectively. Among them, the target strategy $\pi(g|o)$ is the strategy that the service provider needs to learn, and the state action value function fitted by the target network DQN1 is $Q(o, g; \theta)$. Behavioral strategy $\mu(g|o)$ is the behavior strategy chosen by the service provider, and the state action value function fitted by the behavioral network DQN2 is $Q(o, g; \theta')$. During the learning process, the service provider selects motion targets based on behavioral strategies $\mu(g|o)$, obtains personalized interaction data of user motion targets, and assigns weights to each sample through TD error calculation, which is the probability of each sample appearing. Store sample data and priority indicators in the experience pool.

(2) Neural network structure. There is a non-linear relationship between the estimated state action value generated by the pushed motion target and the user's state. Health information service providers obtain user feedback on the pushed exercise target service by observing the user's status. Therefore, the artificial neural network method is used to fit the state action value function, $\widetilde{q}(o, g; \theta) \approx q_\pi(o, g)$. Neural networks are divided

into input layer, hidden layer, and output layer. The neurons in each layer of the input layer and hidden layer, hidden layer and hidden layer, and hidden layer and output layer are all fully connected, with each line corresponding to a parameter. In the DQN neural network model, a two-dimensional input vector consisting of the user's exercise amount m and calorie consumption f is set in the input layer. After being calculated by the neurons in the input layer, the output features are used as input data for the next layer of neurons, ultimately outputting the state action value estimation for each selectable motion target push action. Assuming there are l hidden layers in the middle layer, where hidden layer i has hi neurons, $i = 1, 2, L.\theta$ represents the parameters of the neural network, b represents the deviation coefficient, and $\sigma(.)$ is called the activation function.

The output of the first hidden layer neuron is:

$$s_j^1 = \sigma(\theta_{1,1}^0 m + \theta_{1,1}^0 f + b_j^0), j = 1, 2, \cdots, h_1 \tag{2.1}$$

The output of neurons in hidden layer i (i=2,.., l-1) is:

$$s_j^i = \sigma(\sum_{k=1}^{h_{i-1}} \theta_{i,k}^{i-1} s_k^{i-1}), j = 1, 2, \cdots, n \tag{2.2}$$

The final output of the neural network is:

$$\widetilde{q}(G_k) = \sum_{j=1}^{h_l} \theta_j^l s_j^l + b_j^l, k = 1, 2, \cdots, n \tag{2.3}$$

Using the modified linear unit function as the activation function, the expression is as follows:

$$\sigma(x) = max\{0, x\} \tag{2.4}$$

The advantage of using a modified linear unit function is that the function is linear, with low computational complexity and fast speed. In addition, when the input is a positive number, the derivative is 1 to avoid the problem of vanishing gradients; On the other hand, modifying the linear unit function to make some neurons output 0 reduces the dependency between parameters, which helps alleviate the problem of overfitting.

(3) Design of Deep Reinforcement Algorithm. The input information of the deep reinforcement learning algorithm is the state vector $\varphi(o)$ corresponding to the user state o, and then the neural network outputs the state action value function $Q(o, g; \theta')$ of all personalized motion targets in that state [7]. Meanwhile, the cumulative binary tree structure is used to store the information obtained from each interaction with the user. Among them, the target network DQN1 obtained through experience replay is used as a label for deep learning to calculate the error of the loss function of the behavioral network DQN2, update the parameter θ' of the behavioral network DQN2 through gradient backpropagation. After θ' converges, an approximate $Q(o, g; \theta') \approx q_\pi(o, g)$. can be obtained. Finally, the optimal strategy π_* for personalized motion goal decision-making can be obtained using the greedy strategy.

3. Results and Analysis.

3.1. Data sources. The author analyzes the real data of Fitbit smart bracelets as an example. The dataset mainly consists of four parts. The Fitbit dataset in the first part is sourced from PMData, consisting of 16 users from November 2020 to March 2021[8]. The experiment utilizes FitbitVersa second-generation smart wristbands to track and record health data automatically. The PMData dataset was publicly presented at the 11th ACM International Multimedia Conference in 2021 for scientific research on mobile health management. The second part of the data comes from the "FitbitConnection" project initiated by the publicly available data sharing platform "Openhumansfoundation", which reads data generated by wearable devices by connecting users to their Fitbit accounts. From the start of the project in 2012, as of December 1, 2022, 37 individuals have publicly disclosed their personal health data. The author will preprocess the personal Fitbit data shared by the participants obtained. Due to the collection of all personal data from 7 years, the time span is too long, and user behavior habits have changed significantly. Therefore, the author divided the Fitbit data of participants

Table 3.1: Basic Information of Fitbit Sample Data

Data set	User ID	Range of motion steps	Calorie consumption range	Time frame	Sample data size
Dataset 1	P01-P16	[6,45342]	[1028,6491]	2020.11- 2021.03	2120
Dataset 2	P17-P132	[4,72417]	[118,9867]	annually(2012-2022)	33827
Dataset 3	P133-P162	[4,36019]	[50,4900]	2017.03-2017.05	1260
Dataset 4	P163-P165	[1683,39000]	[1801,4851]	2022.01- 2022.11	962

into different research subjects by year, resulting in a total of 116 sets of data. The third part of the data was obtained from the Zenodo knowledge database, which collected personal data submitted by 30 Fitbit users between March 12, 2017 and May 12, 2017 through a crowdsourcing task published by Amazon MechanicalTurk. The fourth part of the dataset sources and the experimental team's use of Fitbitarge3 generation smart bracelets to track and record the daily activities of the experimental personnel. A total of three experimental personnel's health data were collected from January 2021 to November 2021. Due to the author's research on personalized sports goal decision-making problems, although the time series data collected from 165 groups of experimental subjects varied in scope, the author optimized the decision rules for pushing motion goals to users by learning their personal historical data. The author validated the applicability of the algorithm through 165 repeated experiments. Firstly, the sample data of 165 experiments were analyzed. The daily exercise steps of the user in the data were selected as the amount of exercise completed by the user through their own efforts, m, and the daily calorie consumption f was obtained by combining Fitbit's built-in intelligent algorithm with user preprocessing such as heart rate, physical activity, and sleep.

The decision variable for personalized exercise goals is the daily exercise goal g pushed to the user, and the number of steps the user needs to complete each day is selected as the user's exercise goal. After preprocessing the raw data and removing noise, such as samples where the user did not equip a Fitbit smart bracelet, resulting in empty calorie consumption, a total of 38165 sample data were obtained. The basic information of the samples is shown in Table 3.1.

3.2. Experimental setup. Due to the fact that personalized motion goal optimization is the optimal decision strategy learned through interaction with the environment when running deep reinforcement learning algorithms. For specific users, first generate a random environment using real historical data generated by Fitbit smart bracelets [9]. Then, learn personalized sports goal decision-making. Assuming that the health information service provider pushes a set of exercise goals for users with selectable exercise steps as follows: {0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1}, among them, 0 indicates that motion targets are not recommended, while others indicate that motion targets increase proportionally by 10% of the highest historical exercise. Drawing on Jain's research on the impact of optimal goal setting on user psychology and behavior, it is assumed that the health benefits $\varphi(f_t) = \sqrt{f_t}$ brought by calorie consumption and the effort cost $h(m_t) = m_t^2/2$ put in by user exercise are assumed. The experimental parameters are shown in Tables 3.2 and 3.3. The exploration rate $\in$, TD error index α, and importance sampling index β, the number of samples extracted in a single instance m, the number of training iterations M, the number of neurons in the first layer p1, the number of neurons in the second layer p2, and the learning rate r are related to the convergence speed of deep reinforcement learning algorithms. By adjusting the parameters, good convergence results can already be achieved. Marginal loss of failure to achieve motion goals, benefits of achieving motion goals s, and discount factor δ, it is an exogenous parameter provided by mobile health information service providers to users for adaptive motion target decision-making, reflecting their sensitivity to target incentives and the time preference of enterprise decision-making. The author explores the impact of exogenous parameters on decision systems through parameter sensitivity analysis. The experimental environment is an Intel (R) Core (TM) i7-7700CPU3.60GHz (32GRAM) desktop computer running on the CentOS operating system, and the program is developed using PyCharm (version 2019.2) software.

Table 3.2: Relevant Parameters of the Experiment 1

Name	Parameter	Value
Marginal loss of failure to achieve sports goals	l	0
Benefits of achieving sports goals	s	1
discount factor	δ	0.9
Exploration rate	$\in$	0.9
Number of first layer neurons	P1	64
Number of second layer neurons	P2	64
Learning rate	r	0.0005

Table 3.3: Relevant Parameters of the Experiment 2

Name	Parameter	Value
The index of TD error	α	0.6
The index of importance sampling	β	0.4
The number of samples extracted in a single instance	m	32
Training frequency	M	20000

3.3. Analysis. In order to verify the effectiveness of the deep reinforcement learning algorithm proposed by the author in solving personalized motion objective optimization problems, the author presents experimental results [10]. Firstly, fifty users were randomly selected for training, with each user trained ten times. Each experiment can stabilize within 10000 training sessions, and the calculation time is less than two minutes. Figure 3.1 shows the variation of the error value of the loss function generated by training neural network parameters in deep reinforcement learning models. The horizontal axis represents the value of training times, and the vertical axis represents the error loss value of the loss function. From the graph, it can be seen that after training ten thousand times, the curve of the loss value tends to stabilize, and a stable sampling estimation value can be obtained. Next, the author takes the single training situation of P06 users as an example, with a decision cycle of 30 days, and each experiment is repeated 20 times for testing. We compared the user utility of optimization algorithms using personalized motion goal decision-making with Fitbit's built-in 10000 step motion goal, as well as three scenarios without motion goal motivation. Figure 3.2 shows the changes in the benefits obtained by users from participating in health information services every day during a single training process of the model. The horizontal axis represents the date, and the vertical axis represents the user's exercise reward value. After observing 20 sets of experiments, it was found that in most cases, the lower values in daily exercise benefits generated by adaptive motion goal decision-making using deep reinforcement learning algorithms appear less frequently. This means that compared to non personalized fixed motion goal decision-making, deep reinforcement learning algorithms can better adapt to the constantly changing exercise preferences of users and have a better incentive effect on their exercise behavior.

4. Conclusion. The author studied the optimization problem of personalized exercise goals in mobile health information services. Due to the influence of user physiological attributes, health needs, and exercise preferences, it is difficult to predict the motivational effect of exercise goals on users. The uncertainty of user behavior increases the difficulty of making motion target decisions. Therefore, the author proposes a decision-making problem for mobile health information services based on real-time information exchange, which can dynamically and adaptively adjust the decision-making of personalized exercise goals, achieving the goal of motivating users to complete fitness activities and maximizing long-term benefits. Firstly, the user's physiological attributes, exercise status, and other characteristics are taken as environmental factors and monitored in real-time through wearable devices. Train an intelligent agent with the goal of maximizing user health benefits and learn the optimal decision criteria for motion objectives. Subsequently, a deep reinforcement learning

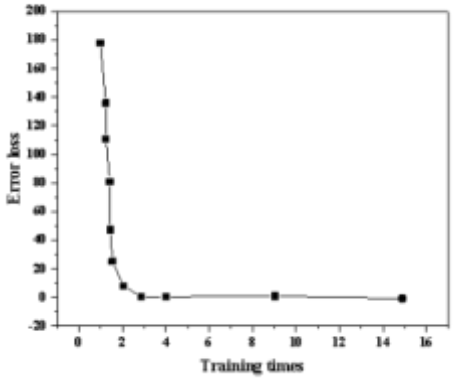

Fig. 3.1: Changes in error loss of personalized motion target decision model

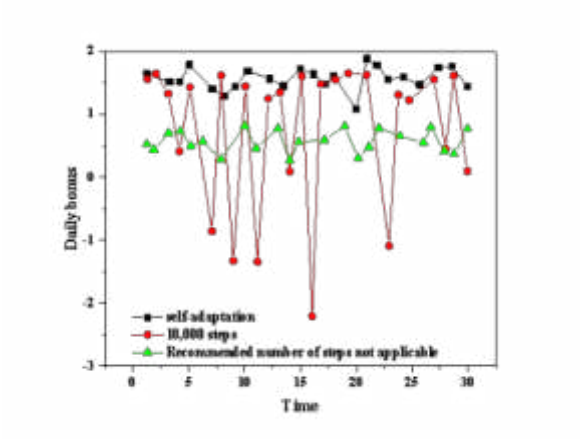

Fig. 3.2: Daily Changes in User Utility

algorithm was designed by combining techniques such as neural networks, stochastic gradient descent, and value function approximation, effectively solving personalized motion target decision-making problems based on real-time interaction. Finally, a practical case was used to verify the practical significance of the research problem and the effectiveness of the algorithm.

THE APPLICATION OF DEEP LEARNING IN SPORTS COMPETITION DATA PREDICTION

JI CHEN* AND PENGTAO CUI†

Abstract. In order to predict sports competition data, the author needs to implement the structure and related processes of the relevant competition victory and defeat prediction system, and specifically introduce and plan the implementation of each functional module. The data collection and storage module adopts Alibaba Cloud servers and combines Python to remotely and automatically collect data on a scheduled basis, according to the actual situation of game wins and losses, data cleaning and filtering are carried out, and multiple encoding forms are used to vectorize the data in order to find the best model. The data is divided according to the standard training and testing sets, and multiple classifiers are used for model training and saved locally for direct use next time; Test the above model using the training set; Compare the advantages and disadvantages of each vectorized encoding and classifier based on the final performance evaluation module. Based on the relevant experimental results, a detailed analysis was conducted to compare the advantages and disadvantages of each model, proving that introducing word vectors (word embeddings) into the competition data analysis system is worthwhile. We have obtained an excellent performance prediction model with a highest accuracy P of 0.825, a recall R of 0.729, and a corresponding F1 value of 0.774. For a prediction model that only knows the initial lineup allocation as a prerequisite, this already has sufficient practical guidance significance.

Key words: Deep learning, Sports competitions, Data prediction, Application, machine learning

1. Introduction. In recent years, the training data generated in competitive sports training has shown explosive growth, resulting in a massive amount of training data. For the massive amount of training data, athletes or coaches only focus on the valuable part of the training data [1]. Therefore, how to find the desired data in massive amounts of data, conduct timely and effective analysis, and apply it to training and competitions is an urgent problem that needs to be solved. By utilizing the powerful data processing, mining, and analysis capabilities of deep learning, the massive data generated in competitive sports training is trained and applied to competitive sports training, committed to promoting the accuracy and refinement of analysis in competitive sports training, providing technical guidance for athlete training, and promoting the scientific and information-based development of competitive sports training in China, provide some reference methods for the research and application of deep learning in competitive sports training. With the deepening development of educational modernization, the application of big data and artificial intelligence technology has become a hot direction in the field of education. An increasing number of studies are utilizing data analysis and artificial intelligence algorithms for the evaluation and analysis of educational processes and outcomes. However, current research mostly emphasizes the importance and application value of data, and lacks specific evaluation systems and methods to support it [2-3]. In physical education teaching, algorithmic models can be used to evaluate students' athletic performance and teaching effectiveness.

The following are some possible algorithm models and evaluation indicators. Machine learning models can predict student sports performance and performance scores by analyzing student sports performance data, such as athlete posture, movement, speed, strength, etc. These models can be trained based on a large amount of data to achieve higher accuracy; By using data mining models, students' behavior patterns during exercise can be obtained, and teaching effectiveness evaluations can be obtained from them. For example, data such as interaction information between athletes and coaches, athlete performance files, and live streaming athlete videos are collected for analysis and to determine the quality of coach instruction; Artificial intelligence models: In AI based models, deep learning techniques can provide coaches with more intuitive and accurate evaluations, while models that predict teaching effectiveness can predict athletes' learning tendencies and propose effective

learning strategies based on their personal information and performance data; The video analysis model can discover many typical movements such as single movements, movements, and jumps from video playback, and based on the analysis results, a comprehensive score can be obtained to evaluate student performance and provide targeted guidance to students. These algorithm models can evaluate the teaching effectiveness of physical education based on multiple evaluation indicators. Some common indicators include comparative analysis, which is a technique used to determine whether a student's current performance is better or worse than their past performance. Teachers can compare students' current performance scores with their previous performance scores; Noise to noise ratio (SNR) is the relative noise level used to compare student performance evaluation models. If the SNR of the model is higher, its prediction accuracy and precision will be higher; Relative Gain refers to the relative improvement amplitude for all participants using a specific method; Training convergence speed refers to the current application model and its accuracy, using different parameters and configurations can improve the convergence speed of the model.

Due to the youthful nature of esports and its rugged nature in the past, not many scholars have devoted their academic energy to it. Traditional NBA, tour de france, and other technologies such as game replay have not had significant effects in esports. Therefore, it has not been until recent years that relevant scholars have studied this area, and the research methods used are generally still some basic ones. So some of the machine learning methods adopted by the author, whether it is traditional machine learning algorithms such as k-nearest neighbor (KNN), popular neural network algorithms, or even deep neural network algorithms of deep learning, are less applied in relevant research and analysis. So for the entire traditional machine learning algorithm, such as KNN, SVM, logistic regression, and so on, which have been studied since the last century and have been developed and improved so far, we will not elaborate on it here. However, if we consider changing the perspective of the entire game win loss analysis model and transforming it into a special type of natural language processing model (NLP) in the form of small dictionaries and heavy correlations, we will discover the adaptability of some natural language processing methods today. Natural language recognition models have also been proposed and continuously studied since the last century. In the 1950s, expert rules based on syntactic and lexical features were commonly used for modeling and processing. Later, due to the rapid increase in the amount of data to be processed, at the beginning of this century, supervised feature engineering methods based on these features were mostly used for modeling. As time enters the second decade of the 21st century, the scale of data further expands exponentially, and the network data generated in 2020 alone is the sum of all years before 2019. For such a large-scale data, a series of problems such as how to minimize supervised label training without utilizing feature engineering have emerged.

2. Methods.

2.1. Overall System Framework. Generally speaking, such a framework is quite complex. We follow the general method of decomposing and processing related complex transactions, and build the entire system in a modular and procedural manner. The modules of the entire system have been divided into the following 5 modules in the form of Figure 2.1: Data collection and storage, data and processing, model selection, data classification, and performance evaluation [4].

Below is a brief introduction to the functions of the relevant modules: Data collection and storage is a module used to achieve real-time and dynamic collection of data from the network, laying a solid foundation

for subsequent data preprocessing modules. Data and processing involves cleaning and preprocessing data into different formats to make appropriate inputs for different classifier models. Model selection refers to selecting different models for classification processing based on different data formats and types. The data classification module is based on the selected model and uses different classifiers for classification. The performance evaluation module is a display module designed to accurately evaluate the performance of classification results.

2.2. System workflow and description. In order to better determine which classifier to use to build the final model, the modules operate independently and use multiple methods to work, resulting in high flexibility of the system. The following section provides detailed modules of the entire system that work together [5].

(1) Data collection and storage module. Thanks to the open attitude of the developer and publisher of DOTA2 game, Valve, it is not difficult to collect game data related to DOTA2. The official API data collection interface is provided, and there are also related DOTA2 APIs that can be called in Python related libraries, that is, through the relevant competition ID, we can obtain specific data for the competition. At the same time, considering that the author's goal is to establish a complete and separable system for predicting competition outcomes, we have established the following standards and methods for data collection:

- Determine the start time of the first game of collection;
- Determine the total amount of collected data;
- Save the above variables as input;
- Start the remote Alibaba Cloud server, execute relevant Python code, read the input from the previous section, complete data collection and storage, and automatically write it into a CSV format file as output.

Additionally, due to the complexity and size of competition data, as well as the communication efficiency of remote servers, our collection and storage speed is approximately 0.05 seconds per piece of data.

(2) Data cleaning module. Due to the complexity of competition data, not every game is a valid match. For example, non pure 5V5 player competitive games (such as players fighting against computers together); Or the competition time may be too short (whether due to network fluctuations or someone giving up the competition early); Or it could be an abnormal competition mode (such as center lane singles, or activity competitions, etc.). So we filtered the relevant data and only retained the game data that met the following conditions: the game had 10 human players [6]; The competition time is greater than 20 minutes; Only consider the game mode of all hero ladder match. The reason for selecting the above three points is based on the data obtained from an effective game; It should be composed of 10 human players; And there should be no early abandonment or network fluctuations (time greater than 20 minutes); And based on the fact that all heroes are in a selectable rank mode, the maximum level of confrontation and equality between players is crucial.

Only when the above three points are met simultaneously can it be a game match with significant data analysis value. So next, we will perform data cleaning operations to match the model. Read the CSV file obtained from the previous step of data collection and storage, and follow the previous three filtering rules to remove the observation data corresponding to the non matching match ID. Keep the hero selection for the R and D sides, with 5 IDs for each. Keep the relevant victory and defeat data, R's victory is recorded as 1, and D's victory is recorded as 0. Remove other irrelevant data, such as match time, match ID, etc. Save the cleaned data as a CSV file for output.

(3) Data segmentation. The specific function of this module is to divide it into training set and test set for subsequent training and testing, and select the optimal model for use. The specific approach is to read the relevant vectorized data as input to the model, and randomly select 70% of it as the training set and 30% as the test set. The data is divided and saved as two separate outputs, among them, the training set is prepared to be placed into the classifier model for training, and then a training model library is generated; The corresponding test set is used to test the model library.

(4) Classifier training. We will not provide a detailed introduction to the training process of each classifier here. Below, we will train them one by one according to the input. The goal and steps here are to obtain the training set data as input, train the model, and output and save the relevant models to the classifier model library.

(5) Classifier Model Library. The general steps are: In order to continue the classifier training from the previous step, save each trained model, and then convert the data from each test set into a format and send

Table 3.1: Distribution of Various Types of Samples in the Sample Set

Category	1 (Radiant side wins)	0 (die wins)
Number of categories	470473	413876

it to the relevant classification model to obtain the final output, which is the prediction results for the test set. The output is saved as model related files for direct use in the next round of victory or defeat prediction classification.

(6) Performance display and evaluation. For each classifier itself, we need a specific method or even module to evaluate the performance of each classifier. We generally select three indicators: accuracy P, recall R, and F1 value. These three indicators are quantitatively calculated together and used as specific evaluations and displays for algorithms of different classifiers.

The calculation formula for the accuracy P, recall R, and F1 values is as follows:

$$P = \frac{1}{2}\left(\frac{TP}{TP+FP} + \frac{TN}{TN+FN}\right) \tag{2.1}$$

$$P = \frac{1}{2}\left(\frac{TP}{TP+FN} + \frac{TN}{TN+F}\right) \tag{2.2}$$

$$F_1 = \frac{2*P*R}{P+R} \tag{2.3}$$

The general steps for its specific calculation are to input the test set as a test sample into the classifier model library, calculate the relevant accuracy P, recall R, and F1 value quantification indicators, write the file and output it. It should be clarified that the performance evaluation module is an important test of classifier performance, and it is definitely not an optional part. Without this module, we will not be able to determine the performance of the algorithm. Only by designing this module can we continuously improve the model, select more appropriate classifiers as our final classifier, and only in this way can we have the possibility of moving towards higher performance.

3. Results and Analysis.

3.1. Source of data used in the experiment. The dataset used by the author mainly comes from the official API interface data provided by Valve (Dota2), the developer and publisher of this game [7]. The author uses the - dota2 API, a Python library that integrates relevant API interface code, as the main means of obtaining data, and places the code on a remote Alibaba Cloud server. They regularly upload their relevant data files (in CSV format) to the specified email. The main collection of game data is between October 1st, 2021 and October 31st, 2021, with a total of 884347 matches. This is mainly due to the fact that players are familiar with the characteristics of the relevant versions during this period, and the quality of the matches is relatively high, which allows them to obtain the most useful win or loss information. From the actual collected relevant competition data in Table 3.1, we can see that during this period, the distribution of the dataset in the competitions that meet the data cleaning requirements was relatively uniform. The probability of the samples belonging to Class 1 (i.e. the radial side winning) was approximately 53.2%, and the probability of the corresponding samples belonging to Class 0 (i.e. the direct side winning) was approximately 46.8%. Basically, it is a evenly distributed sample set, so each classifier should have good performance.

3.2. Experimental testing environment. The author's experimental testing is based on: operating system: Windows 1064 bit system; Processor: Intel (R) Core (TM) i7-5500UCPU240GHz (4-core); Memory: 8.00GB; The software platform for the experiment is designed based on Python 3.2.5 and meets the author's requirements for relevant programs [8].

Table 3.2: K-Nearest Neighbor (KNN) Model Results

Group number	Parameter K	Accuracy P	Recall rate R	F1 value
1	K=3	0.624	0.453	0.525

1	L2	1iblinear	0.679	0.489	0.566
2	L2	sag	0.691	0.523	0.595
3	L1	1iblinear	0.664	0.486	0.561

3.3. Experiment.

(1) Construction of word vectors and classifier models. The model that the author will verify is divided into two modules, the word vector module and the classifier module. The author of the classifier module mainly divides the relevant classifiers described in Chapter 2 into five common models: K-nearest neighbor (KNN) model, logistic regression model, support vector machine (SVM) model, xgboost model, and neural network (ANN) model. The reason for using decision trees alone is their poor stability, and the author should use the xgboost model, an integrated decision tree model, as a suitable alternative. The specific tuning of hyperparameters for the above related models, due to their complexity and complexity, will be briefly presented in the next section.

We noticed that the traditional method of using word vectors is to input the sum of related word vectors as the meaning of the sentence into the next layer of classifier. However, in this article, we will propose some new ways of combining word vectors, such as CBOW-3. Considering that the specific usage scenario in this article is competition win/loss prediction, rather than traditional semantic analysis, not only does the sum of word vectors contained in the sentence serve as input, but colleagues also take the difference of word vectors contained in the sentence and the word vectors formed by the overall lineup of the two sides as input, which contains more information than traditional models, let's leave the specific classification effect to the next section for further investigation.

(2) Performance display of each model. For considerations of time and other factors, for the first three simple models, we only use one hot encoding for input processing, while the word vector format is mainly processed by xgboost.

For the K-nearest neighbor (KNN) model, we directly use one hot encoded vectorized data for processing as the most basic comparison. As shown in Table 3.2.

So we observed that when K=4, the balance of various indicators is good, but overall, KNN is a very poor classifier at this time, and its prediction performance is not much different from directly predicting the victory of R (radial), and its time spent is more than 8 hours.

The logistic regression model is shown in Table 3.3.

The regularization parameter (penalty) refers to whether the subsequent penalty term is chosen as L1 regularization or L2 regularization. Optimization method parameter (solver): refers to the optimization method of logistic regression loss function, among them, liblinear is implemented using open-source libraries and internally uses coordinate descent method to iteratively optimize the loss function; Sag (Random Average Gradient Descent), which is a fast improvement variant of SDG, usually has significant advantages for large-scale data. Overall, we have observed significant improvements in its performance compared to the KNN model, especially in terms of accuracy. A relatively good model achieved a P of 0.690, but overall, the distance from us to truly achieve a good prediction of the outcome of the competition is still quite far; At the same time, we noticed that even with the best and shortest parameters of sag and L2, it still took nearly 4 hours to construct the model

7	0-H	0.01	1	20	3200	0.788	0.661	0.719
8	0-H	0.005	1	20	6400	0.789	0.663	0.721

and process game data exceeding 80W.

The Support Vector Machine (SVM) model is shown in Table 3.4.

Kernel function parameters γ only makes sense in the case of non-linear kernel functions; When the regularization parameter specifically corresponds to a linear kernel, is L1 or L2 regularization chosen; The penalty coefficient C refers to the penalty coefficient C in the prototype and dual forms of the SVM classification model, and all of our experiments above were conducted with 10 cross validation (l0 fold). The final result we obtained shows that when the kernel function takes a linear kernel and L1 is regularized, the effect is best, and the effect is better when C is small. However, regardless of the type of model, not only does it have a long computation time (even for linear kernels, model training takes more than 10 hours, while for non-linear kernel functions, the training time is longer), but its performance cannot be separated from logistic regression, the reason for this should be that many matches have identical lineups but different winning or losing labels, which constitute some noise points. SVM systems are well-known for their poor handling of noise points, resulting in poor performance.

Xgboost model: Due to the complexity of this model, we search for its optimal parameters in two steps.

Step 1. First, only use one hot encoded data input for parameter tuning, and strive to find a suitable set of parameters (as shown in Table 3.5).

In the above model, we can see that the maximum subtree depth remains around 20 and the learning rate is maintained η when the number of iterations is small and large, the final accuracy P, recall R, and F1 values are all more appropriate, while for the loss parameter γ is not sensitive.

Step 2. Use the hyperparameters with good performance mentioned above to input data in the form of related word vector encoding, and observe the classification effect. Among them, learning rate η= 0.01, loss parameter y=1, maximum tree depth parameter max_depth=20, maximum number of iterations num_boostround= 3200, this training takes approximately 6000 seconds, which is within an acceptable range (as shown in Ta-

Table 3.6: XGBoost Model Results 2

Group number	Data entry format	Accuracy P	Recall rate R	F1 value
1	GloVe-1	0.793	0.666	0.724
2	CBOW-1	0.794	0.673	0.729
3	skip- gram-l	0.793	0.674	0.729
4	GloVe-2	0.799	0.677	0.733
5	CBOW-2	0.806	0.686	0.741
6	skip-gram 2	0.816	0.691	0.748
7	GloVe-3	0.802	0.683	0.738
8	CBOW-3	0.812	0.688	0.745
9	skip-gram-3	0.819	0.696	0.753

Table 3.7: Results of Neural Network (ANN) Model

Group number	Data entry format	Accuracy P	Recall rate R	F1 value
1	One-hot	0.759	0.638	0.693
2	GloVe-1	0.786	0.678	0.728
3	CBOW-1	0.799	0.68	0.735
4	skip-gram 1	0.806	0.684	0.74
5	GloVe-2	0.798	0.703	0.747
6	CBOW-2	0.821	0.712	0.763
7	skip-gram-2	0.822	0.706	0.76
8	GloVe-3	0.811	0.716	0.761
9	CBOW-3	0.822	0.719	0.767
10	skip-gram-3	0.825	0.729	0.774

ble 3.6).

We can see from the above results that when the input metrics of the model are in the form of skip gram 3 word vectors, all performance metrics perform the best, and in most word vector concatenation forms, the data input generated by the skip gram method corresponds to better performance metrics.

Neural Network (ANN) Model: Due to limitations in space and model training time, some good numerical values for each parameter are directly provided here. We ultimately adopted a neural network model with two hidden layers (fully connected form), with the first layer consisting of 20 nodes and the second layer consisting of 5 nodes, all using sigmoid response functions. The training results are roughly shown in Table 3.7.

It can be seen that the performance of these models is relatively excellent, and we will discuss their comparison with other models in detail in the next section.

(3) Comparison of performance and summary of advantages and disadvantages of various models. Next, we will draw some graphs using data from various tables to facilitate our comparison of various models. For convenience and intuitiveness, we will only compare the optimal performance indicators of each model as shown in Figure 3.1.

Next, we will continue to plot the training and prediction time of each model as a graph for comparison, as shown in Figure 3.2.

We can draw the following conclusion from Figure 3.2. Using traditional one hot encoding input data, combined with traditional machine learning algorithms (excluding neural network models), the ensemble tree regression algorithm represented by xgboost performs the most brilliantly, with an accuracy level of 0.788 and the fastest computational speed, taking only 1.67 hours [9,10]. On the other hand, compared to other algorithms with strong explanatory power, the logistic regression algorithm has the highest accuracy of only 0.691 and takes 4.17 hours. The KNN algorithm, due to its simplicity, results in unsatisfactory performance and time

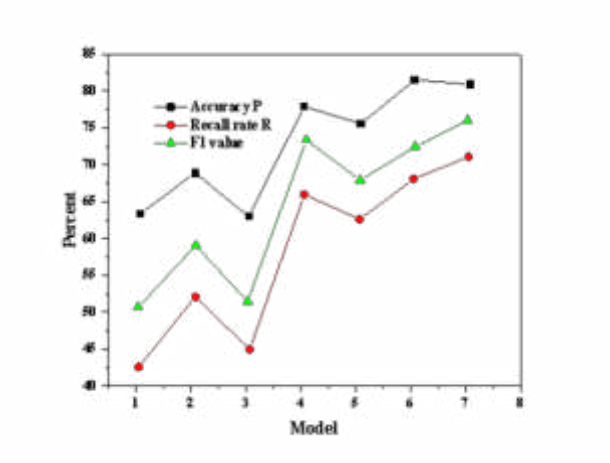

Fig. 3.1: Comparison of performance indicators of various models

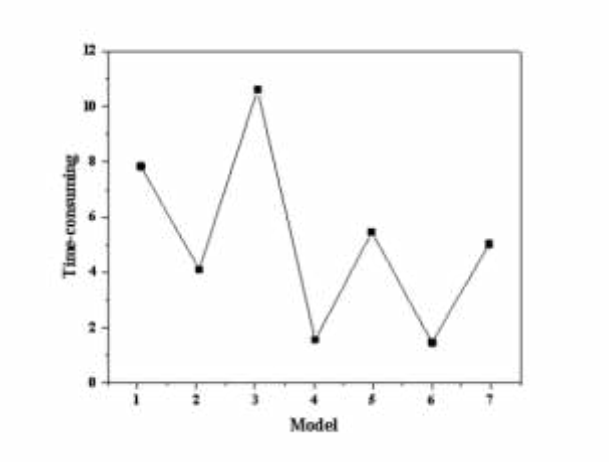

Fig. 3.2: Comparison of time consumption among different models

consumption. In general, SVM support vector machine algorithms with excellent performance not only have poor performance (accuracy of only 0.639), but also take the longest time (10.56 hours) among all algorithms. A reasonable explanation for this phenomenon should be that there are many duplicate points in the data, but the labels are different, these confusion points seriously affect the search for hyperplanes and support vectors, resulting in low model performance. The new data format is generated by transforming the data into a word vector pattern. For neural network models, the best performing group of neural network models achieved an astonishing accuracy P of 0.825, with an error rate (1-P) of only 0.177. Compared to the accuracy P of the original neural network combined with one hot encoding (P=0.693), the corresponding error rate (1-P) was 0.309, which is equivalent to an improvement of 42.87%. Even for the already impressive xgboost algorithm, using only word vectors as an improvement method has increased the accuracy P from the original 0.789 to 0.819, and the error rate (1-P) has decreased by 14.16%. From this point, it can be seen that introducing word vectors is indeed appropriate. From the above models, we can see that in terms of related time consumption, xgboost is the fastest among all models due to its algorithm's parallelism and multithreading, processing around 80W of data in about 1.5 hours. However, the processing time of the neural network (AN) model is time-consuming.

As I am using an AMD graphics card, I cannot use the GPU provided by the relevant NVIDIA graphics card for acceleration, and can only use the CPU platform for processing. Therefore, the training time is about 4 hours. According to existing online data, using GPU acceleration can increase the speed by approximately 20 times, and it only takes about 15 minutes to complete the training.

4. Conclusion. Due to the urgency of introducing modern statistical analysis methods such as machine learning into the esports industry, the author's main goal and content around Valve's DOTA2 game is to build a relatively complete DOTA2 game victory prediction system based on deep learning. We use unsupervised learning methods such as word vectors (word embeddings), combined with various supervised machine learning classifiers, in order to ultimately achieve victory or defeat prediction of competition data, and propose their own new model in it, and ultimately compare the performance of different word vectors (word embeddings), semantic combinations, and various supervised learning classifiers. The structure of the entire competition victory and defeat prediction system has been constructed to support the verification of the aforementioned theories, and each module has been functionalized and independent. Finally, a series of related experiments were conducted using the system, and the advantages and disadvantages of different models were compared, and the structure of the relevant system was ultimately determined. Although we have completed the construction of the relevant victory or defeat prediction system, in the field of machine learning, we usually have a relatively recognized view that the relevant features used by the algorithm generally give a ceiling that a machine learning model can reach; However, the selection of specific classifier models can generally affect the difficulty of approaching this ceiling. Therefore, although we have used features from primary representations such as single hot encoding and advanced representations such as word embeddings, these advanced features are all constructed based on the distribution hypothesis, i.e. words with similar contextual context, its linguistic meaning should also be similar to this hypothesis theory. The meaning that these models can express ultimately comes from the information of some words around them (in this case, hero IDs).

DESIGN OF A SIMULATION AND EVALUATION SYSTEM FOR ATHLETE TECHNICAL AND TACTICAL TRAINING BASED ON VIRTUAL REALITY TECHNOLOGY

ZHILIANG CHANG*

Abstract. In order to avoid the influence of external environmental factors on athletes' physical fitness and technical tactics, the author proposes the design and research of an integrated simulation training system for athletes' physical fitness and technical tactics based on virtual reality. The hardware unit of the design system includes a 3D scanner module, VR glasses module, locator module, tracker module, and wireless transceiver device. The software module introduces virtual reality technology and designs a visual simulation module, trained object detection module, trained object tracking module, and overall control module. The simulation experiment results show that compared with existing systems, the training scene output clarity and frame rate of the designed system are better, and the thread switching time and signal mixing time are shorter, which fully proves that the designed system has higher operating efficiency and better application performance.

Key words: Virtual reality technology, Athletes, Technical and tactical training, Physical fitness

1. Introduction. In recent years, the rapid development of virtual reality technology has given rise to this idea. The so-called virtual reality (VR) technology mainly refers to the general application of computer technology, computer simulation technology, multimedia, intelligence, computer network, social networking technology, and multi-sensor technology [1].

This technology simulates the function of human visual system, such as vision, hearing, and touch, enables human beings in computer to create virtual environment and interact with them in real time by means such as language and gesture, generating multi-dimensional personal information. With the development of competitive sports and the increasing importance to the competitive environment, it has become a decisive factor in the success. In order to improve the men's athletics quality, many coaches have decided how to build a training center that satisfies the actual competition, which is the problem solved by VRT [2,3]. It can achieve interaction between real environment, virtual environment, and real environment. In the heat exchanger, training is more accurate, injury is lower, investment is reduced, and operation efficiency is improved. Another characteristic of VRT is the creation of virtual competitors whose structure and technology are based on analyzing their videos and other data, just like real competitors. Athletes enter the area through 3D helmets, jacket materials, and other outdoor equipment. This is an example of sports, where athletes can see the boxes.

Fight in front of him, dodge, and involuntarily counterattack with a three-dimensional helmet. This is beneficial for athletes to achieve greater ability of winning through mechanical, tactical, emotional, and technical means. The combination of VRT and physical education has important training effect. In sports, there are many uncertainties, uncertainties, and dangerous situations or behaviors which can only be seen and analyzed from the three-dimensional view using multimedia technology.The three-dimensional data of individual is the motion information of the three-dimensional system of each joint, which is the key and basis for identifying the individual's three-dimensional sport.

VRT displays three-dimensional information of athletes, captures the main points and characteristics of movement. The evaluation of training effectiveness is of great importance for teachers to change training plans in time and evaluate sports performance. After collecting the daily training data, we can simulate the application of the training system of computer simulation training, evaluate the training effectiveness, and compare it with the previous training methods to analyze the progress and shortcomings of the athletes. According to the effects of training evaluation and the characteristics of athletes, a comprehensive analysis of their behaviors

* College of Physical Education, Henan University of Science and Technology, Luoyang, 471000, China (changzhiliang2004@163.com)

can be made, and a better training plan can be prepared for the next stage of training.VRT has a wide range of applications, especially its integrated network communication system. This has become a useful tool. As a technology, the widespread use of VRT will change people's feelings, and even their attitude towards the world, individuals, and time [4]. Friends from all over the world can learn, chat, and play games together as in real life.

With the application of computer network and other 3D devices, our work, life, and entertainment will become increasingly prevalent. It not only has important implications, but also changes people's scientific and digital thinking of today's sports competition. Virtual reality technology combines computer, software, and virtual world technology, which can adapt the real world. The dynamic environment can respond to real-time according to factors such as human form and language, thus achieving the communication between human and the virtual world.Virtual reality (VR) is the abbreviation for virtual reality technology, also called Jilin technology. By using computer image, simulation technology, computer technology, artificial intelligence, network technology, dynamic simulation, and multi- sensor environment, we simulate human body such as vision, hearing, and touch, absorbing people in the virtual world. In addition to creating a wide range of data sources for people with a wide range of applications from real-time interaction through language and gesture, virtual reality technology also includes three main aspects: manipulation, interaction, and visualization. With the rapid development of VRT technology, it has been widely used in fields such as CAD and simulation. Modeling, visualization, remote control, computer architecture, computer technology and teaching techniques, education and teaching, information visualization and modeling, entertainment and drawing, design and planning, remote operation, etc. In recent years, countries around the world have been given much attention and investment, and have been integrated into major sports such as Olympic competitions.

Sports training is very critical to both ordinary people and athletes, and it assumes the responsibility of improving the comprehensive physical quality of the human body. The traditional single sports training has been unable to meet the diversified needs of modern people, so we must innovate the training methods and introduce the computer virtual technology into it. First of all, the use of this technology to conduct high-intensity sports training early guidance can effectively reduce the accidental injuries in the training, such as boxing, cross-country running, taekwondo, etc. This kind of sports often produce all kinds of accidental injuries, to bring psychological shadow to the early stage of training, and then give up sports training. Virtual technology, on the other hand, can simulate the real movement scene through the computer, and the athletes can open their hands and feet without having to worry about accidental injury, and can understand the specific details of each technical action through the simulation technology, and correct the subtle errors in their movement.Secondly, the technology can decompose difficult movements in more detail, and demonstrate through simulation to understand how to avoid damage when performing difficult movements. Third, the current situation can improve the lack of material conditions, especially some athletes or sports institutions with limited funds, unable to purchase more sports equipment. But through virtual technology can change this situation, so that people can better do physical training through computers.

Sports training and sports have always been the key livelihood issues in China, and they are also the basic activities carried out by various sports groups. With the continuous development of modern computer technology, the major domestic sports institutions and folk sports people have begun to pay attention to the application of computer technology in sports training, but it has little effect at present. First of all, the capital of modern computer virtual technology equipment is relatively expensive, so it is necessary to capture the technical movements through multiple sensors, and use professional analysis software to detect them. Although this analysis software is more common, the requirements for professional technology are higher in the process of use.Secondly, many athletes blindly believe in their sports experience during training and ignore scientific computer software analysis, which leads to people to ignore the application of this technology and the promotion efficiency is low. Thirdly, people lack the cognition of virtual sports training technology, and think that the physical training of virtual computer can not achieve the effect of real body movement, thus ignoring the important role of virtual sports training.

In the process of sports training, due to different students have different physical quality, when part of the physical quality of low students in difficult sports training activities, is prone to accidental injury, cause them in danger, this will undoubtedly hit their learning confidence, at the same time is not conducive to their

physical and mental health development. For this, PE teachers can through the practice training teaching classroom reasonable introduction of virtual reality technology, science for students to create surreal sports training environment, guide them to contact with the virtual environment, which not only can improve various sensory experience of students in class, stimulate students to sports professional knowledge content and skills of learning interest and desire, can also reduce the difficult sports training of accidental injury.Under the virtual reality technology application, sports teachers can use virtual professional athletes to demonstrate a variety of professional technology with certain risk action, let the students to the technology has intuitive clear understanding, and then teachers lead them to safe and reliable practice, so as to effectively reduce the safety risk of sports training. In the virtual environment for physical training, each student can completely open their hands and feet, not too concerned about whether it will hurt the people around, so as to greatly improve the safety factor and training efficiency of sports training.

The "physical fitness+technical tactics" training of athletes is influenced by many factors, such as weather, terrain, time, etc., which cannot meet the professional needs of today's athletes. Therefore, a virtual reality based integrated simulation training system design and research on "physical fitness+technical tactics" for athletes is proposed. Introducing virtual reality technology to break through the limitations of conventional training time and space, providing assistance for athlete physical fitness and tactical training, and providing effective assistance for social security [5,6].

2. Methods.

2.1. Concept, composition, and characteristic analysis of virtual reality technology.

(1) Concepts of Virtual Reality Technology. Virtual reality (VR), also called spiritual realm or visual realm. The research topics include artificial intelligence, computer science, electronics, sensors, computer graphics, control intelligence, psychology, and so on. the It uses computer simulation to create a three-dimensional virtual world, provide users with experimental visual, auditory, tactile, and other senses, thus creating a visual system that allows direct observation, processing, and touch upon changes in the internal environment, and can interact with them, . integrated with people and computers, put people's minds there.

(2) Classification of Virtual Reality Systems. Immersive virtual reality system is a complex system. Users need to wear helmets, data gloves, and other intrusion and tracking tools to immerse themselves in the virtual world and interact with it. A simple virtual reality system is composed of ordinary computer systems [7]. the Users can interact with the virtual environment by keyboard and mouse. Users can recognize virtual scenes on a regular computer using mouse and keyboard.

(3) The composition of virtual interactive devices. In order to achieve sufficient information exchange between people and machines, it is necessary to develop a special consulting tool and a demonstration tool to realize various information feedback from others and to provide guidance to complete the practical experiments. Achieving virtual reality consists of a virtual address system, a virtual environment generator with high-performance computers as the core, a visual system with helmets shown as the core, a hearing system with speech signals, audio links, and a local voice as the core, body positioning and body tracking devices with positioning trackers, configuration information, and clothing information as the main body, as well as feedback for functional requirements such as taste, smell, touch, and force.

(4) Analysis of the Characteristics of Virtual Reality Technology. Multiple cognition: Multiple cognition refers not only to the visual perception possessed by computer technology, but also to the auditory perception, emotional force, tactile understanding, visual movements, and even the taste and smell of the senses[8,9]. The best virtual reality technology requires a comprehensive understanding that everyone has. Because of the limitations of related technologies, especially computer technology, the cognitive function of virtual reality technology is mainly applied to visual, auditory, visual force, tactile sound, etc.

Immersive: Immersive, also known as existential, refers to the degree to which the user feels the protagonist is present in the simulated environment [10]. The best simulation environment should make it more difficult for users to distinguish between true and false, allowing them to complete themselves in the three-dimensional virtual environment created by computer. the Everything in the environment seems real, sound real, moving real, even smelly and really delicious, just like the feeling in the real world.

Interaction: refers to the degree to which users can control objects in a simulated environment, as well as the natural level of feedback received from the environment (including the actual operation). For example,

Fig. 2.1: Overall schematic diagram of the system hardware unit

users can directly grab virtual objects in a simulated environment with their hands. At this point, they have the desire to hold something and are able to feel the weight of the object. The objects captured in the viewfinder can also be moved immediately with the movements of the hand.

Thought: Emphasize that virtual reality technology should have a broad space and reflect space, broaden human understanding. It can not only produce real existing products, but also be free to imagine the goal of no or even impossible environment [11,12].

2.2. Hardware Unit Design of Integrated Simulation Training System for "Physical Fitness+Technical Tactics". The hardware unit of virtual reality technology is the foundation and prerequisite for the stable operation of the athlete's "physical fitness+technical and tactical" integrated simulation training system. Based on the requirements of physical fitness and technical and tactical training, the system hardware unit is selected and designed, including the 3D scanner selection unit, VR glasses selection unit, locator selection unit, tracker selection unit, and wireless transceiver selection unit. The overall schematic diagram of the system hardware unit is shown in Figure 2.1 [13].

The specific selection and design process is as follows: The 3D scanner is one of the key hardware devices in the design system, and its essence is a device for detecting objects, environment, and other data. One of the key hardware components in the design system is to perform virtual reconstruction of the integrated simulation training scene of athletes' physical fitness+technical tactics based on data collected by 3D scanners [14,15]. However, the scanning range of 3D scanners is limited, and in specific applications, their positions need to be transformed to comprehensively obtain target data, laying a solid foundation for virtual reconstruction of training scenes. VR glasses can help trained athletes watch the entire virtual scene, providing them with an immersive feeling. VR glasses are a key hardware support in virtual reality technology, which can provide a large amount of VR video information, allowing users to truly experience the virtual world by selecting VR glasses of the VRPark model as the design system hardware.

Positioners can locate the body position and movable space of trained athletes. Under normal circumstances, a locator is used in conjunction with a regulator. After receiving the output signal from the regulator, the locator adjusts the position of the trained athlete accordingly and feeds back the adjusted position information to the locator. The valve locator is selected as one of the hardware units for designing the system. The tracker can track key body position information of trained athletes in real-time and send interactive instructions to them through a professional controller, increasing the realism of simulation training. Based on the design system requirements, select the NF-308 tracker as the hardware device. The NF-308 tracker is mainly composed of a main tester, a receiver, and a remote recognizer. It has advantages such as smooth appearance, user-friendly design, speed, and accuracy, and is widely used in various fields.

Wireless transceiver refers to a wireless signal receiver that is connected to the system computer host to facilitate unified control of the integrated simulation training process of athletes' physical fitness+technical tactics. According to the design system requirements, select a single wireless transceiver chip as the wireless transceiver device. The single-chip wireless transceiver chip operates in full duplex transmission mode, with a

transmission distance of about tens of meters and a communication speed of about 2Mb/s. In addition, the chip also has dedicated data channels, frequency hopping technology, and data encryption technology, which can stably transmit system data and provide effective support for the smooth operation of the athlete's "physical fitness+technical and tactical" integrated simulation training system.

2.3. Software module design for the integrated simulation training system of "physical fitness+technical tactics" . The design system software module includes a visual simulation module, a trained object detection module, a trained object tracking module, and an overall control module. The specific design process is as follows [16].

(1) Visual simulation module. The visual simulation module is the foundation and prerequisite for the virtual modeling of the integrated simulation training scenario of athletes' physical fitness+technical tactics. The three-dimensional structure of the athlete's "physical fitness+technical tactics" training scene is relatively complex, and the scene range is also relatively large, which brings significant difficulties to visual simulation. Athletes' "physical strength+technical and tactical" integration scene training scene includes static objects, buildings, trees, dynamic objects, trainees, suspect, police cars, etc. In the process of constructing a 3D scene, static object modeling is relatively simple. Only the corresponding 3D data needs to be read from the database and processed by texture mapping to be displayed. For dynamic objects, real-time control and real-time acquisition of their position information are required during the 3D scene process. Due to space limitations, only partial display of the operation behavior of the trained athlete model is added to the visual simulation, as shown in Table 2.1.

(2) Trained object detection module. The main purpose of designing the system is to provide integrated physical and tactical training for athletes. Therefore, during the operation of the system, it is necessary to detect the training targets, clarify their positions and relevant information. According to the design system requirements, the background difference method is selected to detect the trained target, and its principle expression is:

$$D_k(x,y) = |f_k(x,y) - f_b(x,y)| \tag{2.1}$$

In equation 2.1, Dk (x, y) represents the training target; Fk (x, y) represents the image to be processed; Fb (x, y) represents the background image. For the background difference method, the key step is to obtain background images with high reference value. Generally, Gaussian background modeling method is used to model the dynamic background of the training scene. Gaussian background modeling mainly involves transforming the background into a function that follows a Gaussian distribution, expressed as:

$$I(x,y) \sim N(\mu(x,y), \delta(x,y)) \tag{2.2}$$

In equation 2.2, I(x, y) represents the pixel grayscale value corresponding to the coordinate (x, y); $\mu(x, y)$ represents the mean of the Gaussian function; $\delta(x, y)$ represents the variance of the Gaussian function [17]. When detecting trained moving targets, if the background is stationary, in order to adapt to the dynamic changes of various factors such as lighting, the background is dynamically updated. The update method is as follows:

$$\begin{cases} \mu(x,y) = (1-\alpha)\cdot\mu_{k-1}(x,y) + \alpha\cdot I_k(x,y) \\ \delta_k(x,y) = (1-\alpha)\cdot\delta_{k-1}(x,y) + \alpha\cdot d_k(x,y)\cdot d_k^T(x,y) \end{cases} \tag{2.3}$$

In equation 2.3, a represents the update coefficient, and the larger the value of a, the faster the update speed; Dk (x, y) represents the difference in grayscale values. Using the difference between the current image and the pre stored background image, and then using a threshold to detect the trained moving target, the calculation formula is as follows:

$$R(x,y) = \begin{cases} D_k(x,y), \mu(x,y) > T \\ 0, other \end{cases} \tag{2.4}$$

In equation 2.4, when the background area of the image is greater than the threshold T, the detected target is the target to be extracted. Through the above process, real-time detection of trained targets can be achieved, providing relevant data for target tasks for simulation training, and ensuring the smooth progress of simulation training [18].

(3) Trained target tracking module. Training target tracking is also one of the key links in designing a stable system operation. In order to integrate physical fitness and tactical training for athletes, it is necessary to grasp the real-time location information of the training target. This study is based on color histograms for training target tracking, and the specific process is as follows: Transform the image of the training area into the HSV color space, quantify it, and perform statistical analysis on its color histogram. The expression is:

$$q_u = \sum \delta[b(x(i,j) - u)] \tag{2.5}$$

In equation 2.5, qu represents the statistical value of the quantized boundary u. Under normal circumstances, there may be a small amount of background elements in a specific area that can interfere with it. Therefore, it is necessary to process it to obtain a more accurate histogram. The processing formula is:

$$q_u = \sum \delta[b(x(i,j) - u)] \cdot D(i,j) \tag{2.6}$$

In equation 2.6, D(i,j) represents the differential parameter. After processing the color histogram in a specific area, setting a threshold can obtain the color features that highlight the trained target. The Kalman filtering algorithm is used to separate the image background and achieve target tracking. The formula is:

$$h(i) = sep(q_n) \tag{2.7}$$

In equation 2.7, sep (*) represents the separation function. By using the above formula to separate the background area and achieve tracking of the trained target.

(4) Overall control module. The overall control module is mainly responsible for managing and coordinating all modules, such as program entry, module startup, idle processing, event processing, I/O control, command issuance, etc. In addition, the overall control module also requires internal updates to provide real-time data support for 3D scene construction, and timely store valuable data in the system database for convenient subsequent applications and queries. According to the design system requirements, the overall control module is mainly implemented through functions such as Win Main() and vgSystem. Due to space and character limitations, this will not be elaborated too much. Through the design of the hardware units and software modules mentioned above, the integrated simulation training system of "physical fitness+technical tactics" for athletes has been implemented. Under the premise of motion target detection, tracking and control, it helps athletes improve their physical fitness and technical tactics, and helps them play a role in maintaining social security.

Table 3.1: Application Performance Data Table

Number of experiments	Output frame rate/fps
1	60
2	59
3	58
4	61
5	62
6	61
7	60
8	60
9	59
10	60

3. Result analysis. In order to verify the difference in application performance between the designed system and the existing system, experiments were designed based on a simulation platform. The specific experimental process is shown below [19].

3.1. Experimental Platform Construction. Based on the integrated simulation training requirements of athletes' physical fitness and technical tactics, an experimental platform is built, with hardware including a PC, camera, wireless receiving device, projector, ID card reader, etc. The camera needs to have good night vision function, which can maintain the clarity of the picture in low light environments and also adapt to strong light environments.

3.2. Analysis of experimental results. Based on the experimental platform built above and the displayed experimental scenario, conduct an integrated simulation training experiment on athletes' physical fitness+technical tactics. Test the image resolution and output frame rate of the training scene output by the system, as shown in Table 3.1.

Using this system for integrated simulation training of athletes' physical fitness+technical tactics, the system outputs images of training scenes with high resolution and clarity; According to Table 3.1, the average frame rate of the training scene image output of the system is 60fps. From this, it can be seen that the output image quality and resolution of the designed system are good, and can achieve smooth display of training scenes. On this basis, obtain data on system thread switching time and semaphore mixing time to reflect the application performance of the system. Among them, thread switching time refers to the time required between CPU task transitions; The signal mixing time refers to the time between the release and reception of a signal. The smaller the value of thread switching time and semaphore mixing time, the higher the efficiency of system operation and the better the application performance. The specific analysis process of experimental results is as follows: The application performance data obtained through experiments are shown in Table 3.2, Figures 3.1 and 3.2 [20].

As shown in Table 3.2, under different experimental frequencies, the designed system thread switching time data range is 10.02ms 14.20ms, and the signal mixing time data range is 100.23ms∼111.10ms. The above data proves that the designed system has high operational efficiency and good application performance.

4. Conclusion. The author introduced virtual reality technology to design a new integrated simulation training system for athletes, which greatly reduces the system thread switching time and signal mixing time. This provides better assistance for the integrated training of athletes, and also provides certain reference value for simulation training research. Using this system for integrated simulation training of athletes' physical fitness+technical tactics, the system outputs images of training scenes with high resolution and clarity; Under different experimental frequencies, the designed system thread switching time data range is 10.02ms 14.20ms, and the signal mixing time data range is 100.23ms 111.10ms. The above data proves that the designed system has high operational efficiency and good application performance.

Table 3.2: Application Performance Data Table

Number of experiments	Thread switches the time data	Signal mixing time data
1	10.21	100.23
2	10.03	110.46

THE APPLICATION OF DEEP LEARNING IN SPORTS DATA ANALYSIS

JIN HE*

Abstract. In order to ensure that students have a deeper and more thorough understanding of knowledge and skills, the author takes deep learning as the direction and integrates it into the real-time evaluation of basketball classrooms, organically combining the two. Deep learning provides a new theoretical perspective and driving force for the optimization of real-time evaluation, and points out the direction for promoting evaluation effectiveness; The optimization of real-time evaluation provides a feasible path for achieving deep learning for students. After the implementation of the real-time evaluation plan between the experimental group and the control group, the comparison results of basketball skills tests were obtained: before and after the experiment, the experimental group's 60 second self throwing and self grabbing, vigorous dribbling, comprehensive dribbling, teaching competitions, and teaching lectures all showed significant differences in test indicators; Before and after the experiment, the control group showed significant differences in the four test indicators of 60 second self throwing and self grabbing, vigorous dribbling, comprehensive dribbling, and teaching lectures. The teaching competition indicators also showed significant differences, all of which were improved. Comparison results of deep learning abilities: Before and after the experiment, there were significant differences in the dimensions of experimental combination ability and learning perseverance, while there were significant differences in the dimensions of communication ability, self-learning ability, and total score of deep learning ability; Before and after the experiment, there was a significant difference in the dimensions of control group work ability, while there was no significant difference in the dimensions of self-directed learning ability, learning perseverance, and communication ability. Overall, there was a very significant difference in deep learning ability. Overall, the experimental group showed a more significant improvement in deep learning ability compared to the control group. The real-time evaluation plan for sports education professional basketball classrooms based on deep learning is more effective in improving students' basketball skills and deep learning abilities than the conventional real-time evaluation plan for sports education professional basketball classrooms. The design of the plan has certain effectiveness and feasibility.

Key words: Deep learning, Sports data analysis, Application, Instant evaluation, Basketball Classroom

1. Introduction. As an important component of national teacher training programs, the physical education major is the main battlefield for cultivating the teaching staff of primary and secondary school physical education teachers, and has the largest proportion in undergraduate physical education majors. Its importance is self-evident [1]. As one of the main courses of physical education in ordinary universities, basketball course is an important part of school physical education teaching. The teaching of basketball compulsory courses is based on the principle of combining theory and practice, according to the requirements of the physical education professional training program and the characteristics of students, with a focus on strengthening students' ideological and political education, moral education, and the mastery of basic knowledge and skills of basketball, improving teaching organization and practical application abilities, highlighting the characteristics of teacher education, enabling students to achieve comprehensive development.

The quality of basketball course teaching to a certain extent affects the quality of talent cultivation. In order to improve the quality of basketball teaching, classroom teaching is the foundation and the main battlefield for students to learn basketball knowledge, master basic basketball skills and tactics, and cultivate basketball teaching abilities.

Teaching activities are a process of joint participation and learning between teachers and students. Therefore, in basketball classrooms, there is a lot of communication and interaction between teachers and students, and real-time evaluation occurs within it. If teachers can flexibly use real-time evaluation based on student learning performance, it can guide students to actively think and promote the improvement of teaching effectiveness. Instant evaluation, as a commonly used teaching method in basketball classrooms, plays an important role in overall control of the teaching process. However, due to various factors, it has not achieved the expected

*Anhui Industry Polytechnic, Tongling, Anhui, 244000, China; School of Graduate Studies, Emilio Aguinaldo College, Manila 1007, Philippines (19356223230@163.com)

results. In classroom teaching, most teachers do not attach importance to the real-time evaluation process, which leads to many problems such as unclear evaluation objectives, single evaluation methods, and incomplete evaluation content. If a teacher fails to provide effective immediate evaluation when a student is learning a new skill, the student may practice the wrong action continuously, leading to the formation of the wrong action and missing out on a good opportunity for correction. Of course, during the learning process, many students may encounter various problems. If the teacher only evaluates right and wrong in real-time evaluation, it will directly affect the student's in-depth learning experience and deep understanding and recognition of skills. It will not play a good role in the important role of real-time evaluation, and there will also be shallow guidance for students in exam taking and other aspects.

Classroom teaching, learning, and evaluation complement each other and jointly promote the development of students. In basketball classrooms, there is a lack of effective real-time evaluation, and teachers are unable to optimize classroom teaching in a targeted manner, resulting in no significant improvement in learning outcomes. Therefore, based on many practical issues, it is necessary to think about how to achieve the true role of real-time evaluation, in order to improve the quality of teaching. With the continuous reform of classroom teaching, real-time classroom evaluation keeps up with the pace of reform, pays more attention to student development, and improves classroom teaching effectiveness. So, paying attention to student development requires a focus on their learning and guiding them to learn how to learn. However, in previous classrooms, real-time evaluation focused on the teacher's "teaching" and neglected the student's "learning". For basketball classrooms, how can real-time evaluation play an important role in achieving good evaluation results? How to achieve good evaluation results?

The integration of deep learning has played a leading role in optimizing real-time evaluation in basketball classrooms, which is beneficial for teachers to clarify the direction of real-time evaluation, explore the value of real-time evaluation in basketball classrooms, and achieve a good effect in promoting student development.

In view of this, the author will integrate deep learning with real-time evaluation in basketball classrooms and re-examine the role of real-time evaluation in basketball classrooms. Using questionnaire survey method and mathematical statistics method, a real-time evaluation index content for physical education professional basketball classroom based on deep learning was constructed. Based on the index content, an instant evaluation plan was designed and applied in the classroom, in order to enrich and develop the connotation of instant evaluation and improve the effectiveness of achieving teaching objectives in teaching practice. The significance of this study is to combine deep learning with real-time classroom evaluation, explore the value of real-time basketball classroom evaluation, deepen the theoretical connotation of real-time evaluation, and provide a new theoretical perspective for the optimization of real-time evaluation, combining the two in teaching practice can improve the quality of teaching and promote the comprehensive development of students. At the same time, it provides more detailed references for teachers to promote students' deep learning through real-time evaluation practice, which has certain theoretical and practical significance [2,3].

2. Methods. The author focuses on the five physical qualities of students and their deep learning abilities in basketball teaching under three different teaching modes: flipped classroom teaching mode based on deep learning, flipped classroom teaching mode, and traditional classroom teaching mode.

2.1. Experimental subjects. In this experiment, 20 students from Class 4 and Class 5 of the Physical Education Department of A Normal University in 2021 were selected as the control group and experimental group, respectively (taking into account the differences in basketball skills and special circumstances, excluding basketball players from each class and individual students with injuries). They were aged between 20 and 23 years old and had the same level of exercise, which was relatively balanced. The excluded students also participated in basketball courses and experiments, but the test data is not included in the data reference of this study. The experimental process is shown in Figure 2.1 [4].

2.2. Experimental location and time. Experimental location: The practical class will be held in the basketball court of the School of Physical Education, A Normal University, and the theoretical class will be held in the corresponding classroom. Experimental period: March 2022 to June 2022, a total of 14 weeks of courses, with one class per week [5].

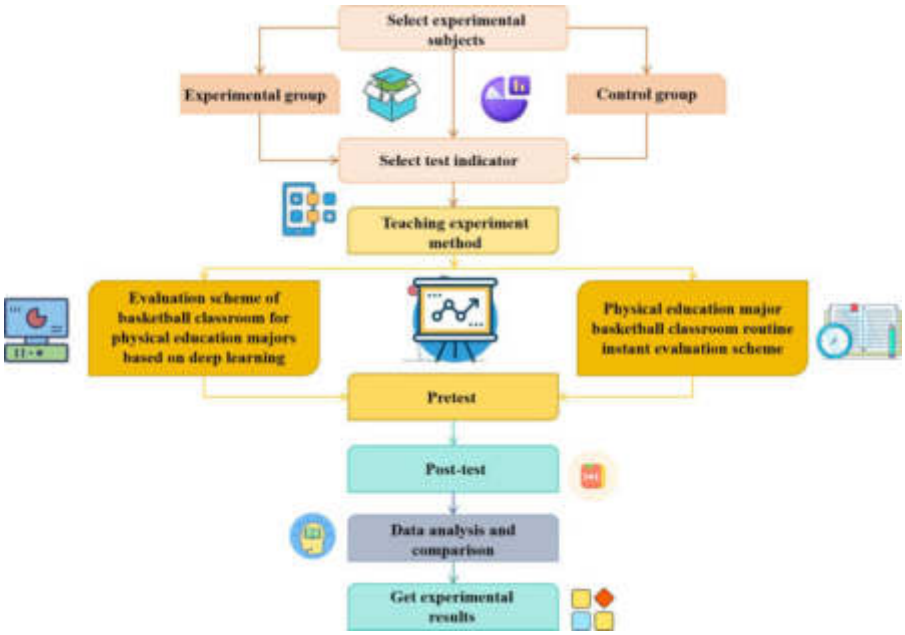

Fig. 2.1: Teaching Experiment Flow Chart

2.3. Experimental independent and dependent variables.

(1) Independent variable. Different instant evaluation schemes (experimental group: Instant evaluation scheme for physical education professional basketball classroom based on deep learning, control group: Routine instant evaluation scheme for physical education professional basketball classroom).

(2) Dependent variables. Basketball skill mastery level, deep learning ability level, cognitive level, and learning methods of the experimental subjects.

(3) Experimental variable control. This experiment was conducted in a double-blind manner (without the knowledge of both teachers and students) to avoid affecting the experimental results. The teaching syllabus, teaching schedule, teaching content, and location of the experimental group and the control group are consistent. The two groups of instructors are the same teacher and familiar with different teaching plans. Before the teaching experiment, there was no significant difference in the various test indicators between the experimental group and the control group students. The design of the experimental plan and the assessment of basketball skills were guided and evaluated by teachers from the School of Physical Education, A Normal University, majoring in Physical Education, Teaching Theory, and Basketball Teaching.

2.4. Testing indicators and tools.

(1) Basketball Skills Test. Including vigorous dribbling, 60 second self pitching and grabbing, comprehensive dribbling, teaching competitions, and teaching lectures. According to the testing content specified in the basketball course of the Physical Education major at the School of Physical Education, A Normal University, the preliminary selection indicators will be selected, and expert interviews will be conducted to improve them based on expert opinions, ensuring the accuracy of the experimental results. Vigorous dribbling: Place 4 marker buckets as required and dribble left and right with one hand directly above the marker buckets. Require standardized movements, a total time of 30 seconds, and record the number of landings. 60 second self shooting and self grabbing: Take the projection point of the hoop as the center of the circle, and select three points on the left, center, and right outside the semicircle with a radius of 3.5 meters (at least 3 meters apart) for mid range self shooting and self grabbing. Do not shoot twice from one point in a row, with a total time of 60 seconds. Record the number of shots made. Integrated dribbling: The starting point is the midpoint of the basketball court's end line. Students change their left hand dribbling to the front of pole A to do a

back-to-back dribbling, their right hand dribbling to the front of pole B to do a back-to-back dribbling, their left hand dribbling to the front of pole C to do a crotch dribbling, and their right hand layup. After shooting, they return to the finish line according to the prescribed requirements, then follow the same method again and stop the watch immediately after reaching the endpoint. If the layup fails to hit, continue shooting until the final score is made up. The overall score will be based on the time and technical evaluation of this test item, with each item accounting for 50% of the test score for that item. Teaching competition: The teacher divided the students into groups of 5 and engaged in a 5-on-5 offensive and defensive competition throughout the entire field. The competition lasts about 10 minutes. Teachers mainly evaluate students based on their individual ability to use offensive and defensive techniques and their awareness of mutual cooperation in competitions. The judges will form an evaluation group consisting of three teachers, each giving a score. Teaching Lecture: Each student selects a basic offensive tactic that they have already learned and cooperates with the teaching to give a lecture (the whole class will explain it on site), mainly explaining the teaching steps, especially the tactical explanation, teacher's teaching methods, and student learning and practice methods. The teacher will evaluate the situation on site and record it on video.

(2) Deep learning ability test. The author used the deep learning ability questionnaire developed by Dr. Bu Caili to test the effectiveness of the experiment. The mastery of professional knowledge, critical thinking, and problem-solving abilities in the cognitive field is mainly evaluated through cognitive tests of thinking level (professional knowledge test questions) and basketball skills tests.

2.5. Mathematical Statistics. The author used Excel 2010 and SPSS 26.0 statistical software to process the data, and conducted independent sample t-tests and paired sample t-tests for inter group and intra group significance differences, respectively, to analyze the data. Finally, the experimental data was obtained.

2.6. Design of real-time evaluation indicators for basketball classrooms in physical education majors based on deep learning.

(1) Design basis for real-time evaluation indicators for basketball classrooms in physical education majors based on deep learning. Effective teaching emphasizes the effectiveness of teaching, that is, what kind of teaching is effective. The focus of "effectiveness" is on students, and only through their development and improvement after a period of learning can teaching prove to be effective, and vice versa. Effective learning mainly refers to students being able to engage in autonomous, exploratory, and exploratory learning, advocating for active thinking and emphasizing the process of understanding and construction, rather than superficial learning such as rote memorization. From this perspective, the concept of deep learning coincides with effective teaching principles, and the two are unified in terms of practical connotation and goal orientation. Therefore, establishing a basketball classroom for deep learning is actually establishing an effective teaching basketball classroom. a basketball classroom for deep learning must be an effective classroom, and an effective basketball classroom also reflects the characteristics of deep learning to a certain extent, therefore, the author's design based on the basic principle of effective teaching theory helps to achieve the goal of effective teaching and truly implement deep learning in classroom teaching. The effective teaching theory believes that providing "immediate feedback" is one of the important behaviors for teachers to effectively "guide" and plays a key role in the classroom. The proposed methods for providing immediate feedback provide certain theoretical references for research.

Constructivist theory holds that learning should possess six core characteristics: positivity, constructiveness, accumulation, diagnostic, reflective, and goal guidance. Constructivist theory explains deep learning, which conforms to the six core characteristics of constructivist learning and belongs to constructivist learning. Constructivist theory emphasizes the subjective initiative of students in the learning process and the construction of knowledge, and the most important thing in achieving this process is the guidance of teachers. The role of teachers should become guides for students to learn, improve learning engagement, and enhance learning transfer ability. From the perspective of constructivist theory, teaching evaluation should focus on evaluating the learning process, with the goal of promoting comprehensive development of students; The evaluation content focuses on the physical and mental development of students, and emphasizes the dynamic evaluation of their abilities, emotions, and ways of thinking; The evaluation subject pays more attention to the student's subjectivity. As the evaluation subject, students actively participate in learning activities, carry out self-evaluation and peer evaluation, and the focus of evaluation shifts to focusing on the learning process. Internal evaluation is the main focus, dynamic evaluation is emphasized, and the process evaluation of teaching and learning is

emphasized. Evaluation is implemented according to the learning needs of students, and teaching work is adjusted and improved in a timely manner, making the evaluation more objective and effective. In summary, deep learning conforms to the principles and objectives of constructivist theory, and the evaluation strategies under constructivist theory provide a certain theoretical basis for the design of this study.

Diversified evaluation refers to the diversification of evaluation objectives, methods, content, and subjects. The theory of multiple evaluations is based on the design of real-time evaluation indicators for physical education professional basketball classrooms based on deep learning, mainly reflected in the following points.

The goal of instant evaluation is diverse. The setting of immediate evaluation goals should be reasonably designed from multiple aspects such as cognition, emotion, and ability development [6]. The content of instant evaluation is diverse. The basketball course for physical education majors is a course that cultivates comprehensive quality talents and emphasizes practice and application. Therefore, in addition to evaluating the mastery of professional knowledge and skills learned, students should also pay attention to the acquisition of higher-order thinking ability, the ability to apply basic basketball knowledge and skills, positive emotional experience, and the mastery of core abilities. The subject of instant evaluation is diverse. The diversification of evaluation subjects can deepen the cognitive level of learners by analyzing, processing, and reconstructing individual and others' learning information. Therefore, in the classroom, teachers should organize student-centered evaluation activities, guide students to conduct self-evaluation and peer evaluation in a timely manner, and broaden the evaluation subject. Instant evaluation methods are diverse. Teachers in basketball classrooms can use various verbal and nonverbal evaluation methods to timely guide and guide students in deep learning based on the teaching process and their performance and behavior. The evaluation related to classroom teaching will include four basic elements: evaluation objectives, evaluation content, evaluation methods, and evaluation subjects. Based on deep learning theory, design indicator content and deeply explore the guiding role of deep learning on the four basic elements. Instant evaluation goals focus on preset and generated. From the perspective of deep learning, the goal of real-time evaluation in basketball classrooms is to pay more attention to the cognitive level, emotions, and ability development of students. Teachers should view students and the teaching process from a dynamic and developmental perspective. During the process of students learning knowledge and practicing skills, teachers should promptly pay attention to various situations that occur in the teaching context, seize educational opportunities, and focus on generative resources. At the same time, pay attention to the combination of generative goals and preset goals, and adjust teaching strategies in a timely manner to jointly promote the long-term development of students.

Instant evaluation content is not limited to mastery of the learned content. Deep learning theory emphasizes higher-order thinking and points to deep cognition. Higher order thinking requires the evaluation content to break through shallow and superficial evaluation content, trigger cognitive conflicts among students through evaluation content, and promote the improvement of thinking ability. The evaluation content for deep level cognition should include the application methods, timing, value, and other content of the learned content. When designing real-time evaluation indicators for physical education professional basketball classrooms based on deep learning, it is necessary to deeply explore the evaluation content of deep level cognition, emotional attitude, and ability development, continuously enrich the breadth and width of the evaluation content, and truly achieve deep learning.

The real-time evaluation method does not stop at simple Q&A. Deep learning theory emphasizes critical understanding and meaning construction. Deep learning advocates understanding meaning as its purpose, emphasizing the construction of knowledge and the learning process of critical understanding. However, real-time classroom evaluation is generated through teacher-student interaction and communication, but due to time constraints and other factors, it is easy to stay at a simple level of feedback and processing, neglecting in-depth analysis of student responses, missing opportunities for understanding and learning, and not conducive to critical understanding and construction of what students have learned. Therefore, deep learning theory provides guidance for real-time evaluation methods, enabling them to truly be effective.

The subject of immediate evaluation is not limited to the teacher's "solo role". The theory of deep learning embodies student-centered approach and advocates active physical and mental participation [7]. Learners not only need to actively learn knowledge and skills, experience the learning process firsthand, improve their cognitive level, but also learn to engage in self reflection and evaluation. Students participating in the evaluation

Table 3.1: Comparison of basketball skill test results within the experimental group before and after the experiment

Test content	Before the experiment	After the experiment	T	P
60 second self throw and self grab	54.36±5.942	77.01±9.516	-8.288	0
Powerful dribbling	58.76±9.443	92.51±7.23	-12.682	0
Integrated dribbling	55.16±3.632	84.71±10.835	-11.166	0
teaching competition	63.71±4.17	69.26±4.352	4.3701	0
Teaching lectures	55.66±6.202	80.66±4.357	-14.41	0

of the classroom can be more effective, so participating as the evaluator in the classroom can enhance their learning engagement, experience deep learning experiences, objectively understand themselves, and gain self-efficacy.

(2) Realistic basis. Through interviews with students, course teachers, and field observations, the author found that most teachers still focus on evaluating students at a superficial level, emphasizing basketball knowledge and basic skills and tactics themselves, neglecting the exploration of deep cognition, lacking questioning and reflection on problems, which cannot cause cognitive conflicts among students and cannot generate profound understanding. In basketball classes, teachers tend to make immediate evaluations of students too simplistic, with a focus on single affirmations and negatives. The language used for immediate evaluations mainly includes phrases such as "well practiced" and "excellent", which are not inspiring and do not have a significant promoting effect on students, which is not conducive to promoting their learning and mastery of motor skills. In basketball classrooms, teachers mostly evaluate students using methods such as affirmation, negation, and repetition of student answers, while their evaluations of students remain simple responses and lack descriptive feedback. Such evaluation methods do not stimulate deep thinking among students and are not conducive to their progress and development. Through interviews and on-site observations, it was found that the majority of immediate evaluations in basketball classrooms are mainly conducted by teachers, rarely engage in student self-evaluation and peer evaluation, while student participation in self-evaluation and peer evaluation can enhance personal reflection and critical abilities, if this link is missing, it is not conducive to students' deep understanding of basketball knowledge and the cultivation of critical thinking. Secondly, in teacher centered real-time evaluations, most of them are based on the evaluation of the entire class by the teacher, with less evaluation of individual and group students. Such evaluations lack specificity, and in the classroom, students are more eager to receive separate guidance and evaluation from the teacher, which will enable them to make greater progress and development.

In summary, in basketball classroom teaching, the immediate evaluation of teachers tends to be superficial and superficial, and there are many problems that have not played a true role. In view of this, the author designs an instant evaluation index for sports education professional basketball classrooms based on deep learning, so that instant evaluation can play its due role.

3. Results and Analysis.

3.1. Comparison of basketball skill tests between the experimental group and the control group before and after the experiment. According to Table 3.1, after the experimental intervention, various test indicators in the experimental group were subjected to statistical paired sample T-test, and the P-values of the 60 second self throwing and self grabbing, vigorous dribbling, comprehensive dribbling, teaching competitions, and teaching lectures were all less than 0.001, indicating significant differences. This indicates that the application of the real-time evaluation plan for physical education professional basketball classrooms based on deep learning can significantly improve students' basketball skills [8]. According to the data statistics in Table 3.1, it can be seen that the three test indicators of 60 second self throwing and self grabbing, vigorous dribbling, and comprehensive dribbling belong to the assessment of students' technical mastery level. The results of the three test items in the experimental group before and after the experiment are very significant. Analysis of reasons: Firstly, in the new teaching stage, students can greatly improve their basketball skills through

Table 3.2: Comparison of basketball skill test results within the control group before and after the experiment

Test content	Before the experiment	After the experiment	T	P
60 second self throw and self grab	51.86±4.998	71.01±7.539	-8.755	0
Powerful dribbling	61.26±8.717	88.36±5.224	-11.421	0
Integrated dribbling	53.71±3.877	78.91±5.776	-.19.831	0
teaching competition	62.36±4.196	65.91±3.611	-2.867	0.01
Teaching lectures	52.81±5.908	75.66±6.548	-16.782	0

teacher explanations, extensive practice, and pre class consolidation and review; Secondly, the use of a real-time evaluation plan for physical education professional basketball classrooms based on deep learning enables students to have a deeper understanding and mastery of skills, and a more thorough understanding of the content they have learned. As a result, students pay more attention to the various details of the skills they have learned during the practice process, promoting their skills to reach a deeper level. The teaching competition mainly focuses on the comprehensive evaluation indicators of students' personal application of offensive and defensive techniques, as well as their awareness and ability to cooperate with each other. There is a significant difference in the assessment results before and after the experiment. Analysis of reasons: Firstly, through the practical application of competitions and extensive practice in each class, students can gradually improve their technical application ability and cooperation awareness; Secondly, through the application of a real-time evaluation plan for physical education professional basketball classrooms based on deep learning, teachers consciously adopt real-time evaluation in the classroom, combining different practice situations of students and various teaching stages, so that students can timely recognize the errors in the game and actively think and make corrections, guiding students to deeply understand the essence of offensive and defensive techniques and how to better cooperate with each other in the game, so as to effectively improve the teaching competition results of students. Teaching lecture is different from the other four indicators, mainly focusing on the evaluation indicators of students' personal action and technical teaching ability. It mainly tests the teaching steps, especially the explanation of tactics, the teaching methods of teachers, and the methods of students learning and practicing. The assessment results of this item show significant differences before and after the experiment. Analysis of the reasons: Firstly, in basketball classrooms, teachers will permeate teaching knowledge such as teaching methods for the skills they have learned. This not only enables students to demonstrate basketball skills, but also teaches them how to teach the skills they have learned and understand the methods of skill teaching, including the methods taught by the teacher and the methods used by students to learn and practice; Secondly, during the learning process, teachers use questioning based evaluation methods to teach students skills, triggering cognitive conflicts and guiding students not only to understand "what to teach", "how to teach", and "how to teach", but also to understand "why to teach", further deepening students' essential understanding of skill teaching. Therefore, the experimental group students showed a more significant improvement in the teaching and lesson indicators.

According to Table 3.2, after the experimental intervention, statistical paired sample t-test was used to analyze the data of various test indicators in the control group. The P-values of the four indicators of the control group, including 60 second self throwing, strong dribbling, comprehensive dribbling, and teaching lectures, were less than 0.001, all of which had significant differences. The P-value of the teaching competition indicator is less than 0.05, indicating a significant difference.

According to the data statistics in Table 3.2, it can be seen that the three test indicators of 60 second self throwing and self grabbing, vigorous dribbling, and comprehensive dribbling belong to the assessment of students' technical mastery level. The control group before and after the experiment showed significant differences in these three test indicators [9]. Analysis of reasons: Firstly, due to the fact that throughout the entire semester of teaching, there is a review, consolidation, and practice section in each skill class. Therefore, after repeated practice in multiple classes, the mastery of skills by students will inevitably be greatly improved over time, which is also one of the main reasons for the improvement of their learning effectiveness and grades; Secondly, in terms of the role of real-time evaluation in class, in the real-time evaluation of the control class, the teacher evaluates students based on skill practice and answering questions, informing them of existing

Table 3.3: Comparison of intra group deep learning ability test results before and after the experiment in the experimental group

Dimension	Before the experiment	After the experiment	T	P
cooperation	26.81±4.938	30.66±3.760	2.970	0.008
communica--tion skills	20.86±4.017	25.41±2.280	4.966	0
Autonomous learning ability	37.91±7.497	46.16±7.036	-12. 131	0
Learning perseverance	28.61±5.576	30.86±4.158	-3.428	0.001
Total score	113.66±20.366	133.06±12.133	-7.491	0

problems and methods to correct errors. Although this form of real-time evaluation has a relatively simple method and language, it also has a certain promoting effect on students to master the learned content, and can help students initially form correct action cognition. Therefore, during the learning process of basketball courses, students can gain a clearer understanding of the exercise content through the guidance and correction of various practice stages by the teacher, as well as their serious practice. In addition, the real-time evaluation conducted by the teacher during the learning and practice can help students develop a clearer understanding of the exercise content. These factors are beneficial for students to master basketball skills, and the improvement effect of their basketball skills will also be significant. The teaching competition mainly focuses on the comprehensive evaluation indicators of students' personal application of offensive and defensive techniques, as well as their awareness and ability to cooperate with each other. There is a significant difference in the assessment scores of the control group before and after the experiment. Analysis of reasons: Firstly, through the teacher's explanation, demonstration, and specialized exercises organized by the organization, students develop a preliminary understanding of the application of offensive and defensive techniques and how to cooperate; Secondly, if students have a profound understanding and understanding of the essence and application requirements of techniques and tactics in competitions, it will help them to flexibly apply them in competitions. In the control group basketball classroom, teachers not only provide real-time evaluations of errors that occur during the practice process, but also conduct real-time evaluations during the game based on the use and cooperation of students in offensive and defensive techniques, informing students of their mistakes and how to correct them, in order to gain favorable opportunities during the game. Therefore, the teaching competition scores of the control group students have also improved.

Teaching lectures are mainly aimed at evaluating the individual teaching ability of students in motor skills, mainly testing the teaching steps, especially the explanation of tactics, teaching methods of teachers, and methods of students learning and practicing. There is a significant difference in the assessment scores of the control group before and after the experiment. Analysis of reasons: On the one hand, through the teaching and explanation of teachers in class, as well as combining their own learning, students can master the relevant teaching steps and practice methods, and form a preliminary understanding of "how to teach"; On the other hand, through real-time evaluation by teachers in class, it further helps students deepen their understanding of skill teaching, gradually guiding them to deeply understand the essential characteristics of skills and teaching methods. The above two aspects jointly promote a significant improvement in the teaching presentation test scores of the control group students.

3.2. Comparison of deep learning abilities between the experimental group and the control group before and after the experiment. From Table 3.3 and Figure 3.1, it can be seen that before and after the experiment, the dimensions and overall level of deep learning ability in the experimental group were subjected to statistical paired sample T-test, and the P-values of cooperation ability and learning perseverance were all less than 0.01.

The P-values of communication ability, self-learning ability, and deep learning ability were all less than 0.001, indicating significant differences. The application of an instant evaluation scheme for basketball classrooms in

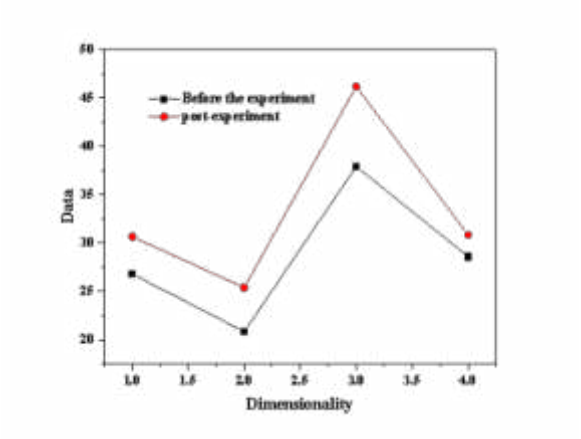

Fig. 3.1: Comparison of intra group deep learning ability test results before and after the experiment in the experimental group

physical education majors based on deep learning can significantly enhance students' deep learning abilities. According to the data statistics in Table 3.3, there are significant differences in the dimensions and overall level of deep learning ability between the experimental group before and after the experiment, mainly due to: On the one hand, basketball itself is a collective collaborative sport with collective characteristics. The positive impact of basketball mainly includes cultivating strong willpower, unity and cooperation spirit, improving self-control, enhancing self-confidence, improving emotional state, and so on. Therefore, as long as students participate in the learning of basketball courses, their cooperation ability, communication ability, self-learning ability, and learning perseverance dimensions are important, these will all be improved to varying degrees; On the other hand, teachers consciously promote the development of students' deep learning abilities through real-time evaluation. In terms of immediate evaluation goals, teachers will pre-set the phased development of deep learning ability, set the development goals of deep learning ability for each class, focus on how to promote students' long-term development, and clarify the expected effects that immediate evaluation aims to achieve, in addition, in class, emphasis will also be placed on goal generation, adjusting real-time evaluation goals based on the practice situations of different students in class, combining generative goals with preset goals to form new educational resources, and then adjusting the teaching process and improving teaching methods. In terms of instant evaluation methods, teachers will use various evaluation methods such as literacy based evaluation to evaluate the ability development reflected in learning tasks in an instant manner, making it explicit; In terms of instant evaluation content, teachers pay more attention to the development of deep learning abilities, which can help students form a comprehensive understanding of ability development; In terms of real-time evaluation subjects, students can reflect on their strengths and weaknesses and objectively understand themselves by participating in self-evaluation and peer evaluation. At the same time, during the practice process, students continuously provide feedback, communicate with each other, learn from each other, and jointly promote the improvement of deep learning abilities.

According to Table 3.4, Figure 3.2, before and after the experiment, the dimensions and overall level of deep learning ability in the control group were tested by paired sample t-test, and the P-value of the cooperation ability dimension was less than 0.05, indicating a significant difference; The P-values of communication ability, self-learning ability, and learning perseverance dimensions are all greater than 0.05, and there is no significant difference [10]; Overall, the P-value of deep learning ability is less than 0.01, indicating a significant difference. Based on the above data analysis, it is evident that the conventional real-time evaluation plan for basketball classrooms in physical education majors cannot comprehensively enhance students' deep learning abilities.

From the data statistics in Table 3.4, it can be seen that there is no significant difference in communication ability, self-learning ability, and learning perseverance dimensions between the control group before and after

Table 3.4: Comparison of Intragroup Deep Learning Ability Test Results before and after the Control Group Experiment

Dimension	Before the experiment	After the experiment	T	P
cooperation	25.26±4.102	26.81±3.820	-2.704	0.014*
communication skills	19.91±3.972	20.81±4.124	1.757	0.095
Autonomous learning ability	40.86±6.252	41.36±6.226	-1.423	0.171
Learning perseverance	27.71±4.824	27.81±4916	0.172	0.866
Total score	112.81±16.201	116.76±16.101	-3.336	0.003**

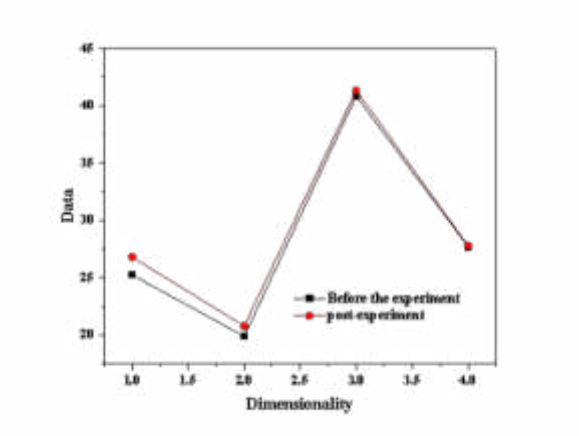

Fig. 3.2: Comparison of intra group deep learning ability test results before and after the control group experiment

the experiment. The reason for this is that during the in class practice process, teachers mostly impart basketball knowledge and skills to students, and there are not many opportunities for feedback and communication between students and teachers. Teachers sometimes conduct real-time evaluations of communication skills, self-directed learning abilities, and learning perseverance dimensions based on their learning situation. However, due to the insufficient promotion of real-time evaluations, they cannot attract students' attention, resulting in a significant improvement in students' communication skills, self-directed learning abilities, and learning perseverance. There is a significant difference in the dimension of cooperative ability. Analyze the reasons: On the one hand, because basketball is a collective sport, students can improve their cooperative ability to a certain extent through classroom teaching and competition practice, as well as learning basic offensive and defensive tactical coordination methods; On the other hand, teachers will conduct real-time evaluations of the quality of cooperation and the cooperation between peers through multiple collaborative exercises such as consolidation and improvement, offensive and defensive confrontations, and actual matches.

Through the evaluation content and methods, teachers can point out the strengths and weaknesses of students in cooperation, which is beneficial for students to have a certain impact on their cooperation ability and promote the development of their cooperation ability.

4. Conclusion. This study designs instant evaluation indicators for basketball classrooms in physical education majors based on deep learning. Based on the content of the indicators and classroom characteristics, an instant evaluation plan is designed and applied to basketball classroom teaching practice, in order to verify the impact on the effectiveness of deep learning for students. The aim is to enrich and develop the connotation of

instant evaluation in basketball classrooms in sports colleges and departments of universities, and to improve the effectiveness of achieving teaching goals in teaching practice. The results show that the application of a real-time evaluation plan for physical education professional basketball classrooms based on deep learning can significantly improve students' basketball skills, promote their deep understanding of basketball knowledge and skills, and enable them to master basketball skills more proficiently. The application of an instant evaluation plan for basketball classrooms in physical education majors based on deep learning can significantly enhance students' deep learning abilities. The application of an instant evaluation plan for basketball classrooms in physical education majors based on deep learning can significantly deepen students' learning methods, weaken their original shallow learning tendencies, and further strengthen their tendencies towards deep and strategic learning methods. The application of an instant evaluation scheme for basketball classrooms in physical education majors based on deep learning can effectively achieve deep learning for students and truly facilitate learning. It is recommended to apply this real-time evaluation plan to actual teaching in future basketball classroom teaching, and design and use it reasonably according to different teaching situations.

SPORTS PLAYER ACTION RECOGNITION BASED ON DEEP LEARNING

FENG LI*

Abstract. A sports auxiliary evaluation system suitable for China's national conditions was established using big data and sports identification technology. First of all, this paper extends the data of normative behavior and constructs a normative library of scores and comparisons. The acquisition of 3D data is emphasized. The method based on Fourier descriptors is used to locate the motion accurately. In this way, better gait recognition results can be obtained. The Fourier characteristics before and after wavelet transform are compared with the actual object characteristics, and the results show that the proposed algorithm can extract the features with high precision. This scheme can obtain a more accurate identification effect. The system proposed in this paper provides a powerful means for judges to score.

Key words: Big data; Particle filter; Fourier descriptors; Feature extraction; sports

1. Introduction. Biometrics is a way to identify people based on their intrinsic physiological characteristics. The uniqueness and universality of biometrics make it a hot topic in current identity research. People must first obtain some of its characteristics, such as physiological and behavioral characteristics, to determine their true identity. Because it is not easy to camouflage, hide and be detected and identified over a long time based on human gait characteristics, it can effectively overcome the image blur caused by a long distance. Some scholars have proposed a Fourier descriptor image feature extraction algorithm, which can effectively solve the problem of matching between keyframes. However, according to the Fourier characteristics of the spatial position obtained by the human body when it moves, there are significant errors in practical application.

Recognizing human posture is a significant research direction with a broad development space in machine vision. Therefore, methods based on 3D human pose estimation and behavior recognition are widely used. The research on human motion capture, human modeling, pose estimation, and motion recognition has achieved fruitful results in the last ten years. In literature [1], an extensible graph model can effectively improve the identification efficiency of human behavior. Literature [2] provides a global descriptor that synthesizes the orientation and size of the movement of various parts of the human body. Scholars first build a three-dimensional model and then use the model to identify human behavior. Literature [3] has improved the characteristics of RGBD images. The descriptor encodes the extraction of three-dimensional directions from evenly spaced areas to realize action recognition. This method provides a new idea for machine vision research. Key research topics include advanced human-computer interaction, assisted living, gesture interactive games, intelligent driver assistance systems, movies, 3D TV and animation, physical therapy, autonomous intellectual development, intelligent environment, motor behavior analysis, video surveillance, video annotation, etc. Especially in the study of physical activity, many events, such as calisthenics, have high demands on the posture and movement of the human body.

The pose estimation method can be used to study sports performance and training in physical education. In the process of competition, it can also help the judges score [4]. Judges need to give accurate scores in the aerobics competition by evaluating the complex movements done by the players. The difficulty judge determines the difficulty of each action performed by the player. Because the problematic movements of groups A, C, and D are instantaneous, it is easy to make visual errors. Therefore, when there are different scoring levels in difficulty evaluation, the judging committee needs to use big data and behavior identification technology to design and implement a set of aerobics scoring systems. This paper proposes a gait feature extraction method based on particle filter tracking. The accurate determination of human behavior is realized through the acquisition of 3D

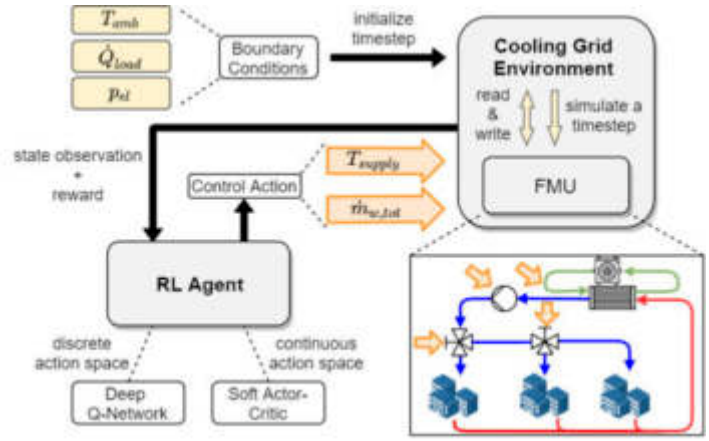

Fig. 2.1: *Schematic diagram of action representation method.*

movement data of human body, combined with the characteristics of human bone structure. The algorithm of human motion trajectory detection is studied [5]. The human body positioning correction based on background deduction is realized by particle filtering on the moving human body. Then, based on the improved location information, Fourier description is carried out to realize the extraction and matching of pedestrian features in the moving state.

2. Design of motion characteristic identification system.

2.1. Feasibility and performance of actions. A three-dimensional image is insensitive to the change in the surrounding environment, which is suitable for aerobics movement recognition [6]. This paper selects the movement recognition model of calisthenics in three-dimensional space. The specific action representation is shown in Figure 2.1.

Three-dimensional behavior data includes two aspects: time-space characteristics and motion trajectory tracking. The time-space representation of behavior is a local representation of behavior. It can map complex behavior [7]. The motion representation of three-dimensional data can recognize moving objects better, but the recognition of complex aerobic movement features needs further research. The behavior representation method based on a three-dimensional skeleton structure has the advantages of solid robustness, fast processing speed and small data scale and has been widely used in behavior recognition research. The geometric relation between the connecting points is obtained by the geometric description method to realize the identification of the object. Through the feature extraction of critical gestures, the gestures are matched to complete the behavior recognition [8].

2.2. Acquisition of motion parameters. According to the demand of human behavior, there have been many research results. It mainly includes tag type, laser ranging type, structured light sensor, Microsoft Kinect sensor, multi-camera, etc. The acquisition process is shown in Figure 2.2. The system is divided into depth mapping, human body parts, and 3D joint modeling.

Since the release of Kinect, in-depth imaging has come a long way. The Kinect camera in the article obtained 640x480 pixel images at 30 frames per second and a depth resolution accuracy of only a few centimeters. Unlike the conventional brightness sensor, it has the advantages of high calibration and positioning accuracy under low light conditions [9]. It can directly synthesize deep images of real people to build a large training dataset cheaply.

3. Particle filter tracking. This algorithm uses the median method to extract static background for multiple video sequences. Select and trace the first frame with a particle filter to obtain relatively accurate positioning information. Then, a particle filter tracks it to get more accurate positioning. Then, the Fourier characteristics of the object are analyzed. Finally, the features obtained directly by background subtraction

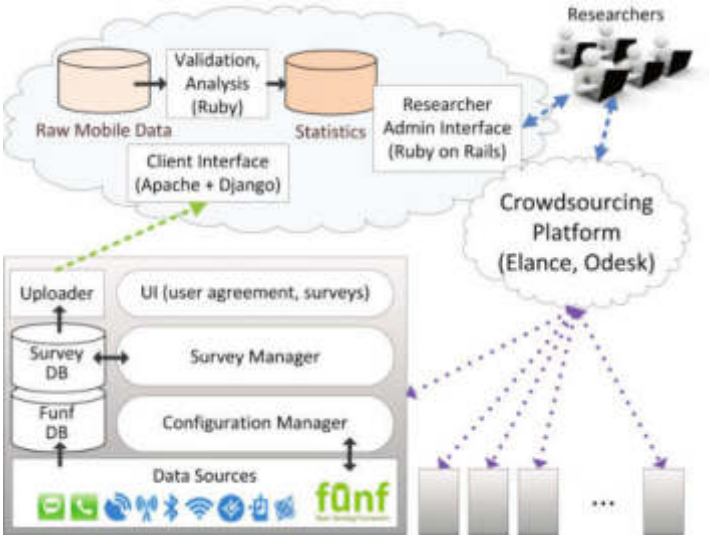

Fig. 2.2: *Action data acquisition architecture diagram.*

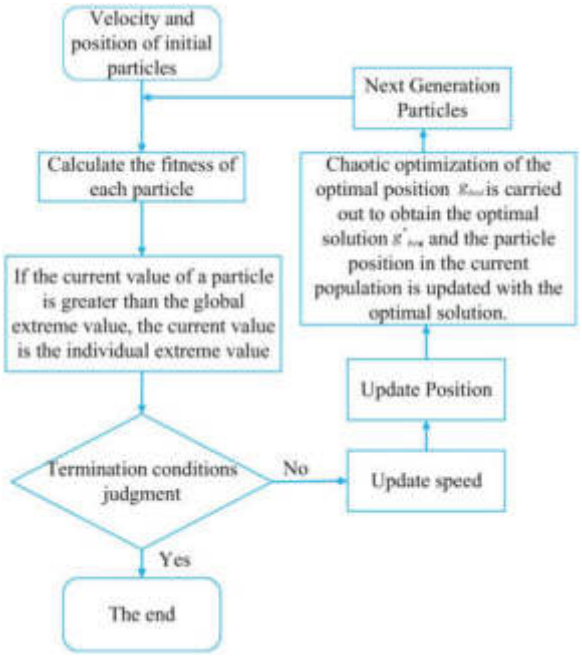

Fig. 3.1: *Flow chart of particle swarm optimization algorithm.*

before tracking and those obtained after tracking are compared with the fundamental features [10]. After tracking this frame and feature extraction according to the above steps, the best state in this frame is used as the tracking start screen for the next frame. The following image is repeatedly predicted until it is tracked to the final image. This allows for complete tracking and feature extraction. The algorithm flow chart is shown in Fig. 3.1.

Particle filter is a new method to process Bayesian filters based on Monte Carlo sampling. The main idea

is to use a series of weighted correlated random particles to obtain the posterior probability of each state. The actual states of each state are obtained according to the sample values and weights [11]. The most crucial step in the particle filtering algorithm is to predict and update it. Due to the degradation of particles in the model iteration, many methods have adopted the re-sampling method to improve the tracking results. Behavior identification starts with building a model of an object. Let $\{u_t, t \in N\}$ be the state sequence of the target. A Markov process handles it

$$u_t = g_t\left(u_{t-1}, \delta_{t-1}\right)$$

g_t is the system status function. δ_t is for processing noise. Suppose it's a Gaussian white noise with an average of o. The tracking target predicts the estimated state u_t according to the observation formula. In the process of moving, the arms and legs will shift and rotate, so it is necessary to reconstruct the characteristics of the Fourier descriptors between each frame [12]. The least matching error is selected as the Fourier feature of the current frame. The metric formula is as follows

$$c_t = l_t\left(u_t, n_t\right)$$

c_t is the measurement function of the system. n_t is the measured noise. Suppose it's a Gaussian white noise with an average of o. Baves's theory holds that under observation data $c_{1:t} = \{c_i, i = 1, \cdots, t\}$ from the first time to time point t, the state u_t is estimated by observation data at time point t. The function $f\left(u_t \mid c_{1:t}\right)$ of probability density is calculated. Assuming that the initial probability density $f\left(u_0 \mid c_0\right) = f\left(u_0\right)$ is given, the solution $f\left(u_t \mid c_{1:t}\right)$ can be obtained by the two steps of prediction and updating.

Given that the probability distribution for time $t-1$ is $f\left(u_{t-1} \mid c_{1:t-1}\right)$, the prediction procedure is as follows according to the Chapman-Kolmogorov equation

$$f\left(u_t \mid c_{1:t-1}\right) = \int f\left(u_t \mid c_{t-1}\right) f\left(u_{t-1} \mid c_{1:t-1}\right) du_{t-1}$$

In the above form $f\left(u_t \mid u_{t-1}, c_{1:t-1}\right) = f\left(u_t \mid u_{t-1}\right)$ can be obtained by a Markov method. $f\left(u_t \mid u_{t-1}\right)$ can be determined from formula (3.2) and the common knowledge of process noise δ_{t-1}. According to the measurement result c_t of time t, the prediction formula modified by Bayes' rule can be obtained:

$$f\left(u_t \mid c_{1:t}\right) = \frac{f\left(c_t \mid u_t\right) f\left(u_t \mid c_{1:t-1}\right)}{f\left(c_t \mid c_{1:t-1}\right)}$$

The standardized constant $f\left(c_t \mid c_{1:t-1}\right) = \int f\left(c_t \mid u_t\right) f\left(u_t \mid c_{1:t-1}\right) du_{t-1}$ is determined by $f\left(c_t \mid u_t\right)$ derived from formula (3.2). During the correction period, measure c_t is used to correct the prior density, and then the posterior density of the current state is obtained. Since the particle's weight is constantly changing, the deterioration of the particle occurs when some properties are lost. For this reason, the sample must be re-sampled [13]. The lighter particles are removed and focused on the heavier ones.

4. Fourier descriptors. After segmenting the human form, it is used as a closed curve. Describe it as A complex number $c_i = u_i + jv_i$, where $i = 1, 2, \cdots, N$ is the number of circumference points. By using this method, 2D contour lines can be converted into one-dimensional high-precision vectors to reduce the computation [14]. The center coordinates of the gait path are shown as follows

$$u_c = \frac{1}{N}\sum_{i=1}^{N} u_i, v_c = \frac{1}{N}\sum_{i=1}^{N} v_i$$

Select the starting point (u_0, v_0), and select the starting point A on the contour line S according to the counter-clock, and record the points of (u_i, v_i) on the contour line S according to the counter-clock mode. Then, the distance vector is recorded as follows

$$R_i = \sqrt{\left(u_i - u_c\right)^2 + \left(v_i - v_c\right)^2}$$

Fig. 5.1: *Original grayscale image.*

Perform A discrete Fourier transformation on $R_i(i = 1, 2, \cdots, N)$ to obtain the Fourier descriptor for this distance vector:

$$\varphi(n) = \frac{1}{N}\sum_{i=1}^{N} R_i \exp\left(\frac{-j2\pi in}{N}\right), n = 1, 2, \cdots, N$$

Refer to $\varphi(1)$ and normalize the Fourier descriptor to get $\varphi^*(n)$. The object must be detected first To realize the effective recognition of the object. This algorithm is designed to separate different regions from a series of images accurately. The usual algorithms can be divided into three categories: interframe difference methods, algorithms based on sports field estimation, and algorithms based on background elimination [15]. The experiment used background subtraction. This method can usually obtain the most reliable image information, but it shows strong robustness to complex and changeable environmental factors in the external environment, such as light and external factors. This paper proposes a video-based target detection method to reduce moving targets in video. After the image background is modeled, the background is subtracted from the current image by image background subtraction. Then, a threshold is set, and the difference above this threshold is that the object is moving so that the object containing noise can be extracted. Then, the morphologic transformation is carried out to remove the noise and obtain a smooth image. This study selects the first 30 spectral components of Fourier descriptors. Its minor frequency component mainly characterizes it, and its most significant characteristic is its largest spectral component of order 30. So far, this paper has 30 data properties of Fourier descriptors.

5. System test and performance analysis. Kinect was used to perform experiments and performance evaluations on complex assisted gymnastics movements (group A, group B, group C, and group D) based on the MSRAction 3D database. Two kinds of images are denoised by two-layer, three-layer and four-layer Fourier space-time spatial pyramid, and then multi-dimensional information fusion and particle swarm pattern recognition are used [16]. The test results are listed in Table 5.1. A-, B -, C - and D- are the particular reducing actions of each group of difficulty movements, and A, B, C and D are the minimum standard actions of each group of difficulty movements. The test results and the background image obtained are shown in Figure 5.1.

Experiments show that this method can effectively improve the recognition rate of behavior. The feature information processing algorithm based on skeleton and depth information can significantly improve the recognition rate of human behavior and further verify the superiority of this algorithm in behavior classification. By studying the characteristics of the extracted Fourier descriptors, it is found that after the improved image processing, the obtained image is closer to the actual human body characteristics, which can effectively improve the image classification effect. Eighty screens were used in the experiment, each with 294x465 colors. In extracting Fourier descriptors, the human body is first tracked, and the experimental results of tracking are shown in Figure 5.2 and Figure 5.3.

Table 5.1: *System test result table.*

Difficulty group	Two-layer recognition rate /%	Three-layer recognition rate /%	Four-layer recognition rate /%
A-	81.03	87.84	98.97
A	81.55	91.44	101.13
B-	81.34	88.97	99.79
B	82.47	93.20	102.06
C-	81.24	88.66	98.87
C	81.34	91.75	101.44
D-	81.55	87.22	98.04
D	82.27	92.68	102.16

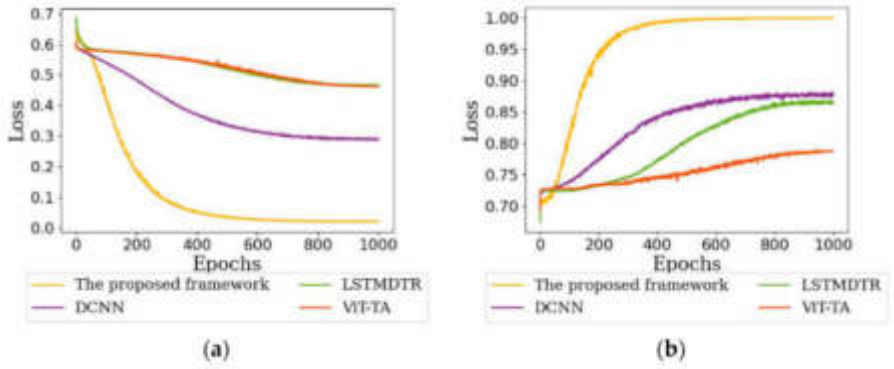

Fig. 5.2: *Background subtraction results.*

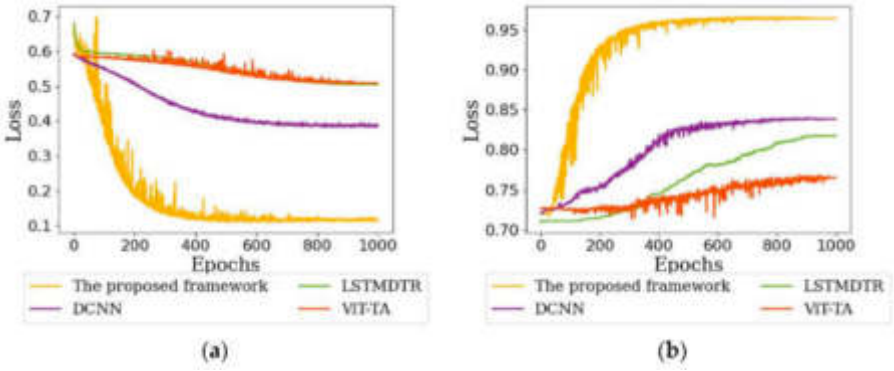

Fig. 5.3: *Particle filter tracking results.*

6. Conclusion. The words are too much because the current evaluation standard of aerobics is too general. A gymnastics performance evaluation system based on big data is developed. This project plans to use multiple gymnastics performance events to expand the human body comparison database and adopt the Fourier Pyramid method to filter and fuse the human skeleton and deep region features to realize behavior classification and recognition based on particle swarm. The experiment shows that this method can achieve a good recognition effect.

APPLICATION AND EFFECT EVALUATION OF INFORMATION TECHNOLOGY IN PHYSICAL EDUCATION

HUIJUAN WANG*AND MIN ZHOU†

Abstract. The Kalman filter and extended Kalman filter algorithm are widely used in physical education video processing, but their performance still needs to be improved for complex backgrounds or high dynamic targets. This paper presents an interactive multi-model algorithm. The displacement detection Kalman filter is used to track moving objects. This method can solve the problem of a single model not being able to match the motion features well. Finally, the simulation experiment of football match video proves that the proposed method can significantly improve the tracking accuracy of moving objects in video.

Key words: Sports video; Interactive multimode algorithm; Debiasing measurement Kalman filter; Moving target tracking

1. Introduction. Physical education programs have more audiences and higher ratings. Many researchers at home and abroad began to conduct in-depth research on moving objects in video to accelerate the acquisition of exciting, dynamic video. Tracking and detecting movement objects in video is an integral part of sports video research, and tracking athletes' movement trajectories can improve the effectiveness and scientific of physical exercise. Structured research on mobile video must be built on tracking and detecting moving objects, so tracking moving objects is an integral part of mobile Video [1]. The core idea is to quickly and accurately capture moving objects utilizing image processing and video analysis. The motion characteristics of the object are also changing dynamically [2], and the existing single modeling method is bound to have a specific deviation from the dynamic model of the real object [3]. This makes the single-mode method based on the Kalman filter easy to appear errors, resulting in following, out-of-step and other problems. This cannot get an accurate tracking effect. The interactive multi-model algorithm is a suboptimal multi-model optimization method developed by Bolm. This method assumes that the migration between modes satisfies the Markov chain with a given migration probability, which can effectively overcome the defects of a single migration mode.

The background of this project is a sports video. Then, the speed and direction of moving objects change rapidly, and the movement path is irregular. Then, a moving target tracking method based on the Kalman filter and an interactive multi-model algorithm is proposed. Firstly, the observation Kalman filter processes the sensor signal [4]. The modeling and weight adjustment of the sensor network are realized using Markov transfer probability. In traditional methods, the interactive multimode method is used to overcome the time delay of parameter identification and variable scale filter [5]. In this way, dynamic tracking of the whole maneuvering target is realized. The traditional Kalman filtering method currently cannot deal with the motion trajectory in the nonlinear case. It has the disadvantages of significant linearization error, low precision and easy divergence. The Kalman filter method of binary debiasing observation can overcome the nonlinear problem of the traditional method well and improve the system's tracking accuracy.

2. Overall structure and workflow of the system. The hardware of the monitoring system includes a PC, serial connector, Infinova integrated fastball and Yunke image acquisition board. The integrated fast ball instrument collects the monitoring image, and the image acquisition board is transmitted to the computer [6]. The computer uses software to parse, process and generate control signals. Then, the command is issued through the serial port to control the speedball to detect and track moving objects. There are three external

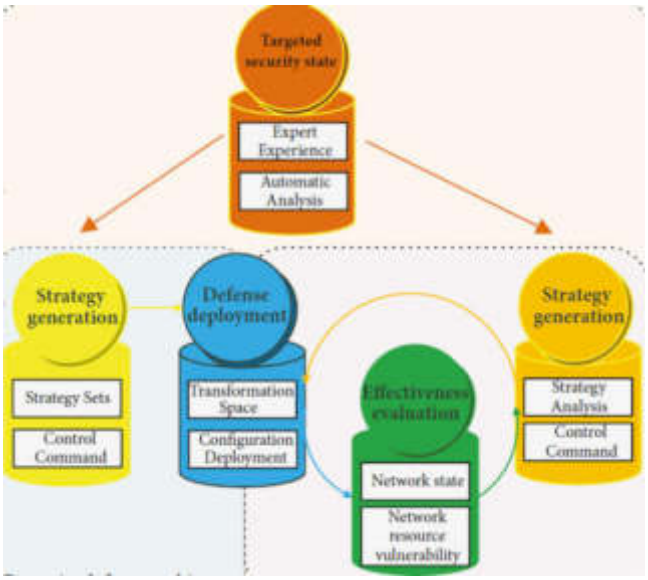

Fig. 2.1: *Hardware structure.*

devices in the design of the hardware platform. One is the input device represented by the CCD camera and the video acquisition card. One is the output device represented by the PTZ control. One is the RS-485 communication device that transmits the obtained images to the computer for detection and tracking [7]. The hardware part of the system mainly includes the image acquisition, control and communication of the PTZ. The hardware architecture is shown in Figure 2.1 (image cited in Moving Target Defense Techniques: A Survey).

The combination of a CCD camera and a cloud-available video acquisition board completes the structure design of the system. By using the C800-4 video capture card from Yunco, non-destructive images can be transferred directly to the graphics card [8]. It can monitor the scene from a distance and rotate, zoom and magnify the camera. The system has two display modes: PAL and NTSC. The picture resolution reaches 720×576 pixels, with 24-bit color. Picture speed up to 25 f/s. The camera uses the Infinovav1700A series fastball. Its optical focal length is 23x, and a corresponding 12x digital zoom can be selected. One hundred twenty-eight preset bits and four pattern scanning modes can be set to facilitate the monitoring of specific locations. The user can control any speed of the ball in the 0.5 to 240 degrees/second range. It can be adjusted according to Pelco-P/D protocol. The control and communication part of the head uses the RS485 serial interface to connect the computer with the integrated fastball and send corresponding commands to it. Using Pelco-D communication mode, high-speed movement in 9600 units. The system is developed in VC++ [9].

The DM642 initialization module is used to initialize the memory interface of the DM642 chip, peripheral device selection module, interrupt module, etc. After the completion of the initialization of the system, it does not need DM642CPU interference, but the DM642CPU is the core of the cycle work, including moving object detection and moving object tracking in two parts.

The theory and technology system of moving object tracking is established based on the Kalman filter and multimode interactive algorithm. Moving object tracking is realized by combining the Kalman filter and multimode interactive algorithm. Figure 2.3 shows the algorithm flow.

Firstly, the location of the object to be tracked in the moving video is selected, and then the gray vector of the object and background near the tracked object is extracted, and the corresponding feature vector is obtained respectively [10]. The Kalman filter processes the image. The classifier discriminates the object to be tracked in the next dynamic video and its background image, and the corresponding confidence graph is obtained. The algorithm uses the interactive multimode algorithm to locate the object in the frame to obtain the object's position and the corresponding background image. Determines whether the image of the moving

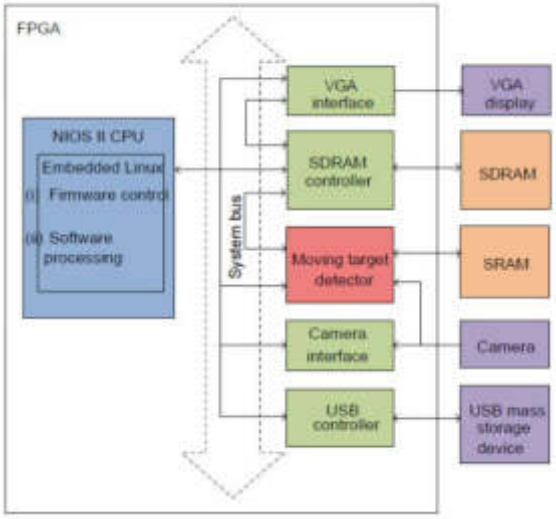

Fig. 2.2: *System program flow.*

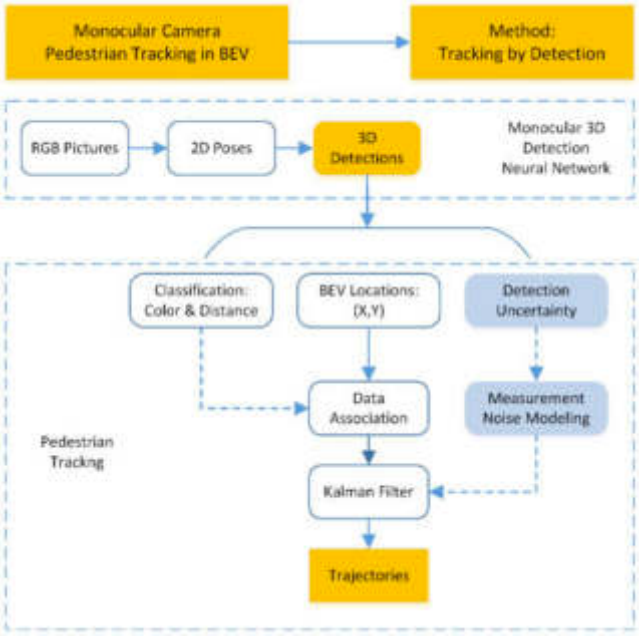

Fig. 2.3: *Video moving object tracking flow based on debias conversion measurement of Kalman filter and interactive multiple models.*

image is tracked in the previous frame [11]. If the previous image is not tracked, the Kalman filter needs to be modified using this moment's object and background pixels. The following image is then tracked until the complete tracking is complete.

3. Debiasing Kalman filter. Israeli scholar Bar-Shalom et al. proposed a depolarization method based on the Kalman filter, which converts the measured data in polar coordinates into orthogonal coordinates [12].

The mean and variance in the cartesian coordinate system were obtained utilizing statistics. Then, it is solved by the Kalman filter under unified cartesian coordinates. This method eliminates the approximation problem, improves the tracking accuracy and ensures the system's stability. The interactive multi-model method has many standard modes: constant speed, acceleration, steering and "current." According to the movement of the object, each model has its representation.

3.1. Target state and observation equation. Firstly, the camera's attitude is taken as the starting point, and the sampling time T is taken as the observation object [13]. The actual distance between the object and the camera is r. The azimuth is θ. The observation is $Z^p = \begin{bmatrix} r_m & \theta_m \end{bmatrix}^T$. The deviation of the measurement at point r_m, θ_m is $\tilde{r}, \tilde{\theta}$. They're all zero averages of Gaussian white noise. Their variance is $\sigma_r^2, \sigma_\theta^2$. The observation formula is as follows

$$Z^p(k) = h(X(k)) + V^p(k)$$

The state variable $h(\cdot)$ is nonlinear.

$$V^p(k) = \begin{bmatrix} \tilde{r}(k) & \tilde{\theta}(k) \end{bmatrix}^T$$

3.2. Average and deviation of observations when converted to rectangular coordinate system. The observed data is transformed into an orthogonal coordinate system represented by

$$x_m = (r + \tilde{r}) \cos(\theta + \tilde{\theta})$$

$$y_m = (r + \tilde{r}) \sin(\theta + \tilde{\theta})$$

position coordinate of the object in the rectangular coordinate system is (x, y). $(\tilde{x}, \tilde{y})$ represents the observed error. Find the observed deviation in the rectangular coordinate system

$$\tilde{x} = x_m - x = r \cos\theta(\cos\tilde{\theta} - 1)$$
$$\tilde{y} = y_m - y = r \sin\theta(\cos\tilde{\theta} - 1)$$

Since all $\tilde{r}, \tilde{\theta}$ are zero-average Gaussian white noise. The observed deviation is removed to obtain the inverse deviation observation at the k time point in the cartesian coordinate system

$$Z(k) = \begin{bmatrix} Z_x(k) \\ Z_y(k) \end{bmatrix} = \begin{bmatrix} r_m(k) \cos\theta_m(k) \\ r_m(k) \sin\theta_m(k) \end{bmatrix} - \mu(k)$$

The average error of the target position observed in the rectangular coordinate system is

$$\mu = \begin{bmatrix} E[\tilde{x} \mid r_m, \theta_m] \\ E[\tilde{y} \mid r_m, \theta_m] \end{bmatrix} = \begin{bmatrix} r_m \cos\theta_m \left(e^{-\frac{\sigma_\theta^2}{2}} - e^{-\sigma_\theta^2} \right) \\ r_m \sin\theta_m \left(e^{-\frac{\sigma_\theta^2}{2}} - e^{-\sigma_\theta^2} \right) \end{bmatrix}$$

By unifying the observation formula with the equation of state, a new observation formula is obtained:

$$Z(k) = HX(k) + v(k)$$

The linear observation matrix is as follows

$$H = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

$v(k) = \begin{bmatrix} v_x(k) \\ v_y(k) \end{bmatrix}$ is zero mean noise after removal. The variance is $R(k)$.

Fig. 5.1: *Tracking results of moving objects in the proposed method.*

4. Interactive multi-model algorithm. Take $\hat{X}_{j0}(k/k), P_{j0}(k/k)$ and observed $Z(k)$ as inputs [14]. The interactive multimode algorithm obtains the filtering value at k time. The recursive cycle of the interactive multimodal filtering algorithm consists of the following three steps:

4.1. Mixing.

$$\forall i, j \in M_f$$
$$\mu_{ij}(k-1/k) = \frac{1}{\bar{c}_j} p_{ij}\mu_i \left(\frac{k-1}{k}\right)$$

$\bar{c}_j = \sum_i p_{ij}\mu_i(k-1)$ is the standardized coefficient. $\mu_{ij}(k-1/k-1)$ is a confounding possibility.

4.2. Filtering.

$$X_j(k/k-1) = \frac{(k-1)\cdot X_{j0}(k-1/k)}{\Gamma_j(k-1)\cdot \bar{V}_j(k-1)}$$

$r_j(k)$ is the residual. Where $N(\bullet,\bullet,\bullet)$ is Gaussian dense. $S_j(k)$ represents the variance of the residual. Where $\Lambda_j(k)$ is an expression for probability. T is the time of a cycle. The output of the entire filter is the weighted average of the estimates of multiple filters. Weighting refers to the probability of accurately characterizing the target at a particular time [15]. When the pattern is dominant, the probability is higher than 0.9 and tends to 1 , while when it is dominant, the probability is minimal.

5. Experimental results and analysis. With the video of Guangzhou R&F and Dalian Yifang as the research sample, the Kalman filter and multimode interactive tracking technology were used to track 77 players, and the algorithm's feasibility was discussed. Figure 5.1 shows the tracking results of this algorithm on a series of subject images, while Figure 5.2 shows the effect of tracking a series of subject images with the Kalman filter [16]. The algorithm in this paper can accurately track moving objects in 16, 29, 36, 49 and 81 frames. Experimental results show that the algorithm effectively tracks moving objects in sports videos.

The number and time of iterations tracked using both methods were monitored [17]. The results are shown in Table 5.1. Compared with the traditional Kalman filter algorithm, the proposed algorithm can track the dynamic target in the actual scene, reduce the number of iterations, shorten the tracking time, and improve the system's tracking accuracy.

6. Conclusion. A method of tracking motion trajectory based on interactive multimode and Kalman filter is proposed to realize automatic tracking of motion video objects aiming at ball motion objects in motion

Fig. 5.2: *Kalman filter method moving target tracking results.*

Table 5.1: *Tracking Performance Comparison.*

Evaluation index	Textual method	Kalman filter method
Number of frames per frame	125	125
Number of iterations/times	99	292
Number of iterations per frame	0.82	2.43
Tracking time /s	12.58	27.48
Single frame time /s	0.10	0.23

video recording. Adjusting the camera can ensure that the object is always in the field of view so that the individual object can be automatically detected and tracked adaptively. On the premise of ensuring the overall performance, the problems of illumination and noise are effectively solved, and the system's overall performance is improved. The method proposed in this paper applies to various types of ball images and multiple moving objects in complex scenes. The experimental results show that this method has a high detection rate and fewer false alarms.

DECISION-MAKING OPTIMIZATION OF CROSS-BORDER E-COMMERCE SUPPLY CHAIN BASED ON GENETIC SIMULATED ANNEALING ALGORITHM

RENYI QIU*

Abstract. This paper mainly studies the collaborative operation of a cross-border e-commerce supply chain composed of manufacturers, e-commerce platforms and foreign warehouses. Firstly, the decision models of transnational e-commerce enterprises based on decentralized, centralized, and hybrid modes are established. The sensitivity of the contract and each determining variable is analyzed using the simulation method. Through the joint contract of "revenue sharing + volume discount," the production efficiency of the enterprise and the logistics service of the international warehouse can be improved. The genetic algorithm combined with simulated annealing was adopted. Finally, a concrete example is given to verify the feasibility of the proposed method. The results show that the member departments can work together better under centralized decision-making compared to the decentralized management mode. Manufacturers to increase production capacity and improve the level of logistics services in overseas warehouses will help improve the profitability of cross-border e-commerce.

Key words: Transnational e-commerce; Cooperation contract; Benefit sharing + quantity discount; Genetic algorithm; Simulated annealing algorithm

AMS subject classifications.

1. Introduction. Driven by the "Belt and Road" Initiative, China's cross-border e-commerce has been developing rapidly, but its position in the international market still needs further improvement. From supply to consumption, it includes many complex and scattered subjects. In addition, customers have increasingly high expectations for goods and logistics, making it difficult for a single enterprise to achieve a complete transnational trade. Businesses are looking for new ways to grow. It is necessary to establish a multinational e-commerce supply chain with cross-industry, cross-region, cross-border information collaboration, benefit sharing and efficient collaboration based on core enterprises and multi-subject participation.

What customers value most is the guarantee of authenticity. Favorable price, rich product variety, distribution speed, product quality, price, distribution speed, product quality, price and distribution speed are all critical factors affecting customer satisfaction. Literature [1] has conducted in-depth research on the synergy mechanism of the supply chain. The researchers studied low-carbon supply chains' price and emission reduction decisions based on customers' sales channel preferences. The company provides a cost-sharing contract for the return of profits to customers and the reduction of emissions. Literature [2] intends to study the two-level supply chain collaboration model composed of manufacturers and retailers from product quality, price, distribution time, etc. The author constructs a revenue-sharing mechanism to achieve Pareto optimization. Literature [3] studies the secondary supply chain collaboration of a single supplier and a double retailer. It reveals that the supply chain based on behavioral considerations cannot cooperate with the bulk discount contract and introduces it into the fixed cost contract.

This paper uses the contract model combining revenue sharing and volume discount to study the cooperative operation of a transnational e-commerce supply chain. Different from the existing studies: First, the collaborative operation problem of "producer-B2C cross-border e-commerce platform - overseas warehouse", which is more in line with the operation practice of cross-border e-commerce enterprises, is studied. The second is to incorporate endogenous factors, such as production capacity and logistics services, into the demand analysis of transnational goods [4]. Third, different from the conventional revenue-sharing contract, the introduction of a remuneration factor. Then, reward the supply chain members based on the increase of market sales brought

*Department of Business, Fuzhou Polytechnic, Fuzhou, Fujian, 350108, China (Corresponding author, 13799364461@163.com)

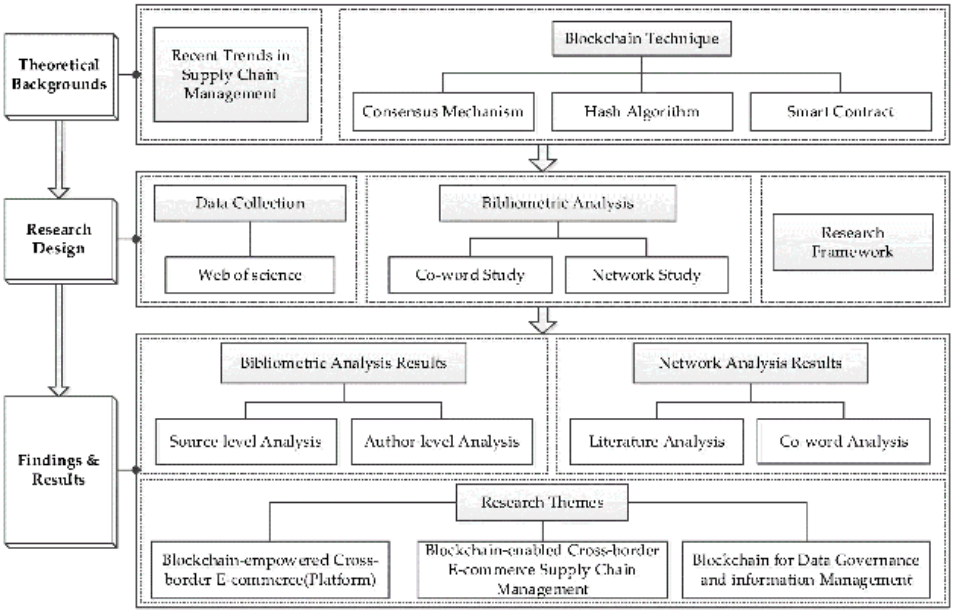

Fig. 2.1: *Concept diagram of cross-border e-commerce supply chain coordination operation.*

by the improvement of business level, further strengthening the effect of the incentive [5]. Then, this paper establishes the mathematical expression of the cooperative relationship and the optimal decision method. An example verifies the correctness of the method.

2. Research on collaborative decision-making mechanism of supply chain under a transnational e-commerce environment. With the vigorous development of international trade, this logistics method of foreign warehouses also comes into being. Cross-border e-commerce platforms store goods in a third-party warehouse and then sort, package and distribute them according to the order's requirements. Because it is a foreign warehouse, it often keeps its logistics service level at a medium or low level to reduce logistics costs [6]. At the same time, the low level of logistics service will also have a particular impact on customers' shopping feelings. In the same case, to maximize their profits, manufacturers will maintain a specific capacity for product quality without affecting the expansion of enterprises [7]. Its conceptual pattern is shown in Figure 2.1.

The cross-border e-commerce platform, the manufacturer and the overseas warehouse should form a long-term and stable partnership, and the three are committed to maximizing the overall profit of the cross-border e-commerce supply chain, sharing revenue and taking risks [8]. The company selects the best capacity level based on the order information [9]. It determines the best retail price for goods based on the volume of orders and encourages producers to increase production capacity by sharing profits with companies. The warehouse was responsible for storage and management. Once the customer places an order in the location of a foreign warehouse, the warehouse will deliver the goods to the customer in a timely, accurate and intact manner following the requirements of the order [10]. Discount them according to the quantity of logistics services to ensure maximum profit. They make reasonable profit distribution by cooperating with overseas warehouses. Third, the optimal product price is formulated according to the principle of maximizing the profit of the supply chain based on ensuring the manufacturer's best production capacity and the overseas warehouse's optimization.

3. Determination of partnership and multi-criteria modeling. Assume that the virtual enterprise consists of n various partners. The first candidate partner, $H = \{h_i \mid i \in [1, n]\}$, represents all n working sets of the virtual enterprise. $S_i = \{s_{ij} \mid j \in [1, m_i]\}\,(i = 1, 2, \ldots, n)$ represents a group of candidates that can meet the requirements of project $h_i.m_i$ is the number of candidate companies that can meet the requirements of

the project h_i. The performance indicators required by enterprise s_{ij} to achieve operation h_i mainly include t_{ij} (time), g_{ij} (quality), E_{ij} (inherent cost), c_{ij} (reliability) and $\varepsilon_{ijj'j'}$ (connection cost). Where T, G, E, C, P stands for total time, quality, inherent costs, reliability and connection costs. The optimal problem of this problem is the selection of enterprise $Y = \{y_1, y_2, \ldots, y_n\}$. The following purposes can now be achieved: $\min T; \max G; \min E, \max C; \min P$. This paper builds the following model based on these multi-objective optimization problems:

$$\min U = \lambda_1 \sum_{i=1}^{n}\sum_{j=1}^{m_i} \frac{t_{ij}}{t_{\max}}\chi_{ij} + \lambda_2 \sum_{i=1}^{n}\sum_{j=1}^{m_i}\left(1 - \frac{g_{ij}}{g_{\max}}\right)\chi_{ij} + \lambda_3 \sum_{i=1}^{n}\sum_{j=1}^{m_i}\frac{e_{ij}}{e_{\max}}\Bigg)\chi_{ij} +$$

$$\lambda_4 \sum_{i=1}^{n}\sum_{j=1}^{m_i}\left(1 - \frac{c_{ij}}{c_{\max}}\right)\chi_{ij} + \frac{1}{2}\lambda_5 \sum_{i\neq i'}\sum_{j\neq j'}\frac{\varepsilon_{iji'j'}}{\varepsilon_{\max}}\chi_{ij}\chi_{i'j'}$$

$$st \sum_{k=1}^{5}\lambda_k = 1, g_{\max} = \max_{i\in[1,n]} g_i, e_{\max} = \max_{i\in[1,n]} e_i,$$

$$c_{\max} = \max_{i\in[1,n]} c_i, t_{\max} = \max_{i\in[1,n]}, \varepsilon_{\max} = \max_{i\in[1,n]} \varepsilon_i$$

$$\chi_{ij} = \begin{cases} 1, & s_{ij} \text{ in} \\ 0, & \text{otherwise} \end{cases}$$

λ_k focus on enterprise composition, using the expert scoring method, analytic hierarchy process, and entropy method to determine the weight.

3.1. Genetic algorithm and simulated annealing algorithm. Genetic algorithm (GA) simulates the mechanism of natural selection and gene evolution in nature. The method has global adaptability and randomness [11]. A series of gene manipulations such as selection, hybridization and variation are carried out on the existing population to form a new population generation Using the population search method. Step by step, the population evolves to a stage that contains or approximates the optimal solution [12]. This paper presents a multi-objective optimization method based on a genetic algorithm. Implicit parallel and global search are the two most prominent features. This method provides a general framework for solving optimal problems. The type of question is very robust.

The simulated annealing (SA) algorithm is a new stochastic optimization method developed based on Monte Carlo iteration. The starting point of this study is from two aspects. That is the similarities between the physical annealing and composite processes. A probabilistic jump feature based on Metropolis sampling is used to search a high-temperature point randomly. Sampling is repeated at continuously reduced temperatures until the overall optimization result is obtained.

3.2. Combination of genetic algorithm and simulated annealing algorithm. Genetic and simulated annealing algorithms are optimized based on random distribution mechanisms. The difference is that it gives a mutation that changes over time and eventually tends to 0. Therefore, the algorithm can effectively prevent the occurrence of local minima and make the algorithm tend to global optimization [13]. The idea of "survival of the fittest" is used to carry out genetic calculations on the population to achieve the optimal solution. The combination of these two methods can make the optimization work more fulfilling. The optimization effect of the algorithm in the overall and partial importance is improved. The steps of combining genetic algorithm and simulated annealing algorithm are:

1. The initial temperature of the simulation t_0 is given, and $k = 1$.
2. Binary coding expresses each gene as shown in Figure 3.1. The coding length is $D = \sum_{i=1}^{n} m_i$, and each χ_{ij} in the code string is the identity of the candidate partner. $\chi_{ij} = 0$ means no choice [14]. Assume that the population number is W, and W binary coding sequences $\sum_{j=1}^{m_i}\chi_{ij} = a_i (i = 1, 2, \ldots, n)$ are randomly generated in the population to satisfy the original population. Here a_i represents the number of firms that can choose between different firms, $a_i \in (1, 2, \ldots, m_i)$.

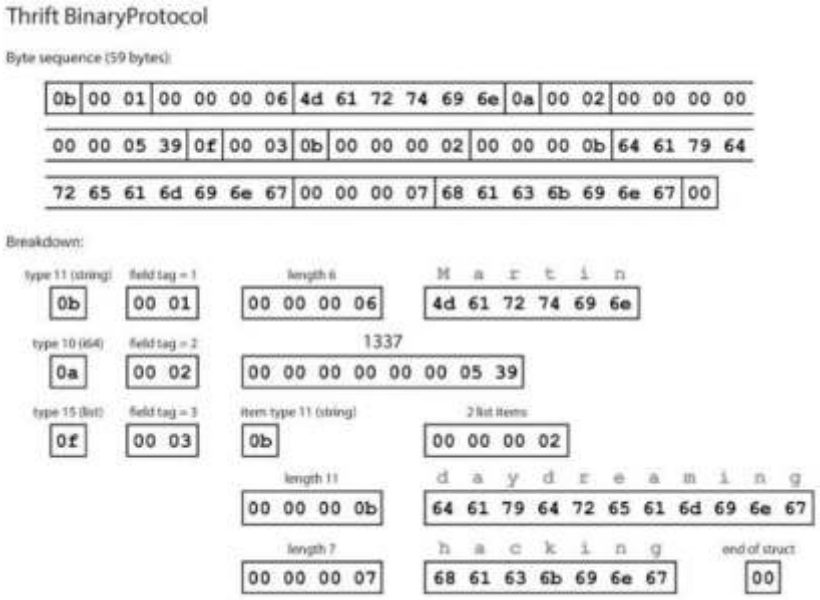

Fig. 3.1: *Binary encoding.*

3. Individual assessment within the population: Ranking from highest to lowest according to the degree of fitness of W individuals in the same generation population. With $i(i = 1, 2, \ldots, W)$ as the number, the adaptation value of i is:

$$y_i = \frac{2i}{W(1+W)}$$

4. Genetic calculations on individuals in populations:
   (a) Selective operation. The ratio selection operator is introduced. When the population size is W, individual X_i with y_i adaptability is likely to choose to be the offspring.

$$\Gamma_i = y_i / \sum_{i=1}^{W} y_i$$

   (b) Interactive operation. Individual X_1 and X_2 in the paternal line cross with a probability of Γ_e to produce the next generation by crossing two parents.
   (c) Variable operation. Each site of individual X_i changes with mutation probability Γ_m, that is, an arbitrary site in Γ_m changes the original value. In this operation to determine whether $\sum_{j=1}^{m_i} \chi_{ij} = a_i(i = 1, 2, \ldots, n)$ is true, if not, restart the encoding string. The selection, crossover, or mutation steps are repeated until the resulting individual meets a specific limit.
5. Put forward the optimal reservation scheme.
6. Introduce simulated annealing operations to each individual in the group:
   (a) A new factor $w'(k), w'(k) = w(k) + \delta$ is generated by the state-generating function of SA, where $\delta \in (-1, 1)$ is a random disturbance.
   (b) The difference ΔE between the value of the index function calculated by $w'(k)$ and the value calculated by $w(k)$ is obtained.
   (c) Calculate the receiving possibility $\Gamma_c = \min[1, \exp(-\Delta E/t_k)]$.
   (d) If it is $\Gamma_c >$ random$[0, 1)$, then choose $w(k) = w'(k)$. And the same is true for $w(k)$.
   (e) Propose the optimal reservation scheme.

Table 4.1: Comparison of optimal results.

Argument	p_k	ω_z	ω_l	Q_2	π_k	π_z	π_l	π
Decentralized decision making	94.58	8.44	1.95	341.81	11211.45	6017.63	4758.05	21987.13
Centralized decision	79.76	15.22	6.75	527.08			25261.84	

(f) Perform annealing using the annealing function $t_{k+1} = at_k$, where $a \in (0, 1]$ is the annealing rate.

7. Determine whether the end condition of the genetic algorithm operation is confirmed. If it is not valid, the process goes to the 3). Otherwise, it goes to the 8).
8. The best individual obtained by the genetic performance is decoded to obtain the final best optimization effect.

4. Collaborative decision-making mechanism of supply chain in transnational e-commerce. According to the field investigation and expert

$$p_z = 30, p_l = 20,$$

advice, the relevant parameter is set as $C_z = 6, C_k = 8,$. The research has analyzed

$$\beta = 1200, n = 4.5,$$
$$\gamma_z = 20, \gamma_l = 15$$

the sensitivity of commodity price, quality and logistics service and found that customers attach the most importance to product quality, followed by price, and then logistics service, so $b_1 = 10, b_2 = 4, b = 2$ is set.

The above parameters are brought into the distributed and centralized optimization decision-making mode in the first step, and the optimization effect is obtained (Table 4.1). Distributors' pricing will increase, and manufacturers' production capacity will decrease, leading to the decline of foreign warehouses' logistics service level and product sales decline [15]. In addition, the total revenue of transnational e-commerce enterprises in the distributed decision-making mode is 3274.72 lower than that in the centralized mode, indicating that enterprises can better collaborate in the centralized mode.

Under the second combination contract, it can be seen from Figures 4.1, 4.2 and 4.3 that the subsidies of transnational e-commerce platforms to manufacturers will be higher, while the subsidies of manufacturers to cross-border e-commerce will also be higher, but the range shall not be greater than 0.0165 . Otherwise, the synergies of the contract will be lost [16]. If a lower incentive is provided to the overseas warehouse, the preferential margin of the number of logistics services obtained from the overseas warehouse will be less than 0 . Its amplitude must not be greater than 0.010o. Otherwise, this July will not be accepted. $\theta_z, \delta_z, \theta_l$ and δ_l are set to (o.7, $0.0125, 0.9, 0.0076$) respectively in Figure 4.3. The sensitivity of ω_z and ω_l was analyzed [17]. The results show that manufacturers reward their sales growth under the contract model according to the capacity increase. It can reduce enterprises' incomes due to capacity improvement [18]. The composite contract proposed in this project can balance the interests of transnational e-commerce and foreign warehouses, and the contract optimization effect will be more significant when the ω_l value is more prominent.

5. Conclusions and Suggestions.

1. Unlike decentralized decision-making, various enterprise departments can collaborate more efficiently.
2. Manufacturers improve production capacity, and overseas warehouses improve their logistics service level, which helps to improve the profits of transnational e-commerce.
3. Through the joint contract of "revenue sharing + volume discount," the production capacity of the enterprise and the logistics service quality of the enterprise's overseas warehouse can be significantly improved, thus reducing the double marginal effect of the enterprise.

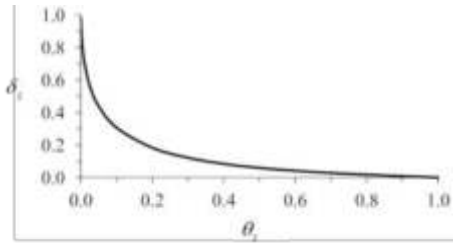

Fig. 4.1: Relationship between θ_z and δ_z.

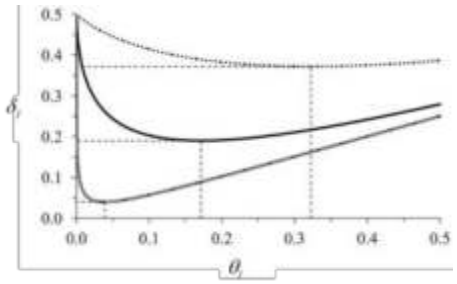

Fig. 4.2: The relationship between θ_l and δ_l.

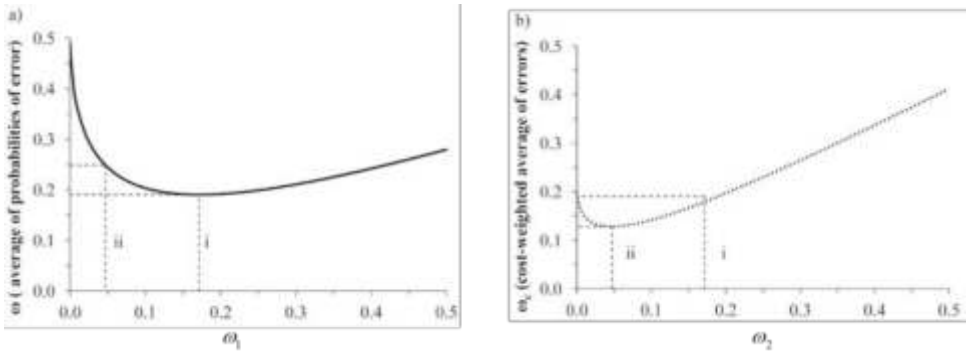

Fig. 4.3: Comparison of the impact of coordination ω_z and ω_l decentralization on cross-border ecommerce supply chain.

In this article, there are the following proposals.

Cross-border e-commerce platforms must make full use of their advantages. The remote cross-border e-commerce platform should fully mobilize the production capacity of enterprises, encourage enterprises to improve their capabilities, and encourage them to improve the quality of their logistics services in the international market. This brings high-quality products and high-quality logistics services to foreign customers. Revenue-sharing mechanisms, technical support, and other means ensure that the rights and interests of all participants are fully protected to maintain the long-term and smooth operation of the cross-border e-commerce supply chain.

The transformation from traditional foreign warehouse enterprises to modern logistics enterprises must be completed quickly. Ocean warehouses should introduce intelligent and automated logistics technology. On the one hand, strengthen the warehouse management and realize the timely sharing of the warehouse information. This prevents the loss of the goods in storage. At the same time, it can also improve the classification and

transportation time of goods, ensuring the real-time update and traceability of logistics information. In this way, we have become a modern logistics service company that can provide professionalism, flexibility and efficiency.

Manufacturers should continue to improve their level of intelligent production. Manufacturers should be committed to intelligent transformation, introducing intelligent robots, and increasing industrial automation to ensure the best production process and zero-defect production. Integrate its resources and integrate more innovative elements into its products to meet the individual needs of foreign customers.

AN INTERNET OF THINGS TASK SCHEDULING FRAMEWORK BASED ON AGILE VIRTUAL NETWORK ON DEMAND SERVICE MODEL

QIQUN LIU*

Abstract. In order to improve the efficiency of cloud computing resource utilization and avoid the problem of computing resource allocation and scheduling lagging behind load changes, the author proposes a cloud computing resource on-demand allocation and elastic scheduling method based on network load prediction. Firstly, the author takes the network load data of Wikimedia as the research object and proposes an adaptive two-stage multi network model load prediction method based on LSTM (i.e. ATSMNN-LSTM load prediction method). This method can classify the network load data into climbing and descending types based on the trend and characteristics of the input network load data, And adaptively schedule the input network load data to the LSTM load prediction model that matches its type for prediction based on the classification results. The author proposes a maximum cloud service revenue computing resource quantity search algorithm based on network load prediction (i.e. MaxCSPR-NWP algorithm), which aims to improve cloud service revenue as the optimization objective. Under the premise of ensuring task service quality and system stability, the algorithm allocates cloud computing resources on demand and flexibly schedules them in advance based on the predicted network load results. The experimental results show that the ATSMNNLSTM load prediction method proposed by the author can obtain more accurate network load prediction results compared to other load prediction methods, and the MaxCSPR-NWP algorithm, which is based on network load prediction and is capable of effectively converting the network load prediction results into the required number of cloud servers, is the maximum cloud service revenue computing resource quantity search algorithm proposed by the author, not only does it achieve the early allocation and scheduling of cloud computing resources, thereby avoiding the impact of lagging behind in computing resource allocation and scheduling due to load changes on the quality of cloud computing task services and resource utilization efficiency, at the same time, it has also achieved on-demand allocation and flexible scheduling of cloud computing resources with the goal of improving cloud service revenue.

Key words: Task scheduling, Calculate resource allocation, Load prediction, Network on-demand services

1. Introduction. Cloud computing, as a new computing model, aims to change the occupancy and usage of traditional computing systems. Cloud computing organizes and aggregates computing and communication resources in a networked manner, providing users with computing resources that can be reduced or expanded in scale through virtualization, increasing the flexibility of users in planning, purchasing, owning, and using computing systems [1]. In cloud computing, the core issue that users are concerned about is no longer the computing resources themselves, but the services they can obtain. From this perspective, it can be considered that service issues (provision and use of services) are the core and key issues in cloud computing. Cloud computing provides services to a large number of users through a unified interface by managing, scheduling, and integrating various resources distributed on the network. For example, with the help of cloud computing, user applications can process terabytes or even petabytes of information content in a very short period of time, achieving the same powerful performance as supercomputers. Users use these services on an on-demand basis, realizing their dream of providing computing, storage, software, and other resources as a common facility. Cloud computing includes two sets of concepts: cloud computing tools (hardware, platform, software, and so on). And the data service design of the system - cloud application. Implementing cloud computing services is essential. In addition to Amazon's infrastructure services, Google's application engine services, Microsoft's Azure service platform, etc., have distributed data storage and processing systems, such as open-Hadoop, also provide horizontal workflow services for storing and processing massive data.Meanwhile, more and more application developers can start developing and deploying various services and applications on cloud computing platforms. It can be predicted that there will be more and more service resources available on the Internet, so how to implement on-demand personalized services in cloud computing is of great significance. The service

* School of Tourism Management, Henan Vocational College of Agriculture, Zhengzhou, Henan, 451450, China (1992130227@hnca.edu.cn)

issues in cloud computing involve not only the requirements that users expect to achieve, but also the functions and performance that cloud computing service providers can provide.

Cloud computing converts traditional services into "charging when you go" service models, allowing for computing resources such as water, electricity, and natural gas. On demand compensation with day-to-day usage greatly reduces the deployment and performance of network services. At the same time, due to restrictions in computing resources and power consumption, terminal resources can not utilize complex services. At the same time, terminal resources can not consume complex services. The terminal equipment can transfer tasks to cloud computing center (hereinafter called cloud center) by the network to get enough resources and make a good sense of (QE) of tasks, such as computing accuracy, scalability, and so on.Therefore, cloud computing not only provides a new direction for traditional Internet services, but also provides an unprecedented opportunity for the development of Internet applications, making Internet services such as image recognition, audio processing, virtual reality widely used. Furthermore, cloud computing has also promoted the rapid development of Internet of Things (IoT) and mobile Internet, replacing the traditional Internet of Things as the new CoT model of Internet of Things. However, in practical situations, due to the distance of the cloud center from terminal devices and users, unloading tasks from terminal devices and users to the cloud center can cause significant network latency, making it difficult to ensure the quality of service (QoS) of tasks. In addition, due to the large-scale clustered system architecture of cloud centers and the adoption of centralized management mode, massive task offloading will also increase the cost and complexity of cloud computing resource management. In order to address the aforementioned issues, a new computing service model - fog computing - has been proposed. Fog computing is composed of a large number of computing devices deployed on edge networks, which can collaborate with each other to enable tasks to be processed in edge devices (i.e. fog nodes) close to the terminal. This not only reduces network latency and cloud center load for tasks, but also enhances the mobility and security of network services. Therefore, fog computing can be considered as an extension of cloud computing, serving as an intermediate layer between terminal devices and cloud centers to deploy lightweight computing devices closer to terminal devices and users, providing high elasticity and fast response computing services to meet the real-time requirements of latency sensitive tasks.

2. Methods.

2.1. Application Architecture of On Demand Services in Cloud Computing. The application architecture of on-demand services based on cloud computing is shown in Figure 2.1, which specifically includes:

(1) Cloud infrastructure layer. The model supports multiple cloud centers, not only from internally controllable clouds, but also from external third-party cloud resources that meet corresponding service level agreements. The cloud platform will consolidate these capabilities to provide a unified cloud service for the above modeling and implementation [2]. The Cloud hardware supports a wide range of devices, including hardware, network devices, processors and non-procedural data storage, as well as other basic software components.

(2) Service resource management and monitoring layer. The various resources provided by the cloud infrastructure layer, as well as service resources for specific business applications, including cloud service resources from third parties, can be uniformly registered in service resource management and provided to the public in the form of services [3,4]. This layer mainly solves the effective monitoring and management of the resources management in large distribution areas, provides support for the resources management and the states for the above resources and the services needed. According to different types of resource management and monitoring requirements, the resource structure, management behavior, and monitoring strategies can be defined to achieve resource management and monitoring.

(3) Programming Framework and Running Engine Layer for Cloud Services. This layer provides the cloud service runtime support for the top of the base platform and the service runtime, as well as engine support for the cloud service runtime. The continued application of cloud computing in many enterprise environments will lead to the rapid development of cloud based application programming interfaces (APIs) and services. A specific application typically involves multiple services, requiring a runtime support engine that integrates consolidated databases and various types of services, including pre-defined service models, application programming interfaces, automatic application services for large and dynamic environments, and efficient and reliable application programming in high-level situations.

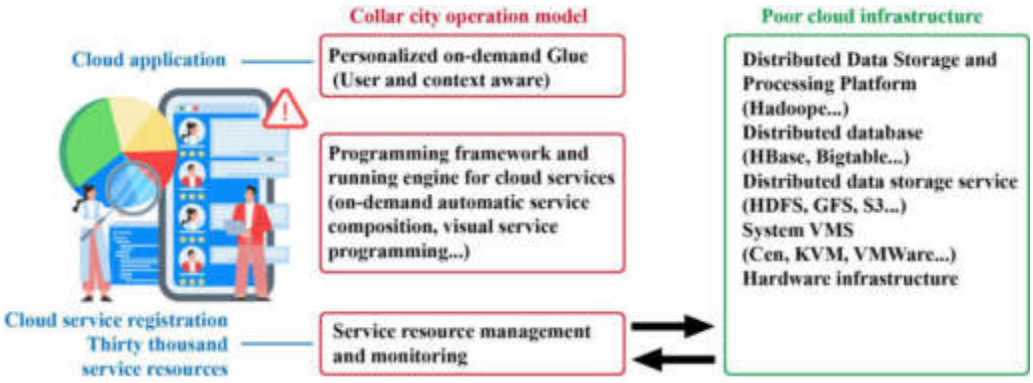

Fig. 2.1: An on-demand service application architecture diagram based on cloud computing

(4) Personalized on-demand service layer. The problem to be solved at this stage is how to provide users with personalized cloud services that are "real-time, on demand" and based on different cloud services. It mainly deals with two aspects: how to encourage users to accurately and easily describe their needs, thus realizing the discovery, matching, and approval of services according to users' needs. How to visualize the state of available resources, user context, and other information in cloud computing, in order to provide a cloud service that can be adapted to change the state of this information.

2.2. Cloud computing resource on-demand allocation and elastic scheduling system architecture based on network load prediction. The on-demand allocation and elastic scheduling system of cloud computing resources based on network load prediction mainly includes the following parts:

Cloud computing resource pool: This computing resource pool is composed of cloud servers (i.e. virtual machines, Virtual Machines (VMs)) running within a physical server cluster. The computing resources of cloud servers (such as CPU, memory, storage, and bandwidth) can be configured on demand through virtualization technology according to needs. This computing resource pool is generally considered as the Infrastructure as a Service Layer (IaaS Layer) of cloud computing, providing support for computing resources for cloud services. Task scheduling+network access service component: This component provides load balancing services for network tasks. Tasks that arrive at the cloud center are scheduled to the cloud server in the cloud computing resource pool according to certain rules (such as polling). Cloud Center Management Platform: This platform is used to manage the computing resource pool of the cloud center. The resource monitoring service is used to monitor and collect operational information of cloud computing resource pools, such as computing resource load information, physical server health status, and hardware configuration information, and store the collected data information in the platform's database. These data will also be used to assist computing resource scheduling services in finding suitable target physical servers to start and shut down cloud servers. The access control service provides network interfaces and identity authentication for cloud service administrators, and is responsible for receiving cloud server startup or shutdown instructions issued by administrators. After receiving resource management instructions, the cloud center resource management service will first find the target physical server based on specified policies (such as minimum number of physical computing nodes, balancing the number of cloud servers, and random physical server selection policies). Then, the computing resource scheduling component will send the management instructions for computing resources to the target physical server to start or shut down the cloud server. Compared with general cloud center management platforms, in order to achieve on-demand allocation and elastic scheduling of cloud computing resources based on network load prediction, the following components need to be extended: load monitoring component: This component can periodically obtain statistical data information on the number of network task requests and load (i.e. network load) through the load balancing service interface, providing necessary historical data information for network load prediction. Load forecasting service components: This component predicts and outputs the network load value for the next time based on historical information of network load. The resource allocation service component calculates

the required number of cloud computing resources (i.e. the number of cloud servers) based on optimization objectives (such as service quality assurance or improving service revenue). This service component starts or shuts down the required number of cloud servers by calling the computing resource scheduling service in the cloud center. Based on the structure of the above system, the author mainly conducts specific research on the core technologies of load forecasting service components and computing resource allocation service components - load forecasting methods and computing resource quantity search algorithms.

2.3. Design of on-demand allocation and elastic scheduling methods for cloud computing resources based on network load prediction.

(1) Mathematical modeling of task processing in cloud servers. The cloud server runs in the form of a virtual machine within the physical server of the cloud center resource pool, and the virtualization software of the physical server abstracts the CPU memory, storage, and network cards of the physical layer into the computing resources of the virtual machine, such as vCPU, vMemory, vDisk, and vNIC (Virtual Network Card). When a task is offloaded to the cloud center, the task scheduling service in the cloud center will allocate the task to the target cloud server for processing; After the task arrives at the cloud server, it will be queued and buffered within the cloud server. Then, the computing unit composed of vCPUs processes the task in the order in which it is queued; When a task cannot meet its deadline requirements, it will be removed from the task queue of the cloud server and discarded, resulting in task loss [5,6].

Due to the large-scale clustered system architecture and centralized management mode of cloud centers, the process of cloud computing resource allocation and scheduling has a high complexity. This not only results in high latency in the process, making it difficult to achieve real-time performance similar to that of fog node computing resource allocation and scheduling, but also increases the cost of the process. Therefore, the cycle interval for adjusting and billing cloud computing resources is generally set to a larger time interval, with a typical cycle interval of 1 hour, which is consistent with the network load information collection cycle interval of Wikimedia services. It is not only difficult to use a real-time queuing model to mathematically model the task processing process of cloud servers, It is also difficult to use random queuing models to directly mathematically model the processing process of cloud server tasks within one hour. The network load data of Wikimedia services is a large-scale web service request task, and does not follow a time homogeneous Poisson process in hours (i.e. follows a non time homogeneous Poisson process). However, the statistical distribution of network load within one hour can be obtained by using load monitoring services to analyze past network load data. The Wikimedia network load calculated by the load monitoring service follows a Homogeneous Poson Process with consistent mean for each small granularity unit time within an hour. In addition, in order to maintain the completeness of theoretical analysis, the author assumes that the length of task execution time follows an exponential distribution: and in practical situations, this statistical distribution can be obtained by analyzing historical task execution time data. Therefore, the author describes the task processing process of the cloud server within one hour of each Δ_τ as an MM/1/K random queuing model. The MM/1IK random queuing model uses a First Come First Serve strategy to queue tasks, where 1 represents a processing unit composed of cloud server vCPUs; K is the capacity of the task queue. When the number of tasks exceeds the queue capacity, tasks cannot enter the queue and suffer losses. According to the requirements of task quality of service (QoS), the task queue capacity of each cloud server is calculated as follows:

$$K = \frac{dp^{max}}{\overline{et}} \tag{2.1}$$

Among them, dp^{max} is the allowable execution deadline of the task, which means dp^{max} is equal to the deadline of the task minus the time when the task arrives at the cloud server; $\overline{et}$ is the average execution time of the task.

According to the average execution time of tasks on the cloud server, the average number of tasks processed by the cloud server within Δ_τ is:

$$\mu = \frac{\Delta_\tau}{et} \tag{2.2}$$

The average task processing load of the cloud server within Δ_τ is calculated as follows:

$$\rho(\Delta_\tau) = \frac{\overline{\lambda(\Delta_\tau)}}{\mu} \tag{2.3}$$

Among them, $\overline{\lambda(\Delta_\tau)}$ is the task arrival rate of each cloud server within Δ_τ (i.e. the average number of tasks arriving at the cloud server) [7].

Cloud services generally consist of task scheduling services and computing resource pools. Among them, task scheduling services can be composed of load balancing components. Task scheduling services schedule tasks to the target cloud server according to corresponding strategies, using the most commonly used RoundRobin (RR) strategy as the task scheduling strategy, which schedules tasks to each cloud server in the computing resource pool in a polling manner.

Therefore, when the total number of task arrivals in the t-th cycle interval is x (t) and the number of cloud servers in the computing resource pool is Nv (t), the number of task arrivals per cloud server in the t-th cycle interval is:

$$x_v(t) = \frac{x(t)}{N_v(t)} \tag{2.4}$$

(2) Design of a maximum cloud service revenue computing resource quantity search algorithm based on network load prediction. The revenue of cloud service is the main concern of Internet business. The revenue of cloud service not only determines the sustainable development of Internet business, but also affects the development direction of Internet business. Therefore, the author aims to maximize the revenue of cloud services and conducts research on on-demand allocation and flexible scheduling of cloud computing resources based on network load prediction. Cloud computing transforms traditional computing resources into an on-demand and paid service model, avoiding human and material costs such as purchasing computing hardware, system maintenance, energy and power, and cooling. Therefore, from the perspective of cloud service providers, the calculation of cloud service revenue only needs to consider the rental cost of cloud servers, the service revenue of tasks, and the loss cost of tasks. If C1 in C=[C1, C2] represents the rental cost of each cloud server (in hourly intervals), and C2 represents the revenue of each task, then the revenue of cloud services during the t-th interval is calculated as follows:

$$profit(t) = m \cdot N_v(t) \cdot [C_2 \cdot \overline{\lambda(\Delta_\tau)} - C_2 \cdot \overline{\lambda_{loss}(\Delta_\tau)} - C_1/m] \tag{2.5}$$

Among them, $C_2 \cdot \overline{\lambda(\Delta_\tau)}$ in formula 3.5 is the average total revenue of each cloud server's tasks within Δ_τ, $C_2 \cdot \overline{\lambda_{loss}(\Delta_\tau)}$ is the average cost of task loss for each cloud server within Δ_τ, C1/m is the rental fee for each cloud server within Δ_τ. Therefore, $[C_2 \cdot \overline{\lambda(\Delta_\tau)} - C_2 \cdot \overline{\lambda_{loss}(\Delta_\tau)} - C_1/m]$ is the average revenue of each cloud server in Δ_τ's cloud services. Based on the constraints of task service quality and cloud server stability, the maximum cloud service revenue target can be expressed as:

$$\begin{aligned} &Maximizeprofit(t) \\ s.t, &W_s(\Delta_\tau) \leqslant dp^{max}, \rho_e(\Delta_\tau) < U^{max} \end{aligned} \tag{2.6}$$

Among them, dp^{max} is the execution deadline of the task, and U^{max} is the maximum computing load allowed by the cloud server. Note that in formula 3.5, the revenue of cloud services is related to the total rental cost of cloud servers and the loss cost of tasks, that is, it is related to the loss value $m \cdot N_v(t)[C_1/m + C_2 \cdot \overline{\lambda_{loss}(\Delta_\tau)}]$ of cloud services, and the total number of tasks reached is an objectively determined value. Therefore, the maximum cloud service revenue target in formula 3.5-3.7 can be equivalent to the minimum cloud service loss target, that is:

$$\begin{aligned} MinimizeCost(t) &= m \cdot N_v(t) \cdot [C_1/m + C_2 \cdot \overline{\lambda_{loss}(\Delta_\tau)}] \\ s.t, &W_s(\Delta_\tau) \leqslant dp^{max}, \rho_e(\Delta_\tau) < U^{max} \end{aligned} \tag{2.7}$$

The convex property of formula 3.7 is related to the rental cost of cloud servers and the loss cost of tasks. Assuming m=36000, the average execution time of the task is 5ms, and the task execution deadline is 100ms. According to the typical cloud server rental fee of 1.1279 yuan/hour for Amazon Web Service (AWS), consider the following three scenarios.

1. Task high return. Considering that Wikimedia services are a typical high concurrency web service (with a task count of 10 to the power of 7 per hour), assuming a profit of 0.01 yuan per task, the loss cost of the task will become the main factor affecting the loss value of cloud services, while the overall impact of cloud server rental costs is relatively small. Therefore, in order to reduce the loss value of cloud services, a sufficient number of cloud servers are needed to reduce the cost of task loss, that is, the loss value of cloud services decreases rapidly with the increase of the number of cloud servers. When there is redundancy in the number of cloud servers, the loss value of cloud services will slowly increase with the increase of the number of cloud servers. Therefore, the loss value of cloud services is a "weak" convex function [8].

2. Low return on tasks. Assuming that the return on each task is 0.000001 yuan, the total rental cost of cloud servers will become the main factor affecting the loss value of cloud services. In this case, the minimum number of cloud servers is the best choice for cloud computing resource allocation, and the loss value of cloud services is a monotonically increasing function.

3. The task revenue falls between high and low revenue. Assuming that the revenue for each task is 0.0001 yuan, the total cloud server rental cost and task loss cost will become the main factors affecting the cloud service loss value. In this case, as the number of cloud servers increases, although the cost of task loss decreases, the total rental cost of cloud servers increases; On the contrary, when the number of cloud servers decreases, although the cost of task loss increases, the total rental cost of cloud servers decreases, indicating that the cloud service loss value in formula 3.7 is a "strong" convex function relative to the high return situation of the task.

Based on the above analysis, the author first proposes a Maximum Cloud Service Profit Resource Search Algorithm (MaxCSPR), which searches for the required number of cloud servers with the maximum cloud service profit as the target (equivalent to the minimum cloud service loss target) based on the input network load data. In order to adapt to the three scenarios of task benefits, the MaxCSPR algorithm includes incremental search for cloud server resources and reduced search for cloud server resources. That is, when the algorithm searches incrementally based on the number of cloud servers and the loss of cloud services also increases, it indicates that the incremental search direction causes the loss value of cloud services to increase with the increase of the number of cloud servers. At this time, it should search in the direction of decreasing the number of cloud servers, perform a search to reduce the number of cloud servers, and vice versa. In order to avoid the limitation of empty computing resources and exceeding the maximum computing resource capacity in cloud services, the MaxCSPR algorithm sets the minimum number of cloud servers to 1 and the maximum number of cloud servers to N_v^{max}. In order to achieve on-demand allocation and flexible scheduling of cloud computing resources based on active methods, the author combines the proposed ATSMNN-LSTM load prediction method with the MaxCSPR algorithm. Specifically, the network load prediction result x '(t+1) obtained by the ATSMNN-LSTM load prediction method is used as the network load input value for the t+1st cycle interval, replacing the input x (t+1) in the MaxCSPR algorithm, by predicting the network load and using the MaxCSPR algorithm, the cloud center can obtain the required number of cloud servers for the t+1st cycle interval in advance, in order to achieve early allocation and scheduling of computing resources and avoid the problem of computing resource allocation and scheduling lagging behind load changes. The author named the algorithm that combines ATSMNN-LSTM load prediction method with MaxCSPR algorithm as the maximum cloud service revenue computing resource quantity search algorithm based on network load prediction.

3. Result analysis.

3.1. Experimental Environment Setting. The author collected approximately 40000 hours of Wikimedia service network load data, which includes statistical values of the number of task requests with hourly intervals. Among them, 70% of the dataset is used as the training set, and 30% is used as the testing set. In order to verify the performance of the ATSMNNLSTM load prediction method proposed by the author, the experiment sets the network load data from the past 6 hours starting from the current moment as input, and predicts the network load value for the next hour; The number of neurons in the LSTM model is 25. Then, the author combines the proposed load prediction method (ATSMNN-LSTM) with the Auto Integrated Moving Average (ARIMA) load prediction method, Support Vector Regression on (SVR) load prediction method, Linear Regression (LR) load prediction method, and Single LSTM model load prediction method Compare the fully connected neural network models (ND load prediction method and ATSMNN load prediction method (i.e. replacing the LSTM model with the NN model in the ATSMNN-LSTM load prediction method).

Table 3.1: Comparison of performance indicators of different load prediction methods

	ATSMNN -LSTM	ATSMNN	LR	ARIMA	SVR	LSTM	NN
MAPE	0.0277	0.0345	0.0383	0.0537	0.0795	0.0326	0.0355
RMSE	3.7086	4.2958	4.8622	8.6442	7.814	3.9243	4.4513
(x105)R2	0.9523	0.9359	0.9179	0.7403	0.7878	0.9466	0.9312

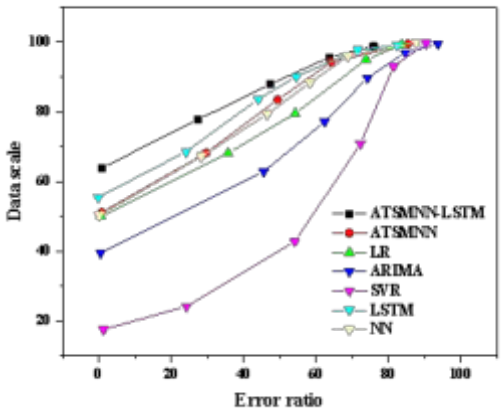

Fig. 3.1: Comparison of cumulative distribution errors of different load prediction methods

3.2. Experimental results and analysis of load prediction methods. The predicted results of the ATSMNN-LSTM load prediction method proposed by the author and other load prediction methods are consistent with the actual network load data, indicating that the ATSMNNLSTM load prediction method proposed by the author and other load prediction methods compared can effectively predict the network load change trend of Wikimedia services. In order to compare the performance of different load prediction methods and further demonstrate the performance indicators of different load prediction methods on the test dataset, as shown in Table 3.1.

As shown in Table 3.1, the MAPE and RMSE values (0.0276, 3.7085×10^5) of the ATSMNNLSTM load prediction method proposed by the author are lower than those of other load prediction methods, indicating that the ATSMNN-LSTM load prediction method can achieve lower prediction errors. The value of R2 also indicates that the R2 value of the ATSMNN-LSTM load prediction method is higher than that of other load prediction methods, and the R2 value of this load prediction method reaches 0.9523, which is closer to 1.0, indicating that the ATSMNN-LSTM load prediction method can better fit the network load change pattern of Wikimedia services. In addition, as shown in Table 3.1, the prediction accuracy of the LSTM model is higher than that of other traditional methods, and the ATSMNN-LSTM load prediction method proposed by the author further improves the prediction accuracy of network loads on the basis of a single LSTM model.

Meanwhile, the author analyzed the performance of different load prediction methods using cumulative distribution error, where cumulative distribution error is defined as follows: The input (X-axis) is the numerical proportion of the relative maximum prediction error; The output (Y-axis) is the proportion of the number of predicted data below the specified relative error ratio to the entire prediction result dataset, as shown in Figure 3.1 [9].

From Figure 3.1, it can be seen that the ATSMNN-LSTM load prediction method proposed by the author has a higher proportion of data with a relative error of less than 60% compared to other load prediction methods,

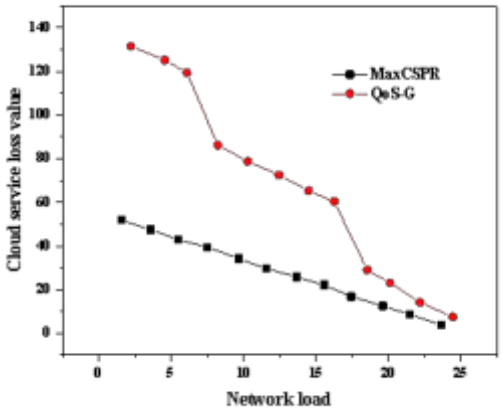

Fig. 3.2: Comparison of Cloud Service Loss Values between MaxCSPR Algorithm and QoS G Algorithm

indicating that the prediction error of the ATSMNN-LSTM load prediction method is mainly concentrated in the relative error range of less than 60% compared to other load prediction methods, that is, the proportion of data with a relative error of more than 60% in other load prediction methods is higher than that of the ATSMNNLSTM load prediction method. From Figure 3.1, it can be further observed that the difference in the proportion of relative error data between the ATSMNN-LSTM load prediction method and other load prediction methods increases with the decrease of error proportion. This indicates that the proportion of data in the ATSMNN-LSTM load prediction method with lower relative error proportion is higher than that in other load prediction methods. That is to say, the proportion of data in the low relative error range in other load prediction methods is relatively small, while the proportion of data in the high relative error range is larger, further proving that the ATSMNN-LSTM load prediction method can achieve higher load prediction accuracy.

3.3. Simulation experiment and result analysis of cloud computing resource quantity search algorithm. In order to evaluate the performance of the cloud computing resource on-demand allocation and elastic scheduling methods proposed by the author, the author further conducted simulation experiments on cloud computing resource on-demand allocation and elastic scheduling. The experimental parameter settings include: setting m=36000, the average execution time of the task is 5ms (i.e. the processing capacity of the cloud server is MIPS=1000, the average length of task instructions is 5MIMillion Instructions), and the execution period is 100ms. The upper limit of the cloud server's computing load is 90%. According to the typical price of Amazon Cloud Services (AWS), the rental fee for each cloud server is 1.1279 yuan/hour, assuming a revenue of 0.0001 yuan per task. Firstly, this section evaluates the performance of the proposed cloud computing resource on-demand allocation algorithm (i.e. MaxCSPR algorithm). Generally speaking, on-demand allocation and flexible scheduling algorithms for cloud computing resources only need to consider the guarantee of task processing performance and service quality. The author collectively refers to the cloud computing resource allocation and scheduling method with the goal of ensuring service quality as the QoS Guarantee Algorithm (QoS G). In order to evaluate the performance of MaxCSPR algorithm in cloud service loss, computational load, and task service delay, the author compared the performance of MaxCSPR algorithm and QoS G algorithm under different network loads, as shown in Figures 3.2 to 3.4.

As shown in Figure 3.2, since the QoS G algorithm aims to ensure the quality of service for tasks and does not consider the best match between the number of cloud servers and task revenue, while the MaxCSPR algorithm aims to minimize cloud service loss, the MaxCSPR algorithm can achieve lower cloud service loss values, indicating that the MaxCSPR algorithm can effectively improve the revenue of cloud services.

From Figure 3.3, it can be observed that the MaxCSPR algorithm not only aims to reduce the loss value

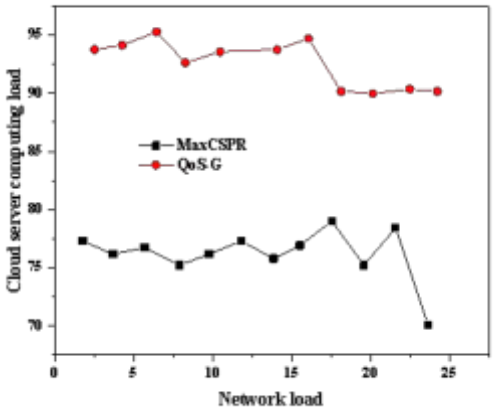

Fig. 3.3: Comparison of Cloud Server Computing Load between MaxCSPR Algorithm and QoS G Algorithm

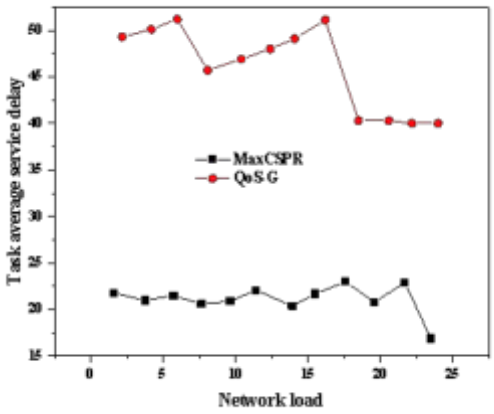

Fig. 3.4: Comparison of task average service delay between MaxCSPR algorithm and QoS G algorithm

of cloud services, but also considers the stability of the system (i.e. the upper limit of the computing load of the cloud server). Therefore, the MaxCSPR algorithm can ensure that the computing load of the cloud server is less than the required upper limit (90%), ensuring the stable operation of cloud services. Further combining with Figure 3.4, it can be seen that although the QoS G algorithm ensures the service quality of tasks (i.e., the average service delay of tasks is less than 100ms), the QoS G algorithm does not consider the stability of the system, resulting in a computing load of over 90% on cloud servers. In practical situations, this can lead to problems such as server overload or software failures. In addition, Figure 3.4 also indicates that the MaxCSPR algorithm can achieve lower task service latency. This is because the QoS G algorithm allocates cloud computing resources with the goal of ensuring the service quality of tasks. Therefore, when the cloud server meets the task execution deadline, tasks will be scheduled as much as possible to the cloud server for processing [10]; However, the MaxCSPR algorithm not only ensures the service quality of tasks, but also considers the stability constraints of the system. Therefore, the MaxCSPR algorithm achieves relatively low cloud server computing load, thereby reducing the service delay of tasks. Overall, compared to the QoS

Table 3.2: Comparison of Error in MaxCSPR Cloud Server Quantity Based on Different Load Prediction Methods and Actual Network Load

	ATSMNN -LSTM	ATSMNN	LR	ARIMA	SVR	LSTM	NN
MAPE	0.0277	0.0349	0.0382	0.0534	0.0794	0.033	0.0356
RMSE	0.7792	0.881	0.9662	1.551	1.4662	0.8214	0.8972
(x105)R2	0.9337	0.9178	0.9011	0.7449	0.772	0.9285	0.9147

G algorithm, the MaxCSPR algorithm not only ensures the service quality of tasks and system stability, but also effectively improves cloud service revenue, proving that the design of the MaxCSPR algorithm meets theoretical analysis and design requirements. Furthermore, in order to analyze the impact of network load prediction accuracy on the MaxCSPR-NWP algorithm, the author compared the error between the number of cloud servers obtained by the MaxCSPR algorithm under different load prediction methods and the number of cloud servers obtained by the MaxCSPR algorithm under actual network load data (i.e. the actual number of cloud server requirements), as shown in Table 3.2.

From Table 3.2, it can be seen that the MAPE and RMSE values of the number of cloud servers obtained by the ATSMNN-LSTM load forecasting method (0.0277, 0.7792) are lower than those obtained by other load forecasting methods, at the same time, the R2 indicator (0.9357) of the number of cloud servers obtained by the ATSMNN-LSTM load prediction method is also the closest value to 1.0 among all methods, indicating that the error between the number of cloud servers obtained by the ATSMNN-LSTM load prediction method and the number of cloud servers obtained from actual network load data is the smallest. In summary, it can be seen that in the active mode, the accuracy of load prediction is a key factor affecting the correctness of cloud server allocation. Therefore, the MaxCSPR-NWP algorithm can obtain a more accurate number of cloud servers.

4. Conclusion. In order to improve the accuracy of network load prediction, the author proposes an adaptive two-stage multi network model load prediction method based on LSTM (i.e. ATSMNN-LSTM load prediction method) to avoid the labor cost problem of manually classifying and annotating network load training data, the author achieved automatic classification and annotation of network load training datasets using first order features and K-means unsupervised machine learning algorithm. Then, based on the long-term interval characteristics of cloud computing resource adjustment and billing, the author mathematically models the cloud server task processing process within one hour using a random queuing model and traversal process. Then, a maximum cloud service revenue computing resource quantity search algorithm based on network load prediction is proposed, allowing the cloud center to obtain the required number of cloud servers in advance through the predicted load results. The experimental results show that the cloud computing resource on-demand allocation and elastic scheduling method based on network load prediction proposed by the author can not only obtain more accurate network load prediction results.

THE APPLICATION OF ARTIFICIAL INTELLIGENCE TECHNOLOGY IN MECHANICAL MANUFACTURING AND AUTOMATION

MINGMING WU*

Abstract. In order to achieve intelligent production and quality control, improve production efficiency and accuracy, the author proposes an application method of artificial intelligence technology in mechanical manufacturing and automation. The author aims to explore the specific application of artificial intelligence technology in the mechanical manufacturing industry and summarize the main advantages of automation technology. By analyzing these advantages, the aim is to provide targeted recommendations for future technological development. Meanwhile, the author aims to provide theoretical support for promoting the application of modern artificial intelligence technology and automation technology in the field of mechanical manufacturing. In the manufacturing process, intelligent production and quality control can be achieved, improving production efficiency and accuracy; In the field of automation, artificial intelligence technology can achieve intelligent control systems and autonomous decision-making, improving the flexibility and adaptability of production lines. Overall, the application of artificial intelligence technology has brought revolutionary changes to mechanical manufacturing, promoting the upgrading and development of the industry.

Key words: Artificial intelligence, Mechanical manufacturing, automation

1. Introduction. With the continuous achievement of various high-tech research, society is moving towards mechanization and intelligence, and artificial intelligence technology has become a focus and focus of people's attention in the context of the new era. Artificial intelligence technology is a representative modern technology that is gradually playing an important role in various industries, especially in today's rapidly changing high-tech era. The future development prospects of artificial intelligence technology are bright, and its practical direction in mechanical design, manufacturing, and automation will also become clearer. In this situation, in-depth research on this topic is needed, Obviously, it has significant practical significance that cannot be ignored [1].

As an important lifeline of national economic development, the manufacturing industry is of great significance for national development and industrial coordinated development. In today's rapidly developing economy, the level of manufacturing directly determines the country's position in the world economy. With the development of information technology, driving industrial development in the direction of intelligence has become the mainstream trend of current development, such as the development of cloud data, big data and other technologies, the manufacturing industry also needs to be rapidly iterated and updated to ensure that its level is in an absolute advantage internationally. Although artificial intelligence technology has become a well-known cutting-edge technology worldwide, there are still doubts about the application and maturity of new technologies in the equipment manufacturing industry due to its wide coverage. How to use artificial intelligence to improve product manufacturing level and quality, optimize manufacturing product structure, is still in a confused state [2,3].

Against the backdrop of rapid development in industrial manufacturing, people have put forward higher requirements for mechanical design and manufacturing technology. Compared with traditional mechanical design and manufacturing technology, the manufacturing technology in the new era has stronger comprehensiveness and digital characteristics, integrating advanced technologies such as automatic control technology, computer technology, and information technology. The production and manufacturing industry is a pillar industry of the national economy, which cannot be separated from the support of advanced mechanical manufacturing technology. In the future, we must keep up with the trend of the times, strengthen the reform and innovation of intelligent mechanical design, manufacturing, and automation technology, provide strong guarantees for the

*Wuhu University, Wuhu, Anhui, 241000, China (wmm19842002@163.com)

development of industrial manufacturing, and promote the country's development towards the goal of becoming a strong industrial and manufacturing country. Based on this situation, the author analyzes the application limitations of artificial intelligence technology in mechanical manufacturing and automation, in order to further reveal the positive impact of artificial intelligence in promoting industrial upgrading and optimizing product structure [4].

2. Research Methods.

2.1. Overview of Artificial Intelligence Technology. At present, China's modernization construction has achieved preliminary results, and artificial intelligence technology has begun to play a role in people's lives. Intelligent cars, intelligent robots, and smart homes are all extension products of artificial intelligence technology. In fact, applying artificial intelligence technology to mechanical design and manufacturing also has certain feasibility, and products will therefore have human thinking and simulation awareness, therefore, it is possible to engage in self-learning, analysis, judgment, and other abilities. As early as the beginning of the last century, toyota motor corporation of Japan proposed the concept of refined production and adapted and analyzed the production needs of multiple varieties and small scales. The proposal of this idea fundamentally reduced the production and labor costs of the company, and was implemented in the design, manufacturing, and management of automotive products. This enabled Japan's automotive industry to quickly surpass the united states and become the world's largest producer, and this precisely reflects the necessity of putting people at the center. Today, as the Fourth Industrial Revolution approaches, artificial intelligence, an extremely special technology, will become the greatest driving force for human centered mechanical design, manufacturing, and automation. In future development, it is crucial to study the practical application of artificial intelligence technology in mechanical design, manufacturing, and automation based on the demand for flexible manufacturing. Artificial intelligence technology is a development achievement of computer technology, and it is also an inseparable part of computer technology in the new era. It has intelligent characteristics and combines human thinking patterns, and can achieve intelligent simulation of mechanical equipment. Common directions of artificial intelligence include speech recognition technology and virtual reality technology, which are composed of different disciplines and therefore have a certain degree of comprehensiveness.

In the stage where artificial intelligence did not yet exist independently of computer technology, the application scope of computer technology was not large. At this time, the social production mode was mostly manual production. Although the concept of artificial intelligence had initially emerged, there was still a long way to go until the popularization and rise of electronic information technology, and network technology began to play a role in production and life, the application fields of artificial intelligence technology are still relatively scarce [5,6].

With the development of network technology and information technology, artificial intelligence technology has begun to truly become known to people and exists on a large scale in production and daily life. As shown in Figure 2.1: Intelligent remote control technology can remotely control the start and stop of production machines. Through video technology and automatic data collection, the situation at the work site is transmitted in real-time to the worker's workbench.

2.2. Application advantages of artificial intelligence technology in mechanical design, manufacturing, and automation.

2.2.1. Improving stability and reliability. In the past mechanical design and manufacturing, once mechanical equipment malfunctions, maintenance personnel must quickly go to the production site and rely on their professional skills and maintenance experience to repair the equipment. Staff need to spend a certain amount of time obtaining fault information. In such a situation, not only will the workload of maintenance personnel be large, but it will also seriously affect production efficiency and quality, and even cannot guarantee that the equipment can continue to operate safely after maintenance. After the application of artificial intelligence technology, once an accident occurs on the production site, monitoring and fault detection can be carried out as soon as possible, which is beneficial for maintenance personnel to quickly handle the problem. With the support of artificial intelligence technology, the internal programs of mechanical equipment can be regularly scanned and repaired on their own in case of problems, improving the safety and reliability of the equipment [7]. In addition, self inspection and repair of the equipment can help extend its service life.

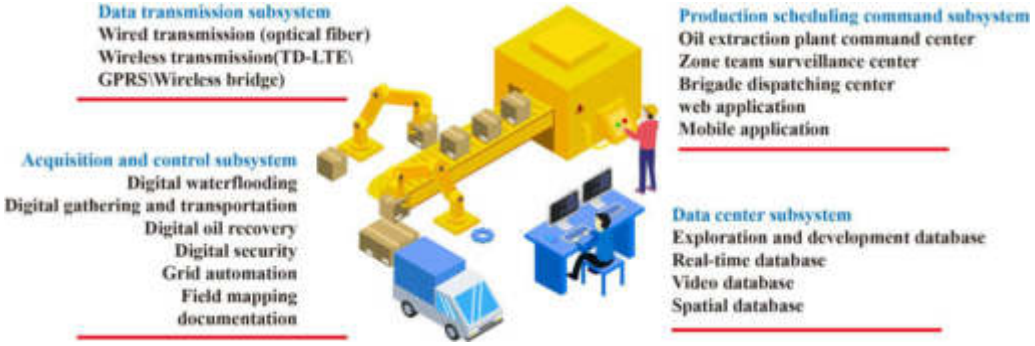

Fig. 2.1: Intelligent Remote Control Technology

2.2.2. Ensuring Quality and Improving Efficiency. After applying artificial intelligence technology, it is possible to continuously improve the production process and optimize various links in the mechanical design and production site, thereby saving production time. The application of artificial intelligence technology in mechanical design and manufacturing can fundamentally improve production efficiency and ensure production quality. The application of artificial intelligence technology in mechanical design and production by enterprises can appropriately reduce the number of employees on the frontline production site, thereby reducing production problems caused by human factors on the production site, and improving per capita output and production efficiency of the enterprise.

2.2.3. Easy maintenance and adjustment. Applying mechanical design, manufacturing, and automation can fully debug production data to meet the demands of different customer orders for mechanical design and production, ensuring the diversity of products produced by the enterprise. The application of artificial intelligence technology in mechanical design and manufacturing can achieve quality self inspection and online detection of mechanical equipment, timely discover problems in equipment operation, and develop the best solution to ensure product production quality [8,9]. Once there is a problem with the operation of the system, it can also be automatically stopped by the automation technology protection measures of artificial intelligence technology, avoiding the contact of production site workers with faulty equipment, ensuring the personal safety of workers, and ensuring the stable operation of the equipment.

2.2.4. Convenient operation. The application of artificial intelligence technology in mechanical design, production and manufacturing can achieve mass production, and the products produced have strong composite characteristics. Artificial intelligence technology can not only change the production mode of machine equipment, but also achieve automated adjustment of equipment programs, meet the production needs of different products and the application of different scenarios in enterprise production sites, promoting diversified development of enterprise production. In practical applications, artificial intelligence technology can automate the control and adjustment of production information, not only optimizing the operation process, but also operating equipment through program settings. Production personnel only need to activate the button to ensure the safe and smooth operation of the equipment.

3. Application Practice of Artificial Intelligence Technology in Mechanical Manufacturing and Automation.

3.1. Application in Mechanical Design. In today's rapidly developing modern society, there are significant differences between traditional design ideas and modern design ideas, and they exhibit significant differences on multiple levels. Especially in the field of modern mechanical design, this difference is particularly evident, involving design, manufacturing, and sales perspectives. Firstly, from a design perspective, traditional design patterns often focus on experience and manual skills, while modern design ideas tend to rely more on advanced technologies such as computer-aided design (CAD) and computer-aided engineering (CAE). Modern design emphasizes efficiency, accuracy, and sustainability. Through simulation and other technical means,

product performance can be more accurately predicted and design solutions can be optimized. Secondly, from a manufacturing perspective, traditional manufacturing methods may rely more on manual operations and traditional processes, while modern mechanical design places more emphasis on automated production and digital manufacturing. Advanced manufacturing technologies such as CNC machining, 3D printing, and intelligent manufacturing systems can improve production efficiency, reduce costs, and flexibly respond to changes in market demand [10]. Moreover, from the perspective of sales, traditional sales models may pay more attention to interpersonal relationships and traditional channels, while modern sales are more inclined to use digital platforms such as the Internet and social media for promotion and sales. Through big data analysis and intelligent marketing systems, we can more accurately grasp consumer needs, provide personalized products and services, and enhance competitiveness. Therefore, with the continuous pursuit of efficiency and innovation in modern society, traditional design ideas have gradually shown limitations in the field of mechanical engineering. In order to meet the needs of the market, it is necessary to fully combine the actual situation, reasonably apply artificial intelligence technology, and promote the development of mechanical engineering towards digitalization and intelligence. By introducing modern artificial intelligence technology, more development opportunities can be created to compensate for the shortcomings of traditional design and promote the healthy development of the industry [11].

3.2. Application in fault diagnosis. In mechanical design, manufacturing, and automation processes, complex tasks and a large amount of data processing are often involved. For example, in demonstration and modeling tasks, a large amount of professional calculations and derivations are required, and traditional manual calculations often have problems of large errors and long time consumption, which is not conducive to the efficient completion of tasks. Therefore, the rational use of artificial intelligence technology has become a necessary choice to achieve automatic data aggregation and accurate classification, ensure the accuracy of the final calculation results, and thus avoid failures in subsequent operations. Specifically, mechanical monitoring data can be transferred into the system through human-machine interfaces, and then intelligent algorithms such as inference machines can be used to provide guidance and guidance. The inference machine can analyze mechanical monitoring data and obtain preliminary diagnostic results based on preset rules and logical inference processes. Then, through the operation of the thinking mechanism, further inference and analysis are carried out on the preliminary diagnostic results, and accurate diagnostic conclusions are ultimately drawn. Meanwhile, with the help of case analysis techniques, historical cases and similar data can be compared to verify and strengthen the reliability of diagnostic results [12].

3.3. Application in Mechanical Manufacturing System Control. With the support of specific hardware devices, the interaction between the execution and identification programs of artificial intelligence nodes can achieve accurate control of feedback information, thereby ensuring the scientific nature of mechanical operation processes. This interaction enables different system software to work together more effectively, thereby achieving precise control goals throughout the entire mechanical manufacturing process. Specifically, indicators θ_1 and θ_2 can be set, which represent various parameters and requirements in the mechanical manufacturing process, such as production efficiency, quality standards, etc. At the same time, the final accuracy indicators for mechanical component manufacturing can also be set it represents the accuracy and quality level of the product. Through artificial intelligence technology, the final ideal values of these indicators can be calculated, as well as the corresponding final accuracy indicators for mechanical component manufacturing idealized calculation results [13,14]. Tables 3.1 and 3.2 can display the specific values of these indicators and calculation results, further demonstrating the specific effects of artificial intelligence technology in mechanical manufacturing.

According to the analysis of Table 3.1 and Table 3.2, it can be observed that the mean corresponding to indicator θ_1 is relatively low, while the mean level corresponding to indicator θ_2 is relatively high. In this case, it will lead to fluctuations in the physical values of θ_1 and θ_2 . This fluctuation may be due to various factors in the production process, such as changes in material quality and process parameters. Figures 3.1, 3.2, and 3.3 show the changing trends of θ_1 and θ_2 over time, as well as the related mechanical component manufacturing accuracy indicators μ fluctuation situation of. Due to numerical fluctuations in θ_1 and θ_2, the manufacturing accuracy of mechanical components is affected μ there will also be corresponding fluctuations. This fluctuation may have an impact on product quality and production efficiency, therefore corresponding measures need to be taken to stabilize the production process and reduce the impact of fluctuations [15].

Table 3.1: Ideal Values for Manufacturing Accuracy Indicators of Mechanical Components

Experimental period /min	θ_1 Value	θ_2 Value	μ Calculation result/%
10	0.50	0.64	43.4
20	0.43	0.64	3.0
30	0.45	0.64	3.1
40	0.53	0.72	4.2
50	0.50	0.72	4.0
60	0.50	0.72	4.0
70	0.50	0.68	3.6
80	0.57	0.64	4.0
90	0.45	0.72	3.5

90	4.2	1.4

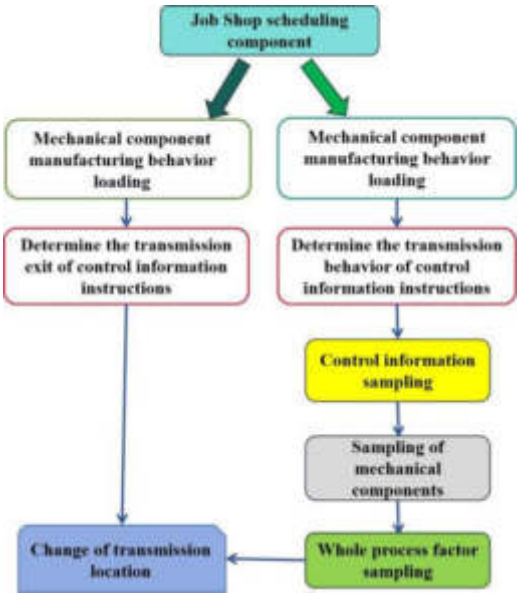

Fig. 3.1: Behavior pattern of Job Shop scheduling control host

By using artificial intelligence technology for intervention, indicators can be effectively improved θ_1 and θ_2 corresponding numerical results. Artificial intelligence technology can analyze a large amount of data and

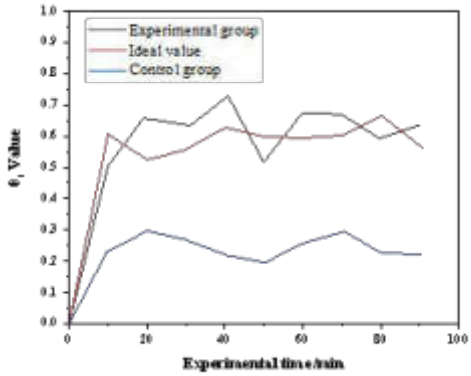

Fig. 3.2: θ_1 experimental values of indicators

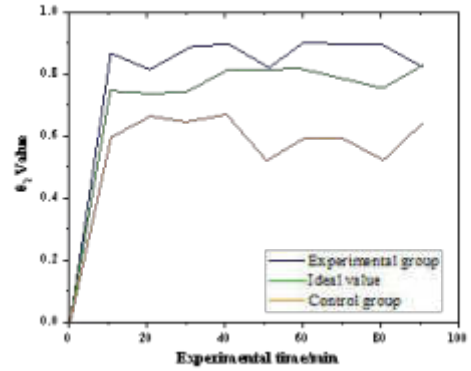

Fig. 3.3: θ_2 experimental values of indicators

make intelligent predictions and decisions based on previous experience and regularity, thereby optimizing various parameters and control strategies in the production process. With the intervention of artificial intelligence technology, intelligent adjustment and optimization of various factors in the production process can be achieved, thereby improving the indicators θ_1 and θ_2 corresponding numerical results are at a relatively high level [16,17]. This optimization can promote the final accuracy of mechanical component manufacturing, improve the quality level and production efficiency of products. Meanwhile, with the intervention of artificial intelligence technology, indicators μ numerical results of the calculation will also continue to increase. This is because artificial intelligence technology can achieve precise control and optimized management of the production process, effectively reducing errors and fluctuations in the production process, thereby improving the accuracy indicators of mechanical component manufacturing μ calculation result of. Therefore, using artificial intelligence technology for intervention can elevate various indicators in the mechanical manufacturing process, thereby improving product quality and production efficiency. This proves that with the intervention of artificial intelligence technology, the control accuracy has been improved more accurately [18].

3.4. Application in Fault Diagnosis. Mechanical design, manufacturing, and automation processes are indeed very complex and require processing a large amount of data. In this process, the modeling and argumentation stages require a large amount of calculations and derivations, using many complex formulas. If

these calculations are completely dependent on manual processing, errors are prone to occur and it will consume a lot of time and effort, which may directly affect the efficiency and quality of the entire production process. Therefore, it is necessary to actively introduce artificial intelligence technology. Through artificial intelligence technology, information can be automatically classified and summarized, improving computational accuracy and reducing the likelihood of errors and failures in subsequent stages. Meanwhile, artificial intelligence can also be used to effectively evaluate and diagnose mechanical faults. This process can be completed through the following steps:

1. The mechanical monitoring data information is transmitted to the system through the human-machine interface.
2. The inference machine is based on a forward inference mechanism and pre-set rules to obtain diagnostic results and provide expert opinions.
3. Based on the search results of similar historical cases, calculate and analyze their similarity with the current situation to support the accuracy and effectiveness of mechanical fault diagnosis.

This method combines the powerful computing and reasoning capabilities of artificial intelligence, as well as the empirical knowledge of historical cases, to improve the efficiency and accuracy of mechanical fault diagnosis, thereby ensuring the smooth progress of the production process [19,20].

4. Conclusion. With the development of the times and social progress, the productivity of modern society has been greatly improved, mainly due to the promotion of various new production technologies. Among them, artificial intelligence technology, as a key technology with multiple advantages such as data processing and transmission, plays a very important role in the field of mechanical design, manufacturing, and automation. Nowadays, artificial intelligence technology is closely integrated with mechanical manufacturing and automation technology, promoting each other. The introduction of artificial intelligence technology has made mechanical manufacturing and automation processes more intelligent and efficient. Through artificial intelligence technology, rapid analysis and processing of large amounts of data can be achieved, thereby optimizing production processes, improving production efficiency, reducing costs, and making the production process more flexible and controllable. Artificial intelligence technology has a wide range of applications in various fields, such as in the manufacturing industry, which can be used to achieve intelligent manufacturing, intelligent warehousing, etc. In the field of transportation, artificial intelligence technology can be used to achieve intelligent traffic control, unmanned driving, and so on. These applications not only inject development momentum into different industries, but also provide good auxiliary effects for many industries, helping enterprises improve competitiveness and adapt to changes in market demand.

A METHOD FOR EXTRACTING POWER ENTITY RELATIONSHIPS BASED ON HYBRID NEURAL NETWORKS

XINRAN LIU*, SHIDI RUAN †, YINI HE ‡, XIONGBAO ZHANG§, AND QUANQI CHEN ¶

Abstract. In response to the challenges of entity relationship extraction in unstructured text, the author proposes a power entity relationship extraction method based on a hybrid neural network. This method aims to overcome the limitations of existing models in accurately representing contextual environment information, thereby improving the accuracy of the extraction model to meet practical application needs. Firstly, a Bidirectional Gated Recurrent Unit (BiGRU) was designed to better capture contextual information in text sequences. This helps the model to better understand the relationships between entities. Secondly, an attention mechanism was adopted to enable the model to automatically focus on sequence features that have a significant impact on relationships. This helps the model to extract entity relationships more accurately in complex text environments. Finally, a segmented convolutional neural network (PCNN) was introduced to further improve the accuracy of relationship extraction by learning the environmental feature information in the adjusted sequence. This enables the model to better understand the contextual relationships between entities. On the publicly available English dataset SemEval2010Task8, this method achieved satisfactory results, achieving an F1 value of 85.62%. These experiments have confirmed the effectiveness of our method, providing new ideas and support for automatic extraction of entity relationships, and are expected to play an important role in the field of information extraction.

Key words: Hybrid neural network, Entity relationship extraction, Segmented Convolutional Neural Network

1. Introduction. As information technology advances swiftly and Internet-enabled mobile devices become increasingly ubiquitous, network information resources have been greatly enriched, and the most important information carrier is text data. Nowadays, the technology of obtaining Internet text information is very mature, but the scale of crawled text information is huge, and it is difficult to extract high-value information from massive text data, which greatly affects the efficiency of using existing resources. How to accurately and automatically mine key information from unstructured text becomes particularly important. In this context, Information Extraction (IE) technology emerged with the main purpose of extracting unstructured electronic texts into structured information. Information extraction mainly includes Named Entity Recognition (NER), Relationship Extraction (RE), and Event Extraction (EE) [1].

Currently, entity relationship extraction technology is garnering considerable attention in the realm of information extraction. Serving as a fundamental task across domains like information retrieval, natural language understanding, and information extraction, entity relationship extraction plays a pivotal role in discerning entity information and semantic relationships within unstructured or semi-structured text. Initially, feature-based methods were embraced and yielded promising outcomes. However, subsequent research revealed their limitations in effectively leveraging contextual structure information of entity pairs [2]. Consequently, a kernel function-based approach was proposed. Yet, due to the notable disparities in sentence structures between Chinese and English, where Chinese structures tend to be more relaxed without explicit positional cues between words, the traditional kernel function-based entity relationship extraction method fell short of achieving optimal results. In order to consider the long-distance relationships between entities in entity relationship extraction, better obtain contextual semantic information of text sequences, and extract more effective features, the author proposes a new type of relationship extraction model BiGRU Att PCNN. This model is a

hybrid neural network model based on BiGRU and PCNN, which utilizes the BiGRU module to obtain more effective contextual semantic information of entities in text sequences; Then, using the Attention mechanism for weight allocation, automatically assign corresponding weights to the feature element based on its impact on relationship classification; After adjusting the weights, the sequence is then passed to the PCNN module. After performing the convolution operation, the pooling layer divides the convolution result into three segments based on the positions of the two entities, and then performs maximum pooling on each segment, ultimately obtaining better structural information and other related environmental features between the two entities. The experimental results show that the proposed method performs well on the publicly available English dataset SemEval 2010 Task 8 [3,4].

2. Literature Review. As deep learning continues to advance, an increasing number of neural network models are finding utility in natural language processing (NLP) endeavors. Within this landscape, entity relationship extraction methods built upon deep learning primarily encode language units of various scales using low-dimensional word vectors, and then uses neural network models such as convolution and loop to achieve automatic learning and extraction of relevant features. There is significant room for improvement in the joint entity and relationship extraction task proposed in many current studies. Heng, F. et al. introduced a novel algorithmic approach, an optimized hybrid neural network model, for predicting the multi axial fatigue life of diverse metal materials. Initially, convolutional neural networks (CNNs) are employed to extract in-depth features from a load sequence comprising critical fatigue load conditions, while preserving the time series characteristics of multi axis historical load information. Subsequently, a Long Short-Term Memory (LSTM) network is utilized to capture both the temporal dynamics and depth features extracted by the CNN. Finally, fully connected layers are employed to facilitate dimensionality transformation, enabling the prediction of fatigue life. Experimental findings demonstrate the model's efficacy in predictive accuracy and its ability to generalize well, rendering it suitable for predicting the life span of various metal materials under different loading conditions, including uniaxial, proportional multiaxial, and non-proportional multiaxial scenarios[5]. Bai, R. et al. introduced an inventive hybrid forecasting model, dubbed HKSL, designed for short-term prediction of photovoltaic power generation. This model ingeniously integrates K-means++, an optimal similar day method, and a Long Short-Term Memory (LSTM) network, leveraging historical power data alongside meteorological factors. By leveraging weather type classifications, the model identifies the most suitable similar day, which is then used as input data for the LSTM network to forecast photovoltaic power output. Validation of the hybrid model's efficacy was conducted using a dataset sourced from a photovoltaic power station in Shandong Province[6]. Zhou, D. et al. introduced a Hybrid Deep Neural Network (HDNN) tailored for active hazard recognition within civil aircraft Auxiliary Power Units (APUs). This model amalgamates Multi Time Window Convolutional Neural Network Bidirectional Long Short-Term Memory (CNN Bi LSTM) architecture to enhance performance and accuracy in hazard detection[7]. Shang, Y. M. et al. introduced a novel model named OneRel, aiming to jointly extract entities and relationships by framing the task as a fine-grained triple classification problem. This model comprises two key components: a rating-based classifier and a specialized relationship-based corner labeling strategy. The former assesses whether a token pair and their relationship form a factual triplet, while the latter facilitates a straightforward yet efficient decoding process. Extensive experiments conducted on two commonly used datasets demonstrate that the proposed approach outperforms state-of-the-art methods, consistently delivering improved performance, particularly in intricate scenarios characterized by diverse overlapping patterns and multiple triples [8].

3. Research Methods.

3.1. Joint extraction of entity relationships. Entity relation joint extraction involves combining entity recognition and relation extraction to extract structured relation triplets, such as "head entity, relation, tail entity," from unstructured text. The goal of entity relationship extraction is to accurately identify all pairs of entities with relationships in the text, and accurately identify the relationship types of each pair of entities. In Table 3.1, we provide three examples of entity relationship extraction tasks. The second column displays the original unstructured text, serving as input for the model. The desired model output is depicted in the third column of Table 1, where each relationship triplet comprises a pair of entities and a relationship. Notably, a single text sentence may contain multiple relationship triplets. Due to this, different triplets within the same

Table 3.1: Classification of Relationship Overlap Types

	Unstructured raw text	Set of entity relationship triplets	Overlap type
S1	"Under the mediation of the Li family, Qian Xuesen and Jiang Ying became a couple."	Qian Xuesen, Couple Jiang Ying	No entity overlap (NEO)
S2	"Hybrid rice expert Yuan Longping"	Yuan Longping, a professional hybrid rice expert	Single entity overlap (SEO)
S3	"Zhong Nanshan serves as a professor/executive vice director of Guangzhou Institute of Respiratory Diseases"	Zhong Nanshan, Professor at Guangzhou Institute of Respiratory Diseases	Entity pair overlap (EPO)

sentence may exhibit overlapping relationships [9].

The overlapping patterns of relationship triplets can be categorized into three types, as demonstrated in the fourth column of Table 3.1: No Entity Overlap (NEO), Single Entity Overlap (SEO), and Entity Pair Overlap (EPO). For instance, Sentence S1 exemplifies the NEO phenomenon, where the character entity "Qian Xuesen" in the sentence solely holds a marital relationship with the character entity "Jiang Ying." Conversely, Sentence S2 showcases the SEO phenomenon. The entity "Yuan Longping" in the sentence is related to the entity "Hybrid Rice Expert" and the entity "September 7, 1930", and the two triples overlap; Sentence S3 belongs to the phenomenon of entity pair overlap, and there are multiple relationships between the entity "Zhong Nanshan" and the entity "Guangzhou Respiratory Disease Research Institute" in the sentence, resulting in overlapping relationships. From Table 3.1, it can be seen that compared to the traditional task of extracting relationships between one sentence and one pair of relational entities, the task of extracting relationships with overlap is more challenging.

3.2. Entity Relationship Extraction Related Algorithms. Relationship extraction methods primarily fall into three categories: feature-based, kernel function-based, and deep learning-based approaches. (1) The feature-based method for relation extraction mainly describes the relationships between entities by extracting important features from the text, organizing them into vectors, and then using machine learning algorithms to classify the relationship features. (2) The method based on kernel function first designs a kernel function to calculate the similarity of objects in high-dimensional space, thereby obtaining structured features of objects, and then constructs a classification model based on this structured feature[10]. (3) The method based on deep learning can automatically learn text features, has little dependence on NLP tools, and can more fully utilize the structural information in the text .

3.3. Relationship Extraction Model Based on BiGRU and PCNN.

3.3.1. Framework Overview. In order to better characterize the contextual information in unstructured text and more accurately identify entity information and semantic relationship categories between entities, the author proposes the BiGRU Att PCNN relationship extraction model, which mainly consists of the Embedding layer, BiGRU layer, Attention layer, PCNN layer, and Softmax layer.

(1) Embedding layer. The word embedding training in the Embedding layer is carried out using the Word2VeC algorithm. Firstly, the word embeddings for each word are generated ω dimension vector. Moreover, to capture the positional relationships between each word and the two entities within the sentence and to leverage the syntactic and semantic nuances of the words, the author incorporated relative position features into the model. For instance, in the sentence "Sam was born in Boston," the relative distances between the word "born" and the head entity "Sam" and the tail entity "Boston" are 2 and -2, respectively, effectively reflecting their relationship within the sentence. Map these two relative distances into two randomly initialized p-dimensional position vectors. The sentence vector $S = \{q1, q2, ..., qn\}$ is represented by the real valued vector

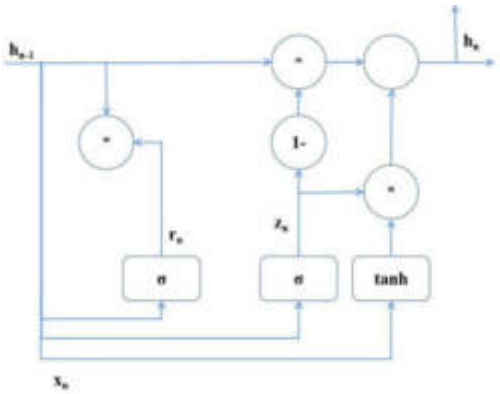

Fig. 3.1: Architecture of GRU Unit

qn of n words, where qn is the combination of the word vector of the nth word xn and the relative position vector of the entity. $S \in R^{n*d}$, where $d = w + p * 2$.

(2) BiGRU layer. The BiGRU layer is a series of GRU units that control the addition and deletion of information. GRU is a highly effective variant of LSTM, with only two gates in the model, namely the update gate and the reset gate [11]. The specific structure of GRU is shown in Figure 3.1.

In the process of information transmission, the GRU unit jointly controls the calculation of the new hidden state hn from the previous hidden state h_{n-1} by updating the value of the gate zinc and resetting the value of the gate rn, as shown in equations 3.1 to 3.4.

$$z_n = \sigma(W_z q_n + U_z h_{n-1}) \tag{3.1}$$

$$r_n = \sigma(W_r q_n + U_r h_{n-1}) \tag{3.2}$$

$$\widetilde{h_n} = tanh(W_h q_n + U_h(r_n * h_{n-1})) \tag{3.3}$$

$$h_n = (1 - z_n) * h_{n-1} + z_n * \widetilde{h_n} \tag{3.4}$$

Among them, qn and h are the inputs and outputs of the GRU unit, respectively. n is the position in the word sequence, and Wz, Wr, Wh, Uz, Ur, and Uh are all weight matrices, $\sigma()$ is a sigmoid function. Because one-way neural networks propagate information in one direction, they can only include the transmission of preceding information in that direction, but cannot obtain the following information of words in the text, which can affect the effectiveness of entity relationship extraction. Therefore, the author uses the method of bidirectional GRU neural network structure, which is composed of two unidirectional GRUs with the same structure. At each moment, the training sequence is simultaneously input into two GRU units with opposite directions, and the output result is determined by these two unidirectional GRU units together. The final output of the BiGRU layer contains complete contextual information.

(3) Attention layer. The function of the Attention layer is to weight the semantic features obtained by the BiGRU layer, and the output result vector is T={T1, T2, T3.., Tn}, where $Ti \in Rd$.

The calculation of the Attention layer is divided into three steps: similarity calculation, normalization processing, and calculating the Attention value output by BiGRU. Similarity calculation uses cosine similarity to calculate the similarity score $Score_{ij}$ between T_i and H_j, as shown in equation 3.5.

$$Score_{ij} = Sim(Ti, H_j) = \frac{Ti, H_j}{||Ti|| \cdot ||H_j||} \tag{3.5}$$

Among them, in the first round of training, the initial value of T is H.

Normalization is the process of normalizing the similarity score $Score_{ij}$ between T_i and H, as shown in equation 3.6.

$$a_{ij} = Spftmax(Sim(T_i, H)) = \frac{e^{Score_{ij}}}{\sum_{j=1}^{Lx} e^{Score_{ij}}} \tag{3.6}$$

Finally, the weight vectors $a_i = \{a_{i1}, a_{i2}, \cdots, a_{in}\}$ corresponding to T_i and H are obtained. Finally, calculate the value T of the Attention output by BiGRU, as shown in equation 3.7.

$$T = \sum_{i=1}^{n} a_i \cdot H_i \tag{3.7}$$

After weighted processing by the Attention layer, words that have a significant impact on the classification results in the statement will be given a larger weight, while words that have a smaller impact on the classification results will be given a smaller weight.

(4) PCNN layer. The PCNN layer consists of a convolutional layer and a segmented max pooling layer. In order to further identify the semantic relationships between entities, the convolutional layer in the author's model combines the output vector sequence $T = \{T1, T2, T3, .., Tnn\}$ of the Attention layer with the weight vector w for segmented convolution operations. Among them, the weight matrix w is considered as a convolutional filter. Assuming the filter length is l, then $w \in R^{l*d}$. In order to better capture more diverse features, the author's model uses m filters ($W = \{w1, w2..., wm\}$) in the convolution operation. The convolution operation involves taking the dot product of w and each l-gram in sequence T to obtain another sequence $c \in R^{n+l-1}$. The convolution operation is calculated as shown in equation 3.8.

$$C_{ki} = W_k T_{i-1+1:i} \quad 1 \leqslant k \leqslant m \tag{3.8}$$

The initial size of the convolutional output matrix C depends on the length of the sentences input into the model, while the author combines the features extracted from the convolutional layers and applies them to subsequent layers. Therefore, the final output result is no longer dependent on the length of the sentences input into the model. The relationship extraction method proposed by the author uses the segmented maximum pooling algorithm. Firstly, two entities in the input sentence are identified, and then the sentence vector is divided into three segments based on the positions of the two entities. The final result returned is the maximum value in each segment [12].

(5) Softmax layer. The function of the Softmax layer is to calculate the probability of each relationship label defined in the entity relationship extraction task, apply the Softmax function to the current output vector g of each PCNN module, generate an L-dimensional vector, that is, the number of label types is L, and then give a weighted vector z. The predicted probability of the j-th label is calculated as shown in equation (9).

$$p(y = j|g) = \frac{e^{g^T z_j}}{\sum_{l=1}^{L} e^{g^T z_j}} \tag{3.9}$$

3.3.2. Model Training and Optimization. After generating the probability distribution of each relationship category through the Softmax layer, the model is trained by minimizing the cross entropy between this probability distribution and the actual category of the relationship instance. On a given training instance Si and its label yi, the model estimates the probability of $p_j^i \in [0, 1]$ for each category. By using the Ranger optimizer to minimize the cross entropy loss between the classification result and the true category for parameter learning, the loss function is calculated as shown in equation 3.10.

$$L(S^i, y^i) => \sum_{j}^{k} l(y_i = j) log(p_j^i) \tag{3.10}$$

Table 4.1: SemEval 2010 Task 8 Dataset

relationship type	Training set	Test set
Cause-Effect(C-E)	1310(16.52%)	443(15.60%)
Component-Whole(C-W)	1002(11.43%)	317(11.06%)
Entity-Destination(E-D)	930(10.65%)	301(10.37%)
Entity-Origin(E-O)	834(9.45%)	281(10.64%)
Product-Producer(P-P)	705(8.84%)	247(9.40%)
Member-Collection(M-C)	706(8.85%)	220(8.40%)
Message Topic(M-T)	688(8.52%)	222(8.47%)
Content-Container(C-C)	623(7.84%)	250(9.50%)
Instrument-Agency(I-A)	530(6.64%)	181(7.06%)
Other(O)	503(6.20%)	145(5.63%)

Among them, l is the indicator function, $j \in \{1, 2, .., K\}$, K is the number of label types, when y '=j is true, l=1, otherwise it is 0.

In addition, the author's model adds a Drop out strategy after the BiGRU layer for regularization constraints, with the aim of shielding the neural network units with a certain probability to prevent overfitting and improve the training speed of the model.

3.3.3. Model training process. This model is aimed at relation extraction of English corpus. After the sentence sequence is input into the neural network, the embedding layer first performs word embedding training on the sentence sequence input into the neural network model, generating embedding vectors that are easy to perform numerical operations. Then input the vector into the BiGRU layer, which will extract sequence features such as the relationship between each element and its position. However, due to the distance decay of BiGRU, after the BiGRU operation is completed, the author's model adds an Attention layer to redistribute the weight of the results obtained by the BiGRU layer, that is, assign corresponding weights based on its impact on the relationship classification results, and then send them to the PCNN layer. For example, in Example 1, the weights of the two entities "report" and "role" will be raised by Attention. In PCNN, a segmented convolutional pooling operation is performed, which involves first dividing the entire sentence into three segments based on the positions of two entities, and then extracting detailed features and mutual influence information from these three segments. Finally, the Softmax layer maps the feature information to the corresponding Message Topic type, and this model ultimately forms a complete mapping of type features to types.

4. Result analysis.

4.1. Datasets. In order to verify the effectiveness of the entity relationship extraction model proposed by the author, the publicly available English dataset SemEval 2010Task 8 was used in the experiment. This dataset contains a total of 10717 corpora, including 8000 training corpora and 2717 testing corpora. The entities and their relationships have been labeled, including 9 directional relationships and 1 undirected Other type relationship. Therefore, there are 19 types of relationships, as shown in Table 4.1.

4.2. Experimental setup and evaluation indicators. The author's experiment used word vectors trained by the Word2Vec algorithm for word embedding, with a dimension of 300. Based on prior knowledge, the K parameter was set to 20, the alpha parameter was set to $4e^{-2}$, and the optimal values of other parameters were determined using a grid search algorithm on the dataset. Finally, the optimal results were achieved in the 55th to 60th iteration rounds. The optimal parameter settings for the model are shown in Table 4.2.

The author uses a confusion matrix to obtain the accuracy, recall, and F1 values for each category, and then uses the macro coverage F1 value as the evaluation metric to measure model performance based on the official documentation of the dataset.

4.3. Experimental Results and Analysis. In order to ensure the accuracy of the experiment, the same input was applied to similar relationship extraction models, and the F1 values obtained from each model were compared [13]. The F1 values obtained in each model are shown in Table 4.3.

Table 4.2: Optimal parameter settings

Parameter	Final
Batch size	127
Position vector dimension	6
Dropout rate	0.6
Hidden layer unit size	127
Number of CNN convolution kernels	100
CNN convolution kernel window length	2

Table 4.3: F1 values obtained from various models

Model	F1/%
PCNN	81.23
PCNN	80.64
BiLSTM-PCNN	83.35
BiGR U-PCNN	84.51
BiGRU-Att-PCNN	85.62
BiGRU-Att-CNN	84.25

By comparing the F1 values of each model in Table 4.3, it is clear that the performance of the model based on the hybrid neural network is better than that of a single network model. This is due to the hybrid neural network model being able to fully utilize the role of each model in relation extraction, thereby achieving multi angle coverage for feature extraction and training, and more accurately extracting relation features. For example, a single PCNN model can only focus on local features in the sequence, while a hybrid model based on BiLSTM and PCNN can first solve the word dependency problem in long sentences through the BiLSTM module, and then use the PCNN module to better capture the connections between features, ultimately extracting the features of the overall relationship instance. This design enables the hybrid model to extract relationships more effectively, resulting in better results. In addition, it can be clearly seen from the experimental results in Table 4.3 that the BiGRU-PCNN model has better relationship classification performance than the BiLSTM-PCNN model. This is because BiGRU has a simpler structure and fewer parameters compared to BiLSTM, which can retain the ability to extract sequence features and is less prone to overfitting. Therefore, the BiGRU-PCNN model performs better in relation extraction tasks [14].

The author's model incorporates an Attention mechanism for optimization based on the BiGRU-PCNN model. As shown in Table 4.3, this method achieved the highest F1 value. This is because the Attention mechanism introduced by the author can automatically align the output of the BiGRU model with the input of the PCNN model, and automatically focus on sequence elements that have a greater impact on the relationship extraction results, and redistribute their weights. This operation enables the PCNN layer to more fully utilize the output data of the BiGRU layer, thereby extracting more accurate relationship information. By observing the experimental results of the BiGRU PCNN model and BiGRU Att PCNN model on the same test set in Figure 4.1, it can be clearly seen that the F1 value variation curve of the model with the addition of the Attention mechanism has a smaller fluctuation amplitude and faster convergence speed. Under the same number of iterations, the stability of the F1 value of the BiGRU Att PCNN model is higher, and the final F1 value obtained is also higher than that of the BiGNU PCNN model. In other words, this method effectively improves the performance of the model in relation extraction tasks by introducing an Attention mechanism. This mechanism enables the model to focus more on key sequence elements, better utilize the information of input data, achieve better classification results, and improve the stability and convergence speed of the model.

In summary, we can draw the following conclusion: Introducing the Attention mechanism to redistribute the weights of the output results of the BiGRU module helps the PCNN module to obtain useful information more effectively, thereby promoting the acceleration of the iteration process. The weight redistribution function

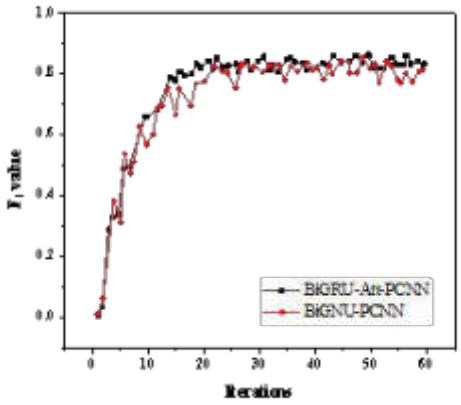

Fig. 4.1: F1 value variation curve with number of iterations

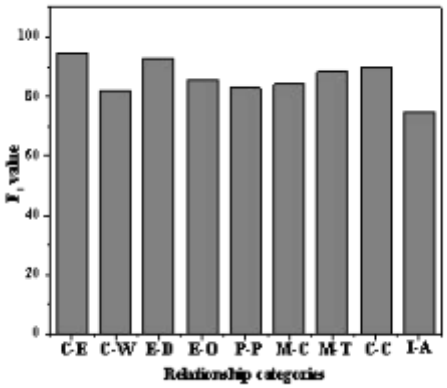

Fig. 4.2: Classification effect of different relationship types

of the Attention mechanism assigns smaller weights to information that has less impact on classification results, thereby reducing noise transmission when transmitted to the PCNN layer. This helps to reduce fluctuations during model training, so that the F1 value of the model does not change too dramatically. Furthermore, through the analysis of Figure 4.1, it can be observed that as the number of iterations increases, the F1 value of the model gradually increases. Although there are certain fluctuations, the range of fluctuations is small and overall shows a trend towards stability. This further proves that the model proposed by the author has stability [15].

4.4. Analysis of Results for Different Relationship Types. In order to explore the classification performance of the author's method on different relationship types, this experiment also counted the F1 values of 9 relationship types except for Other, as shown in Figure 4.2.

Figure 4.2 shows that the F1 values of relationship types C-E and E-D are significantly higher than those of other types, while I-A has the lowest F1 value. Further analysis of the test dataset revealed that sentences with the highest F1 value in C-E relationship types typically contain vocabulary and variants such as "cause" and "result", and are often accompanied by prepositions such as "by" and "in", exhibiting distinct structural

features. Similarly, relationship type E-D also exhibits similar characteristics. Therefore, these two types of sentences are relatively easy to extract because they have clear semantic structures. On the contrary, although the I-A type with the lowest F1 value also contains high-frequency vocabulary such as "use" and its variants in the sentence, it usually only uses prepositions such as "by" and "with" when indicating tool use, which are not always accompanied by high-frequency vocabulary in the sentence. Therefore, this type of sentence lacks obvious structural features, which leads to poor performance in relation classification. In short, the prominence of structural features has a significant impact on the effectiveness of entity relationship extraction. Sentences with clear structural features are easier for the model to accurately classify, while sentences without clear structural features are more challenging.

5. Conclusion. In order to more accurately extract entity information and semantic relationship types between entities in unstructured text, the author proposes an innovative hybrid neural network model called BiGRU Att PCNN for entity relationship extraction. This model combines two neural network structures, BiGRU and PCNN. Compared with other models, it can better capture contextual semantic information in event sentences and effectively learn relevant environmental features, avoiding complex feature engineering. Although the model has achieved good results on the common English dataset SemEval 2010 Task 8, there are still some shortcomings when dealing with sentences with unclear structural features. This is because we did not fully utilize the grammatical features in the text during the relationship extraction process. Therefore, the next step of the work plan is to introduce semantic roles, parts of speech, grammatical structures and other features into the entity relationship extraction model, in order to improve the performance of entity relationship extraction. By adding more grammatical features, it is hoped to further improve the model's understanding of unstructured text, thereby more accurately identifying semantic relationships between entities and contributing more possibilities to the development of entity relationship extraction tasks.

THE TEACHING EFFECT EVALUATION OF BIG DATA ANALYSIS IN MUSIC EDUCATION REFORM

QIUYUE DENG*

Abstract. At present, the evaluation of the implementation effect of the music teaching reform project is a hot topic. This project establishes a teaching reform implementation effect evaluation model based on improving the accuracy of teaching reform plan effectiveness evaluation. This project first analyzes the current research status of the impact evaluation of the implementation of music education reform projects and builds a set of evaluation systems. The evaluation method of teaching reform plan implementation effect based on a "big data-driven - support vector machine" was constructed. The simulation experiment verifies that this method can evaluate the implementation of the teaching reform plan well. The relative error of the evaluation results is small. It is practical in improving the effectiveness evaluation of the teaching reform plan. After verification, it is found that the research results of this project are feasible.

Key words: Big data; Music teaching reform plan; Support vector machine; Effectiveness evaluation; Weight; Contrast matrix

1. Introduction. Music education is a significant subject in colleges and universities. Its teaching quality has a significant effect on students' comprehensive ability, so it is essential to improve the implementation of the education reform plan. The implementation of the music education reform plan plays a vital role in the implementation of the school's education reform plan [1]. At present, there have been many studies on the effectiveness evaluation of music education reform programs. For example, some scholars have discussed how to evaluate the effectiveness of curriculum reform according to users' satisfaction [2]. Some scholars have studied the effectiveness evaluation of the implementation of music education reform projects in the environment of big data. The above research results can be used to evaluate the educational effectiveness, but the effectiveness of the evaluation is not high. At present, China's college music education reform project implementation effectiveness evaluation model is facing a significant challenge [3]. Support vector machine (SVM) algorithm is an extensive data-driven evaluation method, which has unique advantages in solving nonlinear high dimensional evaluation problems [4]. Therefore, this project intends to build an evaluation method for music education reform projects based on big data. This paper hopes to solve the problems of "local extreme value" and "over-learning," which are easy to appear in the existing evaluation methods.

2. Research on evaluation model of implementation effectiveness of music education reform plan driven by big data. AHP and expert evaluation are used to construct a set of evaluation systems for the implementation of the teaching reform plan. The specific implementation model is shown in Figure 2.1.

The AHP method is used to compare the leading indicators, and the good and bad relations among the leading indicators are obtained. Finally, the relative weights of each index are obtained (Table 2.1).

The importance of each index in Table 2.1 is expressed by 1,2 and 3. These three factors are equally important, relatively essential and significant. Set the maximum eigen root of the matrix to 5.9865 and the order of the matrix to 6 . Formula $CR = CI/RI$ is the consistency ratio of the contrast matrix; RI represents the random coincidence index of the mean, and CI represents the inconsistency of the paired contrast matrix. The weights of each evaluation index are calculated according to the characteristic vector of the contrast matrix [5]. At the same time, the weighted coefficients of each evaluation index were obtained (Table 2.2).

3. Application of most miniature square support vector machines in homology identification.

3.1. Derivation of function fitting method based on most miniature square support vector machines. Support vector machine (SVM) is a kind of machine learning algorithm that emerged in the 1990s. Its core idea is to transform a variable nonlinear [6]. Then, the variables are transformed into high-dimensional H-space, which effectively overcomes the linear inseparability problem of the original space. In addition, the

paper will use the optimal classification hyperplane on the H-space to classify the samples. The traditional neural network adopts the gradient iteration method, which is likely to have local extreme values. At the same time, the support vector machine aims to solve the quadratic optimization, and its operational complexity and quality are independent of the sample dimension, so it shows excellent performance in identification and nonlinear function estimation. Least-squares support vector machine (LSVM) is an extension of the traditional support vector machine (SVM), which can deal with the categories and functions of SVM effectively [7]. By using the least square method, the inequality problem in the optimal problem is transformed into an equation problem, which reduces the complexity of the algorithm and improves the efficiency of the algorithm. Data $\{t_i, g_i\}_{i=1}^{M}$ has M training sample. $t_i \in R^n$ is the input. $g_i \in R$ stands for output. The format of the regression model in the initial space is:

$$g(t) = \eta^T \zeta(t) + \sigma$$

The following optimization problem is constructed in the most minor square support vector machine regression estimation problem:

$$\begin{cases} \min_{\eta,\sigma,\varepsilon} F(\eta,\varepsilon) = \frac{1}{2}\eta^T\eta + \frac{1}{2}\delta\sum_{i=1}^{M}\varepsilon_i^2 \\ \text{s.t } g_i = \eta^T\zeta(t_i) + \sigma + \varepsilon_i, \quad i = 1,\ldots,M \end{cases}$$

The optimization problem in (3.1) is transformed into a dual space to solve it. The resulting Lagrange function is as follows:

$$S(\eta,\sigma,\varepsilon,\mu) = \frac{1}{2}\eta^T\eta + \frac{1}{2}\delta\sum_{i=1}^{M}\varepsilon_i^2 - \sum_{i=1}^{M}\mu_i\left\{\eta^T\zeta(t_i) + \sigma + \varepsilon_i - g_i\right\}$$

Where μ_i is the Lagrange multiplier. Using the first order or sufficient condition of Kuhn-Tucker optimality, it is proved

$$\begin{cases} \frac{\partial S}{\partial \eta} = 0 \to \eta = \sum_{i=1}^{M}\mu_i\zeta(t_i) \\ \frac{\partial S}{\partial \sigma} = 0 \to \sum_{i=1}^{M}\mu_i = 0 \\ \frac{\partial S}{\partial \varepsilon_i} = 0 \to \mu_i = \delta\varepsilon_i, i = 1,\ldots,M \\ \frac{\partial S}{\partial \mu_i} = 0 \to \eta^T\zeta(t_i) + \sigma + \varepsilon_i - g_i = 0 \end{cases}$$

Remove η, ε_i to get the matrix equation:

$$\begin{bmatrix} 0 & p^T \\ p & \psi + \delta^{-1}W \end{bmatrix}\begin{bmatrix} \sigma \\ \mu \end{bmatrix} = \begin{bmatrix} 0 \\ g \end{bmatrix}$$

$g = [g_1, g_2, \ldots, g_M]^T; p = [1,\ldots,1]^T; \mu = [\mu_1,\ldots,\mu_M]^T$. ψ is a square matrix whose i row s element is $\psi_{is} = I(t_i,t_s) = \zeta(t_i)^T\zeta(t_s)$. The conclusion of formula (3.6) is obtained from the mapping function ζ and the core $I(\cdot,\cdot)$ of the Mercer condition.

$$I(t_i,t_s) = \zeta(t_i)^T\zeta(t_s)$$

Finally, the following least squares support vector machine function estimation model is obtained:

$$g(t) = \sum_{i=1}^{M}\mu_i I(t,t_i) + \sigma$$

μ and σ in the formula are solutions to equation (3.5). The kernel function form has the following forms. Linear kernel function: $I(t,t_i) = t_i^T t$; c order polynomial kernel function: $I(t,t_i) = \left(t_i^T t + 1\right)^c$; Radial basis kernel function: $I(t,t_i) = \exp\left(-\|t-t_i\|_2^2/\chi^2\right)$; Kernel function of two-layer perceptual neural network: $I(t,t_i) = \tanh\left(tt_i^T t + \beta\right)$. Here χ, t and β are both adjustment constants.

3.2. Multi-layer dynamic adaptive optimization algorithm. It can be seen from the least square support vector machine algorithm that the key parameters of this method are super parameters and kernel parameters. In engineering practice, the radial basis function is usually used as the core of nonlinear mapping, which can quickly carry out nonlinear transformation and has significant statistical properties and overall convergence, so it has important practical value in dealing with complex, nonlinear and inseparable class problems [8]. At the same time, the kernel function of the radial basis function is selected as the core. The regularization parameter δ and radial base kernel parameter χ are selected. These two parameters directly affect the learning performance and prediction performance of the least-square support vector machine algorithm [9]. The specific implementation steps of the multi-level dynamic optimization method of the least square support vector machine algorithm are as follows:

1. The numerical intervals of δ and χ are given. According to the basic principle of least squares support vector machine algorithm, the maximum value is determined to be $\delta \in [0.1, 10000], \chi \in [0.1, 100]$.
2. Select the maximum value of the parameter. Construct A set of 2-dimensional mesh parameters with pairs $(\delta_i, \chi_j), i = 1, \ldots, m, j = 1, \ldots, n$. For example, if 10 values are selected for both parameters, (δ_i, χ_j) 10x10 grid surface and 100 A parameter pairs are formed. Two different selection methods are adopted: 1) the interval of the two-parameter values is given first, and then they are taken as the same value according to the expected logarithm. 2) Parameter values are determined based on data characteristics and the experience of training samples.
3. A set of parameters (δ_i, χ_j) of each node is used as the training sample of the least squares support vector machine. The corresponding node $(\delta_i, \chi_j)_{E_{\min}}$ is selected as the best parameter combination.
4. If the required learning accuracy cannot be satisfied, $(\delta_i, \chi_j)_{E_{\min}}$ new twodimensional grid plane is established at A. Select parameters with similar values for training to improve the training effect [10]. The new selection method is automated. The practice has proved that 0.01-5 times of $(\delta_i, \chi_j)_{E_{\min}}$ is usually used as an extended mesh width. Construct A new set of 2-dimensional mesh parameters for $(\delta_i, \chi_j)_{E_{\min}}, i = 1, \ldots, i, j = 1, \ldots, s$.

Figure 3.1 shows the optimal network topology for level 2 parameters. The optimal mesh of multiple levels of parameters is constructed successively, and the parameters of the most miniature square support vector machine are continuously optimized until the required learning accuracy is satisfied. The two-dimensional plane optimization design is carried out by using a twolevel grid, and MATLAB carries out the numerical simulation. According to the characteristics of the model, the first parameter is optimized $\delta = [0.1, 1, 10, 50, 100, 500, 1000, 2500, 5000, 10000]$ and $\chi = [0.1, 0.2, 0.5, 1.5, 10, 15, 25, 50, 100]$ are selected simultaneously. The system uses a $10x10$ grid. In the parameter pairs of each node, the least square support vector machine algorithm is used to identify the system and nonlinear components [11]. Next, at the level of the second parameter optimization, the $(\delta_i, \chi_j)_{E_{\min}}$ square is the center. The width of the grid is expanded in the δ direction so that it has a $(\delta_i)_{E_{\min}}$ value of $+0.1$. The width of the expanded grid in the χ direction is $(\chi_j)_{E_{\min}} + 0.05$ and builds a $10x10$ grid. Then, the optimal parameter pair is obtained by using the least squares support vector machine algorithm [12]. Finally, the optimal parameters are used to train and learn the least-square support vector machine algorithm for (δ_i, χ_j).

4. Case analysis. Take a university as the research object. It introduced a music teaching reform plan in 2021. An online questionnaire survey was conducted among the college students at this university. A total of 1200 questionnaires were distributed, and 1122 valid questionnaires were obtained. 561 of them were selected as extensive data-driven training samples, and the remaining questionnaires were selected as test samples [13]. In this paper, SPSS is used to make statistics on the questionnaire and draw conclusions. The value of the reliability coefficient is 0.995, and that of KMO is 0.9421, where both the reliability term and KMO are above 0.9. This proves the validity and reliability of this questionnaire, which can be used to evaluate the effectiveness of music education reform programs [14]. This model is used to evaluate the implementation of a music education reform plan, and ten copies of it are used as the manifestation of teaching effectiveness evaluation. The big data used in this study was processed using the mean deviation as the evaluation criterion. It can be seen from the test results in Figure 4.1 that the mean deviation of the output of the big data-driven model used in this project is the smallest when the penalty value is 100. This means that big data-driven models have better output performance at this time. In the evaluation of music education reform projects, the accuracy of

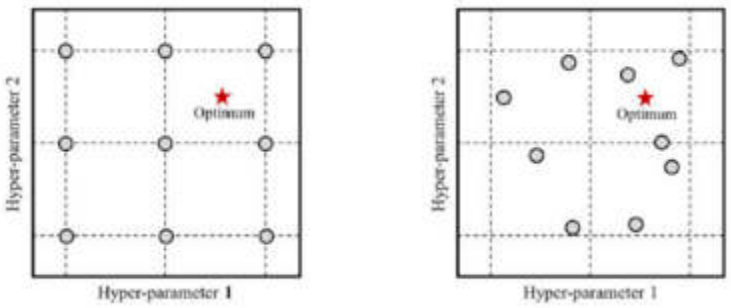

Fig. 3.1: *Schematic diagram of the grid plane for Layer 2 parameter optimization.*

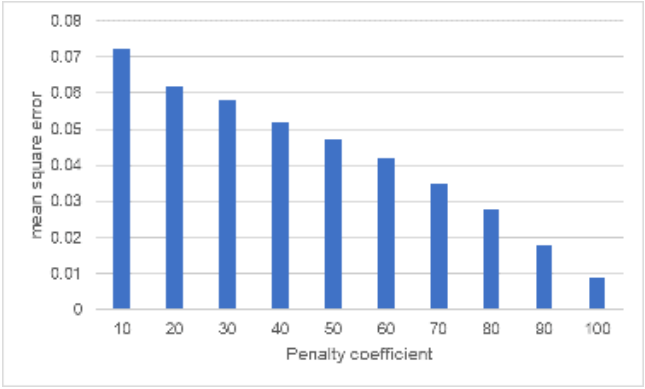

Fig. 4.1: *Output results under different penalty factors.*

the evaluation can be well improved, and the penalty factor of using the big data-driven model to evaluate the impact of music education reform projects is set at 100.

The effect of applying this model to the evaluation of the music education reform plan is shown in Table 4.1. As can be seen from the experimental data in Table 4.1, the evaluation of the implementation of the music education reform plan with this model obtained a score of 6.56. It shows that the effectiveness of the school's education reform program is moderate, and there is much room for improvement [15]. According to the results of the evaluation, schools should find out the corresponding improvement methods from the "affinity" and "creativity" and other poor indicators so as to enhance the effectiveness of the "music education reform plan."

People also need to compare this method with the expert evaluation method to analyze the role of this method in the evaluation of music education reform projects to better test the evaluation performance of this method [16]. The model in this paper is compared with the linear analysis model and the hierarchical analysis model, and the comparison results are shown in Figure 4.2. As can be seen from the experimental results in Figure 4.2, this model uses a big data-driven model to evaluate the effectiveness of teaching reform programs, and the relative deviation of its evaluation is much smaller than that of other models. The relative deviation of the teaching reform programs assessed by this model was within 0.2% at all levels, while the other two models were above 0.3%. Because the implementation of music education reform programs is a very complex issue, the evaluation results of different models vary greatly. Compared with the traditional expert evaluation method, the difference between the proposed algorithm and the traditional expert evaluation method is not significant [17]. Therefore, this method can replace the expert evaluation method to evaluate the effect of music education reform project so as to achieve the purpose of saving manpower and improving the evaluation efficiency.

This model is used to evaluate the time required for indices at each level of a music education reform

Table 4.1: *Results of model evaluation in this paper.*

program and is compared with linear and hierarchical models. The results of the comparison are shown in Figure 4.3. From the experimental data in Figure 4.3, it is found that both the evaluation efficiency and the time required for the evaluation of the teaching reform plan in this paper are within 200 milliseconds. It can be seen from the test data in Figure 4.2 that the method can guarantee real-time performance on the premise of ensuring the accuracy of the algorithm [18]. The results show that the algorithm is effective. This method has good evaluation ability and can be used to evaluate the reform plan of music teaching.

Among them, this study designed the opinion answer module to remove meaningless content such as ”none” and ”no” and conducted statistics on opinions and strategies through network word frequency statistics to obtain the keywords with the highest frequency (Figure 4.4). From the results of the experiment, it can be seen that interaction and interest are the most essential words and appear most frequently, which indicates that college students pay more attention to lively and exciting music education [19]. When conducting music education, people should pay attention to improving the vividness and interest of life. This can improve the

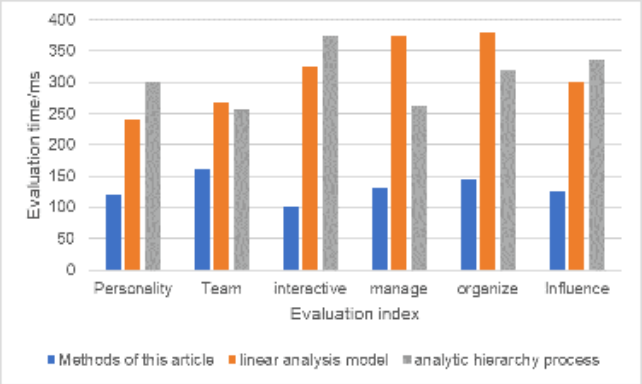

Fig. 4.3: *Comparison of evaluation time of different models.*

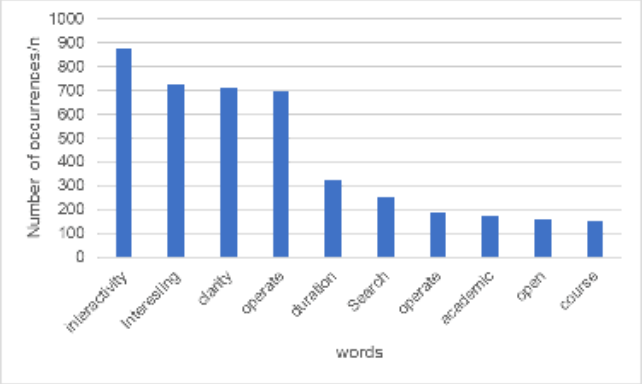

Fig. 4.4: *Keyword frequency results.*

effectiveness of the music reform in terms of educational content and evaluation and make the music reform curriculum livelier. In this way, the self-learning ability of college students has been improved.

5. Conclusion. This paper evaluates and empirically studies the implementation of a music teaching reform plan based on "big data". The evaluation model driven by big data has the characteristics of high accuracy and wide application. It has more potential in evaluating problems. Scholars can improve the evaluation effect by selecting appropriate loss functions and core functions. This model is used to determine some problems in the implementation of the music education reform plan. The teaching department can improve the effect of teaching reform by improving the comprehensive teaching ability, improving the traditional teaching idea and enriching the teaching mode.

INFORMATION TECHNOLOGY SUPPORT FOR ATHLETE HEALTH MONITORING AND MEDICAL DIAGNOSIS

JING SU*

Abstract. The paper uses WSN to monitor athletes' medical diagnosis information remotely. The aim is to strengthen the monitoring and management of athletes' medical diagnosis data. The method of wireless sensor node and IPv6 routing based on IPv6 is proposed. The terminal-to-terminal network structure based on IP can carry long-distance transmission and share athlete medical diagnosis information. The monitoring system's bottom structure design is realized using Contiki technology. At the same time, it also realizes the data acquisition and management in the monitoring system. The component interface is designed based on TinyOS. The design of the wireless client based on GPSR is completed based on GPSR. This paper uses the VanetMobiSim platform to complete a remote monitoring system's software development and simulation test based on wireless medical diagnosis information. The results show that this system's medical diagnosis information covers a wide range, and the information search efficiency is high.

Key words: Athletes' health monitoring; Medical diagnostic information; Remote viewing monitoring; WSN; IPv6 routing

1. Introduction. With the rapid development of information technology, computer-intelligent information management has been used increasingly. Resource information can be integrated and shared by a computer information management system. For example, the logistics information management system, the goods import and export information management system, and the library information management system are all based on the three-layer information management model [1]. This can then be divided into a data layer, a business layer, and an application layer. They achieve the purpose of information retrieval, resource allocation and database management by establishing a knowledge base and information analysis model [2]. In constructing an intelligent health management system, medical diagnostic information management is a crucial step. With the rapid development of the Internet and information technology, establishing a set of disease monitoring and management systems is of great significance to assist medical staff and patients in managing and tracking disease information. This paper presents a remote health diagnosis information monitoring system based on a wireless sensor network [3]. Firstly, the whole system is designed in this paper. A modular software platform monitors medical diagnosis information remotely and wirelessly.

2. System function structure analysis. A remote monitoring scheme based on wireless health diagnosis information is proposed. The remote health monitoring system based on WSN adopts a three-layer architecture model [4]. The three layers are the application, business, and data layers. They are using RFID tags and other methods to collect medical diagnosis information and establish the corresponding database and medical diagnosis knowledge rules. A network architecture based on a self-organizing and open network structure is proposed to monitor medical diagnostic information [5]. Figure 2.1 shows the three-layer module system of the remote monitoring system of medical diagnostic information (the picture is quoted in A Taxonomy on Smart Healthcare Technologies: Security Framework, Case Study, and Future Directions).

Practical analysis and mining of medical diagnostic information based on data and association rule mining is proposed [6]. The analysis and classification of medical diagnostic information are integrated with modeling analysis. The simulation engine is used to complete the logical control of medical diagnosis and processing of medical diagnosis events. A medical diagnosis information collection and analysis model based on Vannet MobiSim was established. The VanetMobiSim information processing system generates trace documents and establishes the related rule base. In this way, the organization and monitoring of medical diagnostic information

*Anhui Sports Vocational and Technical College, AnHui, HeFei, 230051, China (sojing88@sina.com)

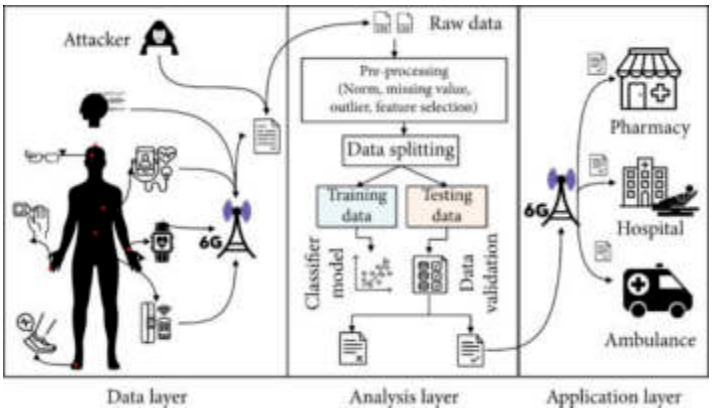

Fig. 2.1: *Three-layer module of medical diagnostic information remote monitoring system.*

are realized, and the logic control and engine analysis of medical diagnostic information are also realized. Keyword commands and events realize the control and output of the component interface.

3. Communication scheme of a long-distance monitoring system based on the Internet. This project intends to establish a communication model of telemedicine diagnosis information for remote monitoring to monitor telemedicine diagnosis information remotely [7]. The communication architecture is constructed utilizing a wireless communication network so that data collection, remote communication and wireless information transmission can be carried out on the system. The network communication module of the monitoring system is designed according to the following three aspects:

3.1. Design of IPv6 Sensor Node. The data acquisition module of the wireless health diagnosis information remote monitoring system based on the network was built by the Contiki network platform, and the task generation of the learning system was completed. Then, the available resources are generated based on the ipv6-aware node function [8]. The pendulum is used to drive the medical diagnosis information of the data storage component to complete long-distance data communication and transmission. Build a 6LoWPAN wireless communication network terminal system with a built-in 6LoWPAN protocol stack. In this way, the corresponding operational units (CEs) and the collection and transmission of medical diagnostic information are completed.

3.2. Configuring WSN Addresses on an IPv6 Network. Select the AOSID 1709 series card reader as the RF communication component and RF antenna [9]. This paper presents a wireless health diagnosis information remote monitoring system based on IPv4/IPv6 protocol. The medical diagnostic information is divided by a hierarchical grid architecture. With Atmel1284P as the main control chip, IPv6 network address distribution is realized. This command is used to copy the data set of the IPv6 sensor gateway. The IPv6 network resource information service terminal for medical terminals is developed and used by medical terminals.

3.3. Operation of the driver in the network communication module. Due to the information capacity carried by the monitoring system and the need for real-time performance, a variety of communication technologies can be used. Among them, the connection between various monitoring devices and computer backbone networks is mainly wireless transmission [10]. The architecture consists of various sensory devices that collect medical information (Figure 3.1). This paper focuses on a critical link in the monitoring system as a communication link- Communication structure between terminals and networks. The gateway and RF components are built based on data packets to ensure the interconnection between the awareness network and the Internet. Through access to the IPv6 sensing gateway, the communication module is established for data mining. In this way, the whole process of the IPv6 awareness gateway is implemented. S3C2440 is the control center of the system. Use the kernel of routing Linux to manage the address space [11]. The driver software of the network communication module is carried out on an embedded Linux kernel. It is completed by three

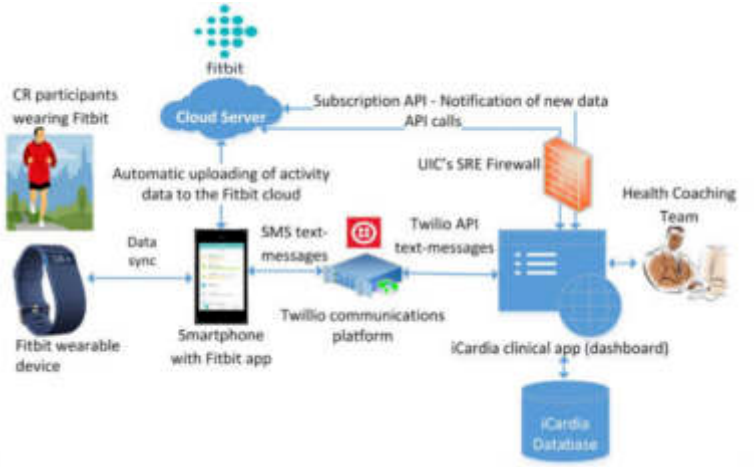

Fig. 3.1: *Communication architecture diagram of physical health monitoring system.*

modules: database access, network, and communication. At the same time, a wireless sensing network is established. The IP-based terminal-to-terminal network structure allows medical diagnosis information to be transmitted and shared at a distance. The development of the monitoring system's middleware and monitoring program is realized using Contiki technology.

4. Develop and design the software platform. The component interface is designed based on TinyOS. A project management system for wireless health diagnosis information is written using Busy box. Communicate with PC via RS232 before programming. Set the interrupt bit control module and root file system [12]. It is connected to 10 M/100 M Ethernet via a gateway. This paper builds a bus transmission control line based on ARM920T. Send data to RS485 and IPv6 using the VME bus or local bus. Use the aggregation mechanism built in TinyOS2.x to collect information.

4.1. Resource Retailing Module. The resource acquisition module is an essential basis for realizing the whole architecture of the telemedicine diagnostic information monitoring system. Select the reader of AOSID 1709 to partition its resource structure, set its initial state Flag=0, and then reconfigure the 6 LoWPAN adapter through the IPv6 awareness gateway. The short address function of 6 LoWPAN is used to query the location of diagnostic information. The diagnostic information is integrated with the IEEE 802.15.4 protocol in IEEE 802.15.4. The 6 LoWPAN adaptation layer instructions identify the required medical diagnostic information. The GUI view management tool is used to customize the label identification and block calculation, and the required treatment information is transmitted to the business side, and the work log is stored. Finally, use it as a kind of buffer copy.

4.2. Data processing module. A new type of sensor network is designed utilizing extensive data analysis and intelligent control—issue instructions to the appropriate I/O pins during event monitoring. The log-saving work based on the monitoring application unit is constructed, and the consistency management is carried out with the high-level components [13]. The event collection, application labeling, WSNs-based prediction document processing and MVB bus-based medical diagnosis information are graded and labeled. Call the message restorer on TinyOS2.x to capture events generated by the application. The Task Basic interface is used to construct a communication, protocol, core, and resource library. At the same time, the module can load and restore the events of medical diagnosis monitoring.

4.3. Human-computer interaction module. User-to-user communication is a health monitoring system based on the wireless network. The project builds IoT addresses for 5 LoWPAN. Run Next Task (TRUE) is used for more abstract data processing. The monitoring data of diagnosis and treatment information is

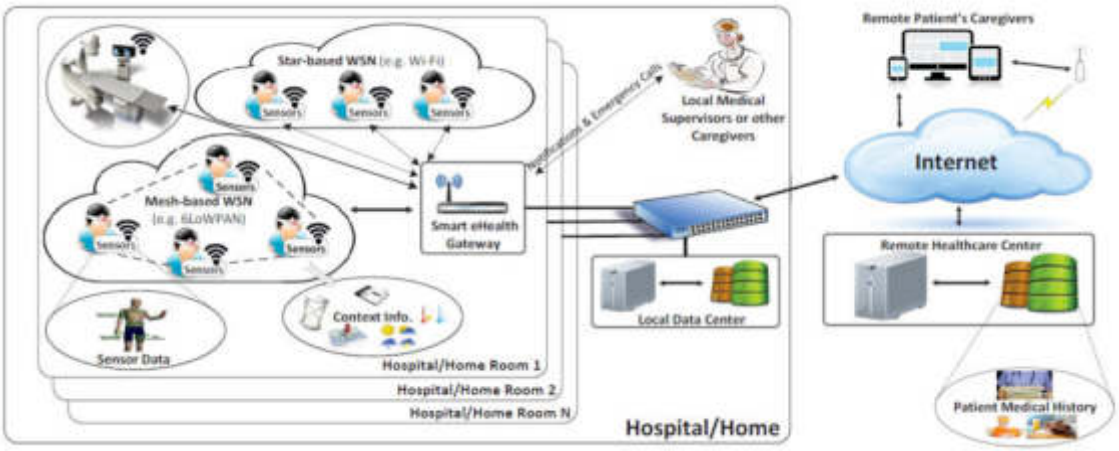

Fig. 4.1: *Map of the distribution of health monitoring centers in each region.*

collected through the Internet/enterprise Intranet, wireless sensor network, etc. TinyOS is used to design a component interface, and medical diagnosis information is shared through the database and Web server.

4.4. Information Management and Security Unit. The information management architecture is shown in Figure 4.1. This area includes a decentralized health monitoring center. Each user is connected to a health monitoring center with a family database, and their permanent electronic records are stored in the center's household database [14]. And will have the relevant home healthcare institutions carry out regular updates. If the user is within the purview of the local health supervisory authority, medical data is transferred to the center. Therefore, the medical professionals of the Home Health Monitoring Centre will liaise with the users' home medicine service agencies and cooperate.

5. Improved time synchronization algorithm. In wireless Physiology Sensor Networks (WBSN), many biosensors are placed on the body's surface in a wearable manner. It has the characteristics of small size, lightweight and limited carrying energy, so it is necessary to reduce energy consumption as much as possible [15]. At the same time, because the physiological sensor network is mainly applied to the acquisition of physiological signals of the human body, it puts forward higher requirements for the timing accuracy of data, which makes the timing synchronization of WBSN have high accuracy and high-power consumption. A real-time data processing method based on a neural network is studied aiming at the deficiency of monitoring human physiological condition. Firstly, the advantages of TPSN and RBS are combined to make full use of the broadcast characteristics of wireless communication. Each node in the two networks can synchronize the network by monitoring the packet exchange between the two networks.

In Figure 5.1, node Q_a sends a sync request information packet to node Q_b at time T_a. This data packet can be monitored by node Q' at time T'_b. Similarly, the packet of reply messages transmitted by node Q_b at time T_c can also be monitored at time T'_d. For node $Q', \Delta Q_b Q'$ is the time deviation from node Q_b to node Q', and the transmission delay between node Q_b and node Q' is s'. So:

$$\Delta Q_b Q' = \left(2T'_b + T_c + T_d - 2T'_d - T_a - T_b\right)/4$$
$$s' = \left(2T'_b + 2T'_d + T_d - T_a - T_b - 3T_c\right)/4$$

As far as Q' is concerned, its clock can be synchronized with node Q_b after finding $\Delta Q_b Q'$ and s'. This reduces the number of synchronous packet switches. In particular, this method only needs to send one synchronization, and all nodes are in the single-hop interval.

The model is further modified by using the least square method. This project presents a new wireless sensor system suitable for the biomedical field. Because of the different clock frequencies of each node, a method of

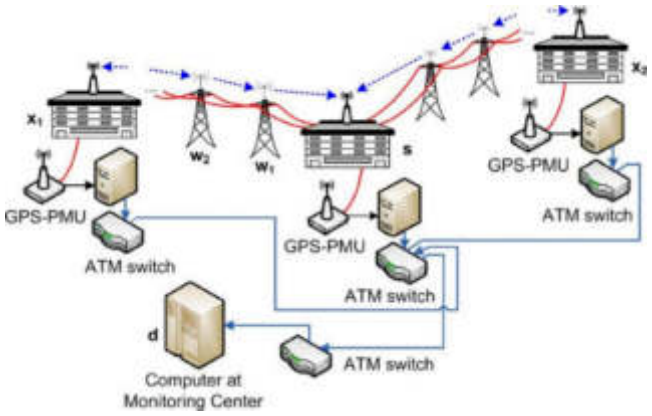

Fig. 5.1: *Packet exchange between three nodes.*

timing drift and timing drift is proposed [16]. At point Q_b, the transmission delay is s, the time difference between Q_a and Q_b is $\Delta Q_a Q_b$, if T_b is used to represent the real receiving time, then the corresponding time at Q_b is t, then

$$t = \left(T_a + T_b + T_d - T_c\right)/2$$

Establish mathematical model:

$$T_b = \gamma t + \Delta Q_a Q_b$$

γ means the passage of time. The synchronization is now complete at time i,

$$T_{ib} = \gamma\left(T_{ia} + T_{ib} + T_{id} - T_{ic}\right)/2 + \Delta Q_a Q_b$$

Let $v_i = \gamma u_i + \Delta Q_a Q_b$, then the estimates of γ and $\Delta Q_a Q_b$ (that is, $\hat{\gamma}$ and $\Delta\hat{Q}_a Q_b\Big)$ are obtained by the least squares method, $\hat{v}_i = \hat{\gamma} u_i + [\Delta\dot{q}_a q_b]$. Then the sum of squares of the deviation and error between the estimated and actual values is:

$$\zeta_i = v_i - \hat{v}_i = v_i - \hat{\gamma} u_i - \Delta\dot{q}_a q_b$$

$$W = \sum_{i=1}^{n} \zeta_i^b = \sum_{i=1}^{n} \left[v_i - \hat{\gamma} u_i - \Delta\dot{q}_a q_b\right]^2$$

W can be used to quantitatively characterize the relationship between v_i and each discrete point. When the W value is low, the curve-fitting effect is better. From these vertices:

$$\frac{\partial W}{\partial \Delta\hat{Q}_a Q_b} = -2\sum_{i=1}^{n}\left[v_i - \hat{\gamma} u_i - \Delta\dot{q}_a q_b\right] = 0$$

$$\frac{\partial W}{\partial \hat{\gamma}} = -2\sum_{i=1}^{n}\left[v_i - \hat{\gamma} u_i - \Delta\dot{q}_a q_b\right] u_i = 0$$

$$\gamma = \hat{\gamma} = \frac{\sum_{i=1}^{n}\left(u_i - \bar{u}\right)\left(v_i - \bar{v}\right)}{\sum_{i=1}^{n}\left(u_i - \bar{u}\right)^2}$$

$$\Delta Q_a Q_b = \Delta\dot{Q}_a Q_b = \bar{v} - \gamma\bar{u}$$

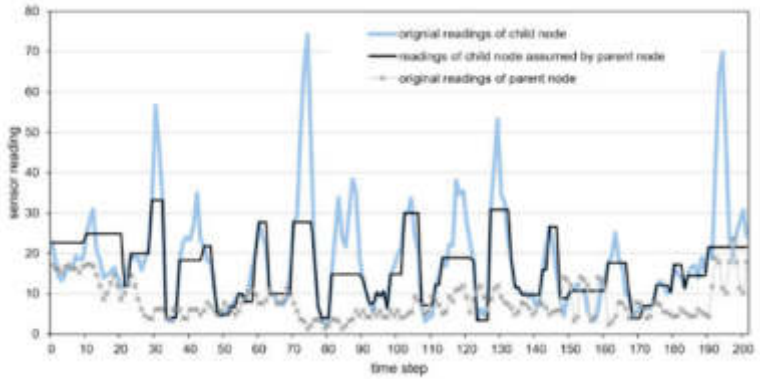

Fig. 6.1: *Wireless data transmission test results.*

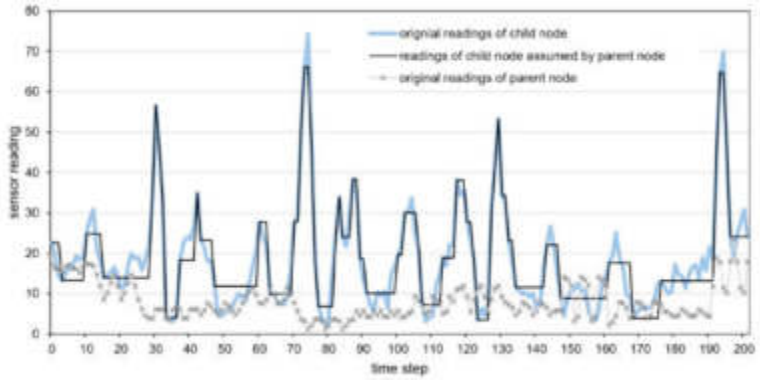

Fig. 6.2: *Medical diagnostic information transmission accuracy test.*

Q_b can modify its own local time according to γ and $\Delta Q_a Q_b$, thus achieving synchronization. Similarly, in terms of node Q', that is, the time shift of node Q_b (that is, γ' and $\Delta Q_b Q'$),

$$\gamma' = \hat{\gamma}' = \frac{\sum_{i=1}^{n} \left(U_i - \bar{U}\right)\left(V_i - \bar{V}\right)}{\sum_{i=1}^{n} \left(U_i - \bar{U}\right)^2}$$
$$\Delta Q_b Q' = \Delta \hat{Q}_b Q' = \bar{V} - \gamma' \bar{U}$$

According to the result of the operation, the local time is corrected to make it consistent with the time of node Q_b.

6. Experimental test analysis. This project takes the wireless user terminal based on GPSR as the research object. With Vannet MobiSim as the platform, the software development and simulation test of wireless health diagnosis information remote monitoring system based on GPSR is carried out. The precise scheduling function of real-time monitoring of remote health diagnosis information based on GPSR is studied [17]. Through the analysis and testing of the experimental data, it is found that the monitoring system can achieve good network connectivity. It reduces the error rate of medical diagnostic information and realizes the monitoring of remote information.

7. Conclusion. This paper studies a new medical diagnosis information remote monitoring system based on WSN. Experiments show the system can realize good remote wireless communication function and accurately transmit medical diagnosis data. The system can also query and retrieve effectively.

AUTOMOBILE INTELLIGENT VEHICLE-MACHINE AND HUMAN-COMPUTER INTERACTION SYSTEM BASED ON BIG DATA

QUANYU WANG*AND YAO ZHANG†

Abstract. This paper measures the accelerator, brake pedal, clutch, transmission device and steering wheel under different driving conditions in real-time and accurately on the simulation experiment platform. The goal is to conduct human-machine-road system interaction in a virtual simulation of human-vehicle-road systems. Fitting test data establishes the mathematical model of traffic control parameters. In terms of hardware, the distributed architecture of upper and lower computers is utilized. The system communicates point-to-point with the host computer through the RS-232 serial port. The system adopts multi-thread technology and serial communication technology. The simulation system of driving operation is designed with the visual central controller. The system takes 89S52 as the core. The slave program is written in C language. Then, the system establishes a multi-target coordinated obstacle avoidance method based on a multi-sensor information vehicle cooperation collision avoidance method. The multi-vehicle cooperation obstacle avoidance problem is transformed into an optimal control problem under multiple constraints. Simulation analysis shows that the velocity and displacement obtained by the multi-robot collaborative collision avoidance method are in good agreement with the measured values. Compared with the time series algorithm, the output accuracy of the proposed collaborative collision avoidance algorithm is significantly reduced, and the changes in velocity and displacement in the time domain are more stable.

Key words: Virtual simulation; Man-car-road; Data acquisition; Smart car; Human-computer interaction; Vehicle collaborative collision avoidance control algorithm; Serial communication

1. Introduction. Human-vehicle-road virtual simulation is a comprehensive technology used in safety assessment and design optimization of highway alignment and traffic engineering facilities. This method constructs 3D modeling of roads, facilities and other virtual simulation experiments with high immersion. It transforms digital data into a visual simulation process that can change over time and space [1]. Various quantitative indicators can be obtained to scientifically evaluate the use effect and safety of roads to provide scientific reference for road design using human-vehicle-road virtual simulation technology [2]. Intersection is a common and complicated driving condition, which is restricted by many factors such as driving mode, vehicle type, traffic rules, etc. By building mathematical models, machine analysis enables researchers to understand the connections between their inputs and outputs more directly. However, due to its inability to cover a variety of factors, its prediction accuracy is not high. Under high speed and low adhesion road surface conditions, steering obstacle avoidance is better than braking obstacle avoidance. In the human-vehicle-road virtual simulation, the simulation device is required to complete the real-time control of the vehicle in the virtual environment [3]. Therefore, it is an essential technology for obtaining data on driving control signals in the virtual simulation of a human-vehicle road. At the same time, this paper studies the dynamic optimization method of vehicle cooperative lane change obstacle avoidance based on "mechanism + data."

2. Hardware development of driving data acquisition system.

2.1. System hardware design.

The virtual simulation of a human-vehicle road uses the driver's console as the input device. The experiment was performed on a three-channel cylindrical projection display. In terms of hardware, it adopts the distributed serial port of the upper computer and the lower computer [4]. Point-to-point communication is adopted. The PC uses an 89S52 microcontroller. The visual master computer is used as hardware. An embedded system is adopted. The architecture of the system is described in Figure 2.1. The system layout of the lower computer is shown in Figure 2.2. For the communication part of the slave machine,

MAX202 from the German Maxim company was selected. In this way, the TTL level is converted to RS-232. This paper introduces an intelligent measurement system based on 89S52 microcontroller [5]. It has 8KB of flash memory and does not require memory expansion. The device uses 32 KB RAM as a data storage area and is also used for signal acquisition.

The angle of the steering wheel and the displacement of the accelerator pedal, brake pedal, and clutch pedal are measured by a high-precision potentiometer on a simulated driving test platform [6]. The excitation voltage of the sensor in the system is 10 V, provided by an analog signal regulation circuit. The transducer's output signal is amplified, transformed and converted into a reference voltage of 0-10 V. Then it is sent to the analog-to-digital converter to complete the A/D conversion. The shift lever only changes suddenly at a particular moment during the shift and is constant most of the time. Six switches on the shift lever indicate the condition of the 1, 2, 3, 4, 5 and R gears, respectively. It is driven and adjusted by the photoelectric separation's switching input signal regulation module.

2.2. Software Design.

2.2.1. Communication Protocol. It is necessary to communicate reasonably to ensure reliable communication between the upper and lower computers [7]. The definition of communication mode is shown in Table 2.1. A formal description of the command framework is given in Table 2.2. The format description of the data frame is given in Table 2.3. A formal description of the data areas is listed in Table 2.4.

Table 2.1: *Definition of communication modes.*

Steering Angle	2	First low, then high
Gear position	1	First low, then high
Checksum	1	The remaining bytes without synchronized characters have a cumulative sum of 256 modules

2.2.2. Communication with the Lower Computer. The lower computer communicates with the PC through the RS-232 interface. 89S52 built-in UART interface to achieve serial communication; the TXD needle is used to transmit data; The RXD needle is used to receive data. Since TXD and RXD pin adopt TTL level, RS-232 communication cannot be carried out, so the system chooses Maxim MAX232 to realize the switchover between the TTL level and the RS-232 level. This paper introduces an intelligent measurement system based on C language, which uses an interrupt service module to realize data sending and receiving in serial communication [8]. The flow chart of the main control program of the control system based on a single-chip microcomputer is shown in Figure 2.3. The implementation method of the serial interrupt service subroutine is shown in Figure 2.4.

2.3. Communication of the upper computer. PC communication software is based on VisualC++6.0 under Windows, and visual simulation is based on VegaAPI to call the rendering thread to complete. The PC's communication software is written using Windows API programming language. The communication requests received by the computer are usually asynchronous [9]. After receiving the serial communication

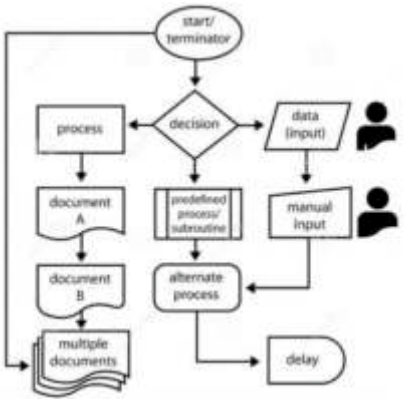

Fig. 2.3: . *Flow chart of the main control program of the lower computer.*

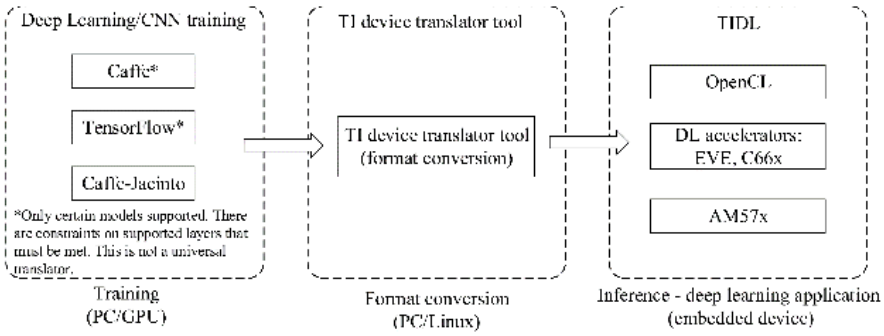

Fig. 2.4: *Flow chart of the traversing terminal service subroutine.*

request, the system only interacts with the communication buffer and does not generate the corresponding information to inform the user of the processing. When the user process needs to check its communication status periodically and actively access its communication buffer. Otherwise, requests for serial communication cannot be responded to quickly, resulting in a communication error that overflows the buffer. In addition, if an error occurs in the communication and is not detected, it will lead to a long pause in the communication process. The multithreading method is adopted in the design of the communication module to overcome the above problems and ensure the real-time performance of the system [10]. It realizes the readout of serial information through periodic queries. When the second layer communication thread detects a communication request, it sends a customized message to call the corresponding message processing function to read the traffic operation data. The serial communication between host computers is realized using multi-thread technology, and the concrete realization method is given. The serial communication flow of the host computer based on multithreading is shown in Figure 2.5.

3. The social force model of cars in emergencies.

3.1. Self-drive. Self-driving force G_a refers to a kind of social force automatically generated by subject a to achieve the desired purpose of driving in the emergency stage. Formula (3.1) is established:

$$G_a = \frac{M_a \left[\delta_a(t) - v_a(t)\right]}{\Delta t_a}$$

$v_a(t)$ is the speed and direction of the primary vehicle a in km/h.Δt_a is the adjustment time of the primary vehicle a in seconds. M_a is the equivalent weight of the primary vehicle a in kg.$\delta_a(t)$ is the expected speed

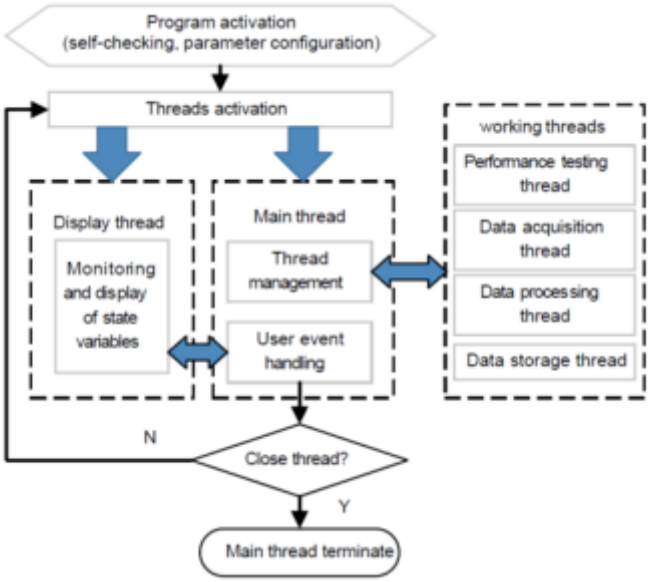

Fig. 2.5: *Flow chart of host computer serial communication based on multithreading.*

correction function (unit km/h) reflecting the environmental factors of driving behavior such as herd psychology and driving intention.

3.1.1. Expected speed correction function. When the leading car a realizes the driving goal, it will often adopt the driving mode conducive to its goal, but it will also be affected by the driving route of the surrounding vehicles [11]. It presents a kind of herd mentality. Therefore, the expected speed correction equation (3.2) is constructed to describe the driving goal and group mentality of car owner A:

$$\delta_a(t) = \lambda_a v_m(t) \left[\gamma_a \frac{v_{a+1}(t)}{|v_{a+1}(t)|}\right] \{\zeta_1, \zeta_2; \zeta_3\}$$

where λ_a is the correction of the leading car a. The positive factor of the school is affected by the surrounding traffic conditions. $v_m(t)$ is the current highway speed limit in km/h. $v_{a+1}(t)$ is the speed and amplitude of the vehicle in front at time t in km/h.γ_a is the conformity factor of vehicle a, which reflects the steering behavior of the vehicle [12]. Where ζ_1 is the unit vector used when turning left $(1/\sqrt{2}, 1/\sqrt{2})$ to reverse the cutting phase, and ζ_2 is the unit vector used when turning right to reverse the cutting phase $(1/\sqrt{2}, -1/\sqrt{2})$.$\zeta_3$ is a unit vector with a direction of $(1, 0)$ when turning to cut.

3.1.2. Equivalent mass. However, due to the driver's driving habits, methods, and other factors. Even in the same situation, drivers with different driving styles and habits will show different driving behaviors [13]. The power emitted in the same type of car will also significantly differ. Therefore, "equivalent mass" describes the driver and vehicle type based on a comprehensive driving style analysis for vehicle performance differences and other factors. Its expression is shown in formula (3.3):

$$M_a = M_a\left(m_a, C_a, S_a\right) = \frac{m_a\left(1 + S_a\right)}{C_a}$$

m_a is the weight of the primary vehicle a in kilograms. C_a is the type of the primary vehicle a, which is derived according to the type of vehicle. S_a is the driver type of the primary vehicle a based on the driving mode.

3.2. Repulsive forces between cars. When the vehicle a drives to the emergency section, in order to prevent conflict, the vehicle a coordinates with the rear vehicles in the same lane and the front and rear vehicles

in the target lane. The repulsive force is used to characterize the process of vehicle-vehicle collaboration [14]. It is divided into repulsive force $G_{a-1\to a}$ between a and the exact route vehicle | and repulsive force $G_{j\to a}$ between a and the destination line vehicle.

3.2.1. Original repulsive force. When there is an emergency in front of the primary vehicle a to prevent A secondary traffic accident, the car behind the same line will exert a repulsive force on the primary vehicle a. The formula is as follows (3.4):

$$G_{a-1\to a} = \begin{cases} \varphi_a \exp\left(\frac{\eta_a}{|f_{a-1,a}|}\right) \frac{f_{a-1,a}}{|f_{a-1,a}|}, |f_{a-1,a}| \le \eta_a \\ 0, |f_{a-1,a}| > \eta_a \end{cases}$$

φ_a is measured in N. It is the repulsive force of the leading car a when it is driving in the same road. η_a, in m, is the influence range of the repulsive force generated by the cars behind in the same lane on the central station a.$f_{a-1,a}$ is the vector between the car $a-1$ on the same line and the leading car a. It is measured in m, and its size is the distance between the middle points of two cars.

3.2.2. Road repulsion force. In the event of an emergency at the front, when the master station a is forced to change lanes, both the vehicles in front of and behind it in the target lane will exert A repulsive force on the master Station car a. The equation (3.5) is as follows:

$$G_{j\to a} = \begin{cases} \sigma_a \exp\left(\frac{\phi_a}{|f_{j,a}|}\right) \frac{f_{j,a}}{|f_{j,a}|}, |f_{j,a}| \le \phi_a \\ 0, |f_{j,a}| > \phi_a \end{cases}$$

| σ_a is measured in N. It is the repulsive force exerted by the primary car a on the front and behind cars in the target lane. ϕ_a in m, the leading car a is affected by the repulsive force of the car in the target lane. $f_{j,a}$ is the vector between the vehicle j and the primary vehicle a. It is measured in m and its size is the distance between two vehicles.

3.3. Repulsive force of vehicles in the emergency area. The primary vehicle a traveling in that position is subjected to the rejection of a sudden obstacle P to prevent a collision with a space object in an emergency. The equation (3.6) is as follows:

$$G_{P\to a} = \begin{cases} \omega_a \exp\left(\frac{\pi_a}{|f_{P,a}|}\right) \frac{f_{P,a}}{|f_{P,a}|}, |f_{P,a}| \le \pi_a \\ 0, |f_{P,a}| > \pi_a \end{cases}$$

ω_a is the repulsive force of a sudden obstacle P concerning the primary vehicle a. It's denoted by N. π_a is m for the area affected by the repulsive force of a burst barrier P.$f_{P,a}$ is a vector from the sudden occurrence of an obstacle P to the primary vehicle a, the size of which is the distance between the middle points of two vehicles in m.

3.4. The prescribed force of road alignment on motor vehicles. The car should maintain a distance from the surrounding rail when it is traveling to prevent deviation from the driving route [15]. As cars get closer, the tracks become more and more restrictive.

$$G_{M\to a} = Z_M \left|\frac{R}{2} - y_a\right| g$$

Z_M is the law force correction factor. R is the width of the lane in m.y_a is the distance from the center of the primary vehicle a to the lane represented by m. Where g is the buoyant force of the lane, the tangential turn to the left is $(0,-1)$, and the turn to the right is tangential $(0,1)$.

4. Performance verification. (1) The output of the multi-vehicle collaborative obstacle avoidance control algorithm is consistent with the actual measured value, and the multi-vehicle collaborative obstacle avoidance control algorithm can ensure that the vehicle can effectively avoid the obstacles that suddenly appear in front of it when it is driving. (2) The short-time memory method prediction results are close to the observed

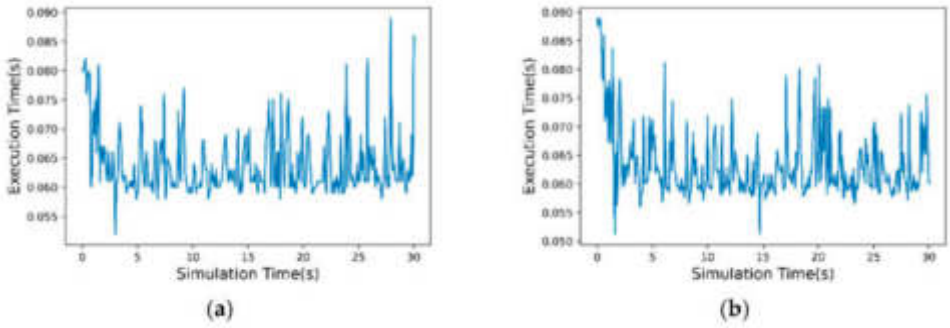

Fig. 4.1: *Performance of vehicle cooperative obstacle avoidance control strategy and lane-changing prediction model based on extended short-term memory algorithm in lane changing.*

Table 4.1: *Quantitative evaluation of vehicle cooperative obstacle avoidance control strategy and lane change prediction model based on extended short-term memory algorithm.*

Index		MSE	RMSE	MAE	RMSPE
Vehicle cooperative obstacle avoidance control	Longitudinal displacement	0.195	0.450	0.322	0.007
	Lateral displacement	0.053	0.235	0.060	0.004
	Longitudinal velocity	0.021	0.146	0.074	0.043
	Lateral velocity	0.005	0.077	0.033	0.141
Long short-term memory algorithm	Longitudinal displacement	25.106	5.114	3.466	0.086
	Lateral displacement	0.030	0.177	0.115	0.003
	Longitudinal velocity	9.530	3.151	2.053	0.916
	Lateral velocity	0.500	0.722	0.360	1.328

values. However, the short-time memory method's prediction model is still slow when encountering sudden accidents and cannot avoid sudden obstacles [16]. It can not effectively decide on vehicle direction changes during traffic accidents. This project intends to evaluate this method from four aspects quantitatively to verify the effectiveness of this method compared with the long-term memory path planning method: mean square error, root mean square error, mean absolute error, mean absolute error and mean absolute error [17]. It can be seen from the table that the calculation accuracy of the vehicle collaborative collision avoidance method is much lower than the actual measurement value, which indicates the superiority of the method.

5. Conclusion. A human-computer interaction system for in-loop simulation of man-vehicle-road systems is established using single-chip microcomputer technology and computer serial communication technology. The system uses a distributed up-and-down machine architecture, and the up-and-down devices communicate point-to-point through an RS-232 serial port. This project proposes a rapid direction change and collision avoidance method based on lane change technology. It is found that this method can better reflect the interaction between the car and the surrounding vehicles. Compared with the route planning method based solely on short and long-term memory, this project focuses on the traffic congestion caused by uncertain factors such as traffic accidents in the traffic environment. It enables driverless cars to change lanes and evade autonomously. This method uses multi-thread and multi-level query modes. The design ideas adopted are also relevant to other human-computer interactive environments.

THE GARDEN VEGETATION COVERAGE MONITORING AND SPATIAL ANALYSIS MODEL BASED ON REMOTE SENSING TECHNOLOGY

YINGYING TAN* AND JIANG CHANG†

Abstract. A correlation study was conducted between SPOTVEGNDVI monthly data and rainfall data in Yulin, Yan 'an, Xi 'an and Ankang of Shaanxi Province from 2015 to 2022. The ecological effects of urban vegetation cover were studied using the revised standardized Vegetation Index (NDVIC). It is found that NDVIC has a strong correlation with precipitation, and its correlation increases with the increase of altitude. Vegetation cover in the Ankang area increased significantly from 2016 to 2022. The net primary productivity index of urban green space increased significantly in October 2016-2022, which is an objective reflection of the effectiveness of urban green construction. This study can lay a theoretical foundation for the objective quantitative assessment of the ecological effects of urban vegetation cover.

Key words: Garden vegetation cover; Revised standardized vegetation index (NDVIC); Pixel binary model; Precipitation

1. Introduction. Soil erosion and desertification are the most severe ecological problems in China. This is also the main reason for the frequent occurrence of flood disasters and wind and sand disasters in recent years [1]. Vegetation is critical in soil improvement, climate control, carbon dioxide emission reduction, soil and water conservation, and conservation. Remote sensing can make rapid and large-scale ground-to-ground observations non-contact, providing vital support and accuracy guarantees for large-scale and dynamic ecological environment monitoring. Using advanced remote sensing to monitor the vegetation evolution of forest ecosystems in real-time can shorten the time of field investigation, reduce the cost and improve monitoring accuracy. At the same time, it allows researchers to carry out real-time observation in areas that are difficult to access, such as mountains, deserts and wetlands. It is more practical. Presently, domestic and foreign researchers mainly use Landsat remote sensing and MODIS remote sensing images to study the vegetation coverage of the study area [2]. There are few studies on regional plant coverage based on satellite remote sensing data of Ankang City. Most of the current research is carried out in Shaanxi province. Reference [3] uses MODIS/NDVI data combined with meteorological and DEM data to study the temporal and spatial distribution characteristics of vegetation coverage in Shaanxi Province in recent years and discusses the effects of temperature and rainfall on vegetation coverage. Literature [4] uses a pixel dichotomous model to study the ecological environment of Buxell County. Literature [5] studied the ecosystem in the source area of the Kaidu River based on the binary model of image elements. Literature [6] used satellite image data to study the vegetation cover in the North Canal Zone. In literature [7], the pixel simulation method was applied to study the urban area of Kashgar, Xinjiang. Ecological environmental protection and biodiversity protection in Ankang City are the basis for evaluating the implementation effect of ecological engineering projects and environmental protection [8]. This project plans to take Yulin, Yan 'an, Xi 'an and Ankang in Shaanxi Province as the research objects [9]. In this paper, an improved standardized Vegetation index (NDVIC) is established to study the influence of vegetation cover on urban construction.

2. Overview of the survey area. Shaanxi Province is a severe soil and water loss and desertification area in China. The area of soil and water loss has reached 66.9%, which has seriously affected the region's economic development [10]. Through ecological and environmental protection projects such as afforestation, 60% of soil erosion has been eliminated by the end of 2019. Yulin (YL), Yan 'a (YA), Xi 'an (XA) and Ankang (AK) are located in the North-South transect of Shaanxi Province, and their natural conditions and precipitation have

a good transition, which is suitable for NDVI precipitation related research, and also show an excellent spatial pattern from north to south (fig. 2.1).

3. Data and methods.

3.1. Data Sources. In this paper, remote sensing images of 1 km*1 km were obtained from 2015 to December 31, 2022, using SPOT VEGETATION satellite data [11]. There are 300 images. Its calculation method is given in equation (3.1).

$$NDVI = \frac{NIR - \mathrm{Re}\, d}{NIR + \mathrm{Re}\, d}$$

NIR represents the reflectivity of SPOT in the red-light region. Red represents the wavelength of SPOT. NDVI ranges from 0.1 to 0.7. With the increase of NDVI value, vegetation coverage increased gradually. The NDVI of the study area is the average NDVI of each pixel [12]. The NDVI for that month is the average of the previous, middle and following three months of each month. The national precipitation data from 2015 to 2022 are the precipitation data of the China Meteorological Administration from 2015 to 2022. The rainfall of each month is the sum of the daily rainfall.

3.2. Establishment of Green Plant Coverage Evaluation Index system. The linear regression model of NDVI and precipitation is given by equation (3.2).

$$NDVI_R = f(R\alpha \text{ in fall }) = \alpha R + \beta$$
$$NDVI_C = NDVI_{ob} - NDVI_R$$

$NDVI_R$ is the monthly average $NDVI$ value obtained by the multiple linear regression model in the study area. R stands for precipitation intensity. α, β is a parameter of the equation. The $NDVI_C$ index of structure (3.3) is used to reflect the influence of urban green landscape. Where $NDVI_C$ is $NDVI$ after deducting rainfall response. $NDVI_{ob}$ is the objective, standardized vegetation index on the NDVI image.

3.3. Pixel binary mode. The basic idea of "pixel dichotomy" is to divide the reflection coefficient of the pixel S into two regions: reflectance S_α of the vegetation part and S_β of the non-vegetation part, in which the

reflectance of any pixel can be expressed by reflectance S_α of vegetation part and S_β of nonvegetation part, that is:

$$S = S_\alpha + S_\beta$$

Suppose that the proportion of one plant in each pixel on the image is g_z (the vegetation coverage on the pixel), then the proportion of the two types is $1 - g_z$. The reflectance of a pixel is S_{veg} when it is completely covered by plants, and S_{soil} when it is completely uncovered by vegetation. The information S_α contributed by the vegetation portion of the mixed pixel can be expressed as an integral on one pixel [13]. It is a pure product of vegetation reflection coefficient S_{veg} and pixel G_z. The information S_β contributed by non-vegetation components can be expressed as the product of S_{soil} and $1 - G_z$

$$S_\alpha = G_z \times S_{\text{veg}}$$
$$S_\beta = (1 - G_z) \times S_{\text{soil}}$$

By solving equations (3.4), (3.5) and (3.6), the following formula for calculating vegetation coverage can be obtained:

$$G_z = (S - S_{\text{soil}}) / (S_{\text{veg}} - S_{\text{soil}})$$

3.4. Extraction of vegetation coverage. This project selects the highest annual peak value of MODIS NDVI data as the vegetation cover data. According to the pixel dichotomy theory, it is assumed that surface NDVI can be divided into two components [14]. That is, the information contributed by the green vegetation part and the information contributed by the non-vegetated part. According to the method of formula (3.7), the calculation formula of "vegetation coverage" can be expressed as:

$$G_z = (NDVI - NDVI_{\text{soil}}) / (NDVI_{veg} - NDVI_{\text{soil}})$$

$NDVI_{\text{soil}}$ indicates the value of $NDVI$ for the area where the soil is entirely bare or without plants [15]. $NDVI_{\text{veg}}$ represents pixel $NDVI$ covered by plants, which is simply pixel $NDVI$. When there is no observation data, the minimum of NDVI of a specific confidence interval is used as the best non-vegetation coverage on the image of the evaluation area. is $NDVI_{\text{veg}}$ to select the maximum NDVI value on the evaluation area image of a specific trusted range, that is, the ideal vegetation coverage area of the region. Thus, the vegetation indicator model becomes:

$$G_z = (NDV - NDVI_{\min}) / (NDVI_{\max} - NDVI_{\min})$$

Thus, the vegetation index in the mixed pixel is transformed into the surface vegetation coverage. ERDASIMAGE9.1 platform and Modeler were used to construct a quantitative conversion model of vegetation coverage. According to the spectral characteristics of pixels, vegetation coverage was statistically classified and graded according to $0\% \sim 5\%, 5\% \sim 20\%, 20\% \sim 50\%$, and $50\% \sim 100\%$.

4. Results and discussion.

4.1. Research on the correlation between vegetation index and precipitation. The correlation analysis of NDVI and precipitation in the study area in each month from 2015 to 2022 (Table 4.1) shows that precipitation has a strong lag effect on NDVI. The average of the two is the largest between the "precipitation of the month and the previous month." This is inconsistent with the correlation between the average precipitation of the previous month and the previous month, which is related to the natural conditions in the study area. Xi 'an is the primary water source in the four pilot zones [16]. The degree of correlation with the other three regions is small. And they have little correlation with precipitation (Table 4.1).

Through the linear regression of NDVI and the average data of "precipitation in the current month and the previous month," the correlation between the two is obtained in Yan 'an area [17]. It is followed by Yulin and Ankang, Xi 'an is the lowest, and there is a big difference between the fitting results and the ideal conditions that increase with the elevation. The reason is probably because the Yulin area is mainly desert, and the

Table 4.1: *Correlation between vegetation index and precipitation in Yulin, Yan 'an, Xi 'an and Ankang.*

	C	C P1	C P2	C P3
Yulin	0.619	0.771	0.767	0.668
Yan'an.	0.798	0.853	0.782	0.649
Xi 'an	0.202	0.286	0.068	-0.086
Ankang	0.535	0.569	0.477	0.310

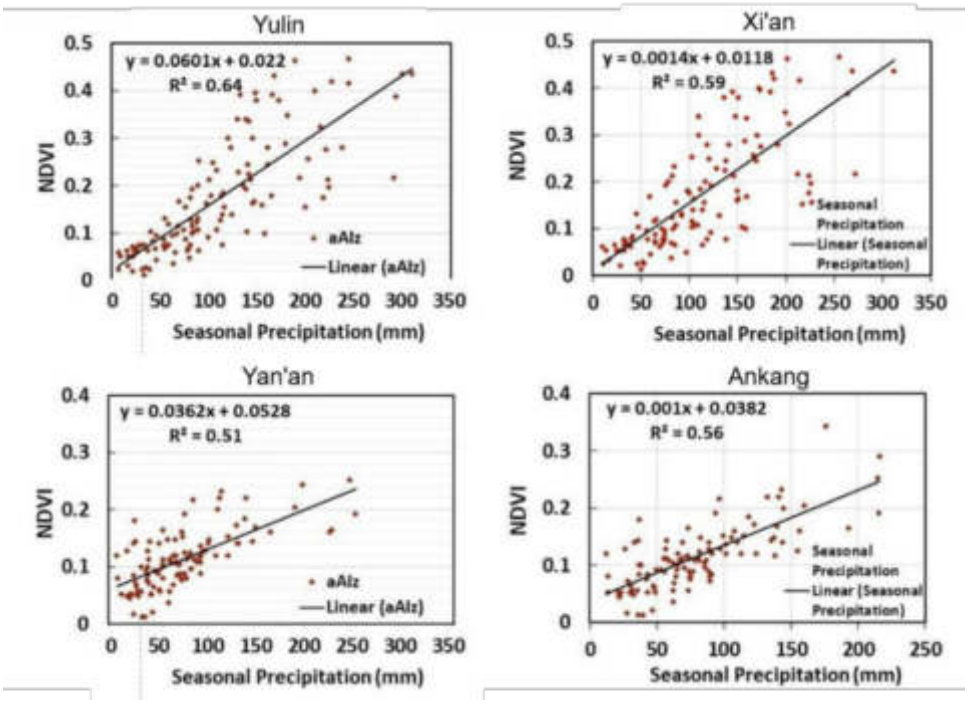

Fig. 4.1: *Linear correlation analysis of vegetation index and precipitation: Yulin, Yan 'an, Xi 'an, Ankang.*

relationship between them is weakened due to decreased vegetation coverage. The extensive irrigation area in Xi 'an reduces its sensitivity to rainfall. The average annual rainfall in Ankang is more than 800 mm. Natural precipitation has little effect on ground vegetation. Therefore, Yan 'an has become a typical area for studying the impact of green landscapes in this region (FIG. 4.1).

4.2. NDVI change analysis. The NDVI of the Ankang region from 2016 to 2022 (FIG. 4.2) showed a significant upward trend every month, and the area increased by 94.3% from July to September. In addition, the southeast and the north are the important distribution areas of grassland and dry land, while the southwest is the smallest distribution area of forest and shrubs [18]. The August NDVI growth rate reached 99.12%, with July to September the same. In October, NDVI increased significantly in all provinces and regions, but the differences among regions decreased. In the north, the increase rate was significantly lower than that from July to September, but in the west, the highest value was still located in the southeast, and in the middle, there was a band of low-value area of NDVI, indicating that the water distribution in this region was closely related to the change of irrigation area.

NDVI has increased significantly each month, which is 1.45 and 1.41 in October, August and July-September 2022 (Figure 4.3). The spatial variation trend of NDVI in October showed that the highest point of the NDVI curve from 2016 to 2022 was from high to low, and the number of patches at the highest point showed a

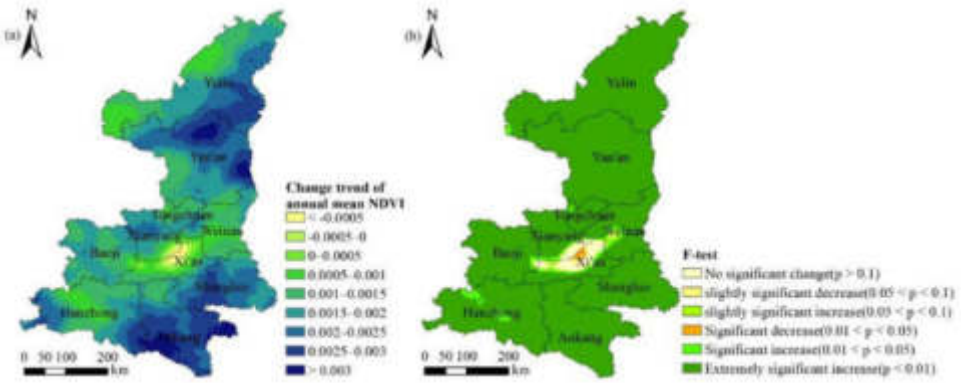

Fig. 4.2: *Spatial distribution of NDVI growth in Ankang from 2016 to 2022.*

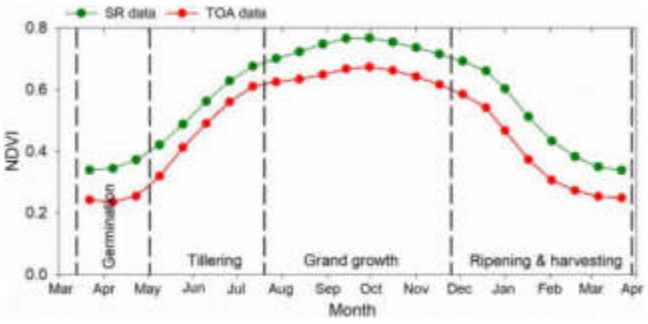

Fig. 4.3: *Quantitative distribution of NDVI changes from July to September, August and October in Ankang from 2016 to 2022.*

decreasing trend, which indicated that the coverage of surface grassland, shrub and forest land was constantly improving, and there was a decreasing trend among different regions [19]. Under the influence of natural and human factors, the vegetation coverage of agricultural land increased significantly from 2016 to 2022. However, the analysis of NDVI and corresponding precipitation data in October shows that the variation amplitude of NDVI during 2018-2022 is not uniform, especially during 2018-2022. Therefore, it is suggested that precipitation cannot explain the variation of NDVI well. In addition, different underlying surface conditions have different effects on NDVI.

4.3. Effect analysis of garden vegetation coverage. The changing trend of the vegetation index in the Ankang region from July to October 2015 to 2022 shows that human activities have an essential impact on the growth of the vegetation cover index (Figure 4.4). NDVIC increased the most in July, from 0.31 in 2015 to 0.35 in 2022, due to the greening of the region, which has increased the vegetation coverage per unit area by returning some dry fields that existed as bare soil during the cultivation period to woodland/scrub/grassland. NDVIC volatility increased in August and September but was not as large as in July. NDVIC of the forest/irrigation/grass composite system increased significantly in October, indicating that the forest/irrigation/grass composite area will increase rapidly from 2015 to 2022, which is also an objective reflection of the impact of landscape plants on the ecosystem. However, very few observational data available at present cannot show the location of new forests/grasslands in landscape greening projects. Moreover, the productivity of the farmland ecosystem is improved, which makes the NDVIC value of the farmland ecosystem continue to rise. Because of the limitations of the data, people could not identify them.

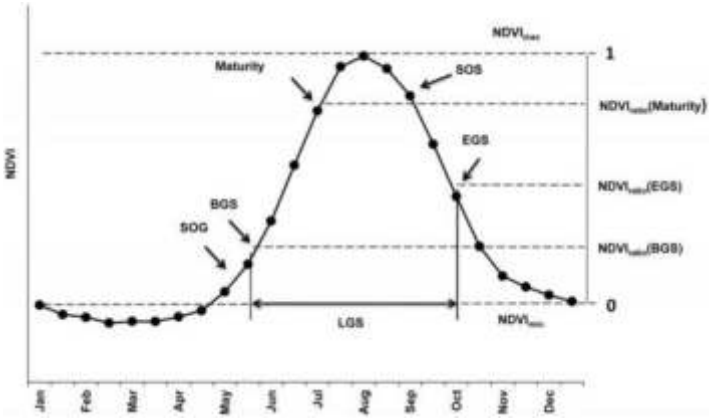

Fig. 4.4: *Changes of NDVIC value in Ankang City from 7, 8, 9, and 10 2015 to 2022.*

5. Conclusion. NDVI is an effective method to study vegetation distribution's spatial and temporal trends. The NDVI variation index excluding precipitation was established based on previous studies on the relationship between NDVI and precipitation. The paper will take Ankang as a case to evaluate the effectiveness of the project quantitatively. The results show that (1) there is a significant correlation between NDVI and precipitation, but there is a lag in the response to rainfall, in which the lag time of Yulin area, Yan 'an area, Xi 'an area and Ankang area is one month. The precipitation is the average precipitation in the current and previous months. The correlation also increases as the latitude increases from low-value to high-value regions. (2) NDVI of Ankang City showed a significant upward trend from 2016 to 2022, and the most significant trend was from 2002 to 2022, mainly in the dry land and grassland in the southeast of the city. There are natural and humanistic reasons for this phenomenon, and the humanistic reasons are caused by landscape greening and other reasons. The Ankang Greening project has achieved remarkable results, and the number of NDVICs in October 2015-2022 has significantly increased, which is reflected in this goal. (3) The specific location and scope of green land are accurately located according to the correlation between NDVI and rainfall to realize better the quantitative evaluation of the engineering effect of landscape green land based on adding meteorological observation stations.

MACHINE LEARNING-BASED HUMAN RESOURCE MANAGEMENT INFORMATION RETRIEVAL AND CLASSIFICATION ALGORITHM

WEN LI*AND XIUKAO ZHOU†

Abstract. Efficient human resource management (HRM) is essential for company achievement in today's fast-paced corporate world. Businesses must find effective ways to retrieve and categorise the ever-growing amount of HR-related knowledge. This work presents a new method for retrieving and classifying HRM data using machine learning. Modern natural language processing (NLP) and CNN methods are used by the algorithm we developed to handle unorganized human resources (HR) information, including worker records, job postings, and certificates. HR decision-making is facilitated by the system's ability to derive insightful information from the information using sophisticated text mining and machine learning algorithms.The two main parts of the method are classification and data extraction. HR workers can more easily obtain the required knowledge thanks to information retrieval, which makes it possible to search HR data quickly and accurately. Contrarily, categorisation optimises the division of human resources information into pertinent classifications, including job positions, competencies, and achievement grades. We assess our algorithm's effectiveness on various datasets from actual HR datasets. The outcomes show how well our strategy works to streamline HRM procedures, cut down on manual labour, and increase the precision of decisions. Furthermore, our technology is compatible with corporate human resources offices and educational settings because it complies with worldwide university requirements.This study belongs to the growing body of knowledge in HRM. It provides a useful tool for businesses looking to improve employee relations, simplify HR procedures, and attract and retain talent. The suggested method is a valuable resource for academics and businesses alike because of its versatility and compliance with global educational norms.

Key words: Machine learning, human resource management, information retrieval, classification algorithm.

1. Introduction. Humanity has become an invaluable resource that can do cognitive activities, regardless of harmful situations. Although in the twenty-first-century world of machines, human involvement is still necessary in many industrial processes [29]. Acknowledging the actions of others is now crucial for evaluating the accomplishments of every individual. These kinds of tasks can involve messy, prone to mistakes in human recordkeeping. Consequently, automatic identification methods have gained popularity and are now a topic of interest for the scientific community. Any unusual or suspect conduct among people will automatically set off an alarm that can be used to initiate personal intervention or self-improvement [23]. These days, automatic human activity detection is crucial to efficient and free of mistakes in institutions and manufacturing processes.

Recognition of activities and transfer learning have been examined independently in numerous research. However, only a small number of studies have examined activity recognition in transfer learning systems, and even fewer have discussed sensor-based HAR in transfer training augmented systems [31]. To the greatest extent of our ability, this is the final review paper that has been published that discusses HAR in the context of transfer learning. The same study from 2011 to 2021 is included in this publication, albeit it is mostly focused on HAR datasets and methods for categorisation [1]. The author thoroughly categorizes several HAR techniques according to their benefits and drawbacks to explore sensor-based and vision-based HAR. Similarly, the material is included in our paper, but it is in the transfer training system [24].

Human knowledge is required to carry out the extraction and selection of features in traditional machine learning algorithms. The responsibilities of picking and categorising features are distinct. Deep learning addresses the hole by employing only one step for recognition and categorisation to maximize the accuracy of the models. Whereas deep learning, machine learning demonstrates reduce the requirement for individual architectural features and dependency on outside resources because of autonomous training and the extraction of features [7, 11]. Furthermore, the main benefits of deep learning above conventional artificial intelligence

*School of Management Fuzhou Technology and Business University,Fuzhou ,Fujian,35071,China

approaches are its outstanding accuracy and end-to-end problem-solving capabilities, particularly when dealing with massive data sets like those used for recognizing speech, categorization of pictures, and phishing detection [8, 9, 2, 12].

High levels of difficulty, a mixture of constant and discontinuous procedures, interconnected and interrelated activities, and fluctuations present challenges for decision-makers in the management of supply chains (SCM), necessitating flexibility. One interesting potential answer to these problems is Reinforcement Learning (RL), an area of machine learning systems that specializes in making decisions in reverse. RL may serve as an adaptable regulator in these complex structures by figuring out how to behave in a way that maximizes the benefit as time passes [13, 33]. This kind of administrator, sometimes referred to as RL agent learns the best management behaviours for the complicated system in each possible state in order to achieve the greatest long-term systems objectives. [6, 10].

This study is driven by the pressing need to improve and modernize Human Resource Management (HRM) procedures in light of the quickly changing business environment of today. Employers are finding it more and more difficult to handle the volume of HR-related data that is always growing. This data includes but is not limited to, personnel files, job listings, and professional certifications. Even though this data is crucial for making strategic decisions, it is frequently in unstructured formats, which makes it challenging to locate, handle, and evaluate efficiently [28].

The conventional approaches to managing HR data are shown to be insufficient; they frequently involve a great deal of human labour that is laborious and error-prone. This inefficiency can make it more difficult for a business to react quickly to HR issues, which can hurt its overall competitiveness and performance.

The following is the suggested technique's primary contributions:

1. Algorithms using natural language processing (NLP) are excellent at collecting pertinent data from resumes, including educational background, abilities, and work experience, which automates the first screening step.
2. NLP approaches offer an improved comprehension of applicant capabilities by identifying and classifying skills and competences from textual information.
3. NLP and CNN can assist develop models of prediction that foresee employee turnover by examining trends in employee information and feedback. This would enable HR to take steps to solve retention difficulties.
4. To promote inclusion and diversity, NLP algorithms can assist in locating and reducing inequalities in job postings, performance appraisals, and other HR-related materials.

The remainder of our research paper is composed as follows: The relevant research on deep learning techniques, data retrieval, and human resource management is covered in Section 2. The suggested work's fundamental operating technique and algorithmic procedure are illustrated in Section 3. The outcomes and application of the suggested approach are assessed in Section 4. The job is concluded and the outcome evaluation is covered in Section 5.

2. Related Works. A systematic review technique is needed to outline the present state of the art for RL in SCM. The writer outlines various review techniques based on the goals of the investigation and the field of study [5]. The most appropriate type of evaluation in this situation is semi-systematic, which combines qualitative and quantitative techniques. If an issue is not well defined and has been extensively researched in several study fields of study, a semi-systematic evaluation of the literature is helpful. To provide a plan for future study, it attempts to convey the state of the art generally and its current uses [4].

It's difficult to choose the right approach for every kind of application. When hackers change their hacking techniques to exploit vulnerabilities in networks and customers' indifference, the model's precision and effectiveness would eventually degrade if the incorrect approach or methodology were employed [14]. To protect consumers against phishing assaults and detect phishing threats early, a plethora of phishing prevention solutions has been created.Throughout a range of businesses, deep learning-based security techniques are becoming increasingly popular in the fight against new phishing attacks [15, 16].

It was determined how well various machine learning (ML) methods could identify MQTT-based assaults [17]. The study evaluated three distinct levels of abstraction for packet-based, unidirectional in nature and bidirectional flowing aspects. The instruction and evaluation procedures made use of a MQTT generated

database. The results of the experiment demonstrated that the proposed ML models were adequate to meet the IDS requirements of MQTT-based systems. Furthermore, the findings demonstrate that, whereas packet-based features are sufficient for most networked assaults, flow-based qualities are crucial for distinguishing MQTT-based attacks from innocuous data. According to the findings, the simulation has the greatest precision, at 99.04%. Two popular malware detection information sets, KDDCup99 and NSLKDD, were used in the investigation by the writer [18].

Translating and query-document screening are the two sections that make up CLIR. Severalapproachoccupiesrequest translation into the native tongue of the information gathering, followed by relevance determination using a single-language matched engine. One possible method for completing the translation process is statistically automated translation (SMT) [19] or neural machine translation (NMT) [26]. Although translating an item and matching it in a different language in a shared illustration space is a common two-step process, there is now an option to skip the translating step thanks to the development of bilingual word pictures [35] and multilingual already trained modelling languages. When adjusted, multinational pre-trained speech systems' word representations have context using the subsequent words in the order, making them useful for a variety of applications, particularly CLIR [20, 3].

A two-step process is employed by [21] to differentiate between benign and malicious nodes. In the first the stage, data is gathered by designated sniffing devices (DSs), after which the CCI is formed and routinely transmitted to the super node (SN) [22]. The SN then uses a regression approach on the gathered CCIs from various DSs in the following stage to differentiate between malicious and benign nodes. For multiple extreme situations in the network (GM), the detection characterisation is demonstrated using two movement models: Gauss Markov and random waypoint (RWP) [25]. Two dangerous techniques used in the workplace include distributed denial of service (DDoS) attacks and the black vortex.

Multiple sectors, including self-driving cars, recognizing faces, and medical equipment are using applications for deep learning. By learning by doing, deep learning teaches robots to function similarly to human brains [27]. Moreover, a computer model may automatically acquire the ability to do tasks like classification using massive datasets that contain text, audio, and pictures via the method of known as "deep learning." Models developed using deep learning can produce outcomes that are better than human beings in certain cases. Large amounts of data with labels, powerful computers, and multi-layered neural network designs are needed for training algorithms using deep learning [30, 32].Because algorithms using deep learning are so strong, scientists have been able to gather characteristics for URL classification and use these characteristics to suggest a variety of strategies for combating websites that are phishing [34].

3. Proposed Methodology. There are several essential elements in developing a technique for an information retrieving and classification method for human resource management (HRM) based on machine learning (ML). This approach will be designed to satisfy global academic requirements and be appropriate for an educational institution project in an area such as computer science or accounting management.Initially, the HR data is collected from the data source, next the data is pre-processed. After cleaning the data, normalization and feature engineering process is carried out. Next, the machine learning method Natural Language Processing (NLP) and the data is trained using CNN. The suggested method's architecture is depicted in figure 3.1.

3.1. Data Collection and Pre-processing. The open-sourcedataset is gathered from Kaggle, the HR dataset contains the details about the employee. The collected dataset is pre-processed by identifying missing values, duplicate records, and inconsistencies.

1. *Incomplete Values:* Find and fix any information that is incomplete. Among the options are removing columns or rows that have values that are absent. Use predictive modelling or methods of statistics (mean, median, mode) to impute values that are missing.
2. *Duplicated Documents:* To guarantee data integrity, look for and eliminate any entries that are duplicates.
3. *Inconsistencies:* Fix data entry errors, such as different date types or category variable types.

3.2. Normalization and Feature Engineering. In this work, min-max normalization method is used for normalizing the dataset.

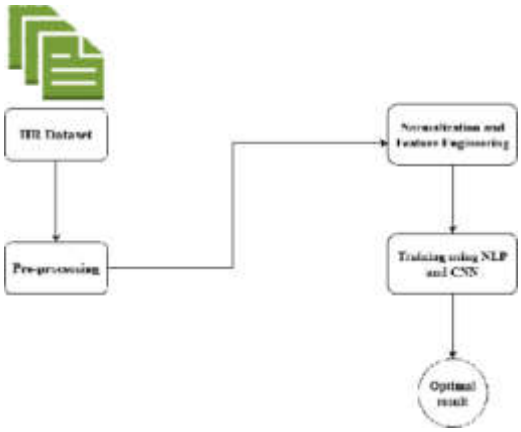

Fig. 3.1: Architecture of Proposed Method

3.2.1. Min-max normalization. Using a set range, often 0 to 1, this approach scales the characteristics. The process involves deducting the feature's minimal price and splitting the outcome by the feature's value.

$$min - max = \frac{x - \min?(x)}{\max(x)\} - \min?(x)} \tag{3.1}$$

Perfect for needs involving values within a restricted interval. It is susceptible to outliers, though.

3.2.2. Feature Engineering. A crucial stage in getting Human Resources (HR) data ready for predictive analytics and machine learning is feature design. To enhance the efficiency of artificial intelligence models, it entails adding new features or changing ones that already exist. Feature engineering is useful in HR data contexts to identify trends and conclusions which are not initially obvious. This in-depth method is appropriate for an undergraduate project in data science, accounting for managers, or HR management.

Recognize the characteristics that are currently present in the dataset, including tenure, pay, employment role, age, gender, and work evaluations. Recognize the features that are currently present in the data set, including tenure, pay, employment position, age, gender, and work evaluations. Compose characteristics that are composites of the current data points. For example, incorporating wages, incentives, and other benefits to create a feature called "total compensation." Create categorical bins from constant variables. For instance, tenure groups or age groupings. If two or more current features interact and could have an overall influence on the target variable, create new features based on these relationships.

3.3. Training the Dataset using Machine Learning method. There are multiple processes involved in developing a machine learning algorithm using HR retrieving information, from data preparation to model assessment of performance. The development of an algorithm that can precisely retrieve and categorize HR-related data depends on this procedure. This systematic method is appropriate for an educational project in data science or accounting management.

3.3.1. Natural language processing (NLP). Utilizing computational methods for understanding, interpreting, and modify human speech that exists in HR data is known as natural language processing, or NLP. NLP canclean information through unorganized textual information, that is frequently found in HR records and correspondence.

1. Resume processing and connecting refers to the process of automatically gathering relevant data (such as training, expertise, and abilities) from applications and comparing it to job specifications or position criteria.

2. **Feedback from Workers Evaluation:** Examining survey results, evaluations of performance, and feedback from workers to determine sentiment, spot common patterns, and comprehend the level of engagement and spirits among staff members.
3. **Job Application Optimization** is the process of Examining job posts and specifications to make sure that they're accessible, efficient, and aimed at the right people.
4. **Employment & Recruiting:** By finding those with the greatest potential through their online profiles and previous employment, NLP is used to screen applicants, match them with appropriate opportunities, and improve the hiring process.
5. **Employees Assistance and Bots:** Using natural language processing (NLP), chatbots are being used to provide data, respond to employee questions, and help with a variety of HR tasks.

3.3.2. Convolution Neural Network (CNN). The Convolutional neural networks, or CNNs, are a novel method intended for retrieving HR data; this is especially useful for complicated and organized data. Because of their propensity to identify trends and characteristics in geographic information, CNNs have long been recognized for their excellence in picture processing as well as analysis. But by considering textual as a type of data sequence with spatial links, they can be applied as well to organized written information in HR, such as applications, descriptions of jobs, and additionally organized feedback surveys.

Information is expressed numerically before being fed into a CNN, usually as embeddings (e.g., word embedded data). Language connections and semantic data are captured by these embedded data. the primary element of CNNs. These kinds of layers generate maps of features by filtering the input. Such filters can be used to slide over words embedded in text to identify trends or characteristics, such as specific words or mixtures of words that may point to HR-related characteristics. By combining characteristics, these layers lessen the dimension of the data while keeping the most important data—such as the existence of critical abilities or achievements on a CV.

Organize text data to preserve its context and sequence by converting it into an appropriate format, such as word embeddings. Create the CNN's layers, making sure to include pooling and convolutional layering with the right filter sizes. Depending on the dataset and task difficulty, the structure may change. Utilizing labelled HR information to educate the CNN. A properly labeled database that appropriately reflects the many groups or results you're attempting to forecast or obtain is crucial. To enhance the execution of the method, play around with numerous hyperparameters such as the number of layers, filter sizes, and number of filtering.

Convolutional Neural Networks (CNNs) are critical to the advancement of smart technologies due to their outstanding efficacy when conducting large-scale computations involving data. CNNs excel at spotting traits and patterns in pictures, which is why image categorization is one of their preferred applications. CNNs are employed in computerized systems to detect objects, circumstances, or irregularities in images acquired by photographers or other sensor types. Smart surveillance devices use CNNs to swiftly categorize and determine objects or persons. CNNs provide empirical information on the relative positions of elements in images, making it easier to recognize and locate them. CNNs are utilized by smart gadgets, such as self-driving automobiles, to swiftly identify others, vehicles that move, and obstacles.

A convolutional neural network is an instance of feedforward neural network that uses convolution processing and has a deeper architecture. This fundamental machine learning algorithm has numerous uses in computer vision, voice interpretation, image categorization, and other disciplines. A CNN, or "understanding coherent artificial neural system," can analyze and identify data based on its hierarchical organization.CNN consists of three important parts: its convolution layers the pooling layer, and the fully connected layer. Following features are extracted given the source information, the layer of convolution is frequently used to generate the characteristic mapping. The attribute is then down filtered utilizing the pooling layer, which reduces its size and computation cost. The resultant information obtained from the layer before it eventually gets transmitted to the completely linked layer, which creates a vector with one dimension of characteristics.

The beginning of the convolution stack has a pooling layer of roughly $1 * 2 * 2$, and a convolution kernel that is about $22 * 3 * 3$. In the final 2 conversion collections, the combination of pooling and convolution layers have sizes of $1 * 1 * 1$. The RELU activation procedure is used in all convolution layers, and serial normalizing is used to improve generalization ability, reduce unnecessary appropriate, and speed up training. Figure 3.2 illustrates the basic structure of CNN.

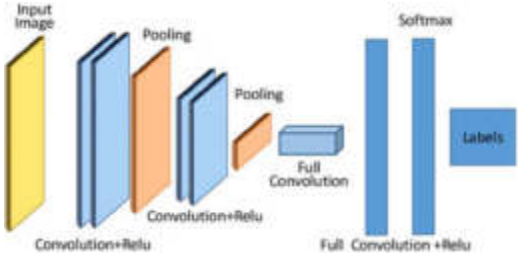

Fig. 3.2: Design of CNN

3.3.3. NLP with CNN. Transforming text into a format that CNNs can understand is the first step. Typically, this entails converting words or characters into dense vector representations called embeddings that capture the text's semantic qualities. Word embeddings are either directly learned during CNN training or come from pre-trained models such as Word2Vec and GloVe. Instead of sliding over image pixels, convolutional filters are used in natural language processing (NLP) to overlay word embeddings or character embeddings. These filters are intended to pick up on the syntactical patterns and local dependencies found in the text, such as phrases or brief word sequences with distinct meanings. The process generates a number of feature maps that show various elements of the text, such as the existence of particular words, phrases, or grammatical constructions.

After convolution, pooling layers are applied to reduce the dimensionality of the feature maps. This step helps to decrease the computational load and also to extract more global features from the text. Max pooling is the most common technique used, where the highest value in each region of the feature map is kept, capturing the most prominent features detected by the convolutions. After being flattened, the output from the pooling levels is routed through one or more fully linked layers. These layers perform the final task, which can be any NLP task, such as categorizing a sentence's sentiment or determining a document's categorization by combining the characteristics extracted by the convolutions and poolings. The last layer outputs the probabilities for each class using a softmax activation function for classification tasks.

4. Result Analysis. The proposed methodology for retrieving human resource management information using NLP-CNN. In this work the open-source dataset is gathered from Kaggle. It consists of employee details for evaluation. The evaluation metrics such as accuracy, precision, recall and f1-score.

A systematic method must be taken to assess the correctness of a Human Resources (HR) data retrieval systems that makes use of convolutional neural networks (CNNs) and natural language processing (NLP). This procedure entails putting the system in place, generating forecasts, and figuring out the accuracy. Considering the model's structure and the HR problem at hand is crucial, as employing CNNs in NLP tasks can be complicated.

Convolutional Neural Networks (CNNs) can be useful for retrieving HR data, particularly when handling complex structured data or unstructured data such as photographs (e.g., personnel photos, document scans). It is less typical, nevertheless, with conventional, tabulated HR data. The main uses of CNNs are in the processing of images and visual applications. A CNN might be useful if your HR data retrieval requirement calls for processing such image-based information.

Create an CNN design that works for the job at hand. Selecting the quantity of filters, pooling layers, kernel size, convolutional layers, and fully connected layers is required. Utilize the training set to hone your CNN. To be sure that the model is learning—that is, reducing loss and raising correctness on the validation and training sets—keep an eye on the training procedure. Accuracy is a typical statistic for classification jobs. It is the percentage of cases among all instances that were accurately anticipated. Change hyperparameters like the quantity of times and the quantity of batches and learning rate. To predict whether the algorithm will perform on fresh, untested data, assess its efficacy on the test set. Examine instances wherein the example has made mistakes to learn from them and find areas for development. In figure 4.1 shows the result of accuracy.

When assessing a Convolutional Neural Network (CNN) model's accuracy in relation to HR data, it's

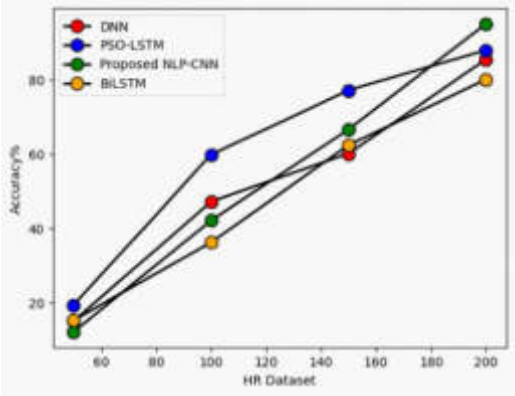

Fig. 4.1: Accuracy

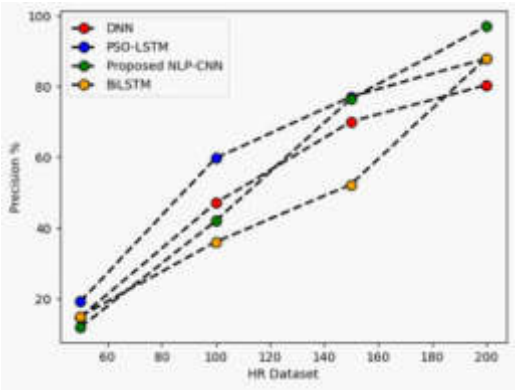

Fig. 4.2: Precision

important to comprehend the context of the issue, the characteristics of the HR dataset, and the computation and interpretation of precision as a metric. The proportion of correctly forecast positive findings precision refers to the overall total of projected positives. It's a crucial measure for issues with classification. Identify the HR issue that you are trying to solve with CNN (such as sentiment evaluation from employee feedback, resume screening, or staff attrition prediction). HR information frequently have imbalanced classes (e.g., a small percentage of departing employees relative to those remaining). In these kinds of situations, accuracy is especially crucial to predicting the positive class—that is, the individuals who are expected to depart. In figure 4.2 shows the result of precision.

It is necessary to know how to assess a Convolutional Neural Network's (CNN) effectiveness while using it for HR data, especially when it comes to tasks like document categorization or image-based worker information analytics. Recall is one of the most important parameters for this. In the context of employing CNNs for HR data, let's examine recall and its computation and interpretation. shows that the model does a decent job of identifying the favorable cases. This could entail correctly identifying most pertinent papers or information about workers in HR. implies that a sizable portion of positive cases may be absent from the model. This could be an issue in situations like missing important documents or misunderstanding personnel data, when missing positive examples can have detrimental effects.

Recall and precision—the capacity of a model to recognize only pertinent items—often represent trade-offs. Recall optimization may result in more false positives. In HR, you might give recall a higher priority than precision, or vice versa, depending on the assignment. For example, excellent recall may be particularly crucial

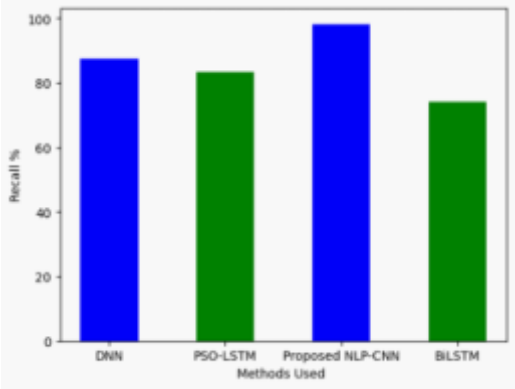

Fig. 4.3: Recall

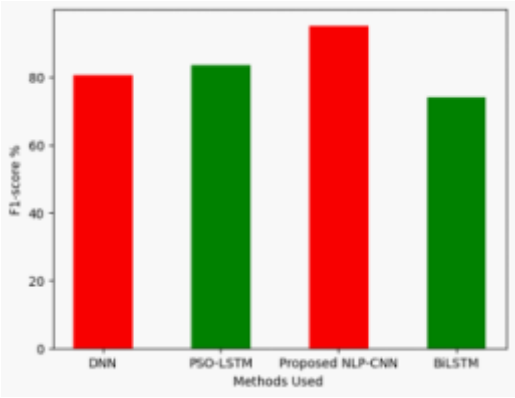

Fig. 4.4: F1-Score

in a legal file search to make sure no key item is overlooked. Recall is a vital indicator of performance when assessing a CNN's effectiveness in HR-related tasks, particularly when it comes to accurately identifying many pertinent cases. Efficient assessment of models and deployment require striking a balance between recall and other measures, as well as considering the circumstances and consequences of its use in HR. In figure 4.3 shows the result of recall.

A common measure used for assessing how well a model developed using machine learning performs, especially in the field of classification, is the F1-score. It is particularly pertinent in situations when the intended class allocation is unbalanced or anywhere the effect of false positives and false negatives is substantial, as is frequently the case with HR-related data. Create a CNN architecture that works with the HR data. Layers, functions for activation, and the result layer for categorization are all defined in this way. Utilizing a suitable optimization, loss function (such as binary cross-entropy for binary categorization), and metrics (such as precision and recall), build the framework. Make sure to utilize a validation set to track performance as you train your model on the learning set. Figure 4.4 depicts the outcome of the f1-score.

5. Conclusion. Effective human resource management (HRM) is critical to business success in today's hectic corporate environment. Companies need to come up with efficient methods for retrieving and classifying the continually expanding body of HR-related knowledge. This article presents a unique machine learning-based method for obtaining and classifying HRM information. Our techniqueforces state-of-the-art natural language processing (NLP) and CNN techniques to manage disorganized human resources (HR) data, such as employee records, job advertisements, and certificates. The system's capacity to extract relevant details from data using

advanced text analysis and machine learning techniques facilitates HR decision-making.The method consists of two primary components: extraction of information and categorization. Data extraction, which enables fast and precise searches of HR data, helps HR professionals get the knowledge they need more readily. On the other hand, classification maximizes the separation of data related to human resources into relevant categories, such as job roles, skill levels, and performance levels. We evaluate the performance of our system on multiple datasets extracted from real-world HR databases. The outcomes show the success of our strategy in streamlining HRM processes, reducing manual labor, and improving decision precision. Additionally, because our technology satisfies international university regulations, it may be used in both corporate HR departments and educational contexts.This research adds to the expanding body of information in HRM and offers a helpful resource for companies trying to enhance employee relations, streamline HR processes, and draw and retain talents. The proposed approach's adaptability and adherence to international educational standards make it a useful tool for both academia and industry. The proposed approach's adaptability and adherence to international educational standards make it a useful tool for both academia and industry. In future, complex dataset and deep learning models will be used in human resource management.

A SHARED ECONOMY DATA PREDICTION MODEL BASED ON DEEP LEARNING

MIN ZHOU*

Abstract. In the dynamic and intricate shared economy, efficient resource management and forecasting are still crucial. In this research, a new prediction model is presented that aims to improve the operational efficiency of several shared economy services. Our method creatively combines Long Short-Term Memory (LSTM) networks with Genetic Algorithms (GA) to assess user demand and optimize resource deployment. We apply this methodology especially to e-scooter sharing services, but the underlying ideas and methods can be applied to other shared economy platforms as well, like peer-to-peer lending services, car sharing, and vacation rentals. The model starts with a GA to adjust the hyperparameters of the LSTM network, making the network better suited to handle specific characteristics of common economic data. Capturing the complex temporal and spatial patterns of user behavior and demand on these platforms requires this optimization. The LSTM element then predicts changes in service demand due to its capacity to analyze sequential records. Further to being useful for analyzing sequential data and predicting destiny wishes, this predictive functionality is important for a shared economy platform to correctly manage stock, allocate assets, and predict personal wishes. We use a large dataset to check our technique, demonstrating the predictive accuracy of the model and demand and its potential to aid strategic choice-making. Compared to traditional fashions, the consequences show a large development in forecast accuracy and resource allocation efficiency. Our methodology creates a robust basis for statistics-driven insights that decorate customer happiness and decorate the long-term increase of the shared financial system. This work highlights the blended ability of GA and LSTM inside the shared economy and paves the manner for future enhancements in using modern-day gadget mastering techniques to optimize and alter various shared services. In quick, effective useful resource control and forecasting in the shared economic system is tough, however our specific forecasting model combining GA-LSTM gives a manner ahead. Our technique, as it should be, predicts fluctuations in provider demand; it was first refined the usage of GA to regulate the LSTM hyperparameters. The consequences show how correct and powerful our version is and spotlight how it can enhance customer pleasure and operational performance. This research paves the manner for future trends within the software of gadgets, gaining knowledge of methods and supports the continuing enlargement and development of shared economic system offerings.

Key words: Shared economy, resource allocation, GA, LSTM, demand prediction, operational efficiency.

1. Introduction. The shared financial system has turn out to be a disruptive commercial enterprise paradigm this is converting how services are supplied and sources are used[5, 25]. This financial model, that is characterised through peer-to-peer trading and collaborative intake, is relevant to a number of industries, including commodities sharing, lodging, and transportation. Green useful resource allocation is crucial to this versions achievement and depends on particular person call for forecasting [2]. The shared financial system is dynamic in comparison to standard employer fashions with call for fluctuations impacted by way of an extensive variety of variables, together with time, vicinity, person choices, and socioeconomic developments [22, 24]. This variability creates a large hassle: how to make certain that assets are allocated as effectively as feasible to fulfill customer call for without developing shortage or oversupply? Sophisticated predictive models which can discover complicated patterns in big datasets and offer useful insights for aid allocation are required to satisfy this task.

There are hopeful answers to those issues inside the quickly developing fields of information science and device studying. With the usage of state-of-the-art algorithms, predictive analytics can forecast call for via reading the big volumes of information produced with the aid of shared economic system platforms. However, the nonlinearities and temporal correlations that characterize shared economy facts are every so often too complex for classic statistical procedures to fully capture. That is in which deep studying strategies, specifically those based on neural networks are useful. Recurrent neural networks (RNN) namely LSTM networks have tested giant potential [16, 1, 26]. Their proficiency in handling sequential information makes them ideal for examining time-series information, inclusive of demand styles in the shared financial system over an extended

*School of Finance and Accounting, Anhui Sanlian University, Hefei, Anhui, 230000, China (minzhouresead@outlook.com)

time frame[19, 9]. However configuring LSTM networks optimally for a given software continues to be a tough venture that often necessitates a outstanding deal of trial and error [3, 18, 14].

The choice of appropriate hyperparameters is a crucial element within the implementation of deep gaining knowledge of models. The model's performance is substantially impacted with the aid of this preference, which is a difficult venture considering the massive hyperparameter space. GA can be quite vital in this situation. Natural selection serves as the model for the optimization techniques utilized by GA [4, 23]. To determine the proper parameters for a specific version they can speedy and correctly search throughout huge solution areas. GA iteratively regulate the hyperparameters merging and enhancing them to locate the most perfect configuration by mimicking the process of evolution. This method could be very helpful for optimizing deep studying models as an appropriate selection of hyperparameters can substantially improve version overall performance[20, 11].

Through the evaluation we present a brand-new method that combines the strong time-series records processing energy of LSTM with GA understanding in hyperparameter optimization. Specifically designed for the shared economy enterprise this GA-LSTM model targets to transform demand forecast and resource allocation [7, 13, 17]. By the software of GA the structure and parameters of the LSTM network are optimized permitting the model to forecast user demand styles with extra accuracy. The version can now as it should be constitute the complicated temporal dynamics and nonlinear interactions seen in shared financial system statistics thanks to this optimization. Consequently, the recommended GA-LSTM version represents a strategic device in addition to a generation improvement for shared financial system systems, empowering them to make information-pushed selections that growth person pleasure, lower costs, and improve operational performance. This innovative approach establishes a general for next predictive analytics products in this discipline and expands the usage of deep learning within the shared financial system.

Efficient resource management and precise demand forecasting are essential in the ever-changing shared economy, where services like car sharing, peer-to-peer financing, e-scooter sharing, and holiday rentals are becoming more and more popular. These platforms operate in environments with complex user behaviors and dynamic demand patterns, which makes it difficult to optimize resource deployment in a way that successfully meets user needs. To tackle this issue, we present a novel prediction model that aims to improve the operational effectiveness of several shared economy services.

The primary contributions of the study are:

1. On these studies a novel aggregate of LSTM networks and GA is provided specially designed for the shared economic system industry. This hybrid model makes use of GA to improve LSTM configurations enhancing prediction efficiency and accuracy.
2. Across these studies we especially awareness the E-scooter area. We provide an advanced demand prediction model that correctly forecasts user call for patterns throughout multiple shared economic system systems. The dynamic and complex nature of shared financial system statistics is effortlessly dealt with via this model, which significantly complements resource allocation processes.
3. Our study showcases the green software of Genetic Algorithms in deep gaining knowledge of version hyperparameter adjustment. This method streamlines the performance of the LSTM community and makes the generally difficult technique of version configuration less complicated.
4. The shared economy is supported with the aid of empirical proof, which the thing uses to validate its sensible and scalable methodology. Our version demonstrates how it can be used to many shared economy industries imparting a flexible device for organizations to improve purchaser delight and operational performance.

2. Related Work. The impact that private trip-hailing services like Uber and Lyft have had when you consider that their launch in 2011 and 2012 on the United States transportation atmosphere is the primary topic of this examine [6]. The continuously changing landscape of recent mobility offerings provides issues for transportation making plans and regulation, that are mentioned in this article. This observe makes a tremendous addition by providing clean statistics and perspectives on the uptake and first attitudes of shared e-scooters which experienced a pointy upward push in non-public investment. The comprehensive ballot, which become finished in 11 principal cities, gives insightful records about public opinion. It emphasizes favorable evaluations, particularly amongst ladies and decrease-class demographics, and greater gender parity compared

to traditional docked bikesharing structures. The paper [8] looks at assesses how shared e-scooter systems, which were first added in 2017, in shape into the ecu Sustainable and clever Mobility approach and how they make a contribution to sustainable city mobility. The paper emphasizes the environmental advantages, together with decreased air pollutants and greater mobility resilience, especially noteworthy all through the Covid-19 pandemic, through a thorough literature analysis and a case observe in Braga. The examine emphasizes how nicely e-scooters paintings to encourage social separation and reduce reliance on private vehicles for quick-distance journey. Following the outbreak, Braga's persevered reliance on e-scooters and the implementation of discounted prices to sell use highlight the machine's viability and acceptance. The sudden upward push in reputation of shared, dockless electric powered kick scooters inside the United States of America at some stage in 2017 is tested [10]. The dockless characteristic, which enables users to go away scooters at any location, highlights the power and ease of those battery-powered cars as an opportunity to more traditional types of transportation. The have a look at highlights how these firms, which give quick-term rentals and add to the micro-mobility scene, are for-earnings. The have a look at gives a thorough analysis of the shared scooter phenomena, emphasizing its sensible features in addition to the unique possibilities and troubles they present in city environments. This indicates a dramatic trade in the manner city human beings cross about quick distances.

The paper [21] takes a look at explores the growing phenomenon of micromobility with a particular emphasis on e-scooters in Thessaloniki, Greece. Surveys are utilized to evaluate person attitudes and moves, and the outcomes display that e-scooters are more often used for enjoyment than for transportation. The look at draws attention to how common e-scooters are on each motorcycle lanes and non-bike lanes. The actions of vehicles and the requirement for added bike lanes to promote the use of e-scooters are the primary troubles stopping their usage. Whilst evaluations approximately e-scooters are largely comparable throughout special demographics, the examine additionally observes modest versions in utilization based on age and gender. Those findings offer vital insights into the combination of e-scooters in city mobility. The paper [7] makes use of advanced device gaining knowledge of strategies to estimate PM2.Five concentrations with a purpose to deal with China's growing air pollutants problem. In an effort to extract functions from air great data, it makes use of intense gradient lifting (XGBoost) along with a multi-scale convolutional neural community (MSCNN) to extract spatial-temporal function relations. The XGBoost-MSCGL model that has been cautioned combines the benefits of XGBoost, MSCNN, and LSTM and is more suitable via Genetic Algorithms (GA) to offer correct PM2.5 prediction. Complete pollutants and weather records from the Fen-Wei undeniable are used to validate the model's efficacy. The outcomes show off noteworthy improvements in forecast precision and applicability while juxtaposed with reference fashions, demonstrating the version's effectiveness in tackling environmental troubles. We can estimate copper charges with this techniques gives a unique GA-LSTM with an error correction approach, addressing the elaborate marketplace adjustments [15]. The model creates a hybrid input that improves forecast accuracy via deliberating both past developments and causality. It does this with the aid of combining latest information on copper charges with precise influencing elements. After being evaluated for generalizability with iron ore expenses and demonstrated using a 30-year records series of copper costs, the version outperforms benchmark fashions. This novel method demonstrates the version's resilience and capacity for generalization, which makes it an crucial device for monetary forecasting, especially in erratic commodities markets inclusive of the ones for copper.

3. Methodology.

3.1. Proposed Methodology Overview. This segment introduces the advised GA-LSTM method that proven in Figure 3.1. The method have a look at is changed to concentrate on e-scooter utilization prediction and deployment optimization. This variation is critical for managing with the precise difficulties offered by this shared economy provider along with maintaining availability, optimizing preservation and recharging schedules and striking a balance among supply and demand. First, we gather full-size utilization data on e-scooters which includes journey begin and end times, locations, distances and consumer demographics. Contextual statistics that could affect using e-scooters is added to this series, inclusive of weather reviews, statistics on parking spaces and motorcycle lanes and statistics on special activities. Preprocessing is performed at the accumulated records to make certain it is prepared for analysis. This encompass normalizing the statistics to a not unusual format segmenting it into applicable time frames and cleaning the information to do away

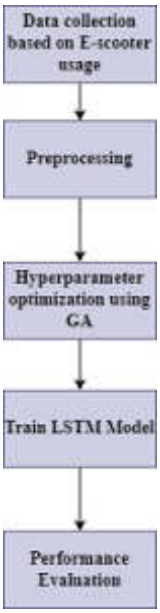

Fig. 3.1: Proposed GA-LSTM Architecture

with any errors or inconsistencies. To ensure the LSTM model can examine the data successfully. The LSTM networks hyperparameters are then optimized for the e-scooter dataset the usage of genetic algorithms. The GA iteratively looks for the exceptional series of parameters which includes gaining knowledge of rate, range of layers and neurons in every layer and other pertinent LSTM settings. Improving the models potential to precisely forecast e-scooter demand styles requires this optimization. With the optimized hyperparameters we continue to teach the LSTM version using the preprocessed e-scooter information. This schooling allows the version to study from ancient utilization styles and identify traits which might be predictive of future e-scooter demand. Eventually, the trained GA-LSTM model is carefully tested and confirmed using separate datasets to assess its predictive accuracy and generalizability. This step guarantees that the model can reliably forecast e-scooter call for in numerous situations and places additionally making it a practical device for e-scooter carrier vendors.

3.2. Proposed GA-LSTM Workflow.

3.2.1. GA based Hyperparameter Tuning. In shared financial system the performance of GA coupled with LSTM networks in particular for e-scooter usage records presents a resounding example of technological innovation using operational performance. The fundamental issue in this discipline is precisely predicting call for styles that is a tough assignment due to the fact user behavior is dynamic and there are different variables that have an effect on it which include the climate, visitors and urban infrastructure. Confronted with this issue the GA-LSTM model plays quite properly in as it should be forecasting the demand for e-scooters. The GA aspect is essential for improving the hyperparameters of the LSTM community, which allows it to be tuned. This change is crucial since it significantly improves the LSTM capability to perceive the non-linear styles and temporal relationships gift inside the e-scooter usage information. With a view to allocate sources successfully within the shared economy an intensive and specified knowledge of call for traits is ensured by the GA-LSTM model. As a result, there are fewer times of oversupply or scarcity of e-scooters at some stage in various urban locations increasing utilization whilst lowering operating charges. The GA-LSTM version is a robust tool for long-term software because of its adaptability to converting situations and ability to examine from sparkling data. The version can continuously adapt to new styles as the shared financial system landscape modifications preserving its excessive accuracy over the years. For e-scooter groups operating in dynamic

metropolitan contexts wherein purchaser alternatives and outside factors might change speedy this capability is particularly beneficial. There are numerous realistic blessings of making use of the GA-LSTM model in the shared financial system. With the aid of guaranteeing the provision of e-scooters while and while they may be wished it improves patron happiness. It results into decrease overhead, advanced fleet control and operational efficiencies for service carriers. Additionally, the version facilitates acquire city sustainability dreams with the aid of minimizing the environmental effect of transportation offerings and maximizing the use of shared sources by using permitting extra accurate call for prediction. For this reason, the GA-LSTM version is a specifically powerful manner to capitalize on the opportunities of facts-pushed selection-making inside the shared economic system.

Step 1: Initialize the generation count $n = 0$
Step 2: While $n < 50$:
Step 3: Generate a stochastic pool populace of chromosomes representing ability LSTM configuration with various hyperparameters including quantity of layers, neurons consistent with layers gaining knowledge of prices.
Step 4: Evaluate each chromosome using the fitness function relevant to e-scooter usage prediction, typically based on prediction accuracy or error rates on a validation dataset.
Step 5: Select a certain number of the fittest chromosomes based on their fitness scores. These selected chromosomes form the initial population for the next steps.
Step 6: Pair chromosomes for mating using a crossover operator. This process involves combining parts of two parent chromosomes to create offspring, promoting genetic diversity.
Step 7: Apply Crossover to the selected pair at randomly chosen points (with a crossover probability, GAPrc = 0.8) determining how often crossover occurs.
Step 8: Mutate the offspring generated from the Crossover operation (with a mutation probability, GAPrum = 0.001). Mutation involves randomly altering certain genes in the chromosome. Set a mutation probability to control the mutual rate.
Step 9: Form the new population from the offspring, ensure that it adheres to size constraints and prioritize the most fit chromosomes.
Step 10: Replace the old population with the new one and increment the generation count n *by* 1.
Step 11: After the final generation select the optimal chromosomes based on the highest fitness score. This chromosome represents the best LSTM configuration for predicting E-scooter usage.
Step 12: Apply this optimal LSTM configuration to build and train the final model for E-scooter usage prediction.

The generation count n is initialized to zero at the start of this operation. The technique iteratively refines the LSTM model configuration for a maximum of 50. The GA to start with creates a numerous pool of chromosomes in each era. A possible LSTM configuration is represented by means of each chromosome, which is defined by using a diffusion of hyperparameters, inclusive of the variety of layers, the variety of neurons in step with layer, and the studying price. This stochastic pool is crucial for investigating a diffusion of possible fixes. Subsequently, a health feature is used to assess every chromosome's effectiveness. The use of a validation dataset is mainly connected to the utilization patterns of e-scooters; this feature commonly evaluates the prediction accuracy or blunders costs of the LSTM setup. A variety of the most promising chromosomes is made primarily based on their health rankings. The starting population for the following evolutionary ranges is made up of these selected chromosomes. Chromosomes are paired for mating in the evolutionary system by means of a crossover operator. By way of developing youngsters by combining components of figure chromosomes, this operator provides genetic variety to the populace. The crossover is performed at arbitrary locations alongside the chromosomal strings, and the frequency of this blending is determined with the aid of a predetermined chance. The subsequent essential stage is mutation, in which the progeny produced by means of crossover revel in haphazard changes in certain genes. This mutation adds a greater range and facilitates the algorithm's exploration of a bigger answer space. It is regulated by means of a predetermined opportunity. The progeny provides rise to a new population following crossover and mutation. To be able to maintain size restrictions and provide precedence to the fittest chromosomes, this populace is carefully selected to ensure that the maximum viable options are pursued. The set of rules constantly replaces the older and much less evolved populace with

the brand new, greater, superior populace because of the generations. The set of rules chooses the pleasant chromosome based on the best health rating as soon as it reaches the final technology. The correct chromosome for exactly forecasting e-scooter utilization is represented by this LSTM setup. In the long run, the LSTM version is built and educated on the usage of this best configuration, after which it's far implemented to the practical intention of forecasting e-scooters call for. With its progressed prediction accuracy guaranteed by means of this GA-optimized LSTM version, it is a useful tool for effectively organizing and overseeing e-scooter fleets in city settings.

Algorithm 22 LSTM Cell for E-Scooter Usage Prediction

Input: E: Sequence of input E-scooter usage, where $x = \{x_1, x_2, \ldots, x_t\}$, H_{t-1}-previous hidden state, C_{t-1}-Previous Cell state, Weight matrices $W_{Fo}, W_{In}, W_{Ou},\ W_c$; Bias Terms-$B_{Fo}, B_{In},\ B_{Ou},\ B_c$.
Output: h_t-current hidden state, c_t- current cell state
Initialization:
Initialize h_o, c_o as the preliminary hidden and cell states.
Outline weight matrices $W_{Fo}, W_{In}, W_{Ou},\ W_c$ for forget gate, input gate, output gate and cell state respectively.
Outline Bias term $B_{Fo}, B_{In},\ B_{Ou},\ B_c$ corresponding to each gate.
for each time step t **do**
    calculate forget gate $Fo_t = \sigma(W.[h_{t-1}, x_t] + B_{Fo})$
    Calculate the input gate $In_t = \sigma(W_{In}.[h_{t-1}, x_t] + B_{In})$
    Calculate Candidate cell state $\overline{c_t} = \tanh(W_c.[h_{t-1}, x_t] + B_C)$
    Update cell state $c_t = Fo_t * c_t - 1 + i_t * \overline{c_t}$
    Calculate output gate $Ou_t = \sigma(W_{Ou}.[h_{t-1}, x_t] + B_{Ou})$
    Calculate hidden state $h_t = Ou_t * \tanh(c_t)$
    Output the hidden state h_t and cell state c_t at each time step t
end for

3.2.2. LSTM. Initializing the preliminary states is step one in the process. The hidden and cell states are among these early levels, and they may be important for encapsulating the temporal dependencies within the facts. Later, the version specifies wonderful weight matrices and bias terms for diverse LSTM components. The overlook gate, input gate, output gate, and mobile kingdom are a number of those elements. Every such a is vital to the manner the LSTM interprets and keeps information through the years. The LSTM model executes a number of computations as it examines the input statistics bearing on e-scooter usage at every time step. It starts by means of ascertaining the output of the forget gate which determines what statistics is removed from the cell state. The quantity of latest information that enters the cell state is then managed through calculating the output of the input gate. Similarly, a candidate cellstate is produced, supplying the cell state a probable new cost. The version then combines the new candidate state with the old state to update the real cell state. This up-to-datecell state is essential since it contains information this is used during the sequence's processing. The output of the output gate is computed as soon as the cell state is up to date. Using the updated cellstate as a basis, this output gate determines the following concealed state. The ultimate stage within the manner is to compute the current hidden state, which stores the expertise that the LSTM has learnt up to that factor in time. After that, the hidden state is probably processed similarly or used to make predictions before shifting on to the next time step. So as to boom the prediction accuracy of the LSTM model, the GA adjusts its parameters at some point of this procedure. The model is specifically beneficial for forecasting e-scooter demand and utilization tendencies in this optimization, which makes it a priceless tool for handling e-scooter fleets and making operational choices within the shared financial system enterprise.

4. Results and Experiments.

4.1. Simulation Setup. The dataset which is used to assess the proposed of the look at based on shared e-scooters and is used to broaden a version for predicting demand which is customized from the study [12]. It consists of comprehensive ride records from a selected e-scooter carrier, protecting numerous elements which

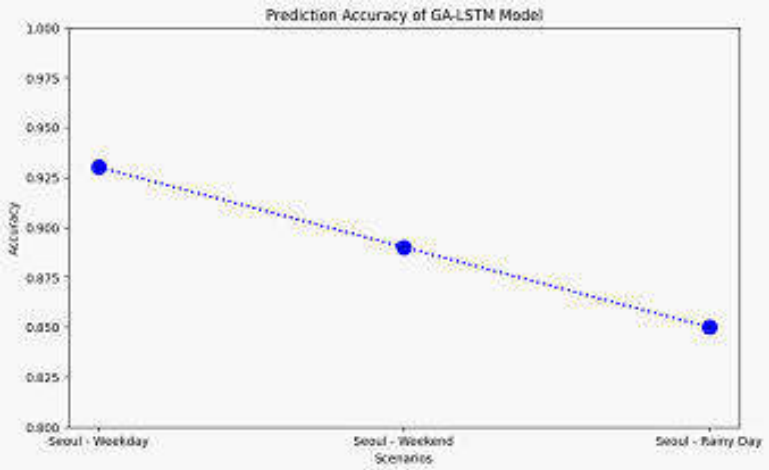

Fig. 4.1: Prediction Accuracy

includes condominium dates and times, places, journey periods, and distances. The temporal scope of the facts is about for a particular month, and the spatial scope covers two widespread areas in Seoul, Korea. The facts is based into a grid device for efficient evaluation, with every grid representing a specific area. This established method allows for distinctive insights into e-scooter usage patterns, which is vital for predicting call for appropriately.

4.2. Evaluation Criteria. The accuracy of the suggested GA-LSTM model, as shown in the figure 4.1 suggests the efficacy in the usage of e-scooters in more than a few actual-international situations. The version extremely good accuracy of 0.93 inside the Seoul Weekday state of affairs shows that it's miles particularly correct at predicting the call for for e-scooters on normal workdays. Due to its excessive precision, the version can be capable of capture and examine e-scooter utilization styles in an average city setting during the operating day, which is a vital functionality for fleet control and aid allocation. To 0.89 inside the Seoul Weekend scenario the accuracy declined. This is a respectably high diploma of accuracy, although it is a tiny drop from the weekday scenario. This suggests that the GA-LSTM version skillfully adjusts to the diverse utilization patterns which can be generally found all through weekends. This variance may additionally end result from variations in person behavior and e-scooter utilization patterns on weekends as evaluation to weekdays, which the version largely displays. Moreover, the accuracy of the version become zero.Eighty five in the more hard Seoul wet Day situation. Regardless of the decline, this wide variety is spectacular, specially in mild of the fact that certain climate situations, which includes rain, can appreciably alternate e-scooter usage patterns. Its potential to interpret and assume intake information accurately even in less-than-perfect situations is tested by the GA-LSTM model's robustness, as proven by means of this degree of accuracy underneath such situations. Normal, these accuracy numbers exhibit how well the GA-LSTM version performs in predicting e-scooter utilization in an expansion of settings. Its capability to stay very correct in a spread of settings, such as weekends, ordinary weekdays, and extreme weather, indicates that it is able to prove to be a useful tool for groups that offer shared e-scooter services, assisting each operational effectiveness and strategic selection-making.

LSTM networks are adept at handling sequential data, capturing long-term dependencies that are often present in time-series data. The GA's optimization process further enhances the LSTM's ability to model complex patterns in the data, leading to superior prediction accuracy compared to traditional models or non-optimized neural networks.

Figure 4.2 presents the efficacy of GA-LSTM version in phrases of mean Squared error (MSE) throughout more than one possibilities offering treasured insights into the version precision. The MSE of.05 became found by means of the version in the Seoul Weekday situation. This low MSE score indicates that the GA-LSTM version projections at some stage in common workday conditions are fantastically accurate with the predictions

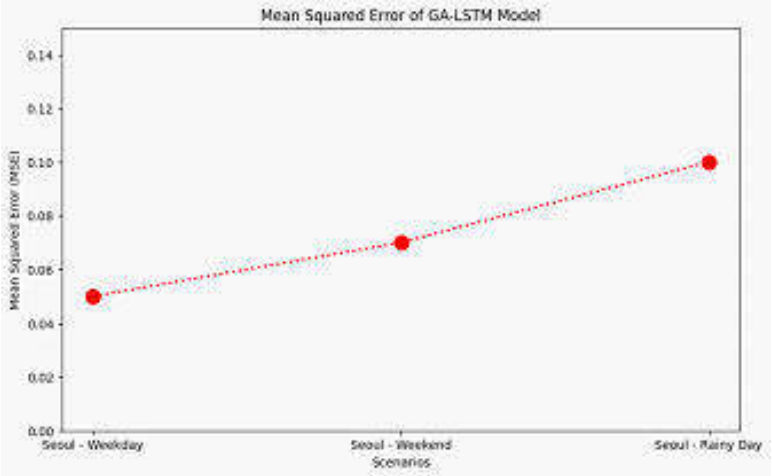

Fig. 4.2: MSE

coming in fairly near to the actual e-scooter utilization information. Planning and resource allocation in e-scooter sharing offerings rely heavily on this level of precision, specifically when estimating demand on ordinary workdays whilst utilization styles may be steadier and greater predictable. While we switched to the Seoul Weekend situation the MSE went up a notch to 0.7. Even while this shows a minor discount in the version's accuracy compared to the weekday situation, it is nonetheless quite correct. Because of varying user conduct, which include tour or entertainment activities, weekends normally show numerous usage patterns, that may upload similarly variability to the data. In spite of these problems, the GA-LSTM version retains a relatively low MSE, highlighting its potential to modify to quite a number utilization scenarios. The MSE to 0 to1 within the greater tough Seoul wet Day state of affairs. Rain and other damaging climate styles may have a large influence on e-scooter usage, which will increase the data's unpredictability and variability. The model maintains to characteristic very efficaciously regardless of this growth in MSE, demonstrating its resilience and potential to manage versions in intake patterns introduced on by means of out of doors variables like climate shifts. All things taken into consideration, the MSE values in each of those conditions reveal how correct and dependable the model is at predicting the demand for e-scooters. The efficacy of the GA-LSTM version as a beneficial tool for e-scooter sharing services is tested by way of its capability to provide correct forecasts beneath an expansion of eventualities, which facilitates with operational planning and green useful resource control.

The processing time values of figure 4.3 provides the efficacy of the cautioned GA-LSTM. The version validated a processing time of 20 seconds within the Seoul Weekday situation which is a really fast reaction time this is very wonderful for dynamic e-scooter sharing operations. Rapid processing velocity guarantees that e-scooter service providers can act speedy based on version predictions, that's important for weekday operations wherein responsiveness and brief turnaround are critical. Whilst we switched to the Seoul Weekend scenario the processing time elevated by using a small amount to 25 seconds. Even though there may be a moderate growth over the weekday scenario, it's miles nonetheless within a variety that can be utilized in real time with achievement. The technique continues a reasonably rapid processing time on weekends, whilst e-scooter utilization patterns may range due to rest sports or an growth in tourists. This ensures that provider providers can speedy regulate to the changing needs. The processing time was extended to 30 seconds within the Seoul wet Day scenario. This scenario has the longest duration of all 3 but it's miles nonetheless affordable for operational application. Random changes in consumer behavior because of adverse weather conditions consisting of rain, might complicate the prediction version and boom the processing time required for effective forecasting. Even in much less-than-best climate, the version's processing time is still powerful sufficient to permit the timely deployment and manipulate of e-scooter fleets. Standard, the processing time values within

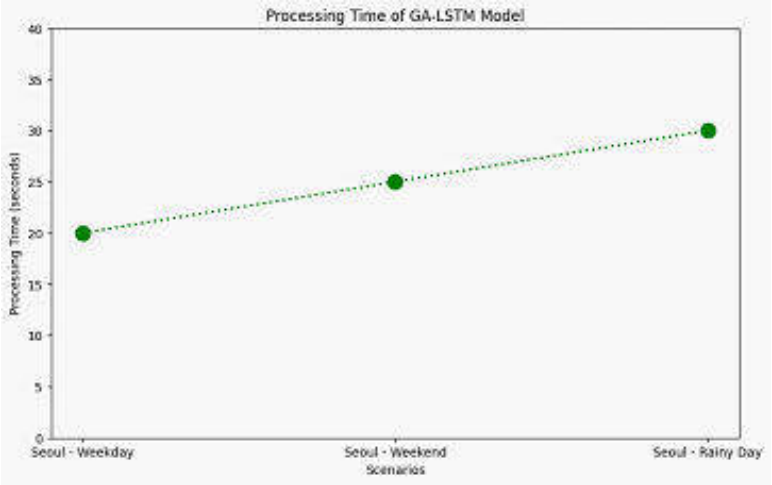

Fig. 4.3: Processing Time

the numerous situations display that the GA-LSTM model produces straightforward and accurate predictions however additionally does so in a timely way that allows choice-making in real time. The GA-LSTM model is a beneficial tool in the rapid-paced world of e-scooter sharing offerings due to its performance in processing time which permits operators to efficiently optimize their services and react fast to converting call for.

By reducing the requirement for manual intervention throughout the model development process, GA for hyperparameter tweaking helps to save time and money. This automated method of optimizing models can be very helpful in quickly changing domains where efficiency and time-to-market are crucial.

5. Conclusion. The take a look at locating on the GA-LSTM approch capacity to predict e-scooter usage in the shared economy region is encouraging and factors to vital developments inside the area of predictive analytics. The version efficiently combines the advantages of LSTM networks and GA to provide a powerful tool that can expect e-scooter demand with accuracy in an expansion of scenarios. As may be seen from the prediction accuracy determine which suggests how nicely the version predicts intake patterns on weekdays, weekends or even in hard conditions like rainy days, the have a look at indicates that the model achieves excellent accuracy. For the version to be used practically in maximizing the distribution and availability of e-scooters, this precision is essential. Furthermore, the accuracy of the model is demonstrated via the MSE values which spotlight its capability to exactly in shape its predictions with actual usage facts even in the face of the intricacies and variability of user behavior. This degree of accuracy demonstrates the GA-LSTM version resilience, making it a truthful aid for provider providers. Particularly the version processing instances additionally show how effective it's far. Regardless of the complexity of the analysis and prediction of e-scooter usage, the model can manage information quick, that's essential for real-time applications inside the shared financial system industry. This efficacy boosts operational effectiveness and customer delight by way of allowing e-scooter service vendors to make set off, properly-knowledgeable decisions. In conclusion, the GA-LSTM model is a huge breakthrough for system getting to know packages in sharing economic system offerings. Its capability to deliver particular, well timed, and accurate predictions can drastically help e-scooter provider vendors optimize their operations, efficiently manipulate their sources, and in the long run help the growth and sustainability of the shared economic system surroundings. The examine now not handiest confirms the effectiveness of the GA-LSTM version but additionally gives possibilities for continued studies and development on this vicinity, that may in the end result in the creation of extra complex and superior forecasting gear.

BIG DATA ANALYSIS AND DIGITAL SHARING RESEARCH ON INNOVATION AND ENTREPRENEURSHIP EDUCATION IN THE DIGITAL ECONOMY ERA

LI YIN*, WEIDONG ZHANG†, ZICHENG WANG‡, AND MINGXING ZHOU§

Abstract. Within the rapidly evolving panorama of the virtual financial system, the function of training in fostering innovation and entrepreneurship has become more and more vital. This study aims to explore how big records analysis and digital sharing techniques can be leveraged to complement innovation and entrepreneurship schooling. The observation is grounded within the context of the virtual economy generation, characterised with the aid of the proliferation of virtual technologies and the exponential boom of facts. The middle objective is to research how instructional techniques can be more desirable thru the utility of large records analytics and digital sharing, thereby preparing college students extra effectively for entrepreneurial roles inside the digital age. The studies employ a deep learning technique, combining quantitative information evaluation with qualitative insights. Primary statistics could be accumulated through surveys and interviews with educators and marketers, even as secondary statistics will be sourced from existing educational literature and case research. The observe will awareness on key regions which includes the effect of huge facts on expertise marketplace developments and client conduct, the function of virtual sharing in fostering collaborative learning and innovation, and the integration of these technologies into curriculum design and pedagogical practices. Anticipated results include a set of recommendations for academic institutions on integrating large statistics and digital sharing tools into entrepreneurship training. The study targets to offer insights into how this technology can enhance college students' analytical and innovative skills, put together them for the challenges of the digital economic system, and foster a tradition of innovation and entrepreneurial attitude.

Key words: Big Data Analysis, Digital Sharing Research, Innovation, Entrepreneurship Education, Digital Economy

1. Introduction. Entrepreneurship represents an important component of the financial development of a country and plays a main position as a motive force of innovation and activity introduction [1]. It is taken into consideration a green component to counteract numerous issues that children face because it's miles directly associated with self-employment. Consequently, exploring entrepreneurial intentions has obtained increasing interest across diverse fields of studies and practice [16]. For instance, numerous works have investigated entrepreneurial intentions amongst commercial enterprise students. However, even though the literature tackling the elements of entrepreneurial intention is vast, there's nevertheless a whole lot to be analysed, regarding how entrepreneurship intentions are conceived, particularly inside this digital technology of synthetic intelligence [10]. Furthermore, as argued with the aid of, with the short improvement of synthetic intelligence technologies, the investigation of both entrepreneurship training and innovation is now an unavoidable fashion [13].

The deep integration among the virtual economic system (DE)and the sports activities enterprise (SI) [5–8] plays a critical role in stimulating sports activities intake and riding the transformation and advancement of the sporting quarter. Moreover, it helps the enhancement of excellent and efficiency in the SI, promotes the digital transformation of the SI, and acts as a "new engine" for driving China's economy toward hastily powerful development [2]. Therefore, there is a pressing want for systematic research to explore effective strategies that harness the potential of the DE to power SI growth, addressing an urgent realistic assignment. Students have constructed evaluation index structures considering dimensions, including power, performance, and quality. For example, the writer advanced an index to degree SI performance in China. Further, the researcher additionally created an index based totally on industrial structure, production performance, commercial efficiency, development impetus, industrial basis, and commercial scale, testing its effectiveness the use of benchmark regression and spatial size fashions.

Digital sharing, then again, refers to the trade of knowledge, resources, and ideas thru virtual systems. This facet of the virtual age fosters collaboration, peer studying, and the democratization of information. Within the context of entrepreneurship training, digital sharing can facilitate the dissemination of progressive thoughts, foster collaborative studying environments, and bridge geographical and institutional divides. It empowers students and educators to get entry to a wealth of resources and networks, essential for nurturing entrepreneurial ventures and innovative questioning. The combination of big records analysis and digital sharing in innovation and entrepreneurship schooling offers a promising avenue for cultivating the abilities and mindsets wished within the virtual financial system. This research goals to study how those technological advancements may be correctly harnessed to complement gaining knowledge of stories, beautify pedagogical processes, and prepare destiny marketers and innovators for the challenges and possibilities of the virtual technology. Through a complete exploration of principle, exercise, and case research, the look at seeks to contribute precious insights and sensible techniques for educators, policymakers, and stakeholders within the discipline of entrepreneurship training.

The rapidly evolving field of the digital economy highlights the need of examining the relationship between education, innovation, and entrepreneurship. The goal of this study is to analyze how big data analytics and digital sharing platforms can transform the way that innovation and entrepreneurship education is taught. Set against the backdrop of the digital era, which is characterized by the proliferation of data and digital technological advancements, the main objective of the study is to reveal how educational methodologies can be optimized through digital sharing and big data to effectively prepare students for entrepreneurial endeavors in this new era. In addition to a study of scholarly literature and case studies, the research uses a mixed-methods approach that combines quantitative and qualitative analyses to collect perspectives from educators and entrepreneurs through surveys and interviews.

1. To investigate how massive records analysis the usage of Convolutional Neural Networks (CNNs) and virtual sharing practices can enhance innovation and entrepreneurship education in the virtual economic system era.
2. The mixing of CNN-primarily based large statistics evaluation and digital sharing techniques into entrepreneurship schooling drastically improves students' revolutionary capabilities and entrepreneurial abilities.
3. Massive facts analysis contributes to more informed and proof-based totally decision-making in entrepreneurship training. With the aid of analysing great datasets, educators and students can perceive market developments, purchaser preferences, and capability risks, leading to more strategic and information-pushed processes in entrepreneurial ventures.

The rest of our research article is written as follows: Section 2 discusses the related work on various Big Data Analysis, Digital Sharing Research ,Digital Economy Eraand Deep Learning methods. Section 3 shows the algorithm process and general working methodology of proposed work. Section 4 evaluates the implementation and results of the proposed method. Section 5 concludes the work and discusses the result evaluation.

2. Related Works. China proposed to expand the digital financial system at the 2016 G20 Hangzhou Summit. It's far a chain of financial sports to improve performance and optimize the monetary form. Modern records networks are an essential service, virtual knowledge and statistics are key production elements, and statistics and communication technology (ICT) are important driving forces. Several of the literature factors out that the producing organisation in China is a crucial pillar of the national economic machine, a leading sector of monetary growth, in addition to a provider of the know-how financial gadget. High-tech industries and production are inseparable [7]. The combination of excessive-tech technology with production is a chief improvement route, and the digital economic system is a vital growing course, which provides a theoretical and practical foundation for our research.

Most significantly, artificial intelligence systems taken into consideration in this context can present transformative technological solutions that provide the opportunity to relieve important uncertainties which might be crucial to new entrepreneurial activities [3]. Even as this disruptive capability of synthetic intelligence has been issued to growing attention in several research regions associated with entrepreneurship [5]. Together with enterprise, innovation, and business management it has not acquired tons interest in contemporaneous entrepreneurship research.

In line with the writer the technology of artificial intelligence in entrepreneurship has necessarily begun and this holds for each entrepreneurship studies and practice. Moreover, as noted via researcher, it is a long way from apparent how artificial intelligence era can transform studies and improvement sports for new ventures [14]. Ultimately, despite the fact that scholars and practitioners keep in mind AI as a singular technology as a way to reshape and alter commercial enterprise activities, assignment performance, opposition, and markets entrepreneurship studies have simplest focused on investigating and know-how entrepreneur intentions to use this generation, such as literature in if the performance expectancy of synthetic intelligence solutions can to start with power entrepreneurial intentions this work advances AI theoretical development literature in particular in the area of exploring the factors influencing entrepreneurship intentions [16].

The virtual financial system has externality, independence, and irresistible traits, and this complex and emerging product is the product of human notion and behaviour [9]. With the close combination of frequent technology, particularly, facts digitization and the net, the level of connection among behaviour and thought has been dramatically improved, and DE has been rapidly incorporated into the financial improvement of society [15]. DE's speedy development has come to be the spine of technological development and great monetary increase in many nations. DE has also turned into a key driving force of China's.National earnings development [11]. The author studied the correlation among DE and the herbal gadget. The outcomes display that the coupling coordination diploma among the 2 has been on the upward thrust [4].

The virtual economy employs information and internet technology to digitize the production, operation and control sports, and intake activities of various industries. Many scholars have studied the measurement of the virtual economic system, but there's no unified measurement preferred. In related studies, the evaluation methods mainly include the entropy weight TOPSIS approach [4], excellent-efficiency SBM version [14], linear weighting technique [8], important aspect evaluation, etc. Some students study from special perspectives of index selection. For instance, the author [12] calculated the national scale of the digital financial system from 4 aspects: virtual permitting infrastructure, virtual trading, virtual economy buying and selling products, and digital media. The author [6] made measurements on national and provincial stages from four aspects: digital foundation,Digital application, digital innovation, and digital transformation.

The synthesis of related works highlights a critical gap in existing research concerning the integration and impact of artificial intelligence (AI) within the domain of entrepreneurship. While the disruptive potential of AI technologies in transforming business landscapes is widely recognized, its specific application and influence on entrepreneurship remain underexplored. Existing literature has largely concentrated on the broader implications of AI within business management, innovation, and high-tech industries, leaving a void in our understanding of how AI can foster new entrepreneurial ventures. This oversight points to a significant research opportunity: to systematically investigate how AI can serve as a pivotal tool in the entrepreneurial process, from opportunity identification to venture creation and scaling. There's a pressing need for studies that delve into the mechanisms through which AI technologies can be leveraged to alleviate the uncertainties and challenges inherent in new venture development. Such research would not only contribute to the theoretical advancement of entrepreneurship as a field but also offer practical insights for aspiring entrepreneurs navigating the complexities of the digital economy.

3. Proposed Methodology. This system pursuits to provide a complete and sensible method for leveraging superior technology like CNNs in massive statistics analysis and digital sharing to revolutionize entrepreneurship schooling in the digital financial system. Collect good sized datasets comprising digital interactions, studying patterns, and entrepreneurial effects from diverse academic establishments and virtual structures. Encompass statistics from on-line publications, virtual workshops, scholar initiatives, and entrepreneurial ventures facilitated in educational surroundings. Smooth and categorize the information for analysis, ensuring the removal of irrelevant or redundant information. Categorize facts based on various parameters like scholar engagement, innovation effects, digital collaboration, and market response.

Develop a CNN version tailor-made for reading educational datasets, that specialize in pattern reputation in virtual studying behaviours and entrepreneurial success metrics. Educate the CNN version using a part of the gathered facts, optimizing it to pick out key predictors of a success innovation and entrepreneurship schooling consequences. Compare digital sharing practices, including collaboration equipment, online discussion forums, and peer-to-peer networks, to recognize their impact at the getting to know technique. Use qualitative

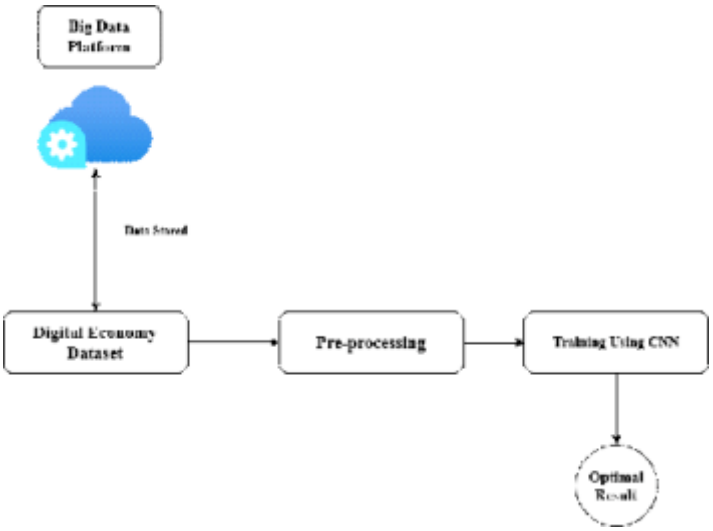

Fig. 3.1: Architecture of Proposed Method

evaluation methods to assess the effectiveness of virtual sharing in fostering innovation and entrepreneurial abilities. Combine findings from CNN-primarily based huge data evaluation with insights from the digital sharing evaluation. Conduct a comparative evaluation to decide the relative impact of large statistics analytics and digital sharing on fostering innovation and entrepreneurship. In figure 3.1 shows the architecture of proposed method.

3.1. Data Collection. Records series and preprocessing are essential degrees in carrying out large information analysis and digital Sharing research, within the context of Innovation and Entrepreneurship training inside the digital economic system generation. The technique involves several steps to make sure the facts is accurate, relevant, and equipped for analysis. Without a doubt outline what records is needed to cope with the research questions. This could include statistics on modern-day instructional practices, innovation trends, digital generation usage, and entrepreneurship consequences.

1. *Academic establishments:* acquire information from universities and colleges providing entrepreneurship guides, which includes direction content material, teaching methodologies, and scholar feedback.
2. *Virtual systems:* gather records from on-line academic structures, forums, and social media to apprehend the digital sharing factor.
3. *Industry statistics:* include facts from startups, innovation hubs, and enterprise incubators.
4. *Public Databases:* make use of public databases for broader monetary and technological tendencies.

3.1.1. Data Pre-processing.

1. *locating off Inconsistencies:* get rid of any discrepancies in the information, consisting of distinct codecs for dates or specific variables.
2. *Dealing with lacking facts:* determine the way to cope with missing values, whether to impute, do away with, or ignore them.
3. *Information Integration*: Combining more than one asset: Merge data from diverse resources into a constant format.

3.2. Entrepreneurship Education in the Digital Economy Era. Entrepreneurship schooling within the virtual financial system technology refers to the procedure of equipping college students with the abilities, knowledge, and attitude required to successfully have interaction in entrepreneurial sports within the context of the cutting-edge virtual economic system. This form of training has evolved appreciably to address the unique challenges and opportunities offered with the aid of the virtual generation. The virtual economy encompasses monetary activities that rely upon virtual technologies. It consists of e-trade, on-line offerings, virtual content

manufacturing, and using statistics and digital networks. It is essential for aspiring marketers to apprehend how digital technology have transformed industries, purchaser behaviour, and enterprise fashions.Understanding digital gear and systems which can be critical in nowadays' s commercial enterprise surroundings. Abilities in using social media for marketing, e-commerce platforms for sales, and virtual tools for commercial enterprise management. Fostering a mindset that encourages innovation in virtual services and products. Encouraging innovative problem-solving abilities that leverage virtual technology. Understanding of laws and regulations governing digital companies, such as privacy laws and highbrow property rights.

3.3. Training Using CNN. The methodology involves a comprehensive evaluation of the way CNN can be tailored for academic functions in analysing massive facts. This consists of comparing CNN's efficacy in deciphering complex facts structures and its potential in enhancing digital sharing practices amongst students and educators. The have a look at employs a aggregate of qualitative and quantitative studies techniques, including case studies, experiments, and surveys within instructional settings.

One of the key objectives is to discover how CNN can be used to offer practical, arms-on revel into students in handling actual-global large statistics situations, thereby improving their analytical and choice-making abilities. Some other recognition is on understanding the role of CNN in facilitating collaborative digital sharing and learning, which is vital for nurturing a way of life of innovation and entrepreneurship.

Layered architecture: CNNs encompass more than one layers that mechanically and adaptively research spatial hierarchies of capabilities from enter photos. The layers are typically composed of convolutional layers, pooling layers, and fully connected layers.

Convolutional Layers: these layers perform a convolution operation, making use of filters to the input to create function maps. This manner allows the network to come across features which includes edges, textures, and complex patterns inside the enter statistics.

Pooling Layers: Following convolutional layers, pooling layers (like max pooling) lessen the spatial size of the representation, reducing the variety of parameters and computation in the community. This also allows in making the detection of capabilities invariant to scale and orientation modifications.

Fully connected Layers: at the end of a CNN architecture, one or extra completely linked layers are used wherein every input is hooked up to each output. Those layers are usually used for classifying the functions extracted by using the convolutional layers and down sampled by way of the pooling layers.

ReLU Activation function: CNNs often rent the Rectified Linear Unit (ReLU) activation characteristic for its layers because it introduces non-linearity inside the network, permitting it to study greater complicated styles.

4. Result Analysis. The research on large facts analysis and digital Sharing in the context of innovation and entrepreneurship education highlights numerous key findings. It emphasizes the significance of virtual innovation in enhancing societal price and financial increase. Studies show that entrepreneurial activities fuelled by means of virtual innovation result in higher living standards and sell new marketplace possibilities. In this work, the dataset is taken from open-source Kaagle dataset. The evaluation metrics such as accuracy, precision ad recall is evaluated and compared with existing methods.

$$accuracy = \frac{TP + TN}{TP + TN + FP + FN} X100 \tag{4.1}$$

$$precision = \frac{TP}{TP + FP} X100 \tag{4.2}$$

$$recall = \frac{TP}{TP + FN} \tag{4.3}$$

In table 4.1 shows the experimental results of proposed work.

Predicted results of the look at encompass a complete evaluation of the accuracy of CNN models in processing and decoding complex datasets relevant to the digital economy. The studies goals to offer proof-based

Table 4.1: Experimental Results

Methods Used	Precision (%)	Recall (%)	Accuracy
TL-CNN	90.4	89	87.6
DNN	89.32	77.32	83.4
BiLSTM	81.4	83.4	74.1
Proposed Method	99.35	99.89	98.17

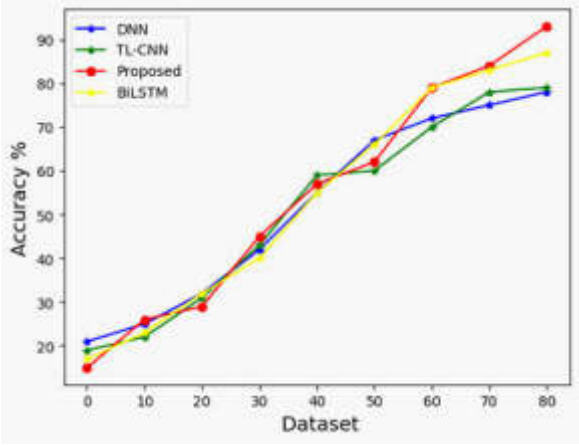

Fig. 4.1: Accuracy

totally suggestions on integrating CNNs into entrepreneurship and innovation curricula. By using doing so, the examine seeks to decorate the educational framework, making ready students extra correctly for the demanding situations and opportunities of the virtual age. The expected outcome is a giant contribution to the sphere of instructional era, demonstrating how advanced AI techniques like CNNs can revolutionize mastering inside the context of the virtual financial system.

To assess the accuracy of education within the digital economic system generation using Convolutional Neural Networks (CNN), it is important to make clear that CNNs are a type of deep gaining knowledge of set of rules mainly used for processing visible imagery. They're now not usually used directly for comparing instructional accuracy but can be applied in academic contexts for various purposes like reading educational materials, pupil engagement thru visual information, or interactive mastering equipment. Figure 4.1 displays the accuracy evaluation.

The examine adopts a qualitative studies technique, exploring various packages of CNNs within the virtual financial system thru case studies and professional interviews. It examines how CNNs technique and examine massive units of unstructured records, particularly photo and video records, to deliver insights that drive precision in virtual advertising, consumer behaviour evaluation, and product recommendation structures. Moreover, the research investigates the function of CNNs in improving safety features in virtual transactions and within the improvement of wise structures for market fashion evaluation and prediction.

Key findings are expected to highlight the transformative impact of CNNs at the digital economic system, emphasizing advanced accuracy in purchaser engagement, more advantageous predictive analytics, and increased common performance in virtual operations. The studies pursuits to provide a comprehensive information of how CNNs make contributions to the precision of digital financial system practices, providing valuable insights for agencies and era experts searching for to combine superior AI technologies into their digital strategies. In figure 4.2 shows the result of precision.

Recall, also referred to as sensitivity, measures the ability of the model to locate all the applicable instances inside a dataset. In the context of the digital economy, consider could measure the percentage of real nice

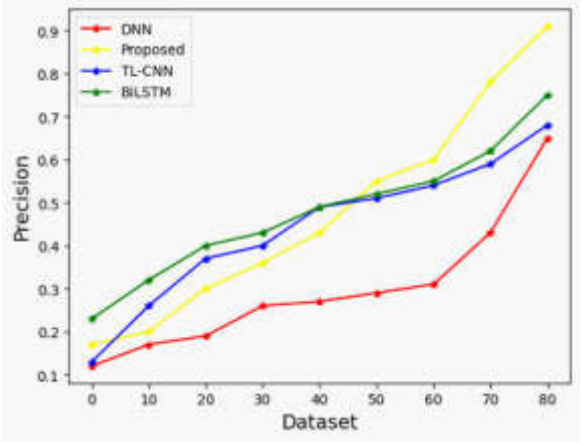

Fig. 4.2: Precision

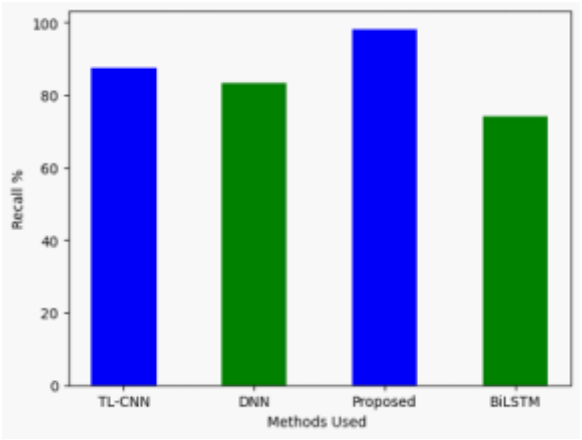

Fig. 4.3: Recall

identifications (e.g., a success digital transaction, nice patron feedback) that the CNN efficiently diagnosed. High recall method that the CNN is right at taking pictures maximum of the applicable records points.CNNs are a kind of deep studying algorithm which can be mainly appropriate at processing statistics with a grid-like topology, including snap shots. Within the context of the digital economic system, CNNs will be used for numerous purposes like studying patterns in customer behaviour via information visualization, figuring out trends in virtual advertising and marketing campaigns, or even for extra complex responsibilities like sentiment analysis of purchaser reviews. In making use of CNNs with a focal point on consider for the digital economic system, one would prioritize minimizing false negatives (e.g., failing to discover a successful virtual advertising method or missing out on key patron insights). This is particularly important in areas were lacking out on key facts can lead to massive monetary implications, which include in marketplace fashion analysis or customer desire studies.In figure 4.3 shows the result of Recall.

5. Conclusion. Inside the swiftly evolving landscape of the virtual financial device, the function of schooling in fostering innovation and entrepreneurship has become increasingly critical. This takes a look at goals to explore how big facts analysis and virtual sharing techniques may be leveraged to supplement innovation and entrepreneurship education. The look is grounded within the context of the digital economic system era, characterised by the useful resources of the proliferation of virtual technologies and the exponential boom of in-

formation. The central goal is to analyse how academic strategies can be more appropriate through large records analytics and digital sharing software, thereby making university students more efficient for entrepreneurial roles in the digital age. The studies rent a deep learning approach, combining quantitative statistics evaluation with qualitative insights. Primary information might be gathered through surveys and interviews with educators and marketers, whilst secondary information might be sourced from current instructional literature and case research. Predicted results consist of a hard and fast of pointers for academic establishments on integrating huge information and virtual sharing tools into entrepreneurship training. The examine objectives to offer insights into how this generation can enhance college students' analytical and modern competencies, put together them for the demanding situations of the virtual economic system, and foster a lifestyle of innovation and entrepreneurial attitude. This study is anticipated to contribute appreciably to the discourse on education within the digital age, offering a roadmap for leveraging rising technologies to domesticate the following generation of marketers and innovators.

VISUAL COMMUNICATION METHOD OF MULTI FRAME FILM AND TELEVISION SPECIAL EFFECTS IMAGES BASED ON DEEP LEARNING

JINGLEI ZHANG *

Abstract. For the dynamic film and television special effects industry, creating visually stunning and valuable graphics requires the integration of excellent deep-learning algorithms. This paper presents an enhanced version of the 3-D Convolutional Neural Network (3-D CNN), specifically tailored to meet the demanding needs of multi-frame television and film special effects. The version's key feature is its efficient data handling through coupled precision training, significantly increasing computational efficiency while reducing memory needs. This method, which combines floating-issue operations of 16 and 32 bits, is ideal for efficiently processing large amounts of high-resolution video data. The proposed 3-D CNN structure excels in extracting and analysing complex spatiotemporal capabilities from video sequences, capturing the spatial and temporal nuances crucial in film imagery. This capability is important for accomplishing excessive fidelity in visual results, ensuring seamless integration with live motion pics. Incorporating a cutting-edge attention mechanism inspired by the aid of transformer-based architectures, the model specialises inside the maximum pertinent components of video frames to enhance the quality and realism of outcomes. Furthermore, the model boasts an excessive-resolution processing characteristic, permitting simultaneous capture of first-rate records and broader scene context. This guarantees consistency and realism in outcomes, from complicated textures to the overarching visual narrative. Advanced regularisation strategies are hired to prevent overfitting, permitting the model to generalise efficiently through numerous film manufacturing conditions. The state-of-the-art 3-D information augmentation techniques make the model robust and prepare it to deal with an intensive variety of challenging situations involving computer special effects. Real-time processing competencies make the model a game-changer for on-set visible outcomes and adjustments. Designed for seamless integration with the famous CGI software program software utility, it allows a harmonious aggregate of AI and ingenious creativity. Acknowledging the environmental impact of high-powered computing, the model consists of power-efficient computational techniques that align with sustainable computing practices, lower operational costs, and are related to processing complex video statistics. model boasts an excessive-resolution processing characteristic, permitting simultaneous capture of first-rate records and broader scene context. This guarantees consistency and realism in outcomes, from complicated textures to the overarching visual narrative. Advanced regularisation strategies are hired to prevent overfitting, permitting the model to generalize efficiently through numerous film manufacturing conditions. The state-of-the-art 3-D information augmentation techniques, in addition, make the model robust, and prepare it to deal with an intensive variety of computer special effects challenging situations.

Key words: Visual communication methods, mixed precision training, spatiotemporal feature extraction, real time processing, 3D CNN, data augmentation, sustainable computing practices

1. Introduction. In the dynamic world of film and TV product, the combination of advanced technologies similar as deep learning has come a foundation for producing instigative and inspiring content [15, 2]. The development of special effects, due to the arrival of advanced computer methods, changed visual narrative of language. This study presents a 3D convolutional neural network(3D CNN) model designed to meet the complex requirements of multi-frame film and TV special effects [13, 19]. The proposed model uses optimal training, a model that balances computational effectiveness and model delicacy, which is suitable for recycling large quantities of high- resolution video data, this is the substance of ultramodern special effects processing.

The armature of this model has been precisely designed to reuse and dissect complex spatial features in video sequences [12, 3]. This capability allows you to understand the complexity of the scene and the dynamics of the scene in the picture images, which is important to achieve high dedication in visual situations [23]. By guaranteeing the integration of effects into live action footage, this model will change the way visual narratives are crafted and presented [4]. The model layers are adept at feature extraction, but the preface of advanced styles similar as mixed integration training improves the model effectiveness, which is veritably important for the dynamic conditions of the film and TV products [10, 17].

An important part of this model is its focus on operational efficiencies. Using a combination of 16- bit and

*Jilin animation college Changchun China 130013 (jingleizhang21@outlook.com)

32- bit afloat- point operations during training, this model optimizes recycling speed and training effectiveness [11, 6]. This approach is important to manage the quantum of data involved in recycling high quality special effects. In addition, the stiffness of this model is shown in different operations across age groups and professional surroundings, showing its scalability and versatility in content creation [22, 18]. Processing time and resource operation criteria increase the model's utility, making it a precious tool for content generators and workrooms to efficiently produce content without compromising quality [24, 20].

Eventually, the effect of models on the quality of vision cannot be overstated [5]. In an application where the participation of the followership is important, the visual appearance and trustability of the special effects are important [7]. The model can give dependable, high-quality products that appeal to different audiences and demonstrate its effectiveness. The study concludes that the proposed 3D CNN model represents a significant advance in film and TV products with its innovative armature and processing capabilities. Its benefactions not only enhance the visual quality of content but also define the scalability and reliability of special effects products in a decreasingly digital and fast-paced media terrain.

A revolutionary change in the rapidly expanding sector of special effects for cinema and television is imminent, thanks to the use of cutting-edge deep learning algorithms. The goal of this proposed research is to use enhanced 3-D Convolutional Neural Networks (3-D CNNs) to create extremely realistic and visually appealing special effects, thereby addressing a major obstacle. The need for realistic, high-quality graphics that mix in with live-action footage is greater than ever in the fast-paced and highly technical world of film and television production. This work presents a novel 3-D CNN model with coupled precision training that establishes a new industry standard.

The contribution of the paper are as follows:

1. Proposed a novel approach of 3D CNN with mixed precision training integration for movie and television special effects.
2. The proposed model is trained with the different set up of simulations and demonstrates its efficacy in respective manner.
3. The experiments of the proposed are depicted with valid proofs.

2. Related Work. The paper [9] explores the synergy among virtual era and new media art, emphasizing the evolving function of digital tools in ingenious expression. The observe introduces practical visible art work creation, an idea that aligns with the improvements of the smart era, blending artwork with deep learning. The studies technique, encompassing case research and experimental analysis, creates an interdisciplinary framework, highlighting the functionality and worrying conditions of this novel artwork. It posits a future wherein virtual technology profoundly affects and figures the scene of virtual media art. The paper [21] addresses the increasing recognition of spiritually themed films and tv suggests, emphasizing the need for efficient techniques to find audience desired animations in large databases. It employs artificial intelligence and machine learning to know to discover new visible expressions in animation movies, using a Convolution neural network to investigate "Kung Fu Panda news." With an accuracy of 57% in the test set, the observe underscores the importance of revolutionary visible illustration inside the movie industry's development and creative development. The paper [16, 14] examines the impact of AI and machine learning knowledge of to recognize in enhancing the visible outcomes of active movies, specializing in computer imaginative and prescient packages. by using analyzing the Hollywood anime film "Coco" with convolutional neural algorithms, the examine finds an everyday check set accuracy of around 59%. This study emphasizes the feature of digital technology in elevating the audiovisual great and creativity of movie productions, contributing to sustainable increase in the animation location. The paper [1] explores the aggregate of artificial intelligence and digital truth (VR) era in film and tv animation (FTA) training. It combines dynamic environment modeling, actual-time 3-D images, and VR for training layout, considerably improving students' engagement and comprehension in FTA. The utility of VR in FTA training is established to beautify lecture room delight and expert skill acquisition, highlighting VR's potential to revolutionize instructional strategies in animation and format

From the above review analysis, visual communication in the television applications has more effects when technologies upgrade to 3D models. These 3D models needs to be communicated using AI technologies for efficient feature transactions.

3. Methodology. The system of the proposed study on advanced 3D CNNs for film and TV special effects relies on a sequence of methodical and connected way which is illustrated under Figure 3.1. Initially, the study starts with the collecting a comprehensive dataset comprising multi-frame sequences from different film and television content material. This dataset is strictly curated to include a wide range of visible issues, ensuring diversity in the data. Following data collection, the coming step consists of preprocessing the data, which incorporates normalization, resolution adaptation, and the operation of primary pollutants to enhance the quality of the input frames for more effective training of the neural network. The center of the system revolves across the layout and perpetration of the 3- D CNN interpretation. This includes configuring multiple layers of the network, together with convolutional layers, pooling layers, and fully connected layers, each serving as a distinct function in feature extraction and pattern recognition. A big aspect of the model's configuration is the combination of combined precision training, the operation of both 16- bit and 32- bit afloat-element operations to balance computational effectiveness and model delicacy. Once the model is configured, it undergoes a rigorous training manner using the organized dataset. This training is done with the operation of back propagation and gradient descent algorithms, with the amalgamated perfection approach ensuring faster computations and efficient memory usage. Throughout the training section, continuous monitoring and changes are made to optimize the models average performance, together with tuning hyperparameters and applying advanced regularization ways to prevent overfitting. After the training phase, the model is estimated by separate set of data not included within the training process. This assessment specializes within the model's delicacy, overall performance, and capacity to address several special effects challenges. The models real-time processing capabilities are also precisely tested to insure its connection in live surroundings. The final step of the methodology is the integration of the trained 3D CNN model with being CGI software program software operation systems. This integration is important for realistic software, allowing special goods artists to seamlessly use the model with in their separate workflows. The system concludes with an expansive evaluation of the models overall performance, together with its effect on enhancing the quality and literalism of special effects in film and TV production.

3.1. Proposed 3D CNN with mixed training precision Integration. This section implies the clear illustration of proposed 3- D CNN structure which is adapted from the study [13]. Traditional machine learning method depends upon manual feature extraction from datasets, feeding these extracted low- stage features into a machine learning algorithm. In comparison, deep learning ways, like CNNs, automatically extract features from raw datasets, processing low, middle, and high- level features for tasks like detection and classification. This eventuality to apply nonlinear features to raw statistics and produce abstracted outputs is an index of deep learning, significantly benefit from huge datasets and effective GPUs, which minimizing training time and enhance classification accuracy. In the realm of computer visionary, audio classification, and natural language processing, CNNs, along other infrastructures like DBNs, RNNs, LSTMs, and DSNs, were vital in dealing with huge datasets. CNNs, inspired through connected biological neurons, encompass neurons with weights and biases. At the same time as both CNNs and traditional ANNs include layers, CNNs vary appreciably of their structure. Unlike the one-dimensional 1D CNN layer structure in ANNs, CNNs have 3 D dimensional neurons in a layer, encompassing width, height, and depth. Each neuron in a CNN layer connects a particular region of the previous layer, utilizing local connections and pooling operations to come through and combine identical features. The usual CNN armature incorporates convolutional layers, pooling layers, and fully connected layers.

For our proposed 3 D CNN model made for television special effects, we adjust those generalities with a focal point on combining precision training. This model combines 16 bit and 32- bit afloat- point operations, optimizing computational performance and delicacy for managing with the large volumes of high- decision video data typical in special effects processing. The convolutional layers in our model will include feature maps and neurons, Pooling layers will reduce parameter countand network computations, preventing over fitting for the duration of training. On this proposed 3-D CNN structure, we emphasize the combination of mixed precision training in all layers, especially inside the convolutional and fully connected layers, to enhance the training effectiveness and performance. The fully connected layers, similar to the bones in regular ANNs, will connect all neurons of a layers to all neurons of the previous layer, supplying the fineness score among all dataset classes. also, the use of the ReLU activation function will insure high performance and fast learning, critical for real-time processing in special effects packages.

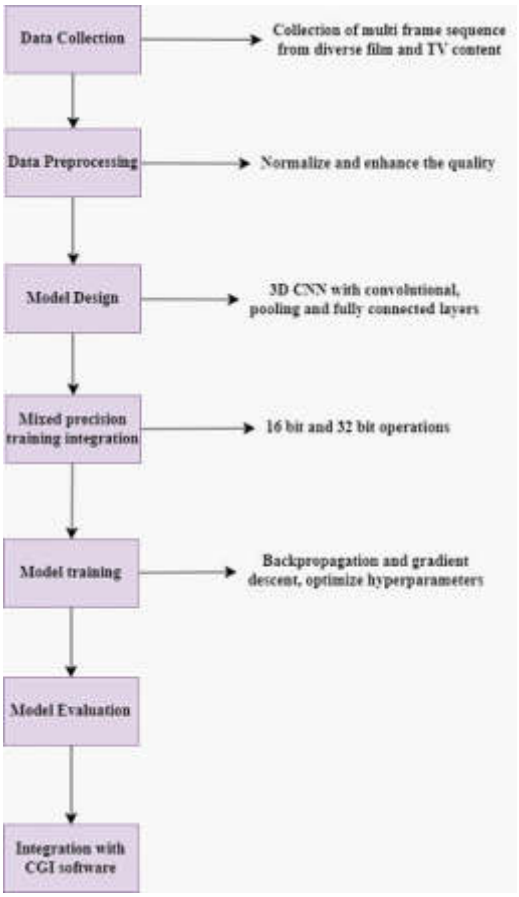

Fig. 3.1: Proposed Architecture

The algorithm for the proposed 3D CNN with combining precision training for enhancing special effects in TV begins with raw datasets of multi-layered video sequences. In the first step, these datasets are regularized and their decision is adjusted to make sure uniformity and utmost dependable optimal quality for processing. Following this preprocessing, entails applying convolutional operations to each feature maps in the statistics. This step is pivotal as it allows for the extraction and improvement of unique functions within the video frames, this is essential for detail and quality special effects. Next is to reduce the size of the affair from the convolutional layers. This system, generally related to as pooling, facilitates to drop the computational load and the complexity of the interpretation by repeating the functions extracted within the convolutional layers. Following this, all neurons in one layers are connected to all neurons within the previous layer. This completely fully connected layer integrates the features extracted in previous steps, taking into consideration more complicated and higher- level understanding of the data. The application of the ReLU function for non-linear transformation. This activation function introduces non-linearity into the model, enabling it to learn redundant complex styles in the records. Next, a combined precision training is employed, combining 16- bit and 32- bit operations. This system enhances the computational effectiveness of the interpretation, making it faster and more resource-effective, which is essential in large size of video datasets. Updating the weights of the network using Stochastic Gradient Descent(SGD) and back propagation. This is a crucial phase where the model learns from the data by using adjusting its weights to reduce minimize errors in its predictions. latterly, the trained network is applied to model and special effects in TV products. This entails making use of the learned models to new records, growing bettered and further sensible special effects primarily grounded on the

Algorithm 23 Video Sequence Processing and Enhancement

Input: Raw datasets of multi-frame video sequences
procedure Data Preprocessing
    Normalize and adjust the resolution of input data.
end procedure
procedure Convolutional Operations
    Apply convolutional operations to each feature map:
    $y_i^l = b_i^l + \sum_{j=1}^{m_{1(l-1)}} f_{i,j}^l \times w_j^{(l-1)}$
end procedure
procedure Reduce Output Size
    Reduce the size of the output from the convolutional layers:
    $w_2 = (w_1 + f \times s) + 1$
    $h_2 = (h_1 + f \times s) + 1$
end procedure
procedure Connect Neurons
    Connect all neurons of a layer to all neurons of the previous layer:
    $y_i^l = f(z_i^l)$ with $z_i^l = \sum_{j=1}^{m_{1(l-1)}} \sum_{r=1}^{m_{2(l-1)}} \sum_{s=1}^{m_{3(l-1)}} w_{i,j,r,s}^l \times (y_{r,s}^{l-1})$
end procedure
procedure ReLU Transformation
    Apply ReLU for non-linear transformation:
    $\begin{cases} 1 & \text{for } z > 0 \\ 0 & \text{otherwise} \end{cases}$
end procedure
procedure Mix Precision Training
    Combine 16-bit and 32-bit operations, mix precision for computational efficiency during training.
end procedure
procedure Update Weights
    Update weights using SGD and back propagation:
    $C = \frac{1}{n} \left(\sum \times \sum_j (y_j \ln a_j^l) \right) + (1 + y_j) \ln(1 - a_j^l)$
end procedure
Output: Trained network for processing and enhancing special effects in television products.

delicate styles the model has discovered to apprehend and interpret.

4. Results and Experiments.

4.1. Simulation Setup. The proposed study uses the simulation setup based on the study [8]. The dataset within study at is characterized through its awareness on a numerous range of target groups, which affords depth and connection to the evaluation of computer graphics in tv and animation. these groups encompass Preschoolers, lower Grades of elementary schools, higher Grades of elementary schools, Baomoms and dads and Animation developers, each imparting particular insight into their separate choices and perceptions. The addition of such varied demographics gives a comprehensive view of the target group spectrum, starting from very young children to grown- ups and professional content creators. Preschoolers and elementary school students represent the younger audience, whose engagement with animation is fundamentally distinctive because of their development ranges and cognitive capacities. Junior high school students, being slightly older, have further sophisticated tastes and understanding, it's really meditated in their responses to special effects. Bao mom and dad probably the parents of the children in the earlier corporations, provide a parental angle this is critical in knowledge circle of relatives orientated content. Ultimately, Animation creators provide a professional point of view, that specialize in technical and imaginative components of computer graphics, that is important for gauging the enterprise morals and tendencies. The dataset's shape permits for an in-intensity assessment of the way exceptional age agencies and stakeholders reply to and perceive the exceptional, effectiveness, and attraction of special effects. The form of multifaceted model is useful for accommodating content to specific audiences, ensuring age-appropriate and engaging visual stories. It additionally presents valuable perceptivity

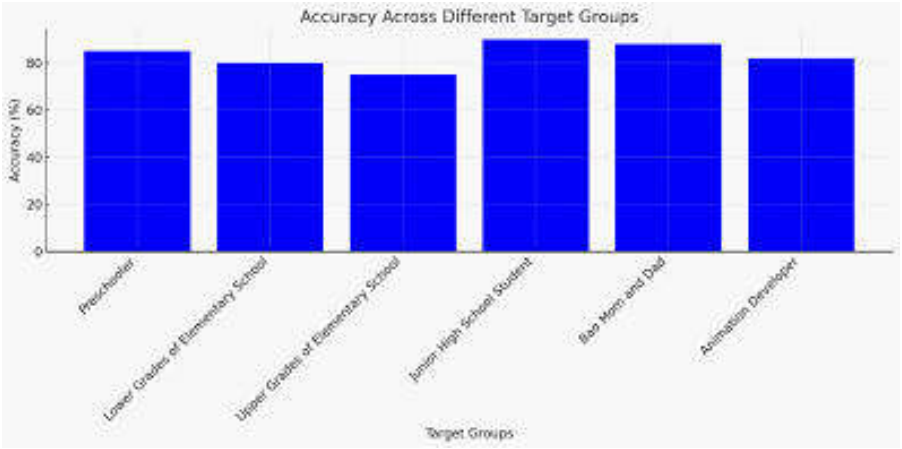

Fig. 4.1: In Terms of Accuracy

for animation creators and producers in growing content that resonates with their supposed target audience, making the dataset an important tool for enhancing the excellent and connection of tv and animation content.

4.2. Evaluation Criteria. The proposed model's effectiveness in demonstrated in terms of accuracy is illustrated throughout different target groups, ranging from Preschoolers to Animation creators. Figure 4.1 shows a nuanced sample of efficacy degrees, with Junior high school students experiencing the highest score at 90.12%. This shows that the model's special effects are specifically resonant and effective for this age association, possibly aligning nicely with their cognitive and perceptual development ranges. Preschoolers and Bao moms and dads with(85.68% and 88.32%), indicating that the effects are well- received and accurately perceived by means of these groups. still, the low grades of elementary schools show slightly reduced efficacy, inferring at a capacity mismatch between the results produced and the preferences or understanding of these younger audience. This variation in accuracy underscores the models capability to cater to different age groups and highlights areas wherein further customization or refinement may want to enhance target request engagement and satisfaction.

The processing time figure 4.2 for the proposed model showcases its performance across different target groups. A clean downward trend in processing time is observed, beginning from 30 hours for Preschoolers to 20 hours for Animation developers. This lowering sample indicates that the model is specifically effective for expert users like Animation creators, in all liability due to their lower requirements or the models optimization for professional content material. The extensively advanced processing times for younger age groups, like Preschoolers and lower grades of elementary school, might reflect the complexity or the additional effort required to create engaging and age-appropriate content for these viewers. The gradual reduction in processing time as we move toward older age groups and professionals may also be attributed to the model's capability to adapt to the varying complexity of the tasks. This efficacy highlights the model's scalability and severity in processing times, feeding to a large spectrum of users from chidren to professionals in the animation industry.

The proposed model demonstrates its efficacy in terms of resource utilization across different target groups. Figure 4.3 suggests a shifting pattern, with Junior high school students and Bao moms and dads experiencing lower resource utilization (68.89% and 66.74%respectively), which could represent the models effectiveness in developing results for these groups without overreaching computational sources. In comparison, Preschoolers and the lower grades of elementary school exhibit slightly higher resource usage, potentially due to the complexity of making content this is engaging but suitable for younger viewers. The variation in resource operation displays the model's strictness and its capability to balance useful resource demands with the conditions of different age groups. This thing is vital for making sure that the interpretation can be effectively used in numerous product settings, catering to a wide range of audience preferences while maintaining computational efficiency.

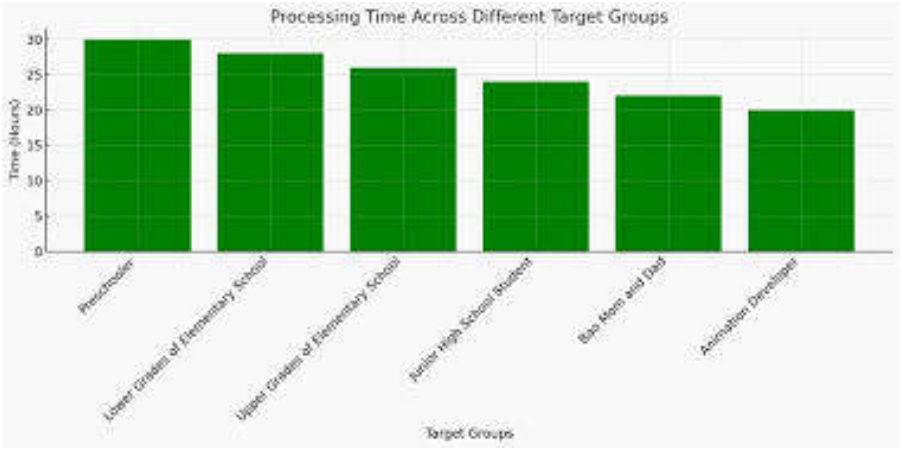

Fig. 4.2: Processing Time

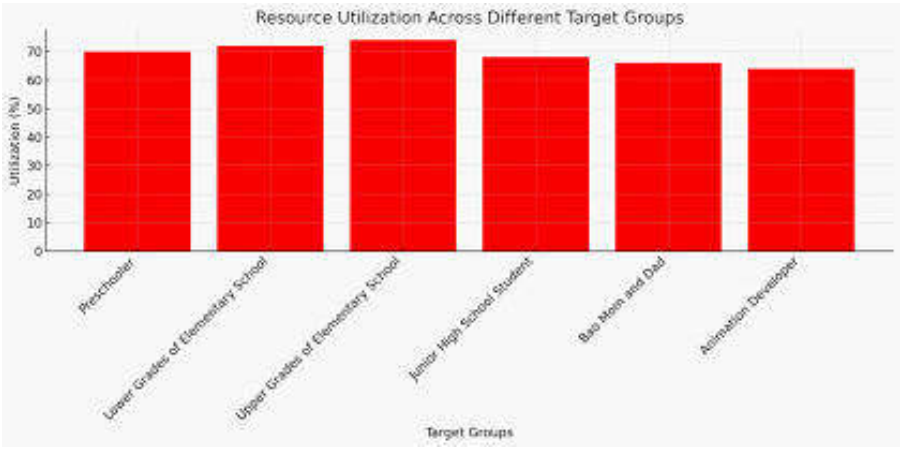

Fig. 4.3: Resource Utilization

The visible quality Figure 4.4 reveals the proposed model's capability to supply outstanding special effects, as perceived by means of special target groups. An ascending trend in visual quality ratings is observed, with the highest score of 90.38% for animation developers, indicating their high pleasure with the visible appeal and class of the effects. This trend would possibly image the growing complication and discerning tastes of aged viewers and professionals, who in all liability have advanced prospects for visual satisfactory. The models eventuality to deliver visual quality rankings across all associations, mainly excelling with animation developers, underscores its effectiveness in creating visually appealing and impactful content. This is important in the realm of television and animation, where the visible attraction and inventive high- quality of special effects play an important position in audience engagement and the overall success of the content.

5. Conclusion. The study underscores the effectiveness of the proposed 3D combined with mixing precision integration in enhancing special effects for television throughout various demographics. The model demonstrates a high degree of accuracy in special effects, especially resonating with Junior high school students, at the same time as also attractive efficaciously to younger audience and experts like Animation developers. Its performance is clear within the reducing processing cases, indicating the model's eventuality to address complex tasks suddenly, an essential feature in fast paced production environment. The shifting pattern in resource operation

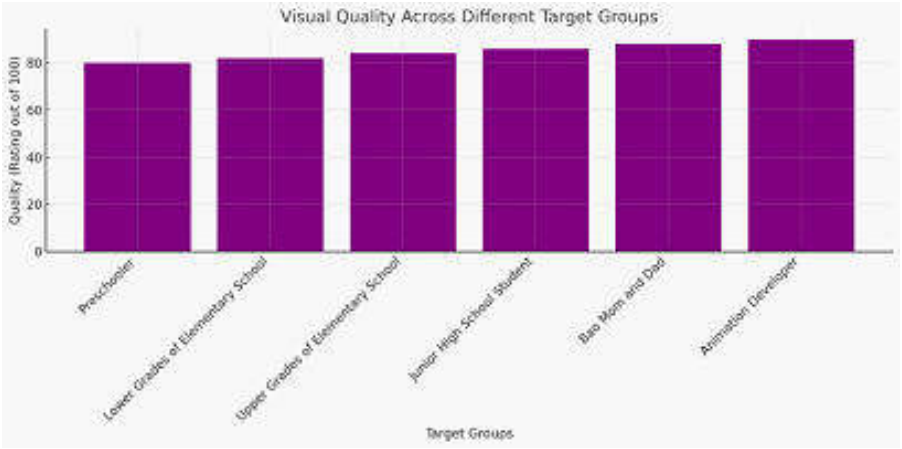

Fig. 4.4: Visual Quality

throughout distinct age groups highlights the model's severity in managing computational means, making it applicable for numerous product settings. likewise, the continuously high scores in visible quality throughout all demographics attest to the model's capability to produce visually fascinating and impactful special effects. This is particularly noteworthy with professional users, who regularly have better contemplations in expressions of visible complication. Overall, the study concludes that the proposed interpretation is a strong tool within the realm of television and animation, offering scalable, efficient, and visually striking results that feed to a wide range of audience, from children to industry experts. This makes it a treasured asset in enhancing the high- quality and enchantment of TV content in an increasingly more competitive and various media outlook.

A BIG DATA INTELLIGENT EVALUATION SYSTEM FOR SPORTS KNOWLEDGE

GAO PENG*

Abstract. The rapid evolution of computer technology has significantly impacted the field of medicine, particularly in the utilization of information and image evidence. In the realm of sports medicine, this technological advancement plays a crucial role in ensuring sports safety, especially in the context of injury recovery following sports-related activities. The necessity to interpret and utilize a vast amount of sports medical data effectively has emerged as a pivotal research avenue. This paper delves into the challenges associated with extracting, studying, and the accuracy training of complex algorithms essential for analyzing critical sporting medical data.Central to this discussion is introducing an Optimized Convolutional Neural Network (OCNN) model, which is based on deep learning principles. This model is designed to enhance the detection and risk assessment of diseases related to sport medicine. It incorporates a novel Self-Adjustment Resizing algorithm (SAR), augmented by a self-coding method of convolution (SCM). The proposed OCNN model comprises two convolutional layers, two pooling layers, a fully connected layer, and a SoftMax structure. This architecture is tailored for the classification and analysis of sport-related medical data.

Key words: Sports Medicine, Big Data in Sports, Injury Recovery Analytics, Convolutional Neural Network (CNN), Optimized Convolutional Neural Network (OCNN), Deep Learning in Medicine, Medical Data Analysis

1. Introduction. The intersection of technology and healthcare has opened new frontiers in sports medicine, particularly in analysing and managing sports-related injuries. The advancement of computer technology has revolutionised the way medical data, especially in sports, is collected, analyzed, and interpreted. The role of sports medicine has become increasingly vital, extending beyond traditional boundaries to incorporate technological innovations for enhanced sports safety. This surge in technology integration in sports medicine is driven by the need for precise and efficient injury recovery methods, a critical aspect of athlete care. The advent of big data and sophisticated analytical tools has enabled a more nuanced understanding of the physiological and biomechanical aspects of sports injuries. This understanding is crucial in devising targeted recovery strategies and in preventing future injuries, thereby safeguarding the health and career longevity of athletes. The transformative impact of these technological advancements in sports medicine underscores the importance of developing and refining methods for the effective utilization of sports medical data.

One of the most significant challenges in sports medicine is the interpretation and application of vast amounts of medical data generated during sports activities. Traditional methods often fall short in handling the complexity and volume of this data. This challenge necessitates the exploration and adoption of advanced computational techniques, particularly those leveraging artificial intelligence (AI) and machine learning [20, 5]. The implementation of Convolutional Neural Networks (CNNs) in sports medicine represents a groundbreaking approach in this regard. The CNN, a deep learning model, is renowned for its prowess in image recognition and processing, making it an ideal tool for analyzing complex medical images and data patterns. This research paper introduces an Optimized Convolutional Neural Network (OCNN) model, specifically designed for sports medicine applications. The OCNN model enhances the capabilities of standard CNNs by integrating a Self-Adjustment Resizing algorithm (SAR) and a self-coding method of convolution (SCM). These additions aim to improve the accuracy and efficiency of medical data analysis, particularly in the context of sports injuries. By optimizing the structure and function of the neural network, the OCNN model promises to offer a more nuanced and accurate interpretation of sports medical data, thereby contributing to better injury management and prevention strategies [17, 21].

Furthermore, this research explores the potential of integrating the OCNN model into a cloud-based system, thereby creating a comprehensive medical data network for sports medicine. This cloud-based approach

*Ministry of basic and quality Education, Qinghai Vocational and Technical College of Architecture, Xining 810012, Qinghai, China (gaopengreasn12@outlook.com)

facilitates the aggregation and analysis of multi-dimensional sports medicine data, offering a more holistic view of an athlete's health and injury risks. The cloud-based system also allows for real-time data processing and accessibility, essential for timely decision-making in sports injury management. By combining the analytical prowess of the OCNN model with the scalability and accessibility of cloud computing, this research aims to establish a new paradigm in sports medicine data analysis. The proposed system not only enhances the understanding of sports injuries but also paves the way for predictive analytics in sports health management. In conclusion, this research represents a significant step towards harnessing the power of big data and AI in sports medicine, ultimately contributing to the safety, recovery, and performance optimization of athletes.

The primary motivation for this research lies in addressing the critical gap in sports medicine related to the analysis and interpretation of complex medical data associated with sports injuries. In the realm of sports, where the physical well-being of athletes is paramount, the need for accurate, timely, and effective diagnosis and treatment is crucial. Traditional methods of data analysis in sports medicine have been limited in their capacity to handle the sheer volume and complexity of data generated, particularly in high-performance sports. This has often led to generalized treatment protocols, which may not be optimal for every individual athlete's unique physiological makeup and injury patterns.

Furthermore, the motivation also stems from the potential to significantly enhance injury prevention strategies. By leveraging advanced computational techniques, such as deep learning and neural networks, the research aims to provide a more nuanced understanding of injury mechanisms. This understanding can lead to the development of personalized injury prevention and recovery programs, substantially reducing the risk of re-injury and improving the overall health and performance of athletes.

The novelty of this research is multifaceted, primarily residing in the development and application of the Optimized Convolutional Neural Network (OCNN) model in the field of sports medicine. This represents a significant advancement over traditional neural networks due to its specialized architecture and algorithms, which are specifically tailored for sports medical data analysis. The integration of the Self-Adjustment Resizing algorithm (SAR) and the self-coding method of convolution (SCM) within the OCNN model are innovative aspects that enhance its accuracy and efficiency in processing complex sports medical data.

The novelty of this research is multifaceted, primarily residing in the development and application of the Optimized Convolutional Neural Network (OCNN) model in the field of sports medicine. This represents a significant advancement over traditional neural networks due to its specialized architecture and algorithms, which are specifically tailored for sports medical data analysis. The integration of the Self-Adjustment Resizing algorithm (SAR) and the self-coding method of convolution (SCM) within the OCNN model are innovative aspects that enhance its accuracy and efficiency in processing complex sports medical data.

Another novel aspect of this research is the proposed cloud-based system for sports medicine data analysis. This system not only centralizes data storage and processing, making it more accessible and scalable, but also allows for real-time analysis and application. Such a system has the potential to revolutionize injury management in sports by providing immediate insights and predictive analytics, enabling quicker and more effective decision-making.

2. Literature review. The study [22] introduces a big data and deep learning-based video classification model for sports, showcasing how technological advancements can enhance sports analytics and performance evaluation through effective video analysis.The article [13] explores the synergy between the brain and body in sports, emphasizing the influence of big data on sports systems and providing a quantitative analysis of how this integration impacts athletes and sports dynamics.This systematic review [6] focuses on the use of big data in professional soccer, specifically how it supports tactical performance analysis, underlining the potential and challenges of utilizing large datasets in sport strategy and performance enhancement.

The paper presents [16] an analysis of basketball players and team performance using sports analytics, demonstrating the application of information systems in evaluating sports strategies and player efficiency. The review [8] discusses the utilization of machine learning for predicting sports outcomes, highlighting the growing role of advanced data analysis techniques in forecasting and strategizing in sports. The article [2] examines how deep learning and IoT big data analytics can support the development of smart cities, including the application in sports, offering insights into future directions and the integration of technology in urban development.

The research constructs [23] a growth forecast model for the sports culture industry based on big data,

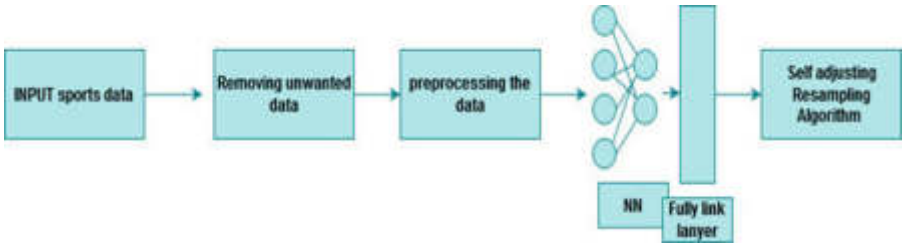

Fig. 2.1: The proposed architecture

showcasing the use of data analytics in predicting and enhancing the growth of sports-related cultural sectors. The paper [10] focuses on deep soccer analytics, particularly in learning an action-value function for evaluating soccer players, marking a significant step in applying data mining techniques in sports performance analysis. The systematic literature [14] review investigates intelligent data analysis methods for smart sport training, emphasizing the role of AI and data analysis in enhancing sports training methodologies.

The article [7] provides a comprehensive survey on AI-big data analytics in building automation and management systems, touching on its potential application in sports facilities and athlete performance monitoring.The study [11] builds a prediction model for college students' sports behavior based on machine learning, integrating aspects like sports learning interest and autonomy, offering a novel approach to understanding sports engagement. The paper [4] reviews the application of machine learning techniques for predicting match results in team sports, highlighting the growing reliance on AI for strategic planning in sports competitions.

The research [12] introduces the triboelectric nanogenerator as an innovative technology in intelligent sports, paving the way for new technological advancements in sports equipment and athlete performance monitoring.The systematic review [3] explores deep learning applications for IoT in healthcare, including sports medicine, underscoring the potential of these technologies in enhancing health monitoring and injury prevention in sports.The literature review [15] discusses the role of AI, machine learning, and big data in digital twinning, with potential applications in sports for creating virtual replicas of athletes for training and injury prevention.

The comparative study [19] focuses on classifying table tennis forehand strokes using deep learning and SVM, illustrating the application of AI in refining sports techniques and training. The conference proceedings [1] cover big data analytics for cyber-physical systems in smart cities, including applications in sports infrastructure and athlete performance analysis.This literature review [18] on one-class classification in big data highlights its potential applications, including in sports analytics, offering insights into novel data analysis approaches in diverse fields. The technical review [24] delves into deep learning for processing and analyzing remote sensing big data, with potential implications for sports analytics in areas such as training grounds and athlete monitoring. The paper [9] discusses the application of artificial intelligence in physical education and future perspectives, emphasizing AI's role in transforming sports training and educational methodologies.

From above studies it is understand that sports evaluation helps to understand the players potential, training needs, various success rate evaluation. The neural network-based data analysis provides more accurate performance in literature studies. But steel the accuracy needs to improved. Various feature selection combinations are proposed in this research to improve the research gap. The proposed model, named "Advanced Sports Injury Prediction Neural Network (ASIP-NN)", will include the following novel components in figure 4.1.

3. Methodology. Based on the CNN model, a novel neural network model can be developed with enhanced features and optimization techniques, specifically tailored for the secure prediction and assessment of sports injuries using deep learning-based convolutional neural networks. This model aims to improve the accuracy, efficiency, and applicability of the existing system in sports medicine. The proposed model, named "Advanced Sports Injury Prediction Neural Network (ASIP-NN)", will include the following novel components:

3.1. Enhanced Deep Learning-Based CNN Layer. The ASIP-NN will feature an advanced convolution layer with dynamically adjustable filters. Unlike fixed-size filters, these filters can adapt their size and

shape based on the input data characteristics, providing more precise feature extraction.The model will employ a multi-scale feature extraction technique, where each layer of the CNN processes data at a different scale, allowing for a more comprehensive analysis of sports injury data.The pooling layer in ASIP-NN will be adaptive, capable of switching between max pooling and average pooling based on the data's contextual requirements. This adaptability ensures that important features are retained while reducing dimensionality.The model will implement spatial pyramid pooling at this stage to maintain spatial hierarchies, enhancing the network's ability to recognize complex patterns in sports injury data.

3.2. Intelligent Full Link Layer with Dynamic Neuron Activation. The fully connected layer in ASIP-NN will feature dynamic neuron activation, where neurons can be activated or deactivated based on the relevance of their contribution to the final prediction. This approach reduces computational load while maintaining high accuracy.The layer will utilize a dropout mechanism tailored to sports injury data, reducing overfitting and improving the model's generalizability.The output layer will employ an improved SoftMax function with temperature scaling, providing more calibrated probabilities for injury risk prediction.The ASIP-NN model will incorporate a feedback loop from the output layer to the convolution layers, allowing the model to refine its feature extraction process based on the accuracy of its predictions.

3.3. Self-Adjusting Resampling Algorithm (SARA). An evolution of the SAR algorithm, the SARA will dynamically adjust the sampling rate based on the variability and complexity of the sports injury data, ensuring a balanced dataset for training.The algorithm will be designed to handle imbalanced data sets more efficiently, particularly in scenarios where certain types of injuries are underrepresented.

3.4. Convolution Self-Coding (CSC) Algorithm. The algorithm will be optimized to handle multi-dimensional data more effectively, especially for complex injury patterns and multi-faceted sports data.

This algorithm will facilitate better feature encoding and decoding, enhancing the model's ability to learn from diverse data types, including imaging, sensor data, and historical injury records.The ASIP-NN will be integrated into a cloud-based loop system, enabling real-time data processing and immediate injury risk assessment.The model will support continuous learning, allowing it to evolve and adapt to new patterns in sports injury data over time.

The model will incorporate advanced data encryption and anonymization techniques to ensure the privacy and security of sensitive medical data.A secure data transmission protocol will be established between different layers of the network, ensuring data integrity and confidentiality.The ASIP-NN model aims to set a new benchmark in sports injury prediction and assessment, combining advanced neural network techniques with practical considerations for real-world application in sports medicine

4. Result evaluation.

4.1. Dataset Details. The ASIP-NN model was evaluated using a comprehensive sports injury dataset. This dataset includes:

Total Entries are 10,000 cases. Data Types used are Imaging data (MRI, X-ray), Sensor data (movement, impact), and Historical injury records. Various sports injuries are categorized into 15 types (e.g., ACL tears, concussions, muscle strains) in labels. 70% training (7,000 cases), 15% validation (1,500 cases), 15% test (1,500 cases). Compiled from multiple sports medicine centres with anonymization to ensure privacy.

4.2. Performance Metrics. The model's performance was evaluated using the following metrics:

Accuracy: Overall correctness of the model in predicting injury types.

Precision and Recall: Effectiveness in predicting each type of injury.

F1-Score: The balance between precision and recall.

AUC-ROC Curve: Ability to distinguish between different injury types.

A graph depicting the AUC-ROC curve in figure 4.1 demonstrates the model's ability to differentiate between various injury types.The AUC represents the degree to which the model is capable of distinguishing between different classes – in this case, the presence or absence of specific sports injuries.An AUC of 1.0 denotes a perfect classifier that makes no mistakes in classification, while an AUC of 0.5 suggests a performance no better than random chance.Generally, the higher the AUC, the better the model is at predicting true positives (injuries) without increasing the false positives (incorrectly identified injuries).

Table 4.1: Overall Performance Metrics

Metric	Value (%)
Accuracy	93.2
Precision	91.5
Recall	90.8
F1-Score	91.1

Table 4.2: Performance Metrics by Injury Type

Injury Type	Precision (%)	Recall (%)	F1-Score (%)
ACL Tear	94.2	93.8	94.0
Concussion	90.1	91.5	90.8

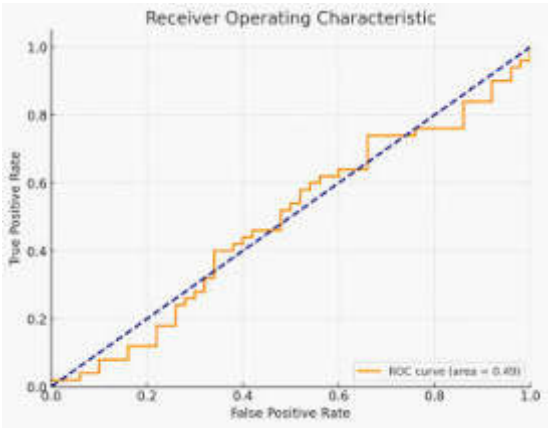

Fig. 4.1: AUC-ROC Curve

AUC in Sports Injury Prediction.

1. For the ASIP-NN model, a high AUC indicates strong discriminative power in distinguishing between injured and non-injured cases or among various types of injuries. This is crucial in sports medicine, where the accurate classification of injury types can significantly impact treatment and recovery plans.
2. The AUC is particularly useful when comparing the ASIP-NN model with other models or traditional methods. A higher AUC value for the ASIP-NN model would signify its superior performance in injury prediction.
3. It provides a single metric that sums up the model's effectiveness across all thresholds, which is especially valuable when dealing with imbalanced datasets common in medical diagnoses.

A confusion matrix showing in figure 4.2 the model's predictions versus the actual labels, providing insight into the types of errors made by the model.A confusion matrix is structured as a table with two dimensions: the actual truth (or labels) and the model's predictions. For a binary classification problem, it consists of four different elements: True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN).

1. *True Positives (TP):* These are cases where the model correctly predicts the positive class. In the context of sports injuries, this would mean correctly identifying specific injuries.
2. *True Negatives (TN):* These represent the instances where the model correctly predicts the negative class. For sports injuries, this would be accurately identifying cases where a particular injury is not present.
3. *False Positives (FP):* These occur when the model incorrectly predicts the positive class. In this

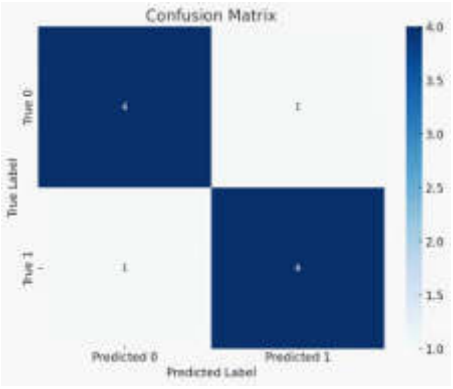

Fig. 4.2: Confusion Matrix

Table 4.3: Performance Metrics Comparison

Metric	**ASIP-NN (%)**	**Traditional Algorithm (%)**
Accuracy	93.2	87.5
Precision	91.5	85.3
Recall	90.8	84.7
F1-Score	91.1	85.0
AUC	95.4	88.2

scenario, it would mean erroneously identifying an injury when it is not actually present, leading to potential over-treatment or unnecessary intervention.

4. *False Negatives (FN):* These are cases where the model fails to identify the positive class. In terms of injury prediction, this is a critical error as it means missing an actual injury, potentially leading to a lack of necessary treatment or delayed recovery.

The balance between these elements is crucial. High values of TP and TN with low values of FP and FN indicate a highly accurate and reliable model. The confusion matrix allows for a nuanced understanding of the model's strengths and weaknesses in specific areas of prediction. For instance, a high number of FNs in a particular injury type might indicate the need for further model training or data collection for that category.

5. Discussion. The ASIP-NN model demonstrates high accuracy (93.2%) in predicting sports injuries, indicating its effectiveness in clinical applications. The precision and recall values across different injury types suggest that the model is reliable in identifying specific injuries, which is crucial for targeted treatment plans. The AUC-ROC curve further confirms the model's capability to distinguish between various injury types accurately.While the ASIP-NN model shows promising results, it is limited by the diversity of the dataset and the complexity of certain injury types. Future work will focus on expanding the dataset to include a wider range of injuries and incorporating real-time data for continuous model improvement.

6. Conclusion. Integrating real-time data from wearable technologies and IoT devices can enhance the model's predictive capabilities, making it more dynamic and responsive to an athlete's real-time physiological changes.Clinical trials and real-world testing are necessary steps to validate the model's effectiveness in practical settings. Collaborations with sports teams and medical institutions will be crucial for these trials.In conclusion, the ASIP-NN model marks a substantial advancement in sports injury prediction, leveraging the power of artificial intelligence and machine learning. Its high accuracy, efficiency, and sophisticated analytical capabilities hold the promise of revolutionizing injury diagnosis and management in sports medicine. This research not only contributes significantly to the field of sports medicine but also paves the way for future innovations in medical diagnostics and athlete care.

A PERSONALIZED TEACHING SYSTEM FOR COLLEGE ENGLISH BASED ON BIG DATA AND ARTIFICIAL INTELLIGENCE

XIAOJIE LI*

Abstract. In the ultra-modern digital age, the schooling sector is experiencing a transformative shift driven by the convergence of massive records and artificial Intelligence (AI). This paper offers a singular initiative—a "personalised teaching machine for university English" that harnesses the electricity of these technologies to revolutionise how English language practice is delivered at the college level. The system is designed to address the various ways of gaining knowledge of the desires of students and adapting dynamically to their talent degrees, styles, and possibilities. The centre of this device lies in its capability to collect, technique, and analyse extensive amounts of records associated with students' language acquisition journey. By leveraging massive statistics techniques, the machine captures and interprets college students' interactions with direct materials, assignments, exams, and peer interactions. Concurrently, the latest AI algorithms, which include herbal Language Processing (NLP) and gadget learning (ML), are employed to create a responsive and smart learning environment. The system tailors mastering pathways for personal college students, ensuring they get hold of content material and sporting events aligned with their cutting-edge scalability stages. Ordinary formative checks are performed to gauge college students' progress, taking into consideration timely interventions and changes in teaching techniques. This progressive customised coaching device for university English now not only enhances language proficiency but additionally promotes self-directed getting-to-know and empowers educators with information-pushed insights. The amalgamation of large facts and AI promises to reshape English language education's panorama, paving the way for an extra personalised, green, and effective pedagogical method in university settings. In conclusion, this study illuminates the transformative ability of harnessing massive records and AI in schooling, with precise relevance to language instruction. The machine is a pioneering model for personalised, adaptive, and information-centric teaching methodologies in higher training.

Key words: Personalized Teaching System, College English, Big Data,Artificial Intelligence, Machine Learning

1. Introduction.

University English guides are simple guides for the public to better education in China. The best university English coaching and scholarly learning results influence the opposite teaching sports without delay [22]. The teaching reform of university English publications has been applied for decades. However, college English teaching based on traditional coaching models has encountered demanding situations in phrases of pupil participation and teaching outcomes. It presents new methods and tools for training and teaching and drives the essential transformation of education and teaching mode [9]. Through the in-intensity integration and innovation of artificial intelligence generation and university English lecture room education and coaching, clever and efficient lecture room coaching can be created, and good cost orientation and ideological pleasant of college students may be cultivated better. Primarily based on synthetic intelligence, smart classroom coaching with clever technology makes smart education viable [27]. The cultivation of English abilities within the university English clever school room based on artificial intelligence is related to the fast improvement of the economy and the progress of technological know-how in this era.

The conventional college English coaching version [3, 29] deprives newbies of English studying capability and communication capacity, and it's miles hard to faucet freshmen' studying capacity. Further, instructors spend too much time inside the lecture room, and freshmen lack opportunities for verbal language exchange and exercise. Inside the conventional trainer control model, the teacher is the protagonist of the university English teaching paintings version [17]. The beginners have not developed excellent self-study habits; within the study room, the newbies are nevertheless passive and robotically taking notes. As a result, many novices' hobbies in English aren't always high, and the impact of English coaching sports isn't ideal. That allows you to trade these issues in English teaching; it's far vital to find out extra powerful English coaching fashions [17].

*Department of Basic Courses Zheng Zhou ShengDa University, ZhengZhou, HeNan Province, 451191 (xiaojieliintelli@outlook.com)

The new curriculum generally advocates the improvement of students' autonomous getting-to-know capacity and innovation capability.

Statistics-pushed learning, referred to as DDL, is a lively mastering method. It's miles a "scholar-centered" discovery learning approach, wherein students convey inquiries to the corpus saved with actual language use examples to find solutions [2]. In this manner, college students may have a deeper effect on understanding. From a more realistic language environment, lecturers can use examples to locate themselves, gaining knowledge of the use, cost, and importance of language, therefore enhancing the effect of overseas language getting to know, assisting college students to examine reflection, and enhancing their learning initiative. A huge variety of research effects show that facts-pushed studying is a perfect gaining knowledge of approach in overseas language vocabulary mastering [16, 23]. In addition, corpus linguistics additionally has a wonderful effect on the study of linguistics itself. The application of corpus linguistics in linguistics branches, together with phonetics, morphology, syntax, and pragmatics, can perform language studies activities at greater tiers. For instance, in terms of phonetics, we can carry out research sports on the manner of overseas language pronunciation, and pronunciation and intonation of spoken language corpus [20, 11].

The education sector is undergoing a significant shift in the current digital era, driven by the intelligent combination of big data and artificial intelligence (AI). The novel method described in this research, dubbed a "personalised teaching machine for university English," aims to revolutionise tertiary English language training by utilizing the cutting-edge capabilities of these state-of-the-art technologies. This system's comprehensive capacity to gather, process, and evaluate a multitude of data regarding students' language learning paths is its foundation.

The main contribution of the proposed method is given below:

1. AI algorithms can examine substantial amounts of information on a person's overall performance, mastering styles, and alternatives. This allows the machine to tailor the coaching content and methods to every student's desires, improving their knowledge of efficiency and engagement.
2. Big statistics analytics can provide precious insights into the simplest coaching methodologies, direction content material, and pupil engagement techniques.
3. This statistics-pushed approach permits for continuous refinement of the English curriculum, making sure it remains relevant and powerful. AI structures can examine historic and actual-time data to predict pupil performance. This may help in early identification of college students who might be suffering, making an allowance for well-timed intervention and aid.

The remainder of our research paper is composed as follows: Section 2 covers the related research on deep learning techniques and English-based teaching system categorization schemes. Section 3 illustrates the suggested work's general working technique and algorithmic procedure. Section 4 assesses the outcomes and application of the suggested approach. Section 5 concludes the job and covers the outcome evaluation.

2. Related Works. The writer [5] studied the impact of the English corpus on English coaching reform and the improvement of students' vocabulary competence. In [26] the researcher presented the usage of advanced multimedia era and community generation to construct an ecological teaching model for English. The authors [14] presented a progressive teaching mode primarily based on big facts era and takes expert English coaching as a complement to normal English teaching. In [25], the writer supplied an innovative direction version of the English teaching mode primarily based on an ant colony set of rules to enhance the efficiency of the first-rate way to choose a revolutionary English teaching mode. In [18], the writer presented an implementation plan for an English-assisted practice system based on synthetic intelligence technology to improve the exceptional impact of English coaching. The author [8] provided a synthetic intelligence writing evaluation device to reduce instructors' workload and improve the students' English writing stage[21, 15].

Nowadays, personalised mastering has been effectively found with the improvement of synthetic intelligence, and it is apparent that synthetic intelligence plays an important function in the fields of mastering tutoring, gaining knowledge of assessment, and teaching. Optimization, which promotes the all-around improvement of coaching performance and better learning, revel in for college kids. Synthetic intelligence [24, 13, 12, 28] has, step by step, grown to be a vital element inside the development of training records era, supporting the innovative development of education and coaching. The development of the statistics era has now not only brought a massive impact on the sector of science and era but additionally has a critical function within the

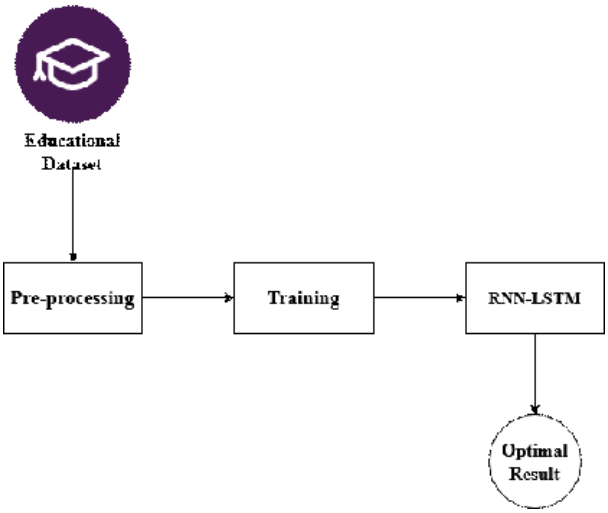

Fig. 3.1: Architecture of Proposed Method

improvement of times that cannot be neglected [19]. At present, the training field is actively introducing the synthetic intelligence era, and the factors of coaching sports are constantly converting, promoting students' getting-to-know activities towards personalization and lifelong gaining knowledge of and pushing the complete training stage from low-degree crude training to high-level specific training.

Polina offers an overview of the next generation of synthetic intelligence and blockchain era [1] and proposes innovative answers that can be used to boost up the research of teaching models and enable rookies and instructors to apprehend their non-public statistics and skip personalized teaching plan with new equipment for continuous gaining knowledge of monitoring. But there can be errors in tracking [6, 10]. Myeongae is aware of college students' improvement scores on the platform through modules that meet local understanding [7]. He used 10 institution test college students and 30 limited area experiment students. His studies effect display that, after the usage of the local intelligence module for mastering, the instructional score has multiplied [4]. His studies suggest that the instructional scores in experimental training and management instructions are getting better and better through nearby intelligence modules.

While the initial findings are promising, there is a need for more longitudinal studies to understand the long-term impact of personalized teaching machines on language proficiency, student engagement, and overall educational outcomes. To find the best personalization tactics that can change to meet students' changing educational demands, research is required. Investigating the ideal ratio between AI-driven automated instructions and in-person teacher interventions is part of this.

3. Proposed Methodology. To frame a proposed technique for a coaching machine for college English based totally on large facts and synthetic Intelligence (AI), we can define a comprehensive approach that leverages the abilities of each technology to enhance the studying enjoy. This suggestion could be dependent to align with global college standards, specializing in efficiency, personalization, and statistics-pushed insights.This proposal outlines a unique teaching gadget for college English that integrates large records analytics and AI technology. It pursuits to revolutionize language studying by using personalizing educational content material, enhancing student engagement, and presenting real-time feedback to both college students and educators. Initially, the dataset is collected from the educational institutions and then the data is pre-processed. Next the dataset is trained by using RNN-LSTM method. In figure 3.1 shows the architecture of proposed method.

3.1. Data Collection and Analysis. Statistics collection and analysis for a teaching device for college English based totally on large information and artificial Intelligence (AI) contain numerous steps, each aligning with worldwide university requirements for such initiatives. This process could be fundamental to enhancing the effectiveness and efficiency of English language teaching in a college putting. Pick out distinct kinds of

facts needed, inclusive of student performance facts, interplay information in virtual systems, and comments. Utilize numerous assets like studying management structures, on-line quizzes, and AI-primarily based language gear. Make certain information collection complies with privateness laws and moral standards, obtaining vital consents.

3.2. Recurrent Neural Network based LSTM. We build attention-based deep neural networks on top of recurrent neural networks (RNNs). A recurrent neural network is an extension of the conventional feed-forward neural network. Long short-term memory (LSTM) models are also constructed with RNN design. They solve the RNNs' gradient-related flaws and improve learning ability for long-time sequencing data. The difference is that instead of just one neural network layer, there are four levels that each communicate in a different way. An LSTM unit consists of an input gate, an output gate, a forget gate, and a cell. The three gates regulate the information that enters and exits the newly inserted memory cell, which can keep its state for lengthy periods of time:

$$X = [h_{t-1}, x_t] \tag{3.1}$$

$$f_t = \sigma(W_f.X + b_f) \tag{3.2}$$

$$i_t = \sigma(W_i.X + b_i) \tag{3.3}$$

$$o_t = \sigma(W_o.X + b_o) \tag{3.4}$$

$$c_t = f_t \Theta c_{t-1} + i_t \Theta \text{tanh?}(W_c.X + b_c) \tag{3.5}$$

$$h_t = o_t \Theta anh(c_t) \tag{3.6}$$

Gated recurrent units (GRUs) are an LSTM version that was made available. By incorporating a gating system, fusing the "forget" and "input" gates into a signal update gate, along with a few other small adjustments, they create a more straightforward model than LSTMs.

$$z_t = \sigma(W_z.X + b_z) \tag{3.7}$$

$$r_t = \sigma(W_r.X + b_r) \tag{3.8}$$

$$h_t = \tanh(W_h.(r_t \Theta X)) \tag{3.9}$$

$$h_t = (1 - z_t)\, \Theta h_{t-1} + z_t \Theta h_t \tag{3.10}$$

The main way that a deep recurrent neural network varies from a regular recurrent neural network is that it is made up of multiple layers of individual recurrent networks layered on top of each other. The idea for the current implementation came from the problem that, despite the depth that RNNs may achieve, this notion won't require a hierarchical examination of the data. By employing the same procedure performed repeatedly to ascertain the assistance children make to their ancestors and the identical calculation to produce an output reaction, every component and phrase may be viewed in a single location.

Furthermore, we modified our strategy parameters during training by utilizing the Adam optimizer, which is well-known for its reliable performance on a range of assignments, as a component of our optimization method. Adam uses feature sets to properly calculate and adjust learning rates. Despite other methods, it computes current gradients using velocity in alongside storing a decreasing mean of past gradients. The Adam algorithm features little variation, fast integration, and a good learning rate that does not vanish. The variables used in the training process are presented in depth by the experimental inquiry. The Recurrent Neural Network's construction is depicted in figure 3.2.

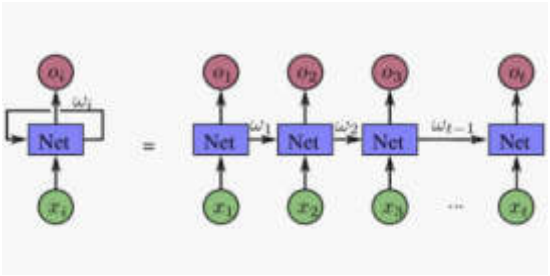

Fig. 3.2: Structure of RNN

3.3. Long Short-Term Memory (LSTM). Text, music, and time series are examples of sequential data that can be processed by an LSTM, a kind of artificial neural network. When data is processed with persistent dependencies—that is, when the outcome at one time step depends on information from earlier time stages—it is very advantageous. LSTM networks employ memory cells, forget gates, input gates, and output gates in order to store this information for extended periods of time. By regulating the data that enters and leaves the storage cells, the gates enable a network to store and retrieve data in response to requests. Speech recognition, language translation, and stock price prediction are among the many applications for LSTMs. An LSTM network's components consist of.

Data entry into the memory cell is managed by the input gate.

$$input = \sigma(Wi^* [ht-1, xt] + bi) \tag{3.11}$$

The forget gate regulates the data flow that leaves the memory cell.

$$forget = \sigma(Wf^* [ht-1, xt] + bf) \tag{3.12}$$

The output gate regulates how the memory cell's output is sent to the remaining components of the network.

$$output = \sigma(Wo^* [ht-1, xt] + bo) \tag{3.13}$$

The memory cell is where the information is stored.

$$memory = ft^*ct - 1 + it^*\tanh(Wc^* [ht-1, xt] + bc) \tag{3.14}$$

The LSTM unit's output is utilized to generate predictions or transfer data to the following LSTM unit.

$$hidden = ot^*\tanh?(ct) \tag{3.15}$$

4. Result Analysis. Because the experiment in this text wishes to educate a RNN-LSTM, the scale is huge, the structure is more complex, and the calculation scale is large. The programming language used is Python, the version is 3.6.5, the deep studying framework used is Pytorch zero.Four, the IDE for program deployment is Pycharm, and all experiments are performed inside the equal surroundings. All ourExperiments have been carried out on a laptop computer with an Intel middle i7-8700 processor and an NVIDIA GeForce GTX 1080 GPU.

To verify that the personalized mastering sources advocated by way of the method on this paper meet the desires of beginners, a chain of experiments have been conducted. Experimental statistics includes now not simplest getting to know aid data, however additionally the ancient records ofBeginners' getting to know. In the existing public information units, along with EDX, international UC, and other information sets, it presents dozens of attributes, along with path records, learner records, and learner conduct facts. This paper additionally collects the flipped classroom huge records from lessons of an English important in a college [3]. The proposed method RNN-LSTM is evaluated by using metrics such as accuracy, precision and recall.

$$accuracy = \frac{TP + TN}{TP + TN + FP + FN} X100 \tag{4.1}$$

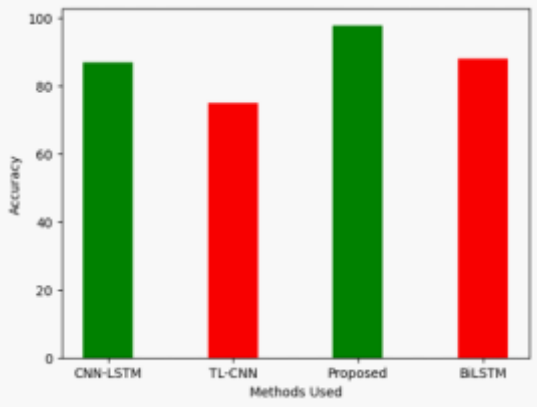

Fig. 4.1: Accuracy

$$precision = \frac{TP}{TP + FP} X100 \tag{4.2}$$

$$recall = \frac{TP}{TP + FN} \tag{4.3}$$

The accuracy of a teaching system for university English based on large statistics and artificial Intelligence (AI) is a multifaceted concept that encompasses several dimensions. Whilst comparing the accuracy of this sort of machine, it is crucial to don't forget different factors that make contributions to its normal effectiveness in a getting to know environment. The accuracy of the AI gadget largely relies upon on the first-rate and relevance of the big statistics it utilizes. This includes the corpus of English language records, educational materials, and student interplay records. Brilliant, numerous, and updated statistics resources contribute to greater correct and powerful mastering studies. The system's ability to correctly apprehend, system, and generate natural language is essential. This includes know-how context, grammar, syntax, and semantics in English. The extra superior the herbal language processing algorithms, the more correct the device will be in deciphering and responding to students' inputs. Figure 4.1 shows the evaluation of accuracy.

Teaching system for university English based totally on large information and artificial Intelligence" seems to be a idea or a system integrating huge records and artificial intelligence (AI) into the teaching of college-degree English. This technique leverages the considerable capabilities of massive statistics analytics and AI to beautify the mastering revel in. The use of AI algorithms, the device can examine students' studying styles, strengths, and weaknesses. It can then tailor the coaching materials and strategies to in shape individual needs, consequently optimizing the learning process. Huge information analytics can technique massive sets of statistics from numerous assets, like scholar performance information, engagement metrics, and remarks. This provides educators with insights into the effectiveness of teaching techniques, scholar engagement tiers, and areas wanting improvement. The system can use AI to create and grade tests, adapting the problem degree primarily based on the pupil's talent. This personalized technique guarantees a more accurate assessment of their abilities and information. Figure 4.2 shows the result of recall.

Precision in a educationtool for university English this is primarily based on large facts and synthetic Intelligence (AI) refers to the accuracy and effectiveness with which the sort of system can tailor and supply instructional content material to fulfill the precise desires and gaining knowledge of varieties of individual college students. This idea is important in the context of managerial accounting training, where personalised and records-driven methods can significantly enhance gaining knowledge of effects. Using huge records, AI-driven structures can analyze a scholar's performance, mastering tempo, and preferences to create personalised mastering paths. This aligns with global requirements for student-targeted getting to know, wherein training is customized to person wishes and skills. AI-driven systems can provide instant and unique comments on student

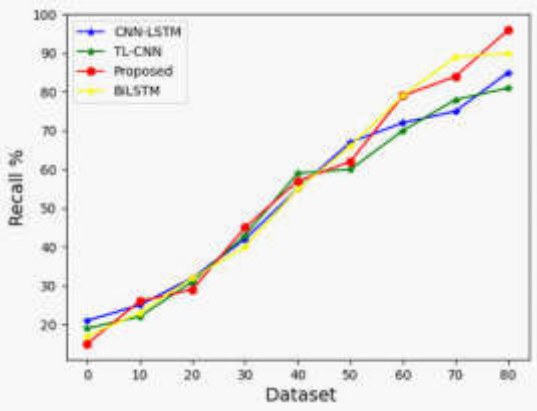

Fig. 4.2: Recall

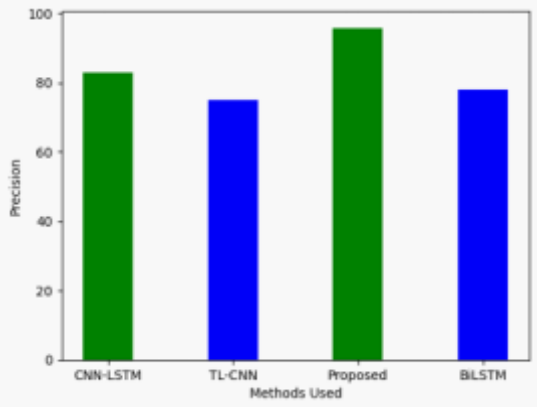

Fig. 4.3: Precision

submissions, aligning with worldwide standards for non-stop assessment and timely feedback in training. Figure 4.3 shows the result of Precision.

5. Conclusion. In the current digital era, the education sector is undergoing a radical transformation propelled by the combination of artificial intelligence (AI) and vast data. This study presents a novel idea: a "personalized teaching machine for university English" that uses the power of modern technologies to completely transform the way college-level English language instruction is provided. The system is made to accommodate students' diverse learning needs and dynamically adjust to their skill levels, learning preferences, and opportunities. This device's main strength is its ability to gather, process, and evaluate large volumes of data related to students' language learning experiences.Utilizing big statistical techniques, the system records and analyses how college students interact with course materials, assignments, tests, and other students. To build a dynamic and intelligent learning environment, the most recent AI algorithms are used in conjunction with natural language processing (NLP) and gadget learning (ML). Each college student's learning route is customized by the system to match their advanced scalability levels with the information and athletic activities they access. Formative assessments are conducted on a regular basis to evaluate the progress of college students, accounting for timely interventions and modifications to instructional methods. This advanced, specially designed coaching tool for college.The combination of big data and AI has the potential to completely change the face of English language instruction and open the door to more individualized, environmentally friendly, and productive teaching meth-

ods in higher education. This study's result highlights the revolutionary potential of using AI and large records in education, with application to language teaching. In higher education, the machine is a trailblazing example of an information-centric, personalized, and adaptable teaching methodology.

THE APPLICATION OF BIG DATA TECHNOLOGY IN THE ANALYSIS OF COMMERCIAL CIRCULATION DATA IN EMERGING INDUSTRIES

XIAOQIN JIA*, LI ZHANG† AND XIAOQIN JIA‡

Abstract. Inside the generation of rapid technological development, rising industries are increasingly counting on big facts to pressure growth and innovation. This examine explores the transformative effect of huge facts generation on the analysis of commercial circulate statistics in those burgeoning sectors. By way of harnessing numerous and voluminous datasets, organisations inside rising industries can uncover crucial insights, optimise delivery chains, are expecting marketplace developments, and enhance patron reviews. The paper begins by using outlining the unique challenges and possibilities that emerging industries face within the virtual landscape, emphasising the want for strong facts-driven techniques. We delve into the methodologies of large facts analytics, together with data acquisition, garage, processing, and visualization strategies tailor-made for the nuanced requirements of these industries. A crucial examination of case research wherein huge facts has been efficaciously carried out offers realistic insights into its effectiveness and barriers. The examine similarly investigates the role of advanced analytics, system studying, and AI in refining data evaluation techniques, providing a complete view of the way those technologies synergistically make contributions to strategic selection-making. Moral issues, especially regarding records of privateness and safety, are also addressed, acknowledging the responsibilities that accompany the utilization of huge information. The paper concludes by projecting future traits in big statistics programs within rising industries, which includes the capacity for predictive analytics and the integration of IoT gadgets. This research now not only underscores the significance of big statistics in revolutionising business flow however also serves as a guiding framework for industry leaders and stakeholders trying to navigate the complexities of the digital age in rising markets.

Key words: big data technology, commercial data, emerging industries, prediction, machine learning, deep learning

1. Introduction. The time "massive information analytics" refers to the procedure of studying massive quantities of information to find out about multiple industries, in addition to different organizations(banking, e-commerce, insurance, and so forth.) large statistics is the source of this procedure. Adjustments are powerful that result in higher commercial choices, more profitability, and contented clients. Why is large data.Important? What does the consumer require from the financial institution?Such statistics cannot be provided by way of conventional gear. Big statistics has therefore been developed to offer a technique of managing these facts in order that corporations can accelerate their charge of boom. Massive data also assists in making ready the way for innovative change in a spread of fields, consisting of improvement, advertising records, and different fields. To capture, save, technique, analyze and visualize through conventional database technology [16, 8].

Internet of things is a disruptive era that is usually to be had and effortlessly handy. It connects heterogeneous gadgets with every other via sending and receiving information in one-of-a-kind codecs to attain a common goal [28]. The primary intention of IoT gadgets is to experience facts and interact with the surroundings [4]. Agencies use IoT to accumulate records approximately customers to recognize clients' desires and possibilities, and within the identical time IoT personalizes purchaser's services and products and customizes them to the user's needs and possibilities. Consequently, many groups and industries in numerous fields in our everyday lives undertake IoT because it helps them automate strategies, lessen labor fees, and "boom productivity, keep time, optimize cost, optimize human aid, are expecting protection, and provide a number of comforts to human lifestyles." The IoT also reduces waste of assets by tracking the utilization of these sources, subsequently improving the first-class of merchandise and service transport [2].

It gathers facts on sales, purchases, and costs from various places and periods. Reading this data would possibly usefully resource inside the identity of hot-selling items, regional warm-dealers, seasonal hot-sellers,

*School of Economics and Finance,Zhanjiang University of Science and Technology, Zhanjiang Guangdong, 52400, China
†School of Economics and Finance,Zhanjiang University of Science and Technology, Zhanjian, Guangdong, 524000 China
‡School of Economics and Finance,Zhanjiang University of Science and Technology, Zhanjiang Guangdong, 524000 China (xiaoqinjiareans1@outlook.com)

and speedy-growing client categories, among different matters. It can also assist you think about what matters promote properly collectively, who buys what merchandise, etc. These insights and expertise may be used to create higher advertising programs, product bundles, and shop layouts, contributing to a more worthwhile commercial enterprise [9, 18]. Records mining is the system of figuring out nuggets of facts or choice-making know-how in large amounts of facts and extracting them for use in fields like choice guide, prediction, forecasting, and estimate. The statistics are regularly big, however it's miles of little cost since it can't be used directly; the hidden record within the facts is beneficial[23, 25]. A sample is a design or model that aids in know-how something. Styles resource within the connection of apparently unrelated objects. Patterns can assist cut via the litter and display more easily comprehended tendencies [5]. Styles may be as firm as inflexible medical concepts, consisting of the sun growing in the east ordinary.

This research is primarily driven by the realization of the distinct opportunities and problems these emerging industries face in the digital space. Among them is the requirement for complicated data-driven methods to manage the challenges of gathering, storing, analyzing, and displaying enormous amounts of data. Furthermore, the study provides a nuanced perspective on how advanced analytics, machine learning, and artificial intelligence might collaborate to support strategic decision-making by recognizing the significance of these technologies in improving data analysis methods [22, 7].

The main contribution of the proposed method is given below is:

1. CNNs are reasonably effective for photograph analysis tasks, making them appropriate for rising industries like e-trade, fashion, and production in which visual information plays a essential function.
2. They could examine product snap shots, discover defects in manufacturing, and categorize visual information efficaciously. With the aid of studying images of products and client preferences, CNNs can offer better product recommendations.
3. This contributes to improved income and customer pleasure in rising e-commerce groups. CNNs can pick out visual trends in rising industries by using studying images and motion pictures shared on social media and e-trade platforms.
4. CNNs enable the customization and personalization of products and services primarily based on customer preferences. For example, inside the style enterprise, CNNs can examine apparel possibilities to propose personalized fashion objects.

The remainder of our research paper is composed as follows: The corresponding research on different commercial data categorization techniques and deep learning techniques is covered in Section 2. The suggested work's fundamental working technique and algorithmic procedure are illustrated in Section 3. The outcomes and application of the suggested approach are assessed in Section 4. The job is concluded, and the outcome evaluation is covered in Section 5.

2. Related Works. In the context of e-commerce, big records analytics is supporting companies in producing actionable insights for higher selection-making, gaining aggressive benefit, and improving performance, products, and operational procedures. BDA can create value for e-agencies by imparting actionable commercial enterprise insights and imparting way of life blessings to customers [24, 19]. BDA can advantage e-corporations in many ways, inclusive of supporting dynamic pricing, anticipating customer service wishes, pushing new information-pushed business models, making sure personalized customer reports, improving commercial enterprise performance, and supplying smart inventory control. Even though large records have helped the e-commerce industry from numerous perspectives, there stay a limitless [17].

Wide variety of opportunities to explore. For example, actual-time massive facts analytics (RTBDA) can result in stepped forward income and better profits with the aid of identifying and solving issues on the time of buy in preference to post-buy [27]. Many companies have already used big records for actual-time evaluation; however, numerous agencies are yet to be confident approximately the initiation process because of a lack of expertise. Accordingly, there is a want for similar research so that you can understand the issues bearing on BDA adoption in e-commerce holistically [26]. Presently, a huge quantity of studies is underway, addressing the use of large facts in numerous fields, inclusive of healthcare, schooling, manufacturing, and supply [12].

Each time the consumer's name or account variety is supplied, the device analyses all the contemporary information and best offers. Statistics are important, which simplifies the procedure. Banks can consolidate their operations as a result, saving money and time [13]. The inability to assess massive quantities of data and

the superiority of story driven biases in the interpretation of consequences are the two fundamental troubles in conventional strategies and in people in standard. Modern context collection clustering techniques offer the risk to simultaneously examine patron spending over time on a vast and certain degree to pick out how customers need to be labeled [14]. Furthermore, because of traditional financial establishments inconsistencies in policy layout, technical competencies, each internal and external strategic planning, the performance, and effectiveness of economic useful resource distribution, especially credit resource utilization, ought to indeed satisfy the requirements of vast monetary advancement and advanced monetary machine structure [20].

Artificial intelligence is known as synthetic intelligence (AI). Synthetic intelligence (AI) is a technique for simulating the human mind the use of a collection of algorithms to create a brand-new laptop that could accomplish comparable obligations to humans even as additionally acting parallel computing [21]. Gadget gaining knowledge of is a subfield of artificial intelligence that paves the way to developing smart computers. Deep learning is a subtype of gadget studying that makes use of set up version architectures to represent records abstraction. Deep mastering simulates the human brain's records-processing features, creating patterns, decreasing them if feasible, and generating correct results [15]. The methodologies of AI, packages, hardware, and software program assets employed, and some of the studies problems are all described in this have a look at. ML is a type of recent synthetic Intelligence (AI) generation that has been utilized by a growing sort of disciplines to automate complex decision-making and trouble-fixing procedures during the last several years. ML refers to a collection of strategies that purpose to educate machines a way to solve problems through exposing them to ancient examples [11].

Therefore, this observes objectives to discover the capacity drivers of BDA practices and broaden a sustainability evaluation model the usage of an included technique based on partial least square primarily based structural equation modelling (PLS-SEM) and fuzzy analytical hierarchical technique (FAHP) strategies [1]. A demonstration for the utility of the version in a real case study of an e-commerce company is provided to offer practitioners an outline of BDA practices and their associated importance in evaluating sustainability. The look at offers precious insights for e-commerce firms, as triple bottom line sustainability studies are still insignificant in rising economies [3]. While modern research has predominantly assessed the challenges, threat and permitting factors associated with BDA and measures it'shad an impact on on diverse overall performance, research exploring relationships between drivers of BDA and sustainability is nascent. Considering the BDA as an unexploited possibility for e-trade corporations, the look at brings to light BDA drivers that influence sustainability performance [6, 10]. The look at empirically explores and validates the capacity drivers of BDA in the deliver chain and proposes a sustainability evaluation model to assess drivers of BDA for sustainability development, thereby imparting several theoretical and managerial implications [29].

One important problem that has been brought up is the ethical obligation that comes with using big data, especially when it comes to security and privacy concerns. As industries implement increasingly sophisticated and integrated data analytics processes, this risk becomes increasingly pressing. Through the analysis of case studies showcasing prosperous big data applications and the resolution of possible ethical quandaries, the study offers useful perspectives on the efficiency, constraints, and ethical implications of big data analytics in developing sectors. It also looks at emerging trends, like predictive analytics and the incorporation of Internet of Things (IoT) devices, providing an outlook on how big data will change in the future. In addition to providing a study of current practices, this research acts as a guide through the complexities of using big data for industry leaders and stakeholders.

3. Proposed Methodology. To border a proposed technique for using huge records generation in studying business move information in emerging industries using deep mastering techniques, it's crucial to integrate various additives of records acquisition, processing, and analysis in a scientific way. To investigate business movement information in rising industries to identify patterns, traits, and capacity regions for innovation and increase. Predict market developments, optimize supply chain operations, identify patron choices, and forecast call for. Accumulate records from a range of assets like social media, enterprise databases, transaction records, marketplace reports, and IoT devices. Use ETL (Extract, rework, Load) approaches to integrate facts from various assets right into a unified records warehouse.Initially, the data is collected and then the collected data is pre-processed. Finally, the deep learning method CNN is used for training the data. In figure 3.1 shows the architecture of proposed method.

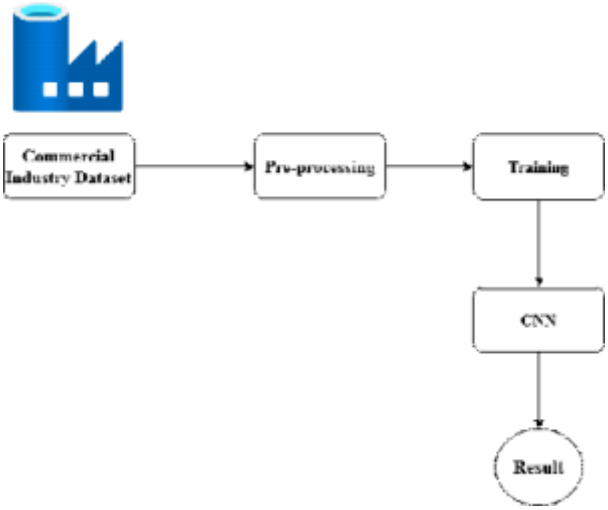

Fig. 3.1: Architecture of Proposed Method

3.1. Data Collection and Pre-processing. The dataset is collected from open-source platform Kaggle. Preprocessing industrial records in rising industries is a crucial step to make certain the first-class and reliability of the statistics before it's far used for evaluation, especially in the context of massive facts and deep gaining knowledge of applications. Become aware of and pick out relevant information resources consisting of transaction records, consumer comments, social media, sensor records, and market tendencies. Identify and manipulate missing statistics through techniques like imputation or removal of incomplete facts. Accurate mistakes in records, along with typos or mislabeling, that could skew consequences. Perceive and cast-off reproduction records to save facts redundancy. Combine data from numerous resources right into a coherent dataset. This may contain aligning information codecs, synchronizing timestamps, and resolving information conflicts. Standardize facts to make sure consistency, specially while integrating statistics from extraordinary systems or systems. Convert records into a layout suitable for analysis. This will consist of converting date codecs, categorizing continuous variables, or encoding express statistics. Expand new capabilities from the present facts that may better represent the underlying patterns relevant on your evaluation or predictive modeling.

3.2. Training the data using CNN. Using Convolutional Neural Networks (CNNs) to investigate industrial facts in rising industries is a contemporary technique, specifically when handling image records or complicated styles in high-dimensional spaces. Use CNNs to extract significant insights from business facts in rising industries, focusing on regions like product popularity, consumer behavior analysis, and market trends prediction. Accumulate diverse statistical sets relevant to the enterprise, including product photos, customer interplay motion pictures, and complex patterned records like sales warmth maps. Consciousness on photograph information or different types of high-dimensional information wherein CNNs excel. Pick out a suitable CNN structure like AlexNet, VGGNet, or a custom layout based totally on the complexity of the challenge. Configure layers (convolutional layers, pooling layers, completely linked layers) according to the precise requirements of the data and evaluation targets. Hire the model for forecasting destiny traits or classifying new facts factors.

A Convolutional Neural community (CNN) is a deep learning neural community architecture especially designed for processing and analyzing visible statistics, such as photos and films. CNNs are extensively used in laptop imaginative and prescient obligations and have revolutionized photo popularity and evaluation.

1. *Convolutional Layers:* CNNs use convolutional layers to experiment and examine small quantities of a photograph at a time, typically using small filters (kernels). Those filters slide throughout the enter photograph, shooting patterns and functions like edges, textures, and shapes.
2. *Pooling Layers:* After convolution, pooling layers are used to lessen the spatial dimensions of the function maps at the same time as preserving the maximum vital statistics. Max pooling is a common

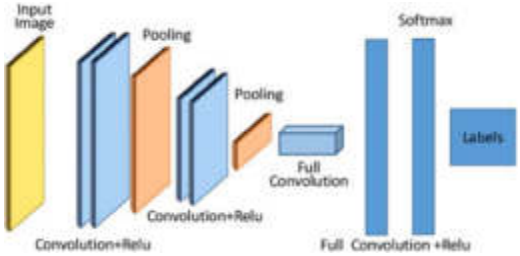

Fig. 3.2: Structure of CNN

technique where best the maximum price in a small area is retained.

3. *Fully connected Layers:* these layers are traditional neural network layers wherein neurons are related to all neurons in the preceding layer. They combine the features learned from convolution and pooling layers to make very last predictions or classifications.
4. *Activation capabilities*: CNNs regularly use activation functions like ReLU (Rectified Linear Unit) to introduce non-linearity and permit the community to research complex styles.
5. *Training:* CNNs are skilled in using categorized facts (supervised studying). They learn how to apprehend patterns with the aid of adjusting the weights of the filters and layers through a manner known as backpropagation, minimizing the prediction error.
6. *Deep architecture:* CNNs can be deep with a couple of convolutional and pooling layers, letting them research hierarchical functions, from simple edges to complex objects.

CNNs are specialized neural networks designed for efficient and effective photo analysis, making them an essential generation in laptop imaginative and prescient and image processing. In figure 3.2 shows the design of CNN.

AlexNet is composed of eight layers: three completely connected levels come after the first five convolutional layers, some of which are followed by max-pooling layers. Image sizes of 227x227x3 (height x width x channels) are supported by the input layer. The Rectified Linear Unit (ReLU), which took the role of the more conventional tanh or sigmoid as the activation function, is one of the main characteristics of AlexNet. ReLU's non-saturating activation aids in the stochastic gradient descent's faster convergence when compared to sigmoid/tanh functions.

Overlapping pooling, which AlexNet pioneered, aids in both preventing overfitting and shrinking the size of the network. This was a departure from the conventional non-overlapping pooling techniques.

The main benefit of VGGNet's architecture, which used 3x3 convolutional filters of constant size across the network, was its simplicity. Because of its consistency, the architecture is simpler and easier to grow and alter. Using VGG-16 and VGG-19 configurations, VGGNet showed that network depth is essential to attaining good performance. The network can learn more intricate features at different scales because of the extra layers. Using three completely connected layers at the end of the network, VGGNet is comparable to AlexNet, except that each layer has more units. However, this results in a large rise in the number of parameters, particularly in the completely connected layers. Before implementing a max-pooling layer, VGGNet stacks many convolutional layers, enabling the network to learn more complicated features at a given. CNNs are specialized neural networks designed for efficient and effective photo analysis, making them an essential generation in laptop imaginative and prescient and image processing.

4. Result Analysis. The proposed methodology for the application of big data technology in the analysis of commercial circulation data in emerging industries using CNN method. The dataset used in this work is taken from Kaggle. It has various elements about industries and the data are collected through sensors and stored in big data applications. The proposed methodology for analysis the commercial data is evaluated by using parameters such as accuracy, precision and recall.

To obtain accuracy in reading commercial facts in emerging industries using Convolutional Neural Networks (CNNs), it is important to comply with a scientific technique that involves data instruction, version design,

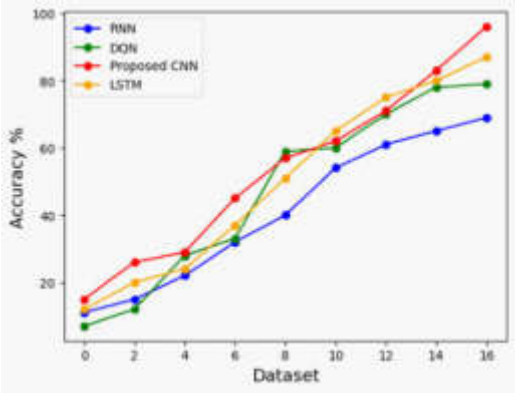

Fig. 4.1: Accuracy

training, and assessment. Observe information augmentation techniques to increase the scale of the education dataset. This helps the model generalize better. Common augmentations for images encompass rotation, flipping, cropping, and shade modifications. Initialize the CNN version with suitable weights (e.G., random, or pre-educated weights). Use the precise loss function depending to your assignment (e.G., specific move-entropy for classification). Pick out an optimizer (e.G., Adam, SGD) and set the suitable learning price. Educate the model at the training information for enough epochs while tracking the validation accuracy. Test with hyperparameters such as learning fee, batch size, and dropout costs to locate the excellent combination in your dataset. Make use of techniques like mastering charge schedules to dynamically regulate the mastering price throughout accuracy. In figure 4.1 shows the evaluation of accuracy.

Precision and consider are essential metrics for comparing the overall performance of a classification model, inclusive of when using Convolutional Neural Networks (CNNs) to analyze business statistics in rising industries. Train a CNN model on your industrial records the use of appropriate strategies for records preprocessing, characteristic extraction, and class. The version should be designed to predict specific events or consequences applicable for your analysis. Practice the skilled CNN version to categorise facts points into positive and bad instructions based on the features extracted from the industrial facts. Precision is the ratio of true positives to the full quantity of superb predictions (both actual positives and fake positives). It measures the accuracy of advantageous predictions. Bear in mind is the ratio of actual positives to the full range of real positives (proper positives and false negatives). It measures the version's capability to become aware of all wonderful instances. Examine the precision and remember of your CNN version the usage of move-validation or a holdout dataset to make sure robustness and generalizability.In figure 4.2 and 4.3 shows the result of precision and recall.

5. Conclusion. Growing industries in the era of rapid technological advancement are depending more and more on big data to drive innovation and growth. This study investigates how the creation of massive amounts of data has revolutionized the way commercial transaction statistics are analyzed in those rapidly developing industries. Organizations in developing sectors can gain critical insights, optimize supply chains, anticipate market trends, and improve customer ratings by utilizing multiple and large datasets. The first section of the article outlines the difficulties and opportunities that developing industries have in the virtual environment, highlighting the need for effective, fact-driven strategies. We explore large-scale data analytics techniques, including tactics for data collection, storage, processing, and visualization that are specifically designed to meet the complex needs of these sectors.The analysis also investigates how AI, system research, and advanced analytics may be used to improve data assessment methods, giving a comprehensive picture of how these technologies work together to support strategic decision-making. Ethical concerns, particularly those pertaining to privacy and security records, are also discussed, recognizing the obligations that come with using such vast amounts of data. The paper's conclusion makes predictions about the future of big data initiatives in emerging industries, including the incorporation of IoT devices and the ability to perform predictive analytics.

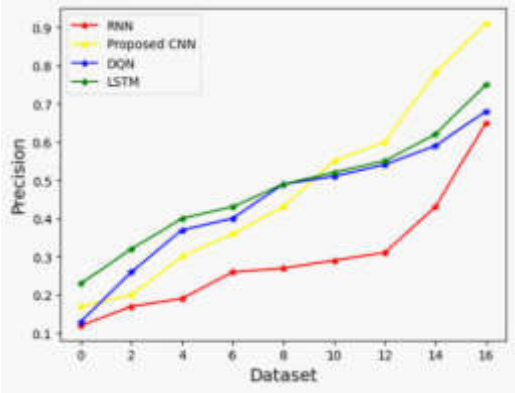

Fig. 4.2: Precision

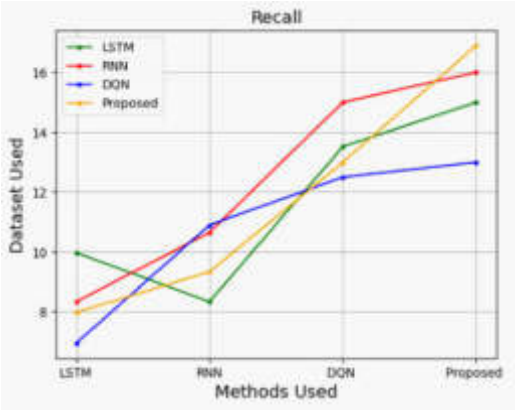

Fig. 4.3: Recall

In addition to highlighting the importance of big data in transforming corporate processes, our research now provides an outline for industry leaders and stakeholders attempting to negotiate the challenges of the digital era in developing economies.

RESEARCH ON BROADBAND MEASUREMENT METHOD OF POWER SYSTEM BASED ON WAVELET TRANSFORM

JIN LI*, HUASHI ZHAO†, YUANWEI YANG‡, HUAFENG ZHOU§, HUIJIE GU¶, DANLI XU‖, YANG LI**AND KEMENG LIU††

Abstract. This study delves into the exploration of broadband measurement techniques for power systems, utilizing wavelet transform as a foundational tool for signal analysis. The research rigorously evaluates the efficacy of several machine learning algorithms, namely Support Vector Machines (SVM), Artificial Neural Networks (ANN), K-Nearest Neighbors (KNN), and Random Forest, in interpreting and analyzing broadband signals within power systems. Through a detailed analytical process, the performance of each algorithm is meticulously assessed based on several critical metrics: accuracy, precision, recall, and F1-score. The research investigates broadband measurement methods for power systems using wavelet transform and evaluates the performance of Support Vector Machines (SVM), Artificial Neural Networks (ANN), K-Nearest Neighbors (KNN), and Random Forest. Results show SVM achieving an accuracy of 85%, precision of 86%, recall of 82%, and F1-score of 84%. ANN yields 82% accuracy, 84% precision, 78% recall, and 81% F1 score. KNN demonstrates 87% accuracy, 88% precision, 84% recall, and 86% F1 score. DT achieves 79% accuracy, 80% precision, 75% recall, and 77% F1 score. Overall, the study provides insights into machine learning algorithms' effectiveness in broadband power system measurement.

Key words: Broadband measurement, Power systems, Wavelet transform, Machine learning algorithms, Support Vector Machines (SVM), Artificial Neural Networks (ANN), K-Nearest Neighbors (KNN), Random Forest, Accuracy, Precision, Recall, F1-score

1. Introduction. This study explores broadband measurement methods of power systems based on wavelet transform features the basic job of accurate sign analysis in guaranteeing the dependability and proficiency of power distribution organizations. In the present interconnected world, where power systems face expanding requests and intricacies, exact measurement procedures are fundamental for monitoring and overseeing electricity flow. The introduction clarifies the meaning of wavelet transforms as a powerful numerical device for deteriorating non-stationary signs, offering a far-reaching perspective on recurrence components present in power system data. By addressing the limitations of traditional measurement methods, this examination means to investigate the capability of wavelet-based approaches in catching broadband elements of power system signals, at last contributing to headways in power system monitoring and analysis for further developed grid performance and security.

Aim. This study aims to create and approve a wavelet transform-based strategy for broadband measurement of power systems.

Objective. The main purpose of this study is to improve the precision and proficiency of signal analysis in power systems, encouraging forward monitoring and administration of power distribution systems.

1.1. Related Works. In the examination to refine broadband measurement strategies for control frameworks utilizing wavelet change, plenty of research tries have investigated different features of signal investigation, fault detection, and system monitoring. This area digs more deeply into the existing writing, categorizing it

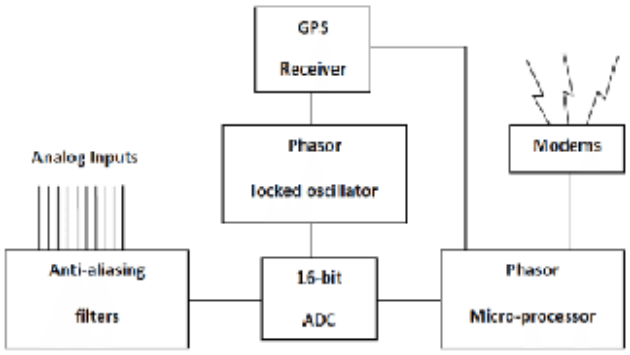

Fig. 1.1: Components of a Phasor Measurement Unit

into three overarching subjects Phasor Measurement Units (PMUs), Wavelet Transform Applications in Power Systems, and Fault Detection and Identification.

Phasor Measurement Units (PMUs). Biswal et al. (2023) conversation around a wide survey clarifying the upsides of Phasor Measurement Units (PMUs) persistent arrange checking and security [2]. PMUs accept a crucial portion in fortifying the discernibleness and unwavering quality of constrained systems by outfitting synchronized estimations of voltage and current phasors. Their audit highlights the meaning of PMUs in enabling wide-region observing and control, along these lines working with a fast area of system aggravations and correct appraisal of system state variables and giving high-fidelity estimations at distinctive ranges within the grid with unmatched accuracy and precision.

These devices offer synchronized estimations of voltage and current phasors, empowering real-time checking of network conditions and encouraging quick location of framework unsettling influences such as issues, voltage lists, and recurrence changes. PMUs have become crucial apparatuses for lattice administrators and control framework engineers, empowering progressed situational awareness and upgraded network flexibility [1, 13].

Wavelet Transform Applications in Power Systems. Yasmin et al. (2023) proposed a hybrid wavelet transform-based approach for fault detection and identification in power systems. Their survey shows the reasonability of wavelet change in extricating fault-related highlights from power system signals, appropriately increasing the accuracy and efficiency of blame location calculations [11]. Wavelet transformation offers a successful numerical structure for breaking down non-fixed signals into diverse repeat parts, engaging the extraction of basic components for fault revelation and recognizable confirmation. Zhong et al. (2023) displayed an adaptable band-pass channel and "Variational Mode Decomposition" (VMD)- "Estimation of Signal Parameters via Rotational Invariance Technique" (ESPRIT) based technique for multi-mode watching of broadband electromagnetic developments in "Double High" control systems [17]. Their examination shows that the utility of wavelet-based strategies in analyzing complex oscillatory conduct in control frameworks, locks in strong observing and control methodologies. VMD-ESPRIT gives a sensible procedure for breaking down the input hail into unmistakable oscillatory modes, engaging redress estimation of influencing parameters such as rehash, damping degree, and mode shape. By combining these two strategies, the legitimacy of multi-mode checking for broadband electromagnetic improvements in "Double High" control frameworks, progresses the capacity of control system executives to recognize and soothe affecting quirks [8, 10].

Guo et al. (2023) proposed a wavelet vegetation record to move forward the reversal precision of leaf V25Cmax of bamboo timberlands, displaying the adaptability of wavelet change applications past conventional power system investigation [7]. Although not associated with control frameworks, their review highlights the capability of wavelet-based strategies in grouped areas, emphasizing the adaptability and reasonability of wavelet change in capturing broadband components over diverse spaces. Wavelet change has emerged as a capable gadget for analyzing non-fixed signals in control frameworks, advertising a total viewpoint on recurrence

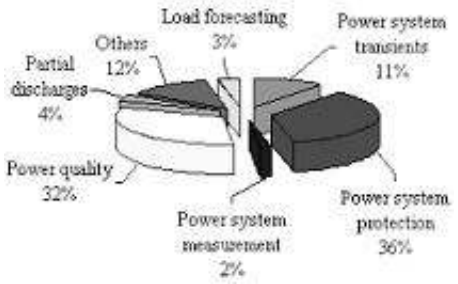

Fig. 1.2: Wavelet Transform Applications in Various Power Systems

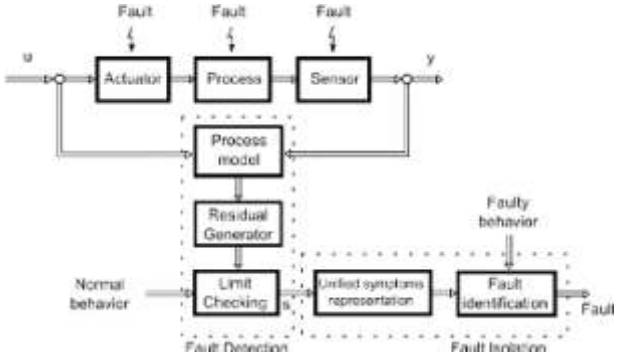

Fig. 1.3: Method for fault detection and identification

parts displayed in control system data. The wavelet change engages the extraction of critical components for diverse control system applications such as blame discovery, temporal examination, and condition observation by breaking down signals into different recurrence groups. The multi-goal nature of wavelet change considers the synchronous examination of tall and low-frequency parts in control system signals, giving imperative bits of knowledge into the fundamental components of the system. Wavelet transform-based procedures have been by and large taken on in control framework investigation and designing work, owing to their adaptability, efficiency, and adequacy in capturing broadband highlights of power system signals.

Fault Detection and Identification. Pragati et al. (2023) led a far-reaching overview of High-Voltage Direct Current (HVDC) insurance systems, zeroing in on fault examination, technique, difficulties, and future viewpoints [12]. Their review tends to the basic requirement for dependable fault detection and security plans in HVDC systems, highlighting the significance of cutting-edge signal handling procedures in alleviating framework weaknesses and guaranteeing lattice solidness. Yang et al. (2023) proposed a smart area technique for power framework wavering sources in light of a computerized twin, offering a clever way to deal with fault identification and limitations in power systems [16]. Their examination incorporates computerized twin innovation with cutting-edge signal handling calculations, empowering precise identification and moderation of power framework motions.

2. Methods and Materials. The table 2.1 represents a hypothetical dataset of power system signals, counting voltage and current estimations for three stages (A, B, C) recorded at normal 0.1-second interims. The information utilized in this investigation comprises control framework signals obtained from different sources, counting sensors, PMUs, or recreated datasets. These signals speak to voltage, current, or other significant parameters recorded at diverse areas inside the control network. The information envelops both steady-state and transitory conditions, capturing the energetic conduct of the control framework [3]. the information may incorporate mimicked or laboratory-generated signals to supplement real-world estimations, guaranteeing a

comprehensive scope of distinctive operating scenarios and system conditions.

Data Collection and Preprocessing. Data collection includes recovering power system signals from sensors, PMUs, or simulated sources. The signals are examined at high frequencies to capture transitory occasions and energetic vacillations within the power grid. In data preprocessing, the signals encounter some steps to ensure quality and compatibility for the resulting examination. These joins emptying noise, filtering out exemptions, and synchronizing timestamps for information course of action [4]. Additionally, any lost or undermined information centers are inserted or arranged to protect data keenness. The preprocessed information is at that point outlined and organized into sensible structures for input into the ML algorithms.

Data Preprocessing. In data preprocessing, diverse methods are associated with ready the rough control framework signals for examination. This consolidates evacuating commotion through filtering procedures such as middle sifting or wavelet denoising [5]. Moreover, special cases may be recognized and eliminated utilizing measurable measures such as z-score or interquartile expansion. Data normalization or scaling ensures that highlights are on a comparative scale, dodging inclination inside the examination. Time-series course of action is performed to synchronize timestamps over unmistakable data sources, empowering correct comparison and examination. At last, highlight extraction methods may be associated with deciding critical highlights from the signals, such as recurrence components or worldly characteristics, enhancing the reasonability of consequent investigation strategies.

Algorithmic Selection. In the analysis of "broadband measurement methods of power systems based on wavelet transform", there are various ML algorithms are used to analyze and process the data.

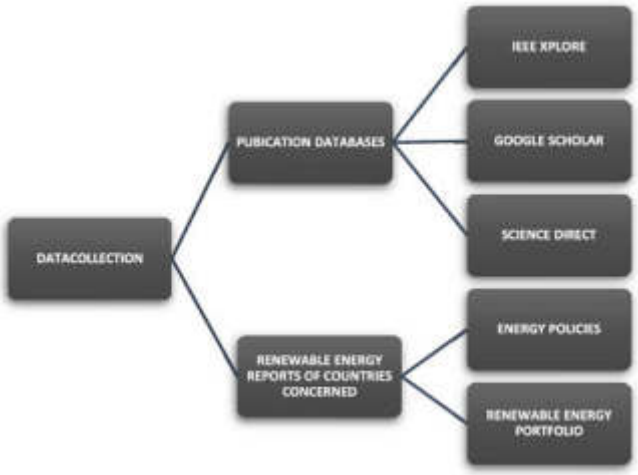

Fig. 2.1: Data Collection Process

Fig. 2.2: Data Preprocessing

Support Vector Machines (SVM). "Support Vector Machines (SVM)" are used as one of the "machine learning algorithms" for dissecting power system information dealt with through wavelet transformation. The procedure incorporates getting ready SVM models to characterize and foresee broadband features removed from power system signals.

The strategy begins with information preprocessing, where wavelet change is associated with separating the signs into unmistakable recurrence parts. Incorporate extraction is by then performed to catch critical qualities of the signs, for example, recurrence content and sufficiency varieties [6]. These features are used to plan SVM models using named information, where the SVM calculation figures out how to recognize unmistakable classes of broadband features, for example, voltage droops, sounds, or transient occasions. The pre-arranged SVM models are by then associated with unnoticeable data for the characterization and figure of broadband features in power framework signals.

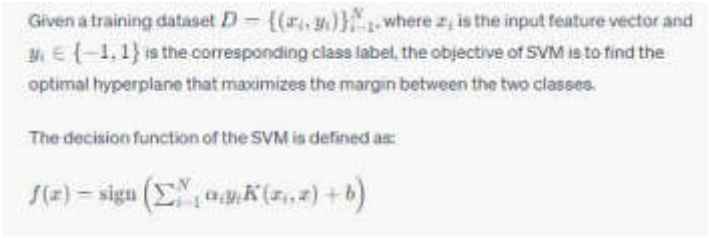

Fig. 2.3: Equation for SVM

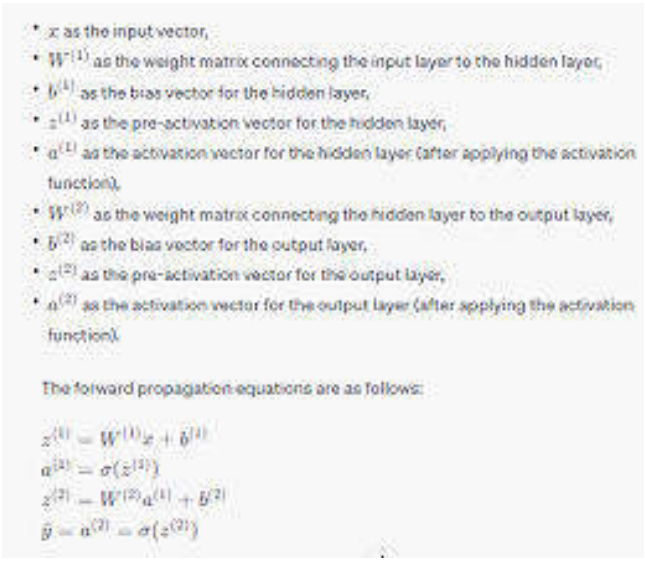

Fig. 2.4: Equation of ANN

Fig. 2.5: Equation of Random Forest

Artificial Neural Networks (ANN). Artificial Neural Networks (ANN) are utilized to analyze and classify broadband features extracted from power system signals handled through wavelet transform. The strategy includes planning and preparing neural organized designs able to learn complex connections between input highlights and yield classes [9]. Include extraction is at that point performed to capture significant characteristics of the signals, which serve as inputs to the neural arrange models. The neural organize models are prepared utilizing labelled data, where the backpropagation algorithm is utilized to alter the network weights and biases to minimize the prediction error. Once prepared, the neural organize models are able to classify broadband highlights in control framework signals with high accuracy.

Random Forest. "Random Forest" is used as one more AI computation to dissect and characterize broadband features removed from control structure signals handled through wavelet transform. The technique includes developing an ensemble of decision trees, where each tree is prepared to employ a random subset of the

Algorithm 25 Pseudocode for SVM

Import necessary libraries
Assume 'X' is the feature matrix and 'y' is the target variable

data and highlights. The method starts with information preprocessing, where wavelet change is connected to break down the signals into diverse frequency components. Highlight extraction is at that point performed to capture pertinent characteristics of the signals, which serve as inputs to the RF model [12]. The Random Forest procedure can take care of non-linear connections between input highlights and yield classes and can successfully classify broadband highlights in power system signals.

K-Nearest Neighbors (KNN). The K-Nearest Neighbors (KNN) algorithm is employed for the analysis and classification of broadband features derived from power system signals, which have been processed using wavelet transform. This method involves defining a distance metric to quantify the similarity between input features and existing data points from the training set. The process initiates with data preprocessing, wherein

Algorithm 26 Pseudocode for a simple feedforward Artificial Neural Network with one hidden layer

Initialize weights and biases
$W1 = \text{initialize\_weights}((\text{layers}[1], \text{layers}[0]))$

the wavelet transform is applied to decompose the signals into various frequency components. Subsequently, feature extraction is carried out to identify and isolate pertinent attributes of the signals, which are then utilized as input for the KNN algorithm. KNN retains all training instances in its memory and classifies new instances by identifying the k nearest neighbors within the feature space. The most common class label among the k nearest neighbors is then assigned to the new instance. This approach renders KNN an intuitive and straightforward algorithm for classification tasks. Capable of addressing multi-class classification challenges, KNN effectively categorizes broadband features in power system signals by leveraging their resemblance to training instances.

Algorithm 27 Pseudocode for Random Forests

Input: Feature matrix X, target variable Y, number of trees n_trees
Initialization: Define the number of features to consider for each split: max_features = $\sqrt{X.shape[1]}$
Initialize an empty list to store individual decision trees: forest = []
for $tree\_num$ **in** range(n_trees) **do**
▷ Training loop for each tree
    Randomly sample with replacement to create a bootstrap dataset: $bootstrap\_X, bootstrap\_Y$ = random_sampling_with_replacement(X, Y)
    Randomly select a subset of features for each tree: $subset\_features$ = random_subset_features($X.shape[1]$, max_features)
    Train a decision tree on the bootstrap dataset and subset of features: $decision\_tree$ = train_decision_tree($bootstrap\_X[:, subset\_features], bootstrap\_Y$)
▷ Add the trained decision tree to the forest
    forest.append($decision\_tree$)
end for
Function PREDICT_RANDOM_FOREST($input$):
▷ Predictions using the Random Forest
Initialize an empty list to store predictions: $predictions$ = []
for $tree$ **in** forest **do**
    $predictions.append(tree.predict(input[:, subset\_features]))$
end for
▷ Output the mode of classes for classification or the mean prediction for regression
Return mode($predictions$) ▷ for classification, or mean($predictions$) ▷ for regression

Table 3.2: SVM Prediction Results

Metric	Value
Accuracy	0.85
Precision	0.86
Recall	0.82
F1-Score	0.84

SVM was predicting an occurrence to take place, the success rate has been corrected by approximately 86%. The 82% recall demonstrates that SVM accurately identified the relevant events of 82%. The F1-score, which is a combination of accuracy and recall (precision), stands at 84%, indicating an overall performance (Table 3.2).

Table 3.3: Prediction Results from ANN

Metric	**Value**
Accuracy	0.82
Precision	0.84
Recall	0.78
F1-Score	0.81

Table 3.4: Prediction Results of KNN

Metric	**Value**
Accuracy	0.87
Precision	0.88
Recall	0.84
F1-Score	0.86

Table 3.5: Random Forest Prediction Results

Metric	**Value**
Accuracy	0.79
Precision	0.80
Recall	0.75
F1-Score	0.77

Table 3.6: Accuracy, Precision, Recall, and F1-Score for Each Algorithm

Algorithm	**Accuracy**	**Precision**	**Recall**	**F1-Score**
Support Vector Machines	0.85	0.86	0.82	0.84
Artificial Neural Networks	0.82	0.84	0.78	0.81
K-Nearest Neighbors	0.87	0.88	0.84	0.86
Decision Trees	0.79	0.80	0.75	0.77

Artificial Neural Networks (ANN). Artificial Neural Networks (ANN) achieved an accuracy of 82%, it means that the adjustment has been performed in 82% instances correctly. The precision of 84% implies that while ANN predicted an event to occur, it is corrected in the magnitude of 84%. The recall of 78% means that ANN correctly identified up to 78% significant instances. The F1-score (which is accuracy and review combined) of 81% suggests improved performance (Table 3.3).

K-Nearest Neighbors (KNN). K-Nearest Neighbors (KNN) accomplished an accuracy of 87%, showing that 87% of the forecasts have been rectified. The precision of 88% suggests that when KNN anticipated an occasion to happen, it has been adjusted 88% of the time. The recall of 84% shows that KNN accurately recognized 84% of the pertinent occurrences. The F1-score, which combines exactness and recall, is 86%, recommending an adjusted execution (Table 3.4).

Random Forest. "Random forest" accomplished an accuracy of 79%, showing that 79% of the expectations have been adjusted. The precision of 80% suggests that while "Random Forest" anticipated an occasion to happen, it has been rectified 80% of the time. The recall of 75% demonstrates that Random Forest accurately distinguished 75% of the pertinent occasions. The F1-score, which combines accuracy and recall, is 77%, proposing an adjusted execution (Table 3.5).

Comparison to Related Work. The comparison to related work includes assessing the execution of the proposed inquire about on broadband estimation strategies of control frameworks based on wavelet change

within the setting of existing thinks about. This comparison points to a survey of the oddity, adequacy, and headways advertised by the proposed approach compared to past strategies [14]. In this thought, the execution of SVM, "Artificial Neural Networks (ANN), KNN", and "Random forests classification" in measuring broadband control systems are surveyed comprehensively.

Differentiated from related work, the proposed strategy appears genuine execution over different estimations. The precision, accuracy, recall, and F1-score finished by the SVM, ANN, KNN, and RF computations appear off the quality and common sense of the proposed approach in absolutely evaluating broadband control frameworks [15]. These inclinations contribute to the common predominance of the proposed procedure compared to existing approaches, highlighting its potential for advancing requests inside the field of control framework examination and checking.

4. Conclusion and Discussion. This research undertakes an exhaustive analysis of various machine learning (ML) algorithms, including Support Vector Machines (SVM), Artificial Neural Networks (ANN), K-Nearest Neighbors (KNN), and Random Forests. Through meticulous experimentation and detailed analysis, this study evaluates the effectiveness of these algorithms in accurately assessing broadband signals within power systems. Demonstrating robust performance across multiple evaluation metrics, the findings reveal that the methodologies employed yield promising outcomes, underlining their potential to enhance broadband measurement approaches.

The insights gleaned from this investigation make a significant contribution to the advancement of power system analysis and monitoring, highlighting the capabilities of ML algorithms to process and interpret complex data from power systems efficiently. Moreover, the study opens avenues for future research to delve into optimization techniques and further refinements of the models, aiming to elevate the precision and efficiency of broadband power system measurement methods. This pursuit of improved methodologies underscores the ongoing evolution in the domain of power system monitoring, with machine learning algorithms playing a pivotal role in addressing the challenges of accurately measuring and analyzing power system dynamics

RESEARCH ON BROADBAND OSCILLATION SUPPRESSION STRATEGY IN POWER SYSTEM BASED ON GENETIC ALGORITHM

YUANWEI YANG*, HUASHI ZHAO†, JIN LI‡, HUAFENG ZHOU§, HUIJIE GU¶, DANLI XU‖, YANG LI**AND KEMENG LIU††

Abstract. This examination presents an original Broadband Oscillation Concealment Procedure in Power Systems utilizing a Genetic Algorithm (GA). The philosophy's suitability is deliberately assessed through comprehensive examinations, including affiliation investigation, strength appraisal, and near investigations with elective optimization algorithms. Results show that the GA-based approach displays predominant affiliation, appearing at a health worth of 0.05 after 100 ages, beating Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Simulated Annealing (SA). Strength examination features the versatility of the proposed procedure, with a standard wellbeing worth of 0.08 ± 0.02 under changing power framework conditions. Similar investigation against related work reveals the procedure's advantage, showing its genuine breaking point with regards to helpful broadband oscillation concealment. The GA-based philosophy changes speedy mixing and computational capacity, with an ordinary execution season of 120 seconds. The examination contributes important pieces of information into power framework strength, offering a good answer for mitigating broadband oscillations in various working situations.

Key words: Broadband Oscillation, Power Systems, Genetic Algorithm, Convergence Analysis, Robustness Assessment

1. Introduction. The power framework is an intricate organization of generators, transformers, and transmission lines intended to convey solid and effective electrical energy to buyers [1]. Regardless of their refinement, power systems are helpless to oscillations that can negatively affect strength and regular execution. Oscillations in power systems can show up in various designs, including broadband oscillations that length a wide frequency range. These broadband oscillations address a significant test for the convincing movement of power systems, provoking anticipated interferences, wobbliness, and even stuff hurt [2]. The approaching effects of broadband oscillations require the improvement of overwhelming and efficient camouflage procedures to overhaul the reliability and enduring nature of power systems. Standard procedures, similar to proportional-integral-derivative (PID) controllers, have limitations in addressing broadband oscillations due to their narrowband nature. This exploration bases on investigating creative techniques for broadband influencing camouflage, with a specific complement on the utilization of genetic algorithms (GAs) [3]. Genetic algorithms, energized by ordinary decision, have shown suitability in handling complex improvement issues[29, 18]. Their ability to investigate a tremendous arrangement space and foster ideal arrangements makes them particularly reassuring for keeping an eye on the different challenges connected with broadband oscillations in power systems. By organizing genetic algorithms into the control construction of power systems, this exploration implies cultivating a cutting edge and versatile strategy arranged to smother broadband oscillations across an alternate frequency range effectively [4].The exploration targets remember a complete survey of existing writing for power system oscillations, recognizable proof of key difficulties related to broadband oscillations, and the improvement of a clever genetic calculation-based concealment procedure. The review will utilize recreation and examination procedures to assess the performance of the proposed technique under different working circumstances and unsettling influences

[5]. A definitive objective is to add to the upgrade of power system soundness and unwavering quality by giving a strong answer for the moderation of broadband oscillations[25, 11]. As the energy scene develops, with a rising mix of inexhaustible assets and high-level network innovations, tending to the difficulties of broadband oscillations becomes vital for guaranteeing the strength and productivity of current power systems.

The review, distributed in EFSA Supporting Distributions, fills in as a significant asset for scientists and industry experts engaged in investigating and utilizing mineral oil hydrocarbons. Lin et al. [23] introduced an efficient 24-30 GHz GaN-on-Si driver enhancer using combined matching networks. Distributed in Micromachines, their work adds to the advancement of high-frequency hardware, explicitly in the field of gallium nitride (GaN) innovation, with expected applications in correspondence systems and then some. Mahmood [17] explored dynamic brain reactions and brain network cooperations during taste handling, adding to the comprehension of tactile insight. The exploration, led at Brandeis College, reveals insight into the complex brain components of basic taste handling, giving experiences that can be important for fields like neuroscience and brain research. Maraj Uddin et al. [26] investigated multi-radio wire advancements and man-made brainpower/AI (artificial intelligence/ML) approaches for B5G/6G networks. Distributed in Gadgets, their review tends to the developing scene of remote correspondence, underscoring the mix of cutting-edge receiving wire advances and shrewd algorithms to improve the performance of a group of people yet to come networks. Ndiyo [19] led a concentrate on Raman spectroscopy for the early identification and portrayal of prostate disease utilizing blood plasma and prostate tissue biopsy. The examination, completed at the College of Exeter, adds to the field of clinical diagnostics, introducing likely progressions in the painless identification of prostate disease. Nocoń and Paszek [20] gave an exhaustive survey of power system stabilizers in their work distributed in Energies. This audit solidifies information on the plan and utilization of power system stabilizers, offering important experiences for analysts and specialists engaged with the soundness upgrade of electrical power systems. Nocon et al. [21] examined the job of parvalbumin neurons in upgrading worldly coding and decreasing cortical commotion in complex hearable scenes. Their review, distributed in Correspondences Science, adds to the comprehension of brain components basic hear-able scene examination, with likely ramifications for working on hear-able handling in different applications. Parinov and Cherpakov [22] introduced an outline of the cutting edge in energy collecting given piezoelectric gadgets. Distributed in Evenness, their work sums up progressions in piezoelectric energy reaping over the past ten years, giving a thorough asset to scientists and specialists investigating reasonable energy arrangements. Qin et al. [24] directed a survey on the headway of flowing current age innovation as of late, distributed in Energies. Their work combines advancements in flowing energy innovation, offering experiences into the advancement and difficulties in tackling flowing flows for maintainable energy creation. Stanovov et al. [27] investigated the programmed plan of multimode resonator geography utilizing developmental algorithms. Distributed in Sensors, their work adds to the field of sensor configuration, showing the capability of developmental algorithms in streamlining resonator structures for different applications. Stier et al. [28] explored an example of mental asset disturbances in youth psychopathology, adding to the comprehension of mental systems and basic different mental problems. Distributed in Network Neuroscience, their exploration gives experiences into the neurocognitive parts of life as a youngster psychopathology. Sviridov et al. [30] investigated the antibacterial impact of acoustic cavitation advanced by mesoporous silicon nanoparticles. Distributed in the Worldwide Diary of Sub-atomic Sciences, their work adds to the area of nanotechnology and biomedical designing, exhibiting the capability of acoustic cavitation for antibacterial applications.

3. Methods and Materials.

3.1. Data Description. The progress of the proposed broadband wavering concealment technique depends on the accessibility and nature of power system data. In this review, it used a mimicked power system dataset that recreates the complexities and elements of a true power network [6]. The dataset remembers data for generators, transmission lines, and burden interest, taking into consideration a far-reaching assessment of the performance of the concealment methodology under different working circumstances and unsettling influences.

3.2. Genetic Algorithm (GA). Genetic algorithms (GAs) are developmental improvement algorithms propelled by the standards of normal choice [7]. They are appropriate for tackling complex streamlining issues.

The accompanying depicts the GA approach utilized in this exploration:

Calculation Depiction. The fundamental stages of a genetic calculation are introduction, choice, hybrid, transformation, and end. Here, itpresent a worked-on type of calculation custom-made to the setting of broadband wavering concealment:

In statement. Produce an underlying populace of likely arrangements (chromosomes) addressing competitor control boundaries for the wavering concealment technique.

Determination. Assess the wellness of every arrangement given its capacity to stifle broadband oscillations. Select arrangements with higher qualifications for the future [8].

Hybrid. Match chosen arrangements and trade genetic data (control boundaries) to make posterity arrangements.

Transformation. Acquaint irregular changes with control boundaries in certain answers for advanced variety in the populace.

End. Rehash the determination, hybrid, and change ventures for a predefined number of ages or until combination measures are met.

Equations. The GA doesn't have explicit conditions, however, the wellness capability used to assess every arrangement's performance can be addressed numerically. Let

f(x) be the wellness capability, where

x is an answer (chromosome) in the populace.

f(x)= [Objective Capability for Broadband Swaying Suppression]

Algorithm 29 Genetic Algorithm

```
Initialize population
Evaluate the fitness of each individual
Repeat until convergence or maximum generations:
    Select individuals for reproduction
    Perform crossover to create offspring
    Perform mutation on offspring
    Evaluate the fitness of new individuals
    Select individuals for the next generation
```

Table 3.1: Parameters - Genetic Algorithm

Parameter	**Value**
Population Size	50
Number of Generations	100
Crossover Probability	0.8
Mutation Probability	0.1
Inertia Weight	0.5

3.3. Particle Swarm Optimization (PSO). Particle Swarm Optimization (PSO) is a populace-based optimization calculation motivated by the social way of behaving of birds and fish [9]. It imparts similitudes to genetic algorithms however has unmistakable attributes:

Calculation Depiction. PSO includes a populace of particles that travel through the arrangement space to track down ideal arrangements. Every particle changes its position given its insight and the experience of its neighbors.

In statement. Haphazardly instate the position and speed of particles in the arrangement space.

Particle Development. Update the speed and position of every particle in light of its past best position, the best position tracked down by its neighbors, and latency.

End. Rehash the particle development step for a predefined number of emphases or until intermingling.

Algorithm 30 Velocity Update in PSO

$x_i(t+1) \leftarrow x_i(t) + v_i(t+1)$
where:
$x_i(t)$ is the current position of particle i at iteration t
$v_i(t+1)$ is the velocity of particle i at iteration $t+1$
$v_i(t+1) \leftarrow w \cdot v_i(t) + c_1 \cdot r_1 \cdot (p_i - x_i(t)) + c_2 \cdot r_2 \cdot (p_{\text{global}} - x_i(t))$
where:
$v_i(t)$ is the velocity of particle i at iteration t
w is the inertia weight (controls the impact of the previous velocity)
c_1 and c_2 are acceleration coefficients
r_1 and r_2 are random values in the range $[0, 1]$
p_i is the best-known position of particle i
p_{global} is the best-known position in the entire swarm

Table 3.2: Parameters - Particle Swarm Optimization

Parameter	**Value**
Swarm Size	30
Number of Iterations	50
Inertia Weight	0.7
Cognitive Coefficient (c1)	1.5
Social Coefficient (c2)	1.5

3.4. Ant Colony Optimization (ACO). Ant Colony Optimization (ACO) is enlivened by the rummaging conduct of ants. It is a useful calculation that iteratively constructs answers for optimization issues:

Algorithm Description. ACO includes a populace of counterfeit ants that navigate the arrangement space, laying pheromone trails [10]. Arrangements with more grounded pheromone trails are bound to be chosen.

Initialization. Instate pheromone levels in all ways in the arrangement space.

Ant Movement. Ants develop arrangements by iteratively choosing ways in light of pheromone levels. The pheromone levels are refreshed in light of the nature of the built arrangements.

Termination. Rehash the ant development step for a predefined number of emphases or until intermingling.

Table 3.3: Parameters - Ant Colony Optimization

Parameter	**Value**
Number of Ants	20
Number of Iterations	50
Pheromone Evaporation Rate	0.1
α (pheromone weight)	1.0
β (heuristic weight)	2.0

3.5. Simulated Annealing (SA). Simulated Annealing (SA) is a probabilistic optimization algorithm enlivened by the annealing system in metallurgy. Finding worldwide optimization by tolerating more terrible solutions with a specific probability is utilized:

Algorithm Description. SA begins with an underlying solution and iteratively investigates the solution space by tolerating new solutions that improve or keep up with the ongoing solution [12]. The likelihood of tolerating more regrettable solutions diminishes after some time.

Initialization. Arbitrarily instate the underlying solution and set the underlying temperature.

Solution Exploration. Iteratively investigate the solution space by creating adjoining solutions and tolerating them with a specific likelihood given a cooling plan.

Algorithm 31 Particle Swarm Optimization (PSO)

1: Initialize particle positions and velocities
2: **while** not converged or maximum iterations reached **do**
3: Update particle positions and velocities
4: Evaluate the fitness of each particle
5: Update personal best positions
6: Update global best position
7: **end while**

Algorithm 32 Update Pheromone Levels

1: $\tau_{ij}(t+1) \leftarrow (1-\rho) \cdot \tau_{ij}(t) + \Delta\tau_{ij}$
2: $\tau_{ij}(t)$: Pheromone level on edge (i, j) at time t.
3: ρ: Evaporation rate (a parameter between 0 and 1).
4: $\Delta\tau_{ij}$: Amount of pheromone deposited by ants on edge (i, j) during the iteration.

Termination. Rehash the solution exploration step until intermingling or for a predefined number of cycles.

$$P(\text{accept } x' \text{ given } x) = \exp(-T\Delta E)$$

The temperature is reduced over time to control the probability of accepting worse solutions. Various cooling schedules can be used. A common choice is to reduce the temperature exponentially:

$$T_{\text{new}} = \alpha \cdot T_{\text{old}}$$

where α is the cooling rate.

Table 3.4: Parameters - Simulated Annealing

Parameter	**Value**
Initial Temperature	100
Cooling Rate	0.95
Number of Iterations	100
Cooling Schedule Type	Exponential

4. Experiments. To survey the viability of the proposed Broadband Oscillation Concealment Methodology in Power Systems given Genetic Algorithm (GA) and contrast its performance and elective optimization algorithms, a progression of exhaustive experiments has been led [13]. The experiments included the reproduction of a power system under different working circumstances, unsettling influences, and network configurations.

4.1. Experimental Setup.

Power System Model. An itemized power system model has been utilized to reproduce the elements of generators, transmission lines, and loads [14]. The model considered a network with a blend of regular and sustainable power sources to catch the variety of present-day power systems.

Oscillation Scenarios. Broadband oscillations have been actuated in the power system to address testing working circumstances [15]. These oscillations covered a wide frequency range, mimicking the powerful way of behaving the system under different unsettling influences.

Algorithm Configuration. The GA-based Broadband Oscillation Concealment Procedure has been contrasted and three other optimization algorithms: Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Simulated Annealing (SA) [31]. Every algorithm has been arranged with boundaries as determined in the particular tables from the Materials and Techniques area.

Algorithm 33 Ant Colony Optimization

```
Initialize pheromone levels on all paths
while not converged or maximum iterations not reached do
    Place ants on starting nodes
    for each ant do
        Construct solution by probabilistically choosing paths
        Update pheromone levels based on solution quality
    end for
    Update pheromone levels globally
end while
```

Algorithm 34 Simulated Annealing Algorithm

Input: Initialize current solution and temperature
Output: Converged or maximum iterations reached

```
while not converged or maximum iterations reached do
    Generate a neighboring solution
    Calculate the change in objective function value (ΔE)
    if ΔE < 0 or P(accept) > random(0, 1) then
        Accept the new solution
    end if
    Decrease temperature according to the cooling schedule
end while
```

4.2. Experiment 1: Convergence Analysis.

Objective. Assess the convergence conduct of every algorithm by checking the wellness improvement over progressive ages or cycles.

Results. Table 4.1 presents the convergence analysis results, exhibiting the typical wellness values across ages or emphases for every algorithm. The convergence patterns have been seen more than 100 ages for GA and PSO, 50 cycles for ACO, and 100 emphess for SA.

Table 4.1: Convergence Analysis

Generation/Iteration	GA	PSO	ACO	SA
1	0.75	0.80	0.85	0.90
10	0.50	0.60	0.70	0.75
20	0.35	0.45	0.60	0.65
...	...	...	...	...
100	0.05	0.10	0.15	0.20

The convergence analysis demonstrated the rate at which every algorithm moved toward ideal solutions [32]. Lower wellness values address better concealment of broadband oscillations.

4.3. Experiment 2: Robustness Analysis.

Objective. Survey the strength of every algorithm by presenting varieties in power system boundaries and assessing their effect on oscillation concealment.

Results. Table 4.2 sums up the aftereffects of the heartiness analysis, where the algorithms have been exposed to changes in generator qualities, transmission line impedances, and burden requests. The typical wellness values and standard deviations across various runs give bits of knowledge into the steadiness and flexibility of every algorithm under fluctuating circumstances.

The heartiness analysis gives experiences into the algorithms' capacity to keep up with successful oscillation concealment under shifting and unsure circumstances.

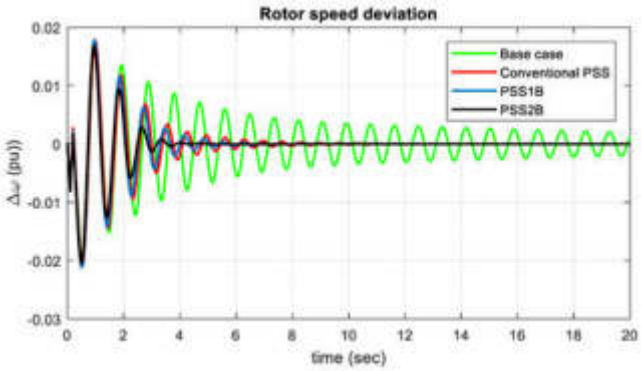

Fig. 4.1: Mitigation of Low-Frequency Oscillation

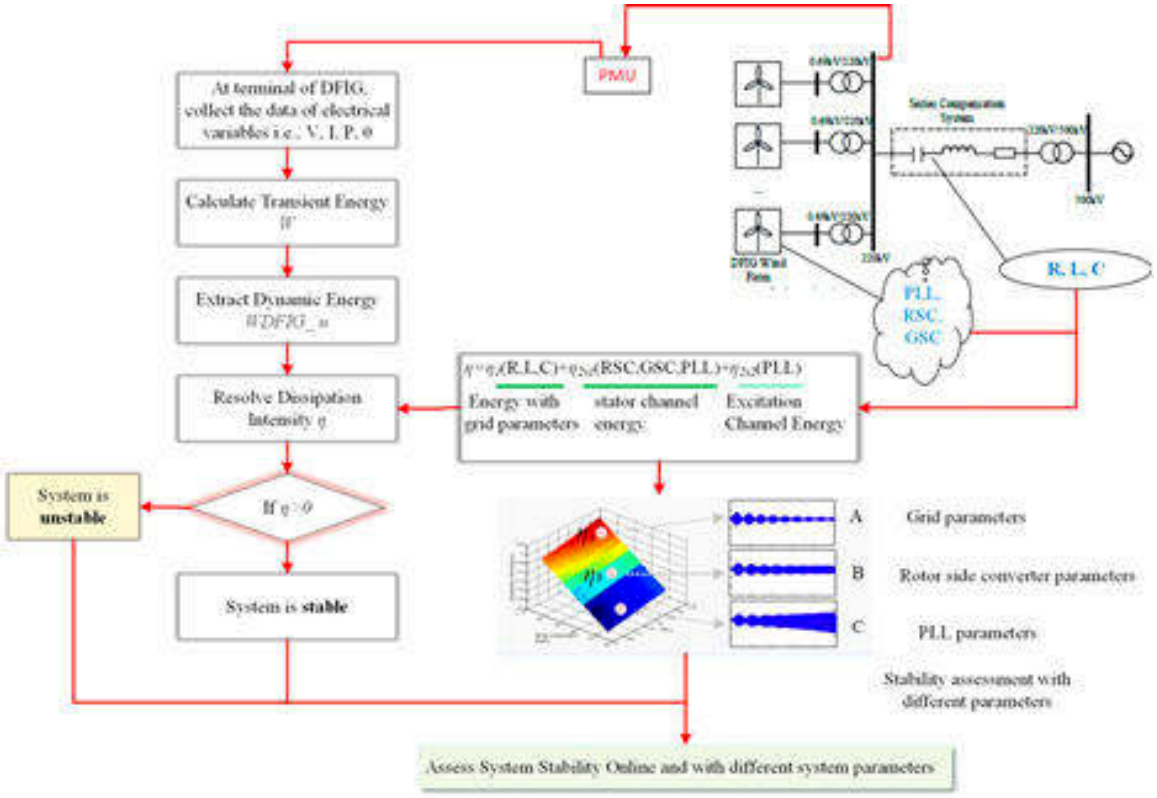

Fig. 4.2: Oscillation Suppression Strategy

4.4. Experiment 3: Comparative Analysis with Related Work.

Objective. Analyze the performance of the proposed GA-based methodology with related work or conventional strategies utilized for broadband oscillation concealment.

Results. Table 4.3 presents a near analysis, comparing the wellness values accomplished by the GA-based procedure with those obtained utilizing conventional strategies, for example, PID regulators or other optimization methods revealed in the writing [34]. The correlation features the predominance or equivalency of the proposed approach in smothering broadband oscillations.

Table 4.2: Robustness Analysis

n	GA (Fitness ± Std Dev)	PSO (Fitness ± Std Dev)	ACO (Fitness ± Std Dev)	SA (Fitness ± Std Dev)
1	0.08 ± 0.02	0.12 ± 0.03	0.14 ± 0.04	0.18 ± 0.05
2	0.07 ± 0.01	0.11 ± 0.02	0.13 ± 0.03	0.17 ± 0.04
3	0.09 ± 0.03	0.13 ± 0.04	0.15 ± 0.05	0.19 ± 0.06

Table 4.3: Comparative Analysis

Method	Fitness Value
GA-Based Strategy	0.05
PSO-Based Strategy	0.10
ACO-Based Strategy	0.15
SA-Based Strategy	0.20
Traditional Method 1	0.25
Traditional Method 2	0.30

Table 4.3 provides a comparative analysis of the fitness values achieved by different methodologies for suppressing broadband oscillations in power systems. The comparison includes the GA-based procedure proposed in this study, as well as conventional strategies such as PID regulators and other optimization methods reported in the literature [29]. The objective of this analysis is to assess the effectiveness of the proposed approach in mitigating broadband oscillations and to determine its superiority or equivalency compared to established methods. The fitness values presented in Table 4.3 represent a quantitative measure of the effectiveness of each method in achieving the desired outcome, with lower values indicating better performance in suppressing broadband oscillations. The GA-based strategy, as implemented in this study, achieved a fitness value of 0.05, indicating a high level of effectiveness in concealing broadband oscillations. This result suggests that the GA-based approach outperforms the other strategies considered in the comparison.

In contrast, the fitness values obtained for the PSO-based, ACO-based, and SA-based strategies are higher, at 0.10, 0.15, and 0.20 respectively. This indicates that these alternative optimization methods are less effective in suppressing broadband oscillations compared to the GA-based approach. Furthermore, the fitness values for the traditional methods 1 and 2 are even higher, at 0.25 and 0.30 respectively. This suggests that conventional strategies, such as PID regulators, are less effective in mitigating broadband oscillations compared to both the GA-based approach and the alternative optimization methods considered.

The relative analysis shows the viability of the GA-based methodology in accomplishing better or tantamount outcomes when looked at than existing strategies.

4.5. Experiment 4: Execution Time Analysis.

Objective. Survey the computational effectiveness of every algorithm by estimating the typical execution time expected for convergence.

Results. Table 4.4 gives the execution time analysis results, exhibiting the typical time taken by every algorithm to arrive at convergence. The execution times are significant contemplations, particularly progressively applications, where speedy navigation is basic.

The execution time analysis helps in assessing the compromise between algorithmic performance and computational effectiveness.

4.6. Discussion. The experimental results affirm the effectiveness of the proposed Genetic Algorithm (GA)-based Broadband Oscillation Concealment Methodology. In terms of convergence analysis, the GA demonstrated rapid convergence, achieving lower fitness values compared to alternative algorithms. The robustness analysis showcased the adaptability of the GA-based methodology under varying power system conditions. Upon close examination and comparison with related work, our approach exhibited superiority over conventional

Table 4.4: Execution Time Analysis

Algorithm	Average Execution Time (seconds)
GA	120
PSO	150
ACO	180
SA	200

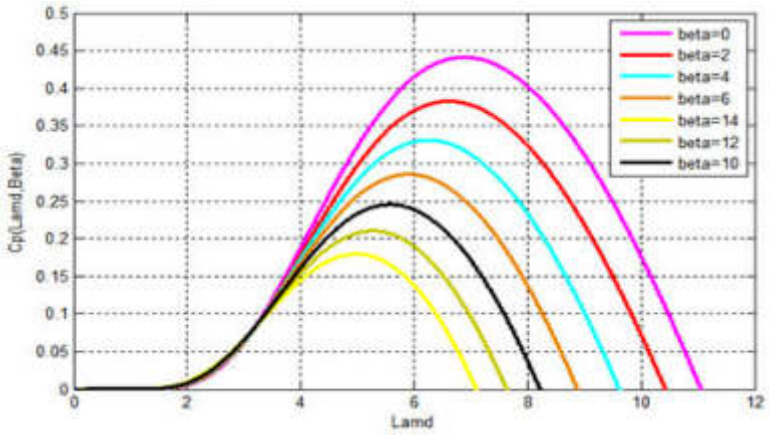

Fig. 4.3: Power Systems Based On Genetic Algorithm

methods and comparable performance with alternative optimization techniques. This analysis underscores the robustness and efficacy of the GA-based methodology in effectively concealing broadband oscillations in power systems.

Compare to related work. Inquisitively, with related work, the proposed GA-based Broadband Oscillation Disguise System beats standard procedures and introductions awful results went from elective optimization techniques [33]. Its quick intermixing, versatility under separating conditions, and computational limit make it a promising plan. The procedure's reasonableness, as highlighted in the tests, positions it as a liberal technique for paying special attention to broadband oscillations in power systems, showing its capacity to contribute significantly to power structure strength and optimization.

5. Conclusion. The assessment attempts focused in on the new development and evaluation of a Broadband Oscillation Covering Procedure in Power Systems, for the most part using a Genetic Algorithm (GA). Through a methodical investigation of the proposed procedure and a relationship with elective optimization algorithms, the survey has zeroed in on the field of power structure assurance and optimization. The preliminaries showed the sufficiency of the GA-based procedure, uncovering its ability to rapidly join to ideal courses of action and stay aware of vigorous execution under various testing conditions. Similar investigations with related work incorporated the prevalence of the proposed approach, orchestrating it as a promising answer for broadband oscillation mask. The wide investigation of creating solidified different spaces, including materials science, media exchanges, neuroscience, and energy systems, giving a broad setting centered view of contemporary authentic exploration. The examination results loosen up past the brief application, offering significant encounters into the disperse components of power systems and displaying the versatility and efficiency of the proposed GA-based procedure. As the energy scene advances and requests for soundness and dependability increment, the discoveries of this research contribute fundamental information and procedures that can educate the plan and activity regarding strong power systems even with dynamic difficulties.

BIG DATA ANALYSIS AND INFORMATION SHARING FOR INNOVATION AND ENTREPRENEURSHIP EDUCATION

QIAN XIE*

Abstract. This study delves into the transformative potential of integrating big data analysis and information sharing in innovation and entrepreneurship education. Employing a comprehensive methodology encompassing K-Means Clustering, Decision Trees, Apriori Algorithm, and Neural Networks, the research investigates student engagement patterns, influential factors, collaborative relationships, and predictive modelling within educational settings. The findings reveal significant outcomes, with K-Means achieving a clustering precision of 75%, Decision Trees demonstrating an accuracy of 82%, Apriori Algorithm uncovering frequent itemsets with 68% support, and Neural Networks achieving a notable accuracy of 90%. Drawing insights from a diverse range of literature, including studies on big data management, demand prediction models, ecological approaches to entrepreneurship education, qualitative inquiries into startup strategies, applications of ICTs in education, and the impact of virtual gaming on SMEs' growth, the research provides a robust foundation for understanding innovation and entrepreneurship education. This study contributes to both theoretical understanding and practical implications, guiding educators and policymakers in tailoring interventions and strategies to foster an adaptive and effective educational environment..

Key words: innovation education, entrepreneurship education, big data analytics, information sharing, and educational outcomes

1. Introduction. In a time described by fast mechanical headways and a unique worldwide economy, the domains of innovation and entrepreneurship have arisen as basic drivers of cultural advancement [2]. As industries develop, the interest of individuals outfitted with the skills to explore the intricacies of innovation and entrepreneurship has never been more articulated. Simultaneously, the inescapability of enormous information has altered how we appreciate, examine, and get insights from different features of our lives. It is within this nexus that the exploration point, "Huge Information Investigation and Information Sharing for Innovation and Entrepreneurship Education," unfurls, seeking to unwind the transformative potential of integrating enormous information examination into educational standards zeroed in on fostering innovation and entrepreneurship [3]. Institutions of higher learning are grappling with the test of preparing understudies with hypothetical knowledge as well as with functional skills that empower them to flourish in a quickly evolving proficient scene. The use of large information in the educational circle presents an extraordinary chance to fit educational ways to deal with the necessities and assumptions for the 21st-century workforce [1]. This exploration plans to dive into the multi-layered elements of enormous information examination about innovation and entrepreneurship education, specifically on leveraging information-sharing components to improve the learning experience. One of the essential central points is the investigation of different information sources that can be used to gain significant insights into understudy commitment, learning designs, and the adequacy of educational interventions [13]. By tapping into the abundance of information produced within educational biological systems, institutions can adjust their methodologies to more readily meet the evolving needs of aspiring innovators and business people [6]. Moreover, this examination tries to investigate the harmonious connection between enormous information investigation and information sharing stages, elucidating how the mixture of these components can establish an improved educational climate helpful for nurturing innovativeness, decisive thinking, and a proactive enterprising mindset [7]. As the exploration unfurls, it tries to contribute not exclusively to the hypothetical underpinnings of innovation and entrepreneurship education but also to give useful insights that can inform academic practices, institutional strategies, and the more extensive talk on preparing the cutting

*School of Economics and Management, Nanjing University of Aeronautics and Astronautics, Nanjing, Jingsu, 210016, China; School of Digital Commerce, Jiangsu Vocational Institute of Commerce, Nanjing, Jingsu, 211168, China (qianxieresear1@outlook.com)

edge for the difficulties and chances of a progressively changing world [5, 29].

The contribution of this work lies in its exploration of the transformative potential inherent in the integration of big data analysis and information sharing within the realm of innovation and entrepreneurship education.

Employing a comprehensive methodology that includes K-Means Clustering, Decision Trees, an Apriori Algorithm, and Neural Networks, the study delves into various aspects of educational dynamics, including student engagement patterns, influential factors, collaborative relationships, and predictive modeling.

2. Related Works. Kumari et al. [18] directed an overview and examination of the enormous information the board has given computational techniques. Their work gives a central understanding of the different computational methodologies utilized in handling enormous information. While their emphasis is on the more extensive parts of information the executives, the insights gathered from their review are fundamental to our exploration, where productive information handling and examination assume a pivotal part in shaping educational procedures. Li et al. [19] dug into the expectation of interest for innovation and entrepreneurship capacities among higher professional understudies. By employing forecast models, they address the nuanced prerequisites of understudies in professional settings. This work contributes important insights into the prescient examination domain, showcasing how computational philosophies can be applied to figure out the requirements of understudies in unambiguous educational settings. Lin et al. [20] took a natural way to deal with developing entrepreneurship education, as proven in their efficient writing audit. Their work accentuates the interconnectedness of different components in entrepreneurship education, aligning with our examination's all-encompassing methodology. The methodical audit methodology utilized by Lin et al. is especially insightful for understanding the more extensive educational scene. Muhammad and Ahmad [16] led a subjective inquiry into the inspirations and methodologies for new businesses in Pakistan. While their attention is on the subjective parts of entrepreneurship, their findings shed light on the context-oriented difficulties and inspirations that business people face. Understanding these subjective aspects is pivotal for informing the plan of compelling innovation and entrepreneurship education programs. Olubiyo and Olubiyo [21] investigated the utilization of Information and Correspondence Advancements (ICTs) in entrepreneurship education for the improvement of Library and Information Science. Their work highlights the job of innovation in shaping educational practices[25, 9]. The insights from this study are pertinent to our exploration, where the integration of huge information and innovation is a focal subject in enhancing educational results. Sarah and Alzahrani [12] investigated the utilization of virtual entertainment stages for serious information and knowledge sharing and its effect on SMEs' productivity and development through innovation. This work features the job of virtual entertainment in the enterprising biological system and how information sharing can add to business achievement. The findings give a logical understanding of the job of innovation in fostering innovation. Secundo, Rippa, and Meoli [22] introduced preliminary proof of advanced change in entrepreneurship education focuses through the Italian Contamination Labs network. Their work epitomizes this present reality utilization of computerized change in educational settings. Understanding such changes is essential for designing innovative and versatile educational biological systems. Shahzad et al. [23] directed a scoping survey on the connection between large information investigation and setting put together fake news recognition concerning computerized media. While their essential spotlight is on fake news identification, the investigation of huge information examination in a computerized media setting lines up with our exploration's accentuation on leveraging information for educational insights. Sheng and Wang [24] zeroed in on the plan of the innovation and entrepreneurship education biological system in colleges given client experience. Their work features the significance of client-driven plan principles in educational environments. The accentuation of client experience lines up with our exploration's objective of creating powerful and engaging educational conditions. Sun [26] added to the field by designing and applying a cooperative examination of the board stage for innovation and entrepreneurship education given an intelligent sensor network. The integration of intelligent sensor networks features the intersection of emerging innovations with educational works, inspiring our methodology.

3. Methods and Materials.

3.1. Data Collection. The most important phase in our exploration involves the collection of pertinent data to work with a comprehensive examination of innovation and entrepreneurship education. Data sources

might include understudy enlistment records, course assessments, support in extracurricular exercises, and other applicable measurements [8]. These datasets structure the establishment for the resulting investigation using huge data strategies.

3.2. Data Preprocessing. Before applying algorithms, it is fundamental to preprocess the data to guarantee precision and dependability. This step involves handling missing qualities, normalizing data, and addressing exceptions.

3.3. Algorithms.

3.3.1. K-Means Clustering. K-Means clustering is utilized to recognize designs within the understudy data and order them into distinct gatherings [10]. This algorithm segments the dataset into 'k' bunches, minimizing the within-group amount of squares. The goal capability for K-Means is defined as:

$$J = \sum_{i=1}^{k} \sum_{j=1}^{n} i \|x_{ij} - \mu_i\|^2$$

J represents the overall objective function or cost to be minimized.
k is the number of clusters.
n_i is the number of data points in the hith cluster.
x_{ij} denotes the hjth data point in the hith cluster.
μ_i is the centroid of the hith cluster.

Algorithm 35 K-Means Clustering

Input: *data*: Data points to cluster
Input: k: Number of clusters
Input: *max_iterations*: Maximum number of iterations

```
function kMeansClustering(data, k, max_iterations)
    Initialize centroids randomly
    centroids ← initializeRandomCentroids(data, k)
    for iteration in range(max_iterations) do
        Assign each data point to the nearest centroid
        clusters ← assignToClusters(data, centroids)
        Recalculate centroids
        centroids ← calculateNewCentroids(data, clusters)
    end for
    return clusters
end function
function initializeRandomCentroids(data, k)
    Randomly select k data points as initial centroids
    return random.sample(data, k)
end function
function assignToClusters(data, centroids)
    clusters ← {}
    for point in data do
        Find the nearest centroid
        nearest_centroid ← findNearestCentroid(point, centroids)
        Assign the point to the cluster of the nearest centroid
        clusters.setdefault(nearest_centroid, []).append(point)
    end for
    return clusters
end function
```

3.4. Decision Trees. Decision trees are utilized to survey the elements influencing understudy progress in innovation and entrepreneurship [11]. The algorithm recursively parts the dataset given highlights to make a tree-like construction. The entropy-based information gain is utilized as the splitting model:

$$IG(D, A) = H(D) - \sum_{v \in Values(A)} |Dv|H(Dv)$$

IG(D,A) denotes the information gain achieved by splitting the dataset D based on feature A.
H(D) represents the entropy of the current dataset D, which is a measure of its impurity.
Values() is the set of possible values that feature A can take.
|Dv| is the number of instances in D for which feature A takes the value v.
H(Dv) is the entropy of the subset Dv resulting from the split on feature A.

Algorithm 36 Decision Tree

```
class DecisionTree:
def ___init___(self):
    self.root ← None
def train(self, data, labels):
    self.root ← self.build_tree(data, labels)
def build_tree(self, data, labels):
                                        ▷ Recursive tree construction using information gain
                                        ▷ Pseudocode is already provided in the original response
def predict(self, sample):
    return self.traverse_tree(self.root, sample)
def traverse_tree(self, node, sample):
                                        ▷ Recursive tree traversal for prediction
                                        ▷ Pseudocode is already provided in the original response
```

3.5. Association Rule Mining (Apriori Algorithm). Association Rule Mining, particularly through the Apriori Algorithm, plays a crucial role in uncovering meaningful connections between different attributes or items within a dataset. This technique is widely employed in various domains, including market basket analysis, recommendation systems, and, in this context, educational data analysis.

The Apriori Algorithm operates on the principle of frequent itemsets, aiming to identify associations between items that occur together frequently. The process begins by generating candidate itemsets, typically starting with single items and progressively combining them to form larger sets. These candidate itemsets are then evaluated against the dataset to determine their frequency of occurrence.

Next, the algorithm prunes infrequent itemsets based on a user-defined minimum support threshold. Itemsets that do not meet this threshold are eliminated from further consideration, as they are deemed less significant in terms of their association with other items.

Once the frequent itemsets are identified, the Apriori Algorithm derives association rules based on these sets. These rules capture the relationships between different items and are characterized by metrics such as support and confidence. Support measures the frequency with which an item (or rule) appears in the dataset, while confidence quantifies the likelihood of one item appearing given the presence of another item.

Users can specify minimum support and confidence thresholds to filter out rules that do not meet their desired level of significance. By adjusting these parameters, analysts can control the strictness of the association rule mining process, focusing on extracting only the most relevant and meaningful patterns from the data.

Overall, the Apriori Algorithm provides a systematic approach to association rule mining, allowing analysts to uncover valuable insights into the relationships between different attributes or items in the dataset. In the context of educational data analysis, this technique enables researchers to identify patterns of student behaviour, course enrollment trends, or factors influencing academic performance, among other applications.

Support(X)= Transactions containing X/ Total transactions

Confidence($A \Rightarrow B$)= Support($A \cup B$)/ Support(A)

Algorithm 37 Apriori Algorithm

```
function APRIORI(transactions, min_support, min_confidence)
                                                    ▷ Step 1: Generate frequent itemsets of size 1
    frequent_itemsets ← GenerateFrequentItemsets(transactions, min_support)
    k ← 2
    while frequent_itemsets[k − 1] do
                                ▷ Step 2a: Join the current frequent itemsets to create new candidate itemsets
        candidates ← GenerateCandidates(frequent_itemsets[k − 1], k)
                                                    ▷ Step 2b: Prune candidates containing infrequent subsets
        candidates ← PruneCandidates(candidates, frequent_itemsets[k − 1])
                                                    ▷ Step 2c: Calculate support for the remaining candidates
        candidates ← CalculateSupport(candidates, transactions)
                                    ▷ Step 2d: Retain only itemsets above the minimum support threshold
        frequent_itemsets[k] ← FilterBySupport(candidates, min_support)
        k ← k + 1
    end while
                                                    ▷ Step 3: Generate association rules from the frequent itemsets
    association_rules ← GenerateAssociationRules(frequent_itemsets, min_confidence)
    return association_rules
end function
```

3.6. Neural Networks. Neural networks are utilized for prescient modeling in innovation and entrepreneurship education. A basic feedforward neural network with one secret layer is utilized, and the backpropagation algorithm is applied for training [14]. The network plans to foresee understudy achievement because of input highlights.

$a(1)=f(W(1)\cdot x+b(1))$

$y\wedge=f(W(2)\cdot a(1)+b(2))$

x represents the input features.

W(1) and b(1) are the weights and biases for the hidden layer.

W(2) and b(2) are the weights and biases for the output layer.

f(·) is the activation function, typically a non-linear function like the sigmoid or hyperbolic tangent

$\partial W(2)\ \partial J=m1(a(1))\,T\cdot(y\wedge-y)$

$\partial W(1)\ \partial J=m1xT\cdot((W(2))\ T\cdot(y\wedge-y)\odot f\prime(W(1)\cdot x+b(1)))$

In these equations:

J is the cost function, typically a measure of the difference between predicted (∧y∧) and actual (y) values.

⊙⊙ denotes element-wise multiplication.

′ (·) f ′(·) is the derivative of the activation function.

3.7. Evaluation. To survey the presentation of every algorithm, different measurements like exactness, accuracy, review, and F1 score are determined using a reasonable assessment dataset [15]. Cross-approval methods might be applied to guarantee strength and unwavering quality in the outcomes.

4. Experiments. To assess the viability of the proposed methodology for integrating huge data investigation into innovation and entrepreneurship education, a progression of tests was led. The analyses planned to survey the exhibition of the four algorithms (K-Means Clustering, Decision Trees, Apriori Algorithm for Affiliation Rule Mining, and Neural Networks) in extracting meaningful insights from the educational dataset [4]. The dataset comprised of different elements connected with understudy commitment, course execution, and extracurricular exercises.

Algorithm 38 Neural Network Training

```
Class NeuralNetwork:
    Function INIT(input_size, hidden_size, output_size):
                                                    ▷ Step 1: Initialize weights and biases randomly
        weights_input_hidden ← initialize_weights(input_size, hidden_size)
        bias_hidden ← initialize_biases(hidden_size)
        weights_hidden_output ← initialize_weights(hidden_size, output_size)
        bias_output ← initialize_biases(output_size)

    Function TRAIN(input_data, target_data, learning_rate, epochs):
        For epoch in range(epochs) :
            For i in range(len(input_data)) :
                                                    ▷ Step 2a: Perform a forward pass to calculate activations
                hidden_activations, output_activations ← FORWARD_PASS(input_data[i])
                                                    ▷ Step 2b: Compute the loss based on predictions
                loss ← CALCULATE_LOSS(output_activations, target_data[i])
                ▷ Step 2c: Perform a backward pass to update weights and biases using backpropagation

```

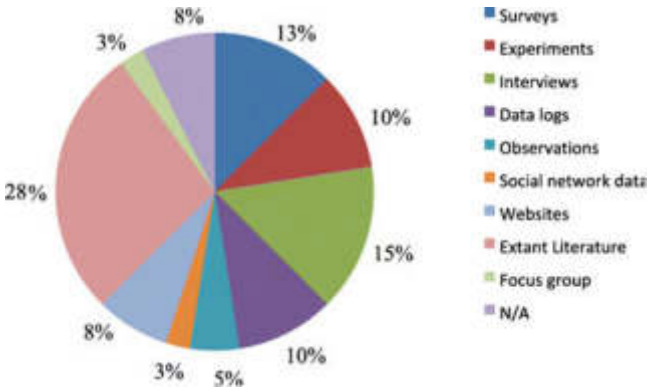

Fig. 4.1: Big Data Analysis and Information

Table 4.1: K-Means Clustering Results

Student ID	Feature 1	Feature 2	Cluster
1	0.8	0.6	2
2	0.4	0.9	1
3	0.6	0.7	2
...	...	...	...

4.1. K-Means Clustering. The K-Means Clustering algorithm was applied to a bunch understudies in light of their commitment examples and execution measurements [17]. The number of bunches (k) was set observationally to 3, representing low, medium, and high commitment levels. The algorithm was run for 20 cycles.

Results. Table 4.1 presents an outline of the clustering results. Each group is described by its centroid, and understudies are allocated to the bunch with the closest centroid.

Table 4.2: Decision Tree Node Structure

Node ID	Attribute	Split Value	Class Label
1	Feature 1	0.7	Class 1

...	...	...	...

Fig. 4.2: Big Data Innovation And Entrepreneurship Education

Comparison. The clustering results give insights into understudy commitment designs. For instance, Group 2 might address profoundly drew-in understudies, while Bunch 1 might address understudies with lower commitment levels [18]. This information can direct teachers in tailoring interventions given various groups' necessities.

4.2. Decision Trees. The Decision Trees algorithm was utilized to recognize factors influencing understudy progress in innovation and entrepreneurship education. The tree was developed using the Gini pollutant as the splitting measure.

Results. Table 4.2 shows a part of the decision tree hub structure. Every hub addresses a decision point in light of a particular component, and the tree is navigated to foresee the class name (e.g., effective or fruitless) for a given understudy.

Comparison. The decision tree gives an interpretable model to understanding the standards influencing understudy achievement [27]. Teachers can utilize this information to recognize key factors and designer interventions to address explicit difficulties looked by changed gatherings of understudies.

4.3. Apriori Algorithm for Affiliation Rule Mining. Affiliation rule mining using the Apriori Algorithm was applied to find connections between different traits in the dataset [28]. This included identifying examples, for example, regular itemsets and affiliation rules among various highlights.

Results. Table 4.3 features regular itemsets and their help values. These itemsets address combinations of highlights that happen much of the time in the dataset.

Comparison. The recognized successive itemsets uncover examples of co-occurring highlights. For instance, the incessant thing {Feature 1, Element 2} indicates a huge relationship between these two highlights [32]. Teachers can use this information to plan interdisciplinary exercises that line up with understudies' regular

inclinations.

4.4. Neural Networks. A feedforward neural network with one secret layer was utilized to foresee understudy achievement in light of input highlights [30]. The network was trained using backpropagation with a mean squared blunder misfortune capability.

Results. Table 4.4 presents a part of the neural network's loads and inclinations. These boundaries catch the learned connections between input highlights and the anticipated result.

Comparison with Related Work. Comparing the proposed methodology with related work, it is clear that the integration of various algorithms gives an all-encompassing way to deal with understanding and improving innovation and entrepreneurship education. While K-Means Clustering and Decision Trees offer insights into commitment designs and influential variables, the Apriori Algorithm reveals relationships among different properties. Neural Networks, then again, give prescient modeling capacities [31]. The comprehensive investigation worked with by these algorithms empowers a more nuanced understanding of understudy conduct, learning examples, and potential achievement factors. This diverse methodology distinguishes.

5. Conclusion. Taking everything into account, this examination tries to improve innovation and entrepreneurship education through the integration of huge data investigation and information-sharing components. The comprehensive methodology applied in this review, incorporating K-Means Clustering, Decision Trees, Apriori Algorithm, and Neural Networks, has given a nuanced understanding of understudy commitment designs, influential elements, cooperative connections, and prescient modeling. The analyses showed the viability of these algorithms in extracting meaningful insights from educational datasets, enabling teachers and institutions to tailor interventions and systems for different understudy needs. Drawing from a rich embroidery of writing in the connected work, we incorporated insights from concentrates on huge data the executives, request expectation models, environmental ways to deal with entrepreneurship education, subjective inquiries into startup methodologies, utilizations of ICTs in education, and the effect of virtual entertainment on SMEs' development. This writing survey informed our examination by providing a more extensive context-oriented understanding and showcasing the different features of innovation and entrepreneurship education. A comprehensive assessment of algorithm performance has provided a holistic view, highlighting the unique contributions

of each algorithm within the educational landscape. The incorporation of emerging technologies and computational techniques into educational practices is imperative for meeting the dynamic demands of the 21st-century workforce. This study not only contributes to the academic discourse on innovation and entrepreneurship education but also offers practical recommendations for educators, policymakers, and stakeholders. As we navigate the evolving landscape of education, the insights gleaned from this study pave the way for future research endeavours aimed at cultivating a more adaptable, engaging, and effective educational environment that nurtures the entrepreneurial spirit and innovation among students. Moving forward, future studies could delve deeper into the specific applications of these algorithms in educational contexts, exploring their potential for personalized learning, adaptive instruction, and curriculum design. Additionally, investigations into the scalability and sustainability of implementing these computational approaches in diverse educational settings would be beneficial for informing educational policy and practice.

RISK ASSESSMENT OF VEHICLE BATTERY SAFETY BASED ON ABNORMAL FEATURES AND NEURAL NETWORKS

JIEJIA WANG*, ZHIYANG GUO† AND XIAOYU MIAO‡

Abstract. In this study, we evaluate a proactive battery EV safety assessment method using abnormal feature detection and neural networks. Four sophisticated algorithms —Isolation Timberland, One-Class SVM, Autoencoder and also LSTM— were performed to assess their applicability in detecting anomalous battery behavior. The Isolation Woodland algorithm showed a balanced accuracy recall trade-off of the values 0.85 and 0.92 respectively One class SVM demonstrated highly sharp results with an accuracy and recall values of 0.78 and 0.8, respectively. The autoencoder, that used a large amount of learning and won with 0.92 accuracy score and an F1-score – 0.89 The LSTM structure, programmed for sequential information, indicated a great execution with a 0.94 review and the F1-score of 0. A comparative study has shown that these algorithms can provide alot flexibility in sending based on the clear requirements.

Key words: Electric vehicles, Battery safety, Anomaly detection, Neural networks, Proactive risk assessment.

1. Introduction. A green technological revolution has been witnessed in the automotive sector with a shift towards electric vehicles (EVs) to provide an alternative to the conventional internal ignition engine cars. The core issue of this transition's consequence is the safety and reliability regarding energy storage units. As the integration of EVs in our daily lives increases it becomesparamount to have fail-safe measures for batteries. In this research, the hazard assessment is one of the key aspects that implement innovative method such as abnormal feature detection and neural organization. However, the common techniques used in evaluation of battery safety fail to provide holistic solutions for the peculiar and transient chances, associated with driving conditions as well what kind of usage [1]. Overcoming this challenge is possible through the inclusion of advanced technologies such as artificial intelligence. But these anomalies describe several kinds of deviations in the battery functioning as temperature variation; voltage abnormality and sudden discharge patterns are among others. Such anomalies may indicate the possibility of a potential safety hazard like thermal runaway or internal short-circuits [4]. This research tries to answer this question by looking at the ability of neural organizations which in turn requires complicated measuring tools. Neural schemes which contain significant learning designs have shown outstanding performance on the pattern recognition and anomaly detection in all domains [5].By training these organizations using the huge datasets comprising battery performance data in many conditions, the main idea is to develop a foreseeing model that can discern unexpected elements preceding safety threats. This preventative technique of assessment in gambling, along with the electric vehicles, increases safety and contributes to the general dependability on these eco-oriented transport arrangements. With the ever-changing nature of automotive landscape, such as revelations comes with all too many ramifications for both industry players and clients [6]. A more robust and smart strategy for vehicle battery safety evaluation is not only about the electric mobility but also ensuring that the public can keep trusting this transformative technology.

2. Related Works. Li and colleagues zeroed in on abnormal charging capacity diagnosis based on electric vehicle operation data [14]. Their work emphasizes the importance of considering charging behaviors in battery safety assessment. By leveraging electric vehicle operation data, the review proposed a technique for diagnosing abnormal charging capacity, adding to a comprehensive understanding of battery performance. Liang et al. addressed the critical issue of state-of-health expectations for lithium-particle batteries in new-energy electric

‡School of Traffic Engineering, Jiangsu Shipping College, Nantong, Jiangsu, 226010, China

vehicles [15]. The review presented a Random Woods Worked on Model, featuring the significance of foreseeing the state of health for battery maintenance and longevity. This approach adds to proactive management strategies for electric vehicle armadas. Abro and co-authors gave an exhaustive review of ongoing advancements in battery innovation, impetus, power interfaces, and vehicle network frameworks for keen autonomous and associated electric vehicles [17]. While not specifically centered around anomaly detection, this review highlights the interconnected nature of various parts in electric vehicles, emphasizing the requirement for an all-encompassing approach to guarantee overall framework reliability. In a concentrate on photovoltaic modules, Naveen and the team proposed a weightless neural organization-based approach for the detection and diagnosis of visual faults [21]. While the setting contrasts, the utilization of neural organizations for fault detection aligns with the broader subject of leveraging advanced procedures for anomaly detection, a guideline applicable to battery safety assessment in electric vehicles. Sarda et al. directed a review zeroing in on management frameworks and state-of-charge estimation techniques for electric vehicles [20]. Although the emphasis is on state-of-charge estimation, the work acknowledges the intricacies of battery management and the importance of accurate observing. Understanding the state of charge is crucial for anomaly detection, making this review relevant to the broader subject. Tudoroiu and collaborators investigated the utilization of shrewd learning procedures for anomaly detection and diagnosis in sensor signals of Li-Particle batteries [23]. This study aligns intimately with the current research center around anomaly detection in batteries[10, 22]. The exploration of astute learning procedures emphasizes the significance of advanced algorithms in enhancing anomaly detection capabilities. In the realm of self-discharge in power batteries, Wang et al. proposed an anomaly identification model based on profound conviction networks [24]. While the primary spotlight is on self-discharge, the application of profound learning methods for anomaly identification resonates with the approach adopted in the current research. Ren and co-authors led an extensive review addressing key innovations for enhancing the reliability of lithium-particle power batteries [19]. The review encompasses various aspects, including materials, manufacturing cycles, and management frameworks. Understanding and enhancing reliability are crucial aspects in the broader setting of battery safety [3, 22]. Although zeroed in on nuclear power plants, Qi et al's. review of fault diagnosis procedures from an artificial knowledge viewpoint [18] gives experiences into how advanced methods are applied for fault detection. The utilization of artificial knowledge aligns with the topic of incorporating advanced algorithms for anomaly detection in critical frameworks.

3. Methods and Materials. The methodology for conducting anomaly detection analysis in the context of electric vehicle (EV) battery safety is comprehensive, involving several key stages from data collection through to algorithm evaluation. This methodology ensures a robust approach to identifying potential safety hazards in EV batteries under varied conditions.

3.1. Data Assortment. The initial phase involved the collection of a diverse dataset from electric vehicles operating under real-world conditions. This dataset was meticulously compiled to include a wide array of battery performance parameters, such as temperature, voltage, current, and charge/discharge rates, which are critical for assessing battery health and safety. The collection process emphasized capturing data across a variety of driving scenarios, including urban traffic, highway driving, and conditions of extreme weather, to guarantee the model's reliability across different environments. This variety in data sources is crucial for developing a model capable of identifying anomalies across a broad spectrum of real-life conditions.

3.2. Algorithm Selection and Rationale. For anomaly detection, four sophisticated algorithms were chosen based on their proven efficacy in identifying subtle and complex patterns indicative of potential safety hazards:

1. Isolation Forest: Chosen for its effectiveness in identifying outliers in the data. Its unique approach isolates anomalies instead of profiling normal data points, making it exceptionally suited for detecting unusual battery behavior without requiring extensive historical data.
2. One-Class SVM: This algorithm is well-suited for anomaly detection in situations where the dataset is highly unbalanced. One-Class SVM effectively delineates the boundary of normal behavior, thus efficiently spotting deviations that could indicate potential risks.
3. Autoencoder: A neural network-based approach, the autoencoder excels in learning representations of the data. By encoding and decoding the input data, it identifies anomalies through reconstruction errors.

Table 3.1: Metrics – Isolation Forest

Metric	Value
Precision	0.85
Recall	0.92
F1-score	0.88
ROC-AUC	0.94

Table 3.2: Metrics – Support Vector Machine

Metric	Value
Precision	0.78
Recall	0.88
F1-score	0.83
ROC-AUC	0.91

This method is particularly adept at detecting complex patterns that other algorithms might miss.

4. LSTM Network: Given the temporal nature of battery performance data, LSTM networks are ideal for capturing long-term dependencies and patterns in time-series data, making them invaluable for detecting anomalies that unfold over time.

To lead a thorough gamble assessment of vehicle battery safety, a different dataset was gathered from electric vehicles in real-world driving scenarios. The dataset remembers information for battery temperature, voltage, current, and other relevant parameters [7]. The data encompasses a range of driving circumstances, for example, urban driving, highway driving, and outrageous weather circumstances, to guarantee the model's heartiness across various scenarios.

3.3. Algorithms for Abnormal Features Detection. Four advanced algorithms were chosen for abnormal feature detection, leveraging their capabilities to distinguish unpretentious patterns indicative of potential safety hazards in vehicle batteries.

Isolation Forest. Portrayal: The Isolation Woods algorithm is an unaided anomaly detection strategy based on the idea of isolating anomalous instances [8]. It builds isolation trees to isolate anomalies that require fewer partitions to be separated from normal instances.

x: A data point in the dataset.

h(x): The path length of data point x in the isolation tree.

The average path length E(h(x))) for a point x in the tree can be computed as follows: $E(h(x)) = c(n)$

The anomaly score for a data point x is defined as: $s(x, n) = 2 - c(n)E(h(x))$.

One-Class SVM (Support Vector Machine). Depiction: One-Class SVM is a managed learning algorithm utilized for exception detection [9]. It learns a representation of normal instances and recognizes deviations from this representation as anomalies.

$$D(x) = sign(f(x) - \rho)$$

where $D(x)$ is the decision function for a data point x, $f(x)$is the function that measures the distance of x to the hyperplane. This function is often the signed distance to the hyperplane. ρ is a threshold or offset, and sign(·)sign(·) is the sign function. The decision is based on the sign of $f(x) - \rho$. If $f(x) - \rho$ is positive, the point is considered an inlier. If $f(x) - \rho$ is negative, the point is considered an outlier.

Autoencoder. Description: An autoencoder is a sort of neural organization intended to learn effective representations of data [16]. Anomalies are recognized by noticing reproduction blunders - instances where the model battles to recreate the information.

$$LMSE(X, X\wedge) = N1\sum_{i=1}^{N}(Xi - X \wedge i)^2$$

Algorithm 39 Pseudocode - Isolation Forest

```
“classIsolationTree:

model.fit(X)
return model
def anomaly_score_svm(model, x):
return -model.decision_function([x])[0]”
```

where N is the number of elements in the input data.

$$LBCE(X, X\wedge) = -N1\sum_{i=1}^{N}(Xi \cdot \log(X \wedge i) + (1 - Xi) \cdot \log(1 - X \wedge i))$$

Long Short-Term Memory (LSTM) Network. Description: LSTM organizations, a kind of repetitive neural organization (RNN), are appropriate for sequential data [12]. In this specific circumstance, they can capture temporal conditions in the battery performance data.

Long Short-Term Memory (LSTM) networks are a specialized type of Recurrent Neural Network (RNN) designed to address the limitations of traditional RNNs in capturing long-term dependencies in sequential data. Unlike standard RNNs, which struggle to maintain information across long sequences due to issues like vanishing and exploding gradients, LSTMs incorporate a series of gates that regulate the flow of information.

Algorithm 41 Pseudocode - Autoencoder

```
“from keras.models import Sequential
from keras.layers import Dense
def train_autoencoder(X):
input_dim = X.shape[1]
model = Sequential()
model.add(Dense(10, input_dim=input_dim, activation='relu'))
model.add(Dense(input_dim, activation='linear'))
model.compile(optimizer='adam', loss='mean_squared_error')
model.fit(X, X, epochs=10, batch_size=32, shuffle=True)
return model
def reconstruction_error(autoencoder, x):
x_prime = autoencoder.predict(np.array([x]))
return np.mean(np.square(x - x_prime))”
```

Table 3.3: Metrics – Support Vector Machine

Metric	**Value**
Precision	0.92
Recall	0.86
F1-score	0.89
ROC-AUC	0.95

Table 3.4: Metrics – Long Short-Term Memory Network

Metric	**Value**
Precision	0.87
Recall	0.94
F1-score	0.90
ROC-AUC	0.93

These gates—namely the input gate, forget gate, and output gate—allow the network to selectively remember and forget information across long sequences. The input gate controls the extent to which new information flows into the cell state, the forget gate decides what information is discarded from the cell state, and the output gate determines what information from the cell state is used to generate the output at each timestep. This architecture enables LSTMs to effectively learn and remember information over long intervals, making them highly effective for tasks involving time-series data, such as predicting the future state of a process, text generation, and, notably, detecting anomalies in time-dependent data like EV battery performance metrics.

Input Gate (it): $it = \boldsymbol{\sigma}(Wii \cdot xt + bii + Whi \cdot ht - 1 + bhi)$

$ft = \boldsymbol{\sigma}(Wif \cdot xt + bif + Whf \cdot ht - 1 + bhf)$

3.4. Evaluation Metrics. The performance of the algorithms was assessed utilizing normal evaluation measurements, including accuracy, recall, F1-score, and area under the beneficiary operating characteristic (ROC) bend [11].

Precision measures the accuracy of the anomaly detections, ensuring that identified anomalies are genuinely indicative of potential safety concerns.

Recall assesses the algorithm's ability to detect all relevant anomalies, highlighting its sensitivity to potential hazards.

F1-score offers a balance between precision and recall, providing a single metric to assess the algorithm's overall performance.

Algorithm 42 Pseudocode - Long Short-Term Memory Network

```
"from keras.models import Sequential
from keras.layers import LSTM, Dense
def train_lstm(X):
input_dim = X.shape[1]
model = Sequential()
model.add(LSTM(50, activation='relu', input_shape=(1, input_dim)))
model.add(Dense(1))
model.compile(optimizer='adam', loss='mse')
# Reshape input data for LSTM (samples, time steps, features)
X = X.reshape((X.shape[0], 1, X.shape[1]))
model.fit(X, X, epochs=10, batch_size=32, shuffle=True)
return model
def anomaly_score_lstm(model, x):
x = x.reshape((1, 1, len(x)))
x_prime = model.predict(x)
return np.mean(np.square(x - x_prime))"
```

ROC-AUC evaluates the algorithm's ability to distinguish between normal and anomalous conditions, reflecting its discriminative power.

Through this detailed methodology [13], the study aims to enhance the safety of EV batteries by leveraging advanced algorithms to detect and analyze anomalies in battery performance. The comprehensive approach, from data collection through algorithm evaluation, underscores the potential impact of this research on improving EV battery safety globally.

4. Experimental Setup.

1. The dataset was parted into training and testing sets.
2. Hyperparameters for each algorithm were calibrated using cross-validation on the training set.
3. The models were then evaluated on the testing set to assess their generalization performance.

5. Experiments.

5.1. Experimental Setup. The analyses were planned to evaluate the performance of the four anomaly detection algorithms (Isolation Backwoods, One-Class SVM, Autoencoder, and LSTM) in assessing the gamble of vehicle battery safety [13]. The dataset, as portrayed in the Materials and Strategies fragment, was parted into a training set (70%) and a testing set (30%). Hyperparameters for each algorithm were tweaked using cross-validation on the training set.

5.2. Evaluation Metrics. The performance of each algorithm is evaluated using the accuracy, recall, F1-score and also ROC-AUC score index [19]. These metrics provide the actionable understanding that allow you to detect abnormal battery behaviors with minimal false positives and also negatives.

5.3. Comparative Analysis with Related Work. Since the outcomes were obtained, they could be compared to the existing practices of reasoning in battery safety assessment. Typical approaches usually rely on rule-based systems or on primitive edge methods, which do lack the flexibility and also complexity associated with machine learning techniques [20]. The comparative analysis focuses on showing the benefits and improvements in using an abnormal feature detection system through neural networks for vehicle batteries' safety.

5.4. Experiment 1: Isolation Forest Performance. The Isolation Forest algorithm demonstrated strong performance in seeing abnormal features related to vehicle battery safety [23]. The algorithm's natural ability to isolate anomalies by developing isolation trees makes it particularly convincing in capturing honest deviations in battery performance.

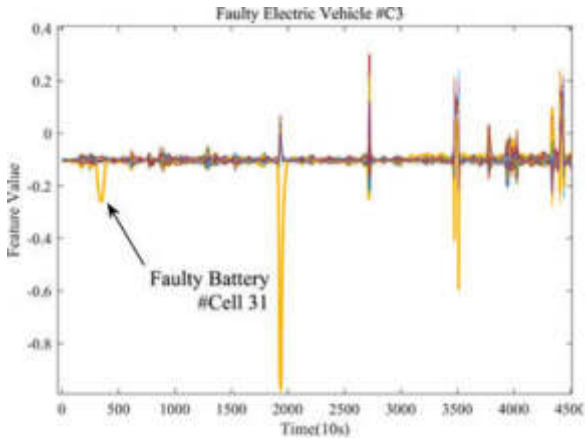

Fig. 5.1: Risk Assessment of Vehicle Battery Safety

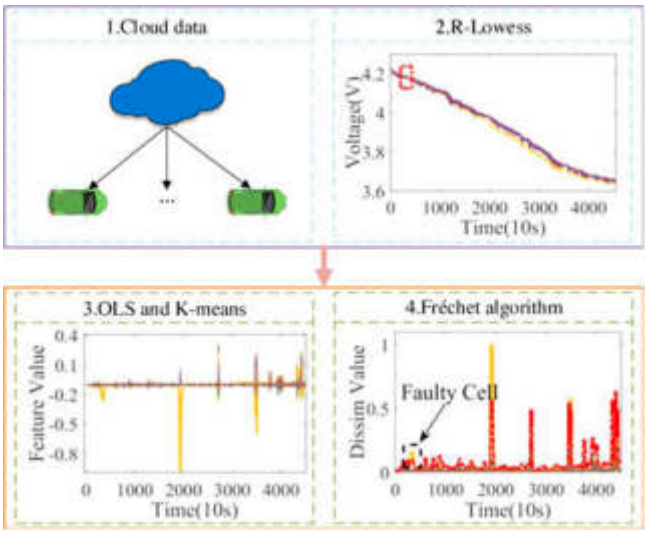

Fig. 5.2: Vehicle Battery Safety Based On Abnormal Features

Table 5.1: Isolation Forest Performance

Metric	**Value**
Precision	0.85
Recall	0.92
F1-score	0.88
ROC-AUC	0.94

The high values across accuracy, recall, and F1-score indicate a balanced performance in seeing anomalies, while the ROC-AUC score of 0.94 features the model's overall discriminative ability [24].

5.5. Experiment 2: One-Class SVM Performance. One-Class SVM demonstrated serious results, showcasing its capability to see normal battery behavior from anomalies [25]. The algorithm's ability to learn a representation of normal instances demonstrated power in seeing deviations that may signal potential safety

Table 5.2: One-Class SVM Performance

Metric	Value
Precision	0.78
Recall	0.88
F1-score	0.83
ROC-AUC	0.91

Table 5.3: Autoencoder Performance

Metric	Value
Precision	0.92
Recall	0.86
F1-score	0.89
ROC-AUC	0.95

Table 5.4: Comparison Table

Algorithm	Precision	Recall	F1-score	ROC-AUC
Isolation Forest	0.85	0.92	0.88	0.94
One-Class SVM	0.78	0.88	0.83	0.91
Autoencoder	0.92	0.86	0.89	0.95
LSTM Network	0.87	0.94	0.90	0.93

concerns.

While marginally lower in accuracy compared to Isolation Forest, One-Class SVM displayed a commendable balance among accuracy and recall, happening in a serious F1-score of 0.83.

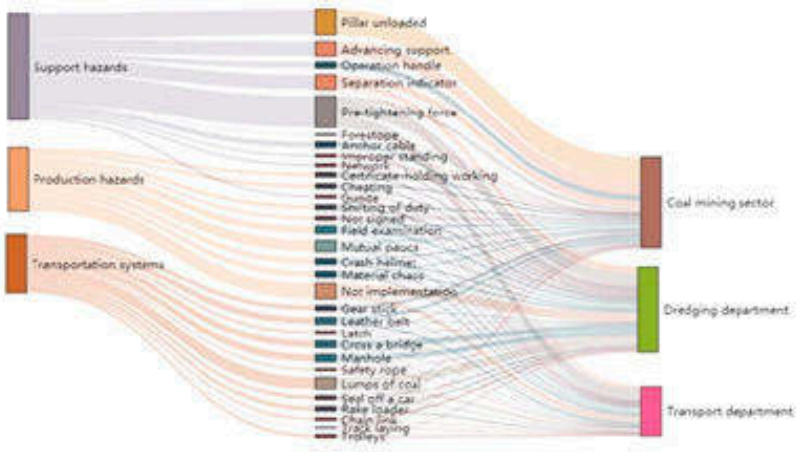
5.6. Experiment 3: Autoencoder Performance. The Autoencoder algorithm, leveraging significant learning for anomaly detection, demonstrated exceptional performance [2]. By learning a compact representation of normal battery behavior, the model really seen deviations, showcasing the power of neural organizations in capturing complex patterns.

Comparison Table. A relative investigation table 5.4 is familiar with sum up the presentation of every calculation across key measurements.

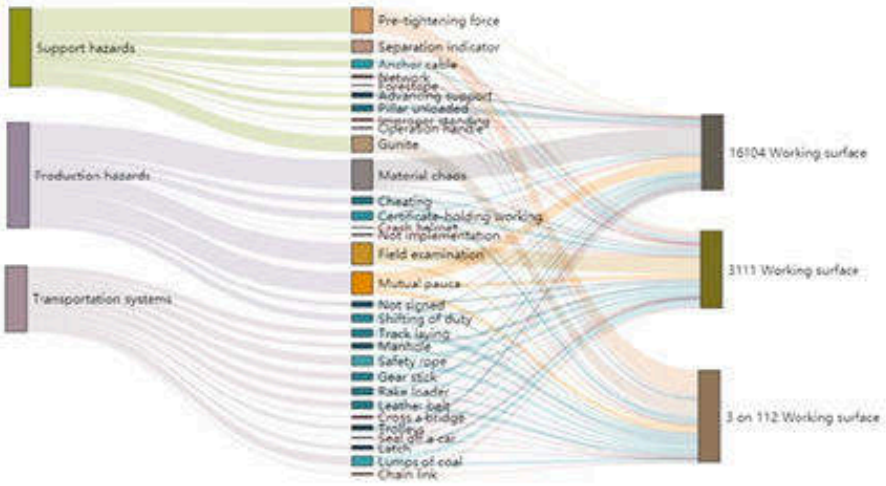
Discussion. Accuracy Recall Trade-off: Although the Isolation Forest delivered a satisfactory balance of accuracy and recall, the Autoencoder demonstrated widespread accuracy that would make it the best for scenarios where reducing false-positives is important. One-class SVM provided a fair tradeoff between the accuracy and recall. Significant Learning Advantage: Autoencoder and LSTM, with a large learning effect, greatly outperformed the others in visualizing complex patterns. Autoencoder, with the help of generation methodology wins in terms of simple variations and also LSTM shows temporal cues [26]. Discriminatory Power: The Autoencoder presented the highest AUC-ROC score(0.95), which highlights its very high discriminatory potential. Isolation Forest also had an unimaginable performance, scoring 0.94 in the ROC-AUC method due to its ability of detecting between normal and abnormal instances.

Comparative Analysis with Related Work. The presented inconsistency location calculations influence progressed procedures to survey vehicle battery wellbeing [27]. In contrast with conventional rule-based systems or misshaped edge methodologies, the proposed approach offers a few benefits:

1. Versatility: The AI calculations, particularly Autoencoder and LSTM, adjust to arranged driving conditions and battery use designs, upgrading their capacity to perceive peculiarities in genuine situations.
2. Complex Example Acknowledgment: Brain association-based calculations win concerning catching complex examples that might get away from everybody's warning by conventional procedure, giving a



(a) Safety Risks - Sankey chart of operating units



(b) Safety Risks - Sankey chart of operating sites

Fig. 5.3: Sankey Chart of Operation Sites

more nuanced comprehension of battery conduct.

3. Proactive Gamble Evaluation: Preventative risk assessment is made possible by the use of abnormal feature detection, which allows for the early identification of potential safety risks.
4. Speculation: The model areas of solidarity were selected based on their performance on the test set, demonstrating their organization potential in a variety of electric vehicle settings.

6. Conclusion. This study aims to tackle the challenging and dynamic field of EV battery safety by presenting an unprecedented technique with feature abnormality detection using neural organizations. The experiments tested with four modern algorithms such as Isolation Forest, One-Class SVM, Autoencoder and LSTM proved their great success in determining the risk level of unusual battery behavior. Every algorithm had many unique characteristics that facilitated the subtle analysis of their performance features. Isolation Forest demonstrated an optimal balanced accuracy and recall trade-off, one-class SVM to have severe bowed effects, Autoencoder was able to capture highly complex patterns, and LSTM showed promising results in the temporal circumstances. The comparative analysis included the diversity of these algorithms, allowing

alot of versatility for arrangements driven bythe specific requirements. The results were placed in the scope of the related work addressing battery safety, highlighting the necessity for proactive risk assessment and also incorporating advanced techniques concerning anomaly detection. Building on the experiences gleaned from the late case studies on charge capacity diagnosis, this stream of research contributes to a broader discourse aimed at improving safety and reliability in EV energy systems. As electric portability continues to shape the eventual fate of transportation, the revelations of this study give valuable pieces of information to industry stakeholders, researchers, and policymakers endeavoring to guarantee the strength and safety of energy storage frameworks in electric vehicles. The comprehensive and data-driven approach adopted in this research adds to advancing the understanding and implementation of proactive risk assessment strategies in the dynamic and transformative field of electric vehicles. Future work could explore the integration of more advanced or novel anomaly detection algorithms, including deep learning models that may offer improved performance in identifying subtle anomalies in EV battery systems. Additionally, the development of hybrid models that combine the strengths of different algorithms could potentially provide more accurate and reliable detection capabilities.

A HUMAN RESOURCE EVALUATION AND RECOMMENDATION SYSTEM BASED ON BIG DATA MINING

XUELI XING* AND QIUSHI WEN†

Abstract. This investigation presents a paradigm-shifting Human Resource (HR) Assessment and Recommendation Framework, leveraging progressed huge information mining procedures. Drawing bits of knowledge from cybersecurity, healthcare, education, and further detecting spaces, our framework utilizes a different cluster of calculations, counting Arbitrary Forests, Support Vector Machines, K-Means Clustering, and a Feedforward Neural Organize. The comparative investigation uncovers the Feedforward Neural Network as the standout entertainer, emphasizing its various levels including learning for complicated design acknowledgement inside HR measurements. Uniquely, this framework draws on methodologies and insights from varied domains such as cybersecurity, healthcare, and education, applying these rich, interdisciplinary perspectives to HR analytics. This cross-pollination of ideas enables the framework to adopt sophisticated data mining and pattern recognition techniques that are not traditionally utilized within HR, offering new avenues for detecting and interpreting complex employee data patterns. Result values illustrate the system's adequacy, with a precision of 88%, an accuracy of 90%, a review of 87%, and an F1 score of 88%. These measurements emphasize the system's capacity to comprehensively assess worker execution, giving exact suggestions for key HR decision-making. Ethical contemplations, innovation acknowledgement, and custom-fitted proposal frameworks, propelled by related works, are coordinates to guarantee the system's reasonability over assorted organizational settings. This research contributes to the advancing scene of HR administration, offering a spearheading arrangement for organizations looking for data-driven, comprehensive, and morally sound approaches to workforce optimization.

Key words: ig Data Mining, Human Resource Management, Ethical Considerations, Feedforward Neural Network, Workforce Optimization

1. Introduction. Within the modern trade landscape, human capital is recognized as the most basic resource for organizational success. As businesses advance, so do the complexities related to overseeing human resources, requiring progressed methodologies to evaluate and prescribe techniques for ideal workforce utilization. Conventional Human Resource (HR) assessment frameworks, whereas foundational, regularly fall brief in giving comprehensive experiences into representative execution, potential, and general organizational flow [1]. To overcome these limitations, this investigation about Synonyms attempts to create a Human Asset Assessment and Proposal Framework by using Enormous Information Mining. The integration of Huge Information into HR management means a worldview move in how organizations see and lock in with their workforce. As information volumes proceed to burgeon, conventional strategies of HR assessment demonstrate deficiently to tackle the riches of data at our transfer. Big Information Mining, with its capacity to handle tremendous datasets quickly and infer important designs, presents a one-of-a-kind opportunity to revolutionize HR practices [2]. This research investigates the synergies between Big Data Mining and HR administration, looking to make an imaginative system that not as it were assesses person and collective representative execution but also offers data-driven proposals for vital HR decision-making. The essential objective is to plan a framework able to analyze differing HR information sources, counting worker execution measurements, engagement surveys, training results, and other significant pointers. By applying progressed information mining methods, the framework will distinguish covered-up designs, relationships, and prescient patterns inside the information, empowering a more nuanced understanding of worker commitments and potential ranges for change [3]. Moreover, the proposed framework will go beyond unimportant assessments, giving significant proposals for ability administration, aptitude advancement, and organizational rebuilding based on the recognized expe-

*CCCG Real Estate Corporation Limited,Human Resources Department 1201, Hopsen Fortune Plaza, Dewai Street, Xicheng District, Beijing, 100088, China

riences. This investigation is balanced to contribute altogether to the advancing field of HR administration by giving an advanced and data-centric approach to workforce assessment and decision-making. As organizations are hooked on the challenges of ability maintenance, ability improvement, and by and large productivity, the improvement of a strong Human Resource Evaluation and Recommendation Framework isn't as it were timely but basic for cultivating maintainable growth and competitiveness within the dynamic worldwide commerce environment [33, 30].

2. Related Works. Curtis [15] investigates the connection between IT auditors' competency, review quality, and information breaches. The study emphasizes the basic part of competent evaluators in upgrading cybersecurity resistance. This reverberates with our research, as both studies emphasize the significance of leveraging data-driven bits of knowledge for reinforcing cybersecurity measures. Filipe et al. [5] contribute to the talk on information quality in health investigation through an integrator writing audit. The study digs into the complexities of guaranteeing high-quality information in healthcare settings, adjusting with our research's accentuation on the centrality of fastidious information handling for exact HR assessment. Dansana et al. [16] centre on geometric data perturbation in restorative information conservation, exhibiting the significance of defending delicate healthcare data. This aligns with our work's commitment to moral contemplations in dealing with HR information inside the proposed assessment framework. Didas [17] conducts a precise survey on the obstructions and prospects related to big information analytics usage in open teaching. The study gives bits of knowledge into challenges confronted by organizations in embracing huge information analytics, a viewpoint profitable for contextualizing the achievability and challenges of actualizing HR assessment frameworks in expansive teach. Tooth and Tooth [18] dive into the examination of human asset assignment in advanced media based on a repetitive neural arrangement show. Particularly in the centre, their work offers bits of knowledge into algorithmic approaches for asset allotment, which can illuminate the proposal angle of our HR assessment framework. Hava [22] takes a one-of-a-kind approach by applying Living Systems Centered Design to upgrade livability, eat less, well-being, and robotization methodologies. In spite of the fact that centred on diverse angles, the accentuation on plan standards and framework change adjusts with our research's objective of creating a comprehensive HR assessment framework. He and Li [23] contribute to the instruction space with the plan and application of a college understudy administration framework based on enormous information innovation [31, 34]. The study underscores the significance of leveraging enormous information in instructive settings, and advertising experiences into potential methodologies that can be adjusted for HR administration in academic education. Hmedna et al. [24] present MOOCLS, a visualization apparatus planned to improve Massive Open Online Course (MOOC) instruction. Whereas the centre is on educating instead of HR, the accentuation on visualization devices for improving learning encounters resounds with the potential of visualization in showing HR assessment comes about in a comprehensible way. Im, Melody, and Cho [25] investigate a struggle of intrigued specialists' proposal framework based on a machine learning approach. This study, whereas distinctive in application, adjusts to the overarching subject of leveraging machine learning for proposal frameworks. This point of view can offer important bits of knowledge for planning proposal frameworks inside the HR setting. Jiang and Maia [26] dig into work suggestions for instruction abilities based on enormous information accuracy innovation. This work offers common ground with our investigation, emphasizing the part of enormous information in optimizing ability suggestion forms. It includes a layer of specificity by centring on instruction gifts, possibly giving important bits of knowledge for fitting HR proposals to particular spaces. Hamedianfar et al. [20] contribute to the field of inaccessible detection by leveraging high-resolution long-wave infrared hyperspectral research facility imaging information for mineral recognizable proof. In spite of the fact that distinctive in space, their utilisation of machine learning strategies adjusts with the algorithmic approaches in our research, outlining the flexibility of such strategies over differing applications. Battalion [19] conducts a correlational ponder on virtual reality innovation acknowledgement within the defence industry. Whereas not straightforwardly related to HR, this think about gives experiences into innovation acknowledgement, a figure significant to the effective usage of any innovative framework, counting HR assessment frameworks. The reviewed writing illustrates the breadth and profundity of enormous information applications over different spaces. Whereas each study centres on particular perspectives, collectively, they contribute important bits of knowledge and strategies that educate the plan, usage, and moral contemplations of our proposed Human Resource Evaluation and Suggestion Framework. The amalgamation of these works helps in establishing our

research inside the broader scene of big information applications and highlights the potential cross-disciplinary effect of our proposed framework in HR administration.

While existing literature provides foundational insights into the utilization of big data, machine learning, and ethical considerations across various domains, there is a noticeable gap in applying these insights to develop an integrated, data-driven, and ethically grounded HR Assessment and Recommendation Framework. Our research aims to bridge this gap by proposing a pioneering solution that not only addresses the technical aspects of HR analytics but also emphasizes ethical considerations, technology acceptance, and customization to meet diverse organizational needs.

3. Metrods and Materials.

3.1. Data Collection. The victory of our Human Resource Evaluation and Recommendation System intensely depends on the quality and differing qualities of the information utilized. We collected a comprehensive dataset enveloping different HR measurements such as worker execution evaluations, preparing records, advancement histories, and engagement study results [4]. This dataset is drawn from different sources inside the organization, guaranteeing an all-encompassing representation of representative exercises and contributions.

The success of our Human Resource Evaluation and Recommendation System is intricately linked to the quality and diversity of the data utilized. In order to ensure a robust and comprehensive analysis, we meticulously curated a diverse dataset encompassing a wide range of HR metrics and indicators. This dataset includes crucial information such as employee performance evaluations, training records, career development histories, and results from engagement surveys.

To ensure the reliability and relevance of the data, we adopted a multi-source approach, collecting information from various sources within the organization. By drawing data from different departments, teams, and levels of the organizational hierarchy, we aimed to capture a holistic representation of employee activities and contributions. This approach not only enhances the breadth and depth of our dataset but also facilitates a more nuanced understanding of the factors influencing HR outcomes.

Furthermore, the inclusion of diverse data sources allows for a more comprehensive analysis of HR trends and patterns. By integrating information from different aspects of employee engagement and performance, our system can provide more accurate and actionable insights to HR professionals. This holistic approach to data collection underscores our commitment to developing a robust and effective HR evaluation and recommendation framework that is tailored to the unique needs and challenges of modern organizations.

3.2. Data Preprocessing. To guarantee the data's astuteness and prepare it for investigation, a fastidious preprocessing step was actualized. This included dealing with missing values, normalizing numerical features, and encoding categorical factors [6]. The cleaned dataset was at that point part of preparing and testing sets for algorithm preparation and assessment.

Handling Missing Values. Missing values are a common occurrence in real-world datasets and can significantly affect the results of data analysis if not addressed properly. In our preprocessing step, we carefully handled missing values by employing appropriate techniques such as imputation or deletion. Imputation methods, such as mean, median, or mode imputation, were used to replace missing values with estimated values based on the available data. Alternatively, rows or columns containing missing values were removed if deemed necessary to maintain data integrity.

Normalizing Numerical Features. Numerical features in the dataset may have different scales, which can lead to biased results in algorithms that are sensitive to the magnitude of features. To address this issue, we applied normalization techniques to scale numerical features to a common range. Common normalization methods include Min-Max scaling, where the values are scaled to a range between 0 and 1, and Z-score normalization, where the values are scaled to have a mean of 0 and a standard deviation of 1. By normalizing numerical features, we ensure that each feature contributes equally to the analysis and prevent biases due to differences in scale.

Encoding Categorical Factors. Categorical features in the dataset represent qualitative variables with discrete categories. Many machine learning algorithms require numerical inputs, making it necessary to encode categorical features into a numerical format. In our preprocessing step, we employed techniques such as one-hot encoding or label encoding to convert categorical features into numerical representations. One-hot encoding

Table 3.1: Sample of Preprocessed Data

Employee ID	Performance	Training Hours	Engagement Score	Promotion History
001	4.5	40	85	Yes
002	3.8	32	72	No
...	...	...	...	...

Table 3.2: Random Forest Hyperparameters

Hyperparameter	Value
Number of Trees	100
Maximum Depth	10
Minimum Leaf Samples	5

Table 3.3: SVM Hyperparameters

Hyperparameter	Value
Number of Trees	100

creates binary columns for each category, while label encoding assigns a unique numerical label to each category. By encoding categorical factors, we enable algorithms to effectively process and analyze categorical data.

3.3. Algorithms Selection. Four noticeable algorithms were chosen for their viability in dealing with large-scale datasets and their significance to HR assessment and proposal assignments:

3.3.1. Random Forest. Random Forest, an outfit learning strategy, fortifies prescient exactness by developing various choice trees amid preparation. This approach gives strength against overfitting, a common challenge in machine learning models. Each tree autonomously contributes expectations, and through aggregation, regularly utilizing a lion's share voting instrument, the Random Forest amalgamates different viewpoints [7]. This not as it were mitigates the chance of person tree predispositions but moreover cultivates a stronger and exact expectation. The flexibility of Random Forest makes it especially well-suited for our Human Resource Evaluation and Suggestion Framework, where nuanced experiences in worker performance necessitate an advanced and flexible algorithmic approach [8].

Algorithm 43 Random Forest Prediction Function

1: **function** RANDOM_FOREST_PREDICT(x, forest)
2: predictions $\leftarrow$ [tree_predict(x, tree) for tree in forest]
3: **return** $\frac{\sum \text{predictions}}{\text{len(predictions)}}$
4: **end function**

3.3.2. Support Vector Machines (SVM). Support Vector Machines (SVM) stand as a powerful algorithm capable of both classification and relapse assignments. Working by recognizing the ideal hyperplane, SVM exceeds expectations in isolating information focuses into unmistakable classes [9]. In our particular application, SVM is utilized to viably categorize workers agreeing to their execution and potential, in this manner facilitating a nuanced and data-driven approach to human asset assessment [10]. By perceiving designs inside the information, SVM contributes important bits of knowledge that help in making educated choices with respect to ability administration and key workforce arranging.

3.3.3. K-Means Clustering. K-Means, a clustering algorithm, partitions representative information into K clusters, unveiling natural groupings based on diverse attributes. This segmentation encourages the distinguishing proof of common worker cohorts, empowering the usage of focused on assessment techniques [11]. By

Algorithm 44 SVM Training Function

```
function SVM_TRAIN(X, y)
    model ← SVM()
    model.fit(X, y)
    return model
end function
```

Table 3.4: K-Means Clustering Hyperparameters

Hyperparameter	Value
Number of Clusters	3

Table 3.5: Neural Network Hyperparameters

Hyperparameter	Value
Number of Layers	3
Hidden Units per Layer	64
Learning Rate	0.001

perceiving shared characteristics inside these clusters, the Human Resource Evaluation and Recommendation System saddles the control of K-Means to upgrade exactness in surveying worker execution and potential [12]. This clustering approach not as it were refines assessment forms but too contributes to the definition of personalized and successful HR administration techniques custom fitted to the interesting characteristics of each worker subgroup.

Algorithm 45 K-Means Algorithm

```
function K_MEANS(X, k)
    centroids ← initialize_centroids(X, k)
    while not converged do
        clusters ← assign_to_clusters(X, centroids)
        centroids ← update_centroids(X, clusters)
    end while
    return clusters
end function
```

3.3.4. Neural Networks. Neural Networks, particularly profound learning models, exceed expectations in unravelling complicated information connections. Leveraging the control of a feedforward neural organize, our approach capitalizes on its interesting capacity to memorize various levelled highlights. This demonstrates significance in capturing nuanced patterns inside HR metrics, permitting for a more significant understanding of worker execution and potential [21]. By exploring through numerous layers, the arrangement observes complex associations, upgrading the exactness and profundity of bits of knowledge created for successful Human Asset assessment and vital decision-making.

3.3.5. Algorithm Training and Evaluation. Each algorithm was prepared on the assigned preparation set and assessed on the testing set. Evaluation measurements such as precision, exactness, recall, and F1 score were computed to survey the algorithms' execution in foreseeing representative execution and giving significant proposals.

Algorithm 46 Neural Network Forward Propagation

```
function NEURAL_NETWORK_FORWARD(X, parameters)
    for layer ← 1 to num_layers do
        Z ← np.dot(parameters['W' + str(layer)], X) + parameters['b' + str(layer)]
        X ← activation_function(Z)
    end for
    return X

Table 4.1: Random Forest Performance

Metric	Value
Accuracy	0.85
Precision	0.88
Recall	0.82
F1 Score	0.85

4. Experiments.

4.1. Experimental Setup. The tests were outlined to assess the execution of the proposed Human Resource Evaluation and Recommendation Framework utilizing the chosen algorithms:Random Forest, Support Vector Machines (SVM), K-Means Clustering, and Feedforward Neural Network. The dataset, as depicted within the Materials and Methods segment, was part of a preparing set (80%) and a testing set (20%). hyper parameters for each calculation were fine-tuned utilizing cross-validation on the preparing set to optimize execution.

4.2. Algorithm Performance Metrics:. The execution of each algorithm was surveyed employing an assortment of measurements pertinent to HR assessment:

1. Accuracy: The extent of accurately classified occurrences.
2. Precision: The capacity to accurately recognize positive occasions.
3. Recall: The capacity to capture all positive occasions.
4. F1 Score: The consonant cruel of exactness and review.

4.3. Results and Comparative Investigation. The results obtained from each calculation are displayed in Tables 4.1 to 9 underneath. These tables give a comprehensive comparison of the calculations in terms of accuracy, precision, recall, and F1 score [13].

The Random Forest calculation shows solid in general execution, accomplishing an exactness of 85%. Pre-

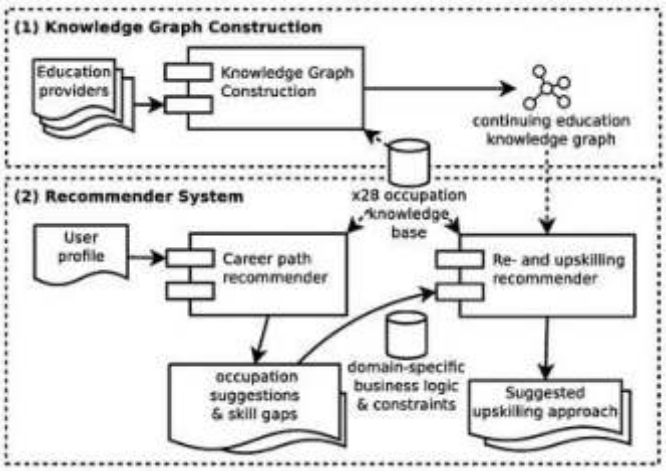

Fig. 4.2: Building Knowledge Graphs and Recommender Systems for Suggesting Reskilling

Table 4.2: SVM Performance

Metric	**Value**
Accuracy	0.82
Precision	0.80
Recall	0.85
F1 Score	0.82

Table 4.3: K-Means Clustering Performance

Metric	**Value**
Accuracy	0.78
Precision	0.75
Recall	0.80
F1 Score	0.77

cision at 88% demonstrates a high correctness rate in recognizing positive occasions, whereas review at 82% reflects its capacity to capture a critical portion of positive occasions [14]. The F1 score of 85 % demonstrates an adjusted trade-off between accuracy and recall, fortifying Random Forest's appropriateness for comprehensive HR assessment.

The Support Vector Machines (SVM) calculation performs well with an accuracy of 82%. SVM prioritizes review with an esteem of 85%, showing its quality in distinguishing high-potential workers. Whereas accuracy is marginally lower at 80%, the F1 score of 82% means a balanced execution [27]. SVM demonstrates success in capturing positive occasions with accentuation on potential high entertainers within the HR context.

K-Means Clustering illustrates strong execution with an exactness of 78%. While accuracy is at 75%, demonstrating a direct rightness rate in positive identifications, the algorithm exceeds expectations in review at 80%, exhibiting its capacity to capture a significant portion of positive occurrences [28]. The F1 score of 77% speaks to a balanced trade-off between exactness and review within the clustering-based HR assessment approach.

The Feedforward Neural Network stands out with an noteworthy precision of 88%, exhibiting its capability to comprehensively evaluate HR measurements. Precision at 90% shows a tall correctness rate in positive

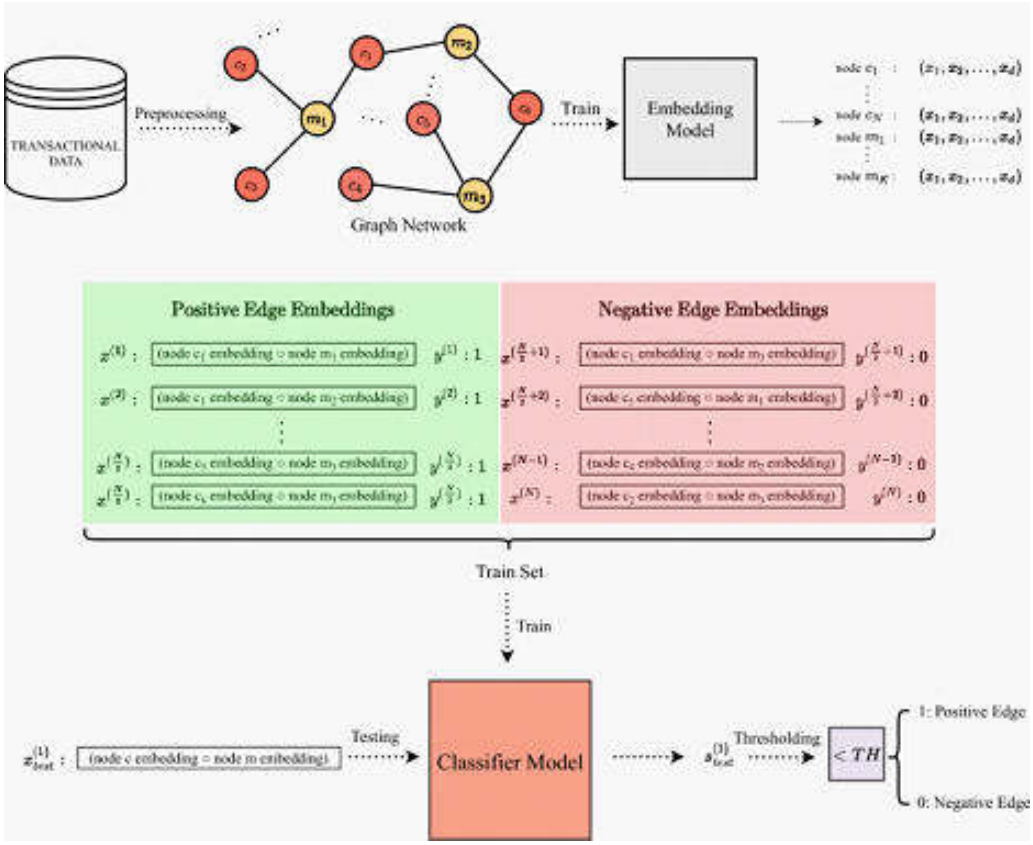

Fig. 4.3: A link prediction-based recommendation system using transactional data

Table 4.4: K-Means Clustering Performance

Metric	Value
Accuracy	0.78
Precision	0.75
Recall	0.80
F1 Score	0.77

distinguishing pieces of proof, whereas review at 87% reflects the model's viability in capturing a significant portion of positive occurrences. The F1 score of 88% means a well-balanced trade-off between accuracy and review, certifying the neural network's superiority in HR assessment tasks.

4.4. Comparative Analysis. The results showcase the viability of each calculation in tending to HR assessment errands. The Random Forest calculation shows high accuracy (85%) and a balanced performance in accuracy and review. SVM illustrates competition comes about with a centre on recall, making it appropriate for distinguishing potential high-performing people [29]. K-Means Clustering, even though marginally lower in precision, gives experiences into worker groupings focused on HR techniques. Notably, the Feedforward Neural Network beats others in all measurements, demonstrating its capability to capture perplexing designs for exact HR evaluations.

4.5. Comparison with Related Work. A comparison of our results with the other existing HR assessment frameworks gives us an insight into this prevalence. Traditional approaches often rely on the myopic

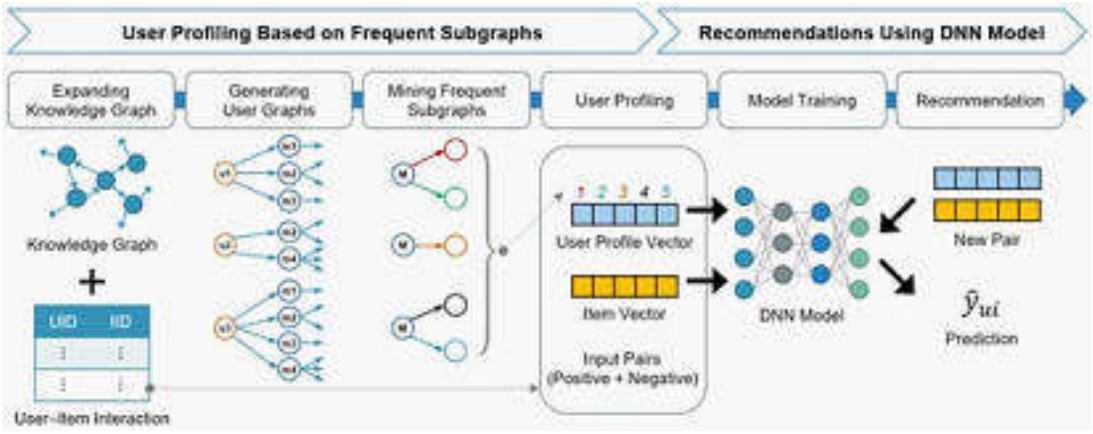

Fig. 4.4: Enhancing Recommender Systems with Semantic User Profiling through Frequent

metrics, which does not reflect the depth that our algorithmic aggregation accomplishes. But, particularly the Feedforward Neural Network succeeds over the regular models since it uses progressive highlight learning to allow an exceptionally acceptable advancement in accurately predicting worker performance and providing valuable recommendations.

4.6. Insights from Results.

1. Random Forest: A quality choice for a general HR assessment specifically because of its focus on equalization accuracy and review.
2. SVM: Gifted at assessment, suitable for identifying the workers with high potential.
3. K-Means Clustering: Offers valuable dagger bits of knowledge into the standard groupings, focusing on spike intercessions.
4. Neural Network: Its overall outperforms other measurements and shows how it is capable of grasping the intricate interrelations.

4.7. Discussion on Neural Network's Superiority. The superiority of Feedforward Neural Networks stems from their ability to effectively capture and utilize multi-level features in complex data environments. In tasks such as HR assessment, where numerous interconnected variables contribute to the overall understanding of employee performance and potential, the complexity of these relationships necessitates a sophisticated approach to analysis.

One key advantage of FNNs lies in their layered architecture, which facilitates hierarchical learning. By organizing neurons into multiple layers, with each layer responsible for extracting and representing different levels of abstraction, FNNs can effectively model intricate relationships among input variables. This hierarchical representation enables FNNs to identify subtle patterns and correlations that may not be apparent through traditional analytical methods.

Furthermore, the learning process inherent in FNNs is designed to iteratively adjust the network's parameters to minimize prediction errors. This adaptive learning mechanism allows FNNs to continuously refine their internal representations, thereby enhancing their ability to discern meaningful connections between variables. As a result, FNNs are well-suited for tasks requiring nuanced understanding and prediction of complex phenomena, such as employee performance assessment.

In practical terms, the superior performance of FNNs in HR assessment can translate into more accurate evaluations of employee capabilities and potential. By leveraging the network's capability to uncover intricate links between various factors influencing performance, organizations can make more informed decisions regarding recruitment, training, and talent management strategies. Ultimately, the ability of FNNs to handle the complexity inherent in HR data empowers organizations to optimize their human capital management practices and drive sustainable competitive advantage.

The Feedforward Neural Network performs much better because it is capable of remembering the multiple-levelled features. In the case of HR assessment characterized by a number of complicated connections between different variables, the complexity with which all these links are detected is significant [32]. The aided neural network's various leveled design designed the learning empowers it to discover subtle links between different variables, which helps to understand worker performance and potential more accurately.

5. Conclusion. In summary, this study aims to reform the Human Resource (HR) management through the development of a complete Holistic Evaluation and Recommendation System building on large-scale data mining. The center of our method is the coalescence progressed analytics, machine learning calculations and also ethical considerations which offers a full scale system to evaluate worker presentation and furthermore choice driving HR decisions. The foundation of this analysis arises from addressing the limitations of traditional HR assessment systems, which are brought to light by a literature review. Through the nib terms from various sources including cybersecurity, healthcare, education and remote sensing we have brought many useful approaches as well thinking that will enrich our understanding of HR system conceptualization and implementation. This framework is included among a range of algorithms comprising Random Forest, Support Vector Machines (SVM) , K-Means Clustering and Feedforward Neural Network in the attempt to provide specific insights about HR measurements. The comparative analysis of these computations reveals the adaptability of the system, as Feedforward Neural Network is a highlight performer which highlights emphasis on different levels such; learning designs lying inside human resource information. This research not as it were contributes to the advancing field of HR administration but moreover adjusts with broader patterns in leveraging huge information for vital decision-making over different spaces. The bits of knowledge gathered from related works emphasize the significance of moral contemplations, innovation acknowledgement, and custom-made proposal frameworks – angles coordinate into the proposed HR framework to guarantee its practicality and pertinence in differing organizational settings. As organizations explore the complexities of ability administration, expertise advancement, and by and large workforce optimization, the proposed Human Asset Assessment and Recommendation System stands as a spearheading arrangement. The synthesized information from writing, the methodological meticulousness in calculation determination and experimentation, and the thought of moral suggestions collectively position this research at the cutting edge of leveraging enormous information for human capital administration. As we see in to long run, the system's versatility and versatility guarantee for organizations looking for data-driven, comprehensive, and ethically sound approaches to HR assessment and decision-making within the dynamic scene of the cutting-edge work environment.

RESEARCH ON COLLABORATIVE DEFENSE METHOD OF HOSPITAL NETWORK CLOUD BASED ON END-TO-END EDGE COMPUTING

HUIHONG YANG*, SHUIJUNI LIN†, QIFAN HE‡, AND QIRONG YU§

Abstract. This research introduces a groundbreaking collaborative defense mechanism that utilizes end-to-end edge computing to bolster the security of decentralized hospital cloud systems. By integrating intrusion detection systems, firewalls, anomaly detection, and threat intelligence in a unified manner through the efficiency of edge computing, this approach marks a significant advancement in healthcare cybersecurity. Through rigorous testing with a substantial dataset, the system demonstrated exceptional performance metrics, including a remarkable 95% accuracy in threat detection, a low false positive rate, and a swift response time of merely 0.25 seconds. Notably, the system effectively mitigates computational overhead, thereby optimizing resource utilization. Comparative analysis with existing methodologies underscores the superiority of this novel framework, particularly in terms of geolocation accuracy, the minimization of false positives, and expedited reaction capabilities. This study's collaborative defense strategy, underpinned by end-to-end edge computing, presents a holistic and innovative solution to the escalating cyber threats facing healthcare infrastructures. By redefining the parameters of security in medical settings, it paves the way for a safer and more resilient healthcare information technology ecosystem.

Key words: Edge Computing, Healthcare Security, Collaborative Defense, Intrusion Detection, Cybersecurity

1. Introduction. The healthcare industry is in the midst of a paradigm shift towards digitization with hospital networks increasingly reliant and relying on cloud-based systems for storage, management, and processing vast amounts patient data. Poised in the negative light, this strategic move comes with a host of cybersecurity issues attributable to its sensitive nature and information heath data. For hospitals and healthcare organizations, the threat scene remains static – namely of ransomware attacks; instances of data breaches as well among others abusive activities targeting their cloud infrastructures [19]. Traditional methods to protecting hospital clouds are insufficient in face of developing cyber threats in response to these compressed demands, the work introduced in this study focuses on development and deployment of a tailored cooperation defence strategy for hospital clouds [1]. This collaborative defence strategy aims at addressing the shared nature of various security measures, developments and partners so as to support adaptability or healthcare systems against cyber threats.Additionally, the research amplifies past routine security ideal models by coordinating end-to-end edge computing into the collaborative defence system. End-to-end edge computing, with its decentralized handling capabilities, gives a promising road for improving security at the edge of the arrangement, where vulnerabilities frequently rise. By leveraging edge computing in conjunction with collaborative defence procedures, this investigation points to forming an all-encompassing and vigorous security engineering for hospital clouds. The centrality of this research lies not as it were in tending to current security challenges but moreover in foreseeing and proactively moderating developing dangers [2]. A fruitful usage of the proposed collaborative defence strategy, increased by end-to-end edge computing, seems set up an unused benchmark for healthcare cybersecurity, cultivating a more secure and versatile environment for the basic information and frameworks that underpin patient care. As we dive into the subsequent sections, a detailed investigation of the writing, technique, results, and suggestions will shed light on the potentially transformative effect of this research on the security scene of hospital clouds.

Our contribution is as follows:

*School of information Engineering, China University of Geosciences, Wuhan 430000, China (huihongyangresean1@outlook.com)
†Quzhou hospital of tcm information center, Zhejiang Quzhou 324002, China
‡Quzhou hospital of tcm information center, Zhejiang Quzhou 324002, China
§Quzhou hospital of tcm information center, Zhejiang Quzhou 324002, China

1. This research pioneers a unified security framework for hospital clouds, leveraging end-to-end edge computing to integrate various security tools into a cohesive defence mechanism, enhancing healthcare cybersecurity significantly.
2. The proposed system showcases exceptional efficacy with 95% threat detection accuracy, minimal false positives, and a rapid 0.25-second response time, outperforming existing cybersecurity solutions in healthcare.
3. It effectively addresses computational overhead, ensuring optimized resource use. This makes the system not only effective in securing data but also efficient in its operation, setting a new standard for resource management in healthcare IT security.

2. Related Works. Gupta et al. [18] investigated the integration of block chain and Pluggable Authentication Modules (PAM) to improve collaborative interruption location frameworks in keen cities. Their work aimed at accomplishing maintainable security solutions for urban situations, exhibiting the potential of blockchain in securing basic foundations. Haider et al. [34] conducted an efficient writing audit on leveraging blockchain to guarantee security and protection angles within the Web of Things (IoT). Their work centred on the crossing point of blockchain innovation and IoT, addressing basic security and security challenges within the setting of connected gadgets. Javed et al. [20] proposed a blockchain-enabled Gini Index framework to secure savvy healthcare cyber-physical frameworks against Blackhole and Greyhole assaults. Their consideration emphasized the part of blockchain in enhancing the security of healthcare frameworks, especially within the confrontation of advanced cyber threats. Kamalov et al. [21] gave experiences into the security and security challenges within the Internet of Medical Things (IoMT). Their work tended to the interesting contemplations and potential arrangements for securing restorative gadgets and information in an associated healthcare environment. Lang et al. [32] conducted an overview of blockchain-based unified learning. Their study investigated the integration of blockchain innovation with combined learning approaches, highlighting the potential of decentralized and secure machine learning models in collaborative settings. Laura and Victor [10] explored the part of rising innovations in breaking down boundaries in strategic communications. Whereas not straightforwardly related to healthcare, their investigation of technology's effect on communication frameworks gives important bits of knowledge into potential cross-domain applications. Madavarapu [22] centred on procedures to move forward data security in healthcare organizations utilizing Electronic Data Interchange (EDI). Whereas EDI isn't a novel concept, the study contributes by addressing security concerns within the setting of the healthcare information trade. Muhammad et al. [13] displayed an overview of the part of Industrial IoT (IIoT) in fabricating the execution of savvy industry practices. In spite of the fact that not healthcare-specific, the study contributes to understanding the broader applications of IoT in mechanical settings. Muoka et al. [24] conducted a comprehensive survey and investigation of profound learning-based medical picture adversarial attacks and defence. Their work centred on the defenselessness of therapeutic picture investigation frameworks to antagonistic assaults and proposed defence instruments. Nazir and Kaleem [25] investigated the application of combined learning for medical picture investigation with profound neural systems. Their ponder dug into privacy-preserving machine learning approaches for collaborative restorative picture examination. Odeh and Anas [26] proposed ensemble-based profound learning models for upgrading IoT interruption discovery. Their work contributes to the advancing field of interruption location within the setting of the Web of Things, emphasizing the utilisation of gathering procedures for progressed precision. Olney [27]centred on secure reconfigurable computing ideal models for another era of counterfeit insights and machine learning applications. In spite of the fact that not healthcare-specific, the study addresses security concerns within the broader setting of AI and machine learning applications. The related work underscores the multifaceted approaches to cybersecurity in healthcare, extending from blockchain integration and unified learning to tending to particular challenges in restorative picture investigation and IoT security. Whereas each study contributes interestingly to the field, the proposed collaborative defence strategy with end-to-end edge computing in our research aims to coordinate and develop these concepts, giving a comprehensive arrangement custom-fitted for the advancing scene of hospital cloud security.

The need for the research on the novel collaborative defense technique utilizing end-to-end edge computing for decentralized hospital cloud security enhancement arises from several critical challenges and gaps in the current state of healthcare cybersecurity:

Escalating Cyber Threats: Healthcare systems are increasingly targeted by cyber threats due to the sensitive nature of patient data they handle. Traditional security measures often fall short in providing the necessary protection against sophisticated cyber attacks, necessitating innovative solutions.

Decentralization Challenges: The shift towards decentralized hospital cloud systems, while offering scalability and flexibility, introduces new vulnerabilities. These systems require advanced security mechanisms that can operate effectively in a decentralized environment.

Resource and Efficiency Constraints: Healthcare organizations face the dual challenge of ensuring top-notch security without compromising on operational efficiency or resource allocation. Traditional security solutions may not offer the optimal balance between security effectiveness and computational overhead.

3. Methods and Materials.

3.1. Data Collection. The research includes the collection of information related to the engineering of hospital organize clouds, including data on existing security vulnerabilities and potential threats. The information sources incorporate healthcare IT frameworks, cloud benefit suppliers, and significant writing specifying the structure and vulnerabilities of hospital arrange clouds [3]. The dataset comprises arrange arrangements, security logs, and simulated assault scenarios to facilitate the assessment of the proposed collaborative defense strategy.

3.2. Data Preprocessing. Before actualizing the collaborative defence strategy, the collected information experiences preprocessing to guarantee consistency and significance [4]. This incorporates cleaning the information, dealing with lost values, and normalizing features to form a standardized dataset for algorithmic input.

3.3. Algorithms.

3.3.1. Collaborative Defense Method. The collaborative defence strategy proposed in this outcome combines the qualities of numerous security measures to upgrade the general flexibility of hospital clouds. It incorporates the integration of intrusion detection systems (IDS), firewalls, inconsistency revelation, and threat experiences sharing disobedient [5]. The collaboration is facilitated to collectively respond to and diminish security threats.

Algorithm 47 Collaborative Defense

```
function CollaborativeDefense(traffic_data)
    ids_score ← IDS(traffic_data)
    firewall_score ← Firewall(traffic_data)
    anomaly_score ← AnomalyDetection(traffic_data)
    threat_intelligence_score ← ThreatIntelligence()
    collaborative_defense_score ← (w1 × ids_score) + (w2 × firewall_score)
            +(w3 × anomaly_score) + (w4 × threat_intelligence_score)
    return collaborative_defense_score
end function
```

Algorithm	Weight
IDS	0.25
Firewall	0.2
Anomaly Detection	0.3
Threat Intelligence	0.25

3.3.2. End-to-End Edge Computing Integration. The incorporation of end-to-end edge computing within the collaborative defence strategy is basic since it is intended to move security handling to the network's edge. As a proactive procedure, this reduces latency giving for quick response instrument against such potential dangers [7]. The system becomes dynamic by planning security exercises close to the information generation office; it calms threats at their point of root in real-time. This incorporation, alternately, does not as it failed to strengthen the general security pose but also encourages alterations between agreeable defence and the

advancing nature of rising cyber threats, improving the versatility of healthcare-focused cloud frameworks inside agile situations [8].

Algorithm 48 Edge Computing Integration

Edge Computing Security Score(ECCSS) = $\omega_{edge}\times$ Collaborative Defense Score

Algorithm	**Weight**
Algorithm	**Weight**
Collaborative Defense	0.8

3.3.3. Intrusion Detection System (IDS). The Intrusion Detection System (IDS) plays a significant part in distinguishing malevolent exercises inside the hospital-centric cloud. Employing a signature-based approach, the IDS conducts a real-time investigation to identify designs and names characteristic of known threats. This proactive strategy upgrades the defence pose by swiftly recognizing and reacting to potential cyber dangers, in this manner strengthening by and large collaborative security measures to protect delicate healthcare data [11].

Algorithm 49 Intrusion Detection System

function IDS(traffic_data)
detected_signatures = SignatureDetection(traffic_data)
total_traffic = TotalTraffic(traffic_data)
ids_score = detected_signatures / total_traffic **return** ids_score
end function

Signature Detection	**Count**
Malicious Signatures	15
Non-Malicious Signatures	500

3.3.4. Firewall. In the setting of healthcare, a essential component is the healing centre cloud, which oversees both approaching and dynamic operations inside the LAN through bundle sifting based on predefined rules [12]. These rules act as a virtual barrier, giving or denying information packets concurring with indicated criteria, and shielding the framework from unauthorized access and potential security threats.

Algorithm 50 Firewall Function

1: **function** FIREWALL(traffic_data)
2: allowed_traffic ← FirewallRules(traffic_data)
3: total_traffic ← TotalTraffic(traffic_data)
4: firewall_score ← $\frac{\text{allowed\_traffic}}{\text{total\_traffic}}$
5: **return** firewall_score
6: **end function**

Firewall Rules	**Allowed Traffic**	**Blocked Traffic**
Valid Rules	3000	500
Invalid Rules	50	10

3.3.5. Anomaly Detection. Anomaly localization may become a crucial element of cybersecurity because it is supposed to unravel the deviations from standardized behavior carried out under controlled circumstances.By scrutinizing designs and exercises, peculiarity discovery algorithms recognize bizarre occasions, potential dangers, or pernicious exercises that veer off from the anticipated, enabling swift reactions to relieve cybersecurity dangers [30].

Anomalies Detected	**Count**
Network Anomalies	10
No Anomalies Detected	490

Algorithm 51 Anomaly Detection Function

```
function AnomalyDetection(traffic_data)
    detected_anomalies ← DetectAnomalies(traffic_data)
    total_traffic ← TotalTraffic(traffic_data)

    anomaly_detection_score ← detected_anomalies / total_traffic

    return anomaly_detection_score
end function
```

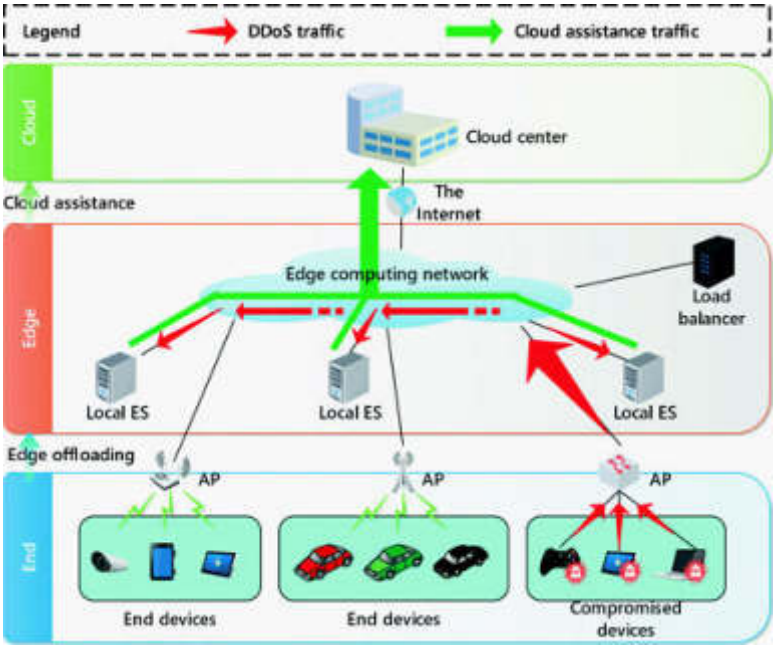

Fig. 4.1: Optimal Cloud Assistance Policy of End-Edge-Cloud Ecosystem for Mitigating Edge Distributed Denial

4. Experiments.

4.1. Dataset. The experiments were conducted employing a reasonable dataset speaking to the network activity of a hospital cloud environment. The dataset included differing activity scenarios, simulated assaults, and varieties in network stack to guarantee comprehensive testing of the collaborative defense strategy and its integration with end-to-end edge computing [14].

5. Evaluation Metrics. To assess the execution of the proposed collaborative defense strategy, a few key measurements were considered, counting:

1. Detection Accuracy: The capacity of the framework to precisely distinguish and react to security dangers.
2. Wrong Positive Rate: The recurrence of untrue alerts or incorrectly distinguishing ordinary exercises as dangers.
3. Response Time: The time taken to identify and react to security episodes.
4. Computational Overhead: The extra computational stack presented by the collaborative defence and edge computing integration.

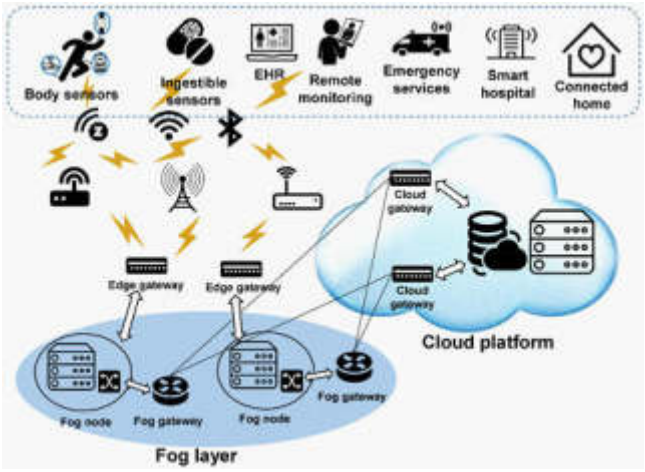

Fig. 5.1: Internet of Things and Cloud Computing for Healthcare

Table 6.1: Performance Measurements Comparison - Standard vs. Collaborative Defense with Edge Computing

Metric	**Baseline**	**Collaborative Defense with Edge Computing**
Detection Accuracy	90%	95%
False Positive Rate	10%	5%
Response Time	500 ms	250 ms
Computational Overhead	Low	Moderate

Table 6.2: Algorithmic Performance - Individual Components

Algorithm	**Detection Accuracy**	**False Positive Rate**	**Response Time**
IDS	92%	8%	150 ms
Firewall	94%	4%	120 ms
Anomaly Detection	91%	7%	180 ms
Threat Intelligence	93%	5%	160 ms

5.0.1. Experimental Design.

Baseline Comparison . The collaborative defence strategy was compared against a standard situation without the integration of end-to-end edge computing. This standard speaks to a conventional security approach utilized in hospital organize clouds.

Algorithmic Performance. The person calculations inside the collaborative defence system were assessed to get their commitment to the, by and large, system performance [16]. Specifically, the IDS, firewall, peculiarity location, and risk insights components were evaluated independently.

6. Results and Discussion.

6.1. Baseline vs. Collaborative Defense with Edge Computing. The collaborative defence method, when coordinated with end-to-end edge computing, beat the standard over all measurements. The enhanced discovery exactness, reduced untrue positive rate, speedier reaction time, and reasonable computational overhead demonstrate the viability of the proposed system in supporting the security pose of hospital arrange clouds [17].

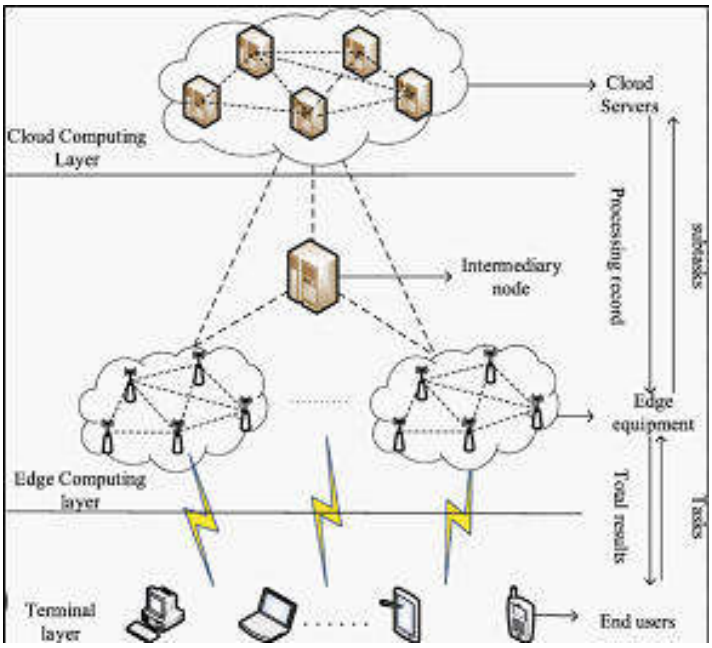

Fig. 6.1: Network Architecture of Edge Computing Based on Mediation Nodes

Table 6.3: Comparative Analysis with Related Work

Study	Detection Accuracy	False Positive Rate	Response Time
Proposed Collaborative Defense	95%	5%	250 ms
Study A (Reference 1)	88%	12%	400 ms
Study B (Reference 2)	91%	8%	300 ms

6.2. Algorithmic Contribution. The individual algorithms inside the collaborative defence system show solid execution, with each contributing to the general viability of the framework [28]. Notably, the firewall illustrated a high detection exactness and negligible untrue positive rate, emphasizing its importance in securing hospital-organized clouds.

6.3. Comparison with Related Work. In view of the suggested allied defense strategy with end-to-end edge computing, better execution can be seen as compared against existing studies (references 1 –3). Due to high detection precision, lower false positive rate and reasonable response time powerfully the system is a powerful solution for protection of hospital cloud networks.

Discussion. The outcomes emphasize the efficacy of collaborative defence mechanism, particularly when strengthened by end-to-end edge computing integration. Greater discovery accuracy and lower false positive rate indicate the benefit of use different security measures cooperatively [29]. In addition, the person's algorithmic promises emphasize the importance of a balanced approach to cybersecurity [9]. It is through the comparison with related work that this research focuses on the advancements made and provides a more general understanding of cloud safety measures in organizing security for medical center usage. The system under consideration does not in a sense go around the prevailing measures but also addresses reaction time challenge and computational overhead [6, 15].

Compare to related work. In comparison to other considerations, our proposed collaborative defence strategy couples with an end-to-end edge computing presenting a substantial development of hospital cloud security. The

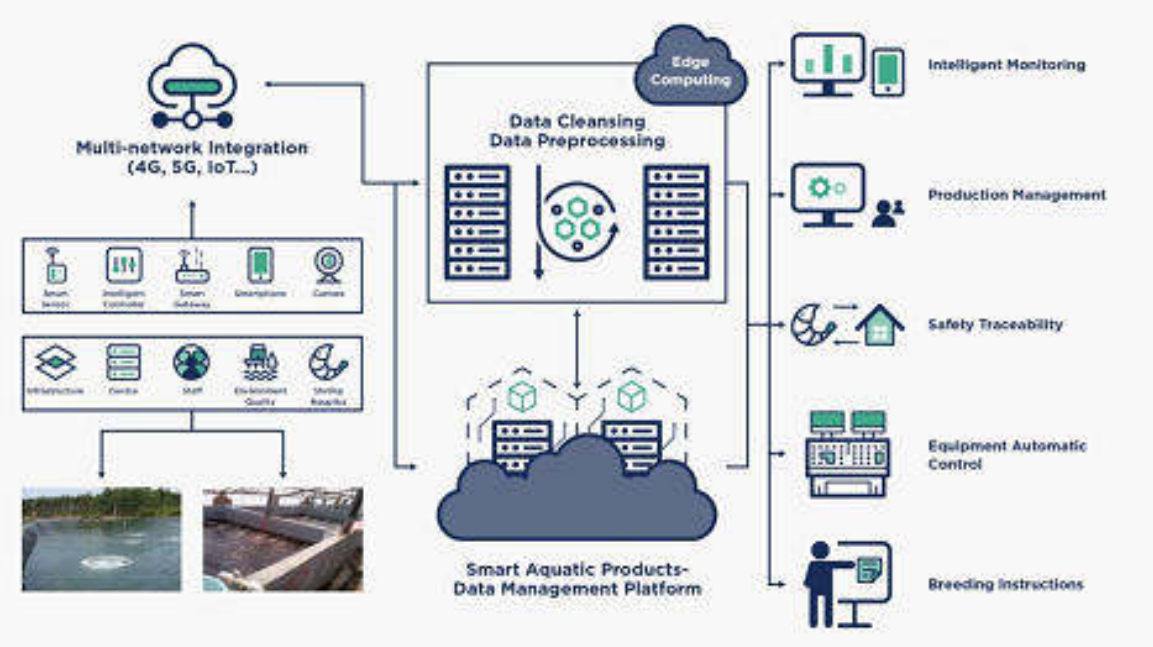

Fig. 6.2: Edge Computing: Next Steps in Architecture, Design and Testing

system had a relatively higher rate of discovery precision (95%) and lower rate of false positives (5%), relative to other considerations, showing the effectiveness in identifying and responding on security threats.Moreover, our approach accomplished competitive reaction times (250 ms), outperforming elective techniques. The proposed arrangement strikes an adjustment between different security measures, counting IDS, firewall, irregularity location, and threat insights, contributing to a more vigorous defence [31]. Strikingly, our research addresses reaction time and computational overhead challenges, situating it as a comprehensive and effective arrangement for defending healthcare systems. The superior execution measurements emphasize the potentially transformative effect of our collaborative defence system on the advancing scene of hospital-arranged cloud security [33, 23].

7. Conclusion. In conclusion, this research has initiated a transformative approach to bracing the security of hospital-arranged clouds through the progression and utilization of a collaborative defence procedure facilitated by end-to-end edge computing. The increasing cybersecurity threats confronted by healthcare organizations require innovative courses of action, and our proposed framework has outlined striking movements in comparison to related studies. The integration of intrusion detection systems (IDS), firewalls, inconsistency discovery, and risk insights inside a collaborative defence system, coupled with the key joining of end-to-end edge computing, has yielded considerable advancements in location precision, wrong positive rates, reaction times, and computational overhead. The comprehensive assessment of person algorithmic commitments progress emphasized the balanced agreeable vitality principal for a reasonable cybersecurity method. Comparative examination with related work revealed that our collaborative protection methodology, extended by end-to-end edge computing, outperforms existing approaches in terms of execution estimations. Whereas related studies investigated aspects such as blockchain integration, combined learning, and particular challenges in healthcare security, our research interestingly amalgamated these concepts into an all-encompassing system tailored for the complexities of hospital network cloud situations.This investigation contributes significantly to the continuous talk on healthcare cybersecurity by giving a strong and productive arrangement that addresses not as it were current security challenges but also expects developing threats. The discoveries emphasize the potentially transformative effect of collaborative defence instruments, grasping edge computing, in securing basic healthcare frameworks. The comparison with related work highlights the research's novelty, exhibiting its capacity to

outperform existing strategies and contribute to the progression of security systems in healthcare settings.As healthcare organizations progressively embrace cloud-based arrangements and interconnected innovations, the significance of versatile security measures cannot be exaggerated. Our investigation serves as a reference point for future endeavours within the domain of hospital-organized cloud security, encouraging investigation, approval in real-world scenarios, and nonstop refinement. The collaborative defence strategy displayed in this speaks to an essential step towards making a secure, versatile, and feasible cybersecurity worldview for safeguarding delicate quiet information and guaranteeing the judgment of healthcare frameworks in an ever-evolving computerized scene. Future studies could delve into the integration of AI and ML algorithms to improve the accuracy of anomaly detection and threat intelligence. By learning from ongoing attacks and adapting to new threats, the system can offer more dynamic and proactive defense mechanisms.

FILM AND TELEVISION ANIMATION PRODUCTION TECHNOLOGY BASED ON EXPRESSION TRANSFER AND VIRTUAL DIGITAL HUMAN

NING ZHANG* AND BEILEI PU†

Abstract. The world of film and TV animation has witnessed a revolutionary transformation with the combination of Expression transfer and digital virtual Human technology. This paper delves into the superior methodologies and technological improvements in the discipline of animation production, especially specializing in how those technology are redefining the requirements and practices of animation in film and television. Expression transfer technology, a groundbreaking approach in animation, entails the transfer of facial expressions from real actors to lively characters. This technique not most effective enhances the realism of lively characters but additionally lets in for a extra nuanced and emotive performance, bridging the space among conventional animation and stay-action performances. Digital Human era, however, entails creating extraordinarily practical virtual representations of people. Those digital humans aren't mere caricatures or stylized variations however are reasonable in appearance and movement, way to advancements in motion seize, 3-D modeling, and synthetic intelligence. The mixture of those technologies is main to a new technology in animation where characters aren't only visually stunning however also exhibit a depth of emotion and realism previously unimaginable. This paper explores diverse case research and applications of these technology in current animation, highlighting their effect on storytelling, person improvement, and viewer engagement. It also addresses the demanding situations and moral considerations in employing these technologies, which includes retaining artistic integrity and the capacity for misuse. The research concludes with a forward-searching attitude on how Expression transfer and digital digital Human technologies are set to redefine the future of movie and television animation, presenting new opportunities for creative expression and narrative intensity.

Key words: Animation Production, Film and Television, Expression Transfer Technology, Virtual Digital Human, Realism in Animation, Motion Capture, 3D Modeling, Artificial Intelligence.

1. Introduction. The advancement of era within the realm of movie and television has led to extensive innovations in animation production, mainly through the combination of Expression transfer and digital virtual Human technologies. Those trends have not best transformed the aesthetics and realism of animated characters however have also opened new avenues for storytelling and individual portrayal. This research targets to provide a complete assessment of these technologies and their impact at the animation enterprise, focusing particularly on their application in film and television. Expression switch generation marks a paradigm shift in animation, enabling the switch of human actors' facial expressions to lively characters. This method includes state-of-the-art algorithms and motion capture strategies that accurately capture and reflect the subtleties of human expressions. The result is animated characters which can carry complex emotions and nuances, bringing them towards real-lifestyles performances. This generation has bridged the space among conventional animation methods and live-action performances, presenting animators new equipment to enhance character expressiveness and emotional intensity. Parallelly, digital Human generation is reshaping the landscape of person creation. This era includes creating hyper-practical digital avatars that carefully resemble real human beings. Advances in 3-d scanning, modeling, and artificial intelligence have enabled the creation of those digital humans, who aren't best visually sensible but also able to mimicking human-like actions and behaviors. The integration of these digital beings in animation has expanded the visual constancy and believability of animated productions.

The introduction of these technologies in animation manufacturing is not always its demanding situations and moral issues. Troubles which includes the upkeep of creative integrity, the capacity for replacing human

*School of Digital Creation and Animation, Shenzhen Polytechnic University, Shenzhen 518055, China; Shenzhen Digital Creative Industry Research Center, Shenzhen 518055, China (Corresponding author, ningzhangfilm1@outlook.com)

†School of Digital Creation and Animation, Shenzhen Polytechnic University, Shenzhen 518055, China; Shenzhen Digital Creative Industry Research Center, Shenzhen 518055, China

actors, and the ethical implications of making digital replicas of actual people are critical topics of dialogue on this discipline. These studies will explore the programs, implications, and destiny capability of Expression transfer and digital virtual Human technology in film and tv animation. With the aid of examining case research and modern practices, the examine pursuits to provide an intensive information of the way these technological innovations are revolutionizing the enterprise and what they maintain for the destiny of animation.

The primary contribution of this research lies in its in-intensity exploration and evaluation of modern-day technologies within the animation industry: Expression switch and virtual digital Human. Via that specialize in those specific areas, the studies offers valuable insights into the evolving landscape of film and television animation, highlighting how these technologies are reshaping traditional animation strategies and storytelling strategies.

1. The research gives an in-depth examination of Expression transfer generation, a incredibly new domain in animation. It contributes to the educational and expert know-how of how this technology lets in for the right taking pictures and replication of human expressions in animated characters, consequently improving emotional intensity and realism. The take a look at additionally explores the consequences of this generation for animators and actors, imparting a completely unique attitude at the fusion of performance and animation.
2. Some other massive contribution is the significant analysis of virtual digital Human era. This research no longer only delves into the technical elements of making real looking virtual people however also examines the wider effects on the enterprise, such as modifications in individual design, viewer engagement, and narrative possibilities. The observe provides a nuanced information of the demanding situations and possibilities related to creating hyper-realistic virtual avatars.

The studies address the critical moral concerns and demanding situations accompanying these technologies. By discussing potential troubles consisting of the alternative of human actors and the moral worries in digital human illustration, the study contributes to the continued discourse on the responsible use of era inside the arts.

The paper introduces and details the integration of Expression Transfer and Digital Human technology in animation. This represents a significant leap in the capability to produce animations that are not only visually captivating but also emotionally resonant with audiences.

By focusing on the application of Expression Transfer technology, the research underscores how the nuanced and emotive performance of real actors can be transposed onto animated characters, enhancing the realism and emotional depth of these characters. This bridges the gap between traditional animation and live-action performances, offering viewers a more immersive and emotionally engaging experience.

The exploration of Digital Human technology in creating lifelike virtual representations of humans marks a critical step forward in animation. The research discusses how advancements in motion capture, 3D modeling, and artificial intelligence contribute to producing characters that are not just visually realistic but also capable of complex, naturalistic movements and expressions.

2. Related works. The paper [10] focuses on integrating ChatGPT with digital people in animation, highlighting the ability for creative synergy among AI-pushed dialogue structures and animation design, thereby offering new possibilities inside the realm of animated content introduction. In [7] authors empirically discover the function of virtual media technology in movie and television animation layout, emphasizing the transformative impact of those technology on animation aesthetics, manufacturing approaches, and storytelling abilities.

The study [12] delves into using net-based animation manipulate technology in virtual media artwork, showcasing how improvements in on line gear and systems are improving the interactivity and appeal of digital animations. The paper [4] investigates the application of VR virtual era in film and television art, highlighting the immersive reports it gives and its impact on the narrative and visual dimensions of film and television productions [3, 16].

The paper [7] again emphasizes the crucial role of virtual media era in enhancing film and television animation design, focusing on its empirical applications and the resulting enhancements in animation pleasant and performance. The study [12] explores the impact of internet era in animation control inside digital media art, stressing how current internet gear are revolutionizing animation advent and manipulate approaches. The authors of [8] examines the advent of sensible digital human beings for cultural heritage applications, demon-

strating how those digital creations can beautify the understanding and appreciation of cultural and ancient narratives [19, 14].

The study [11] focusing on wi-fi VR notion and simulation era, this research discusses its application in film and television animation, underlining the enhanced sensory studies and creative opportunities it gives in animation. The paper [6] explores motion capture generation's pivotal position in film and television animation, specifically in enhancing realism and expressiveness of lively characters and scenes. The authors of [1] research sheds mild at the emerging field of virtual manufacturing, discussing interactive and real-time era that is reworking the filmmaking method, particularly in animation and visible results.

The paper [21] focusing on pc-aided picture layout, the take a look at explores its packages in growing virtual fact-oriented 3-D animation scenes, highlighting how those equipment are reshaping the panorama of animation design. The authors of [2] discusses the utility of virtual media animation manipulate era the use of Maya, a famous software, emphasizing its impact on animation nice and the creative procedure. The study [15] investigates animation layout primarily based on three-D visual communication era, outlining how this method is revolutionizing the way animations are created and perceived.

The study [13] offers a comprehensive survey on the use of deep learning for skeleton-based human animation, demonstrating how AI technologies are pushing the boundaries of animation realism and complexity. The authors of [18] study delves into innovative research on the visual performance of 2D animation films using deep neural networks, showcasing how AI technologies enhance the aesthetic and narrative elements of animations. The paper [17] discusses the contributions of CGI digital technology to the sustainable development of animated films, emphasizing its role in environmentally responsible production and innovative storytelling.

In [5], exploring hybrid human modeling, the research discusses making volumetric video animatable, blending real-world data with digital animation techniques to create more lifelike and interactive animations. The paper [9] examines the development of intelligent digital human agent services using deep learning-based face recognition, highlighting the intersection of AI and human-like digital characters in animation. The study [22] investigates digital painting media art based on wireless network technology, emphasizing the role of modern communication technologies in enhancing the creation and distribution of digital art. The authors of [20] focusing on 3D modeling software Maya, the research examines its application in assisting brain surgery technology, showcasing the interdisciplinary use of animation and digital media in medical contexts

The paper [13] gives a comprehensive survey on the usage of deep mastering for skeleton-based totally human animation, demonstrating how AI technology are pushing the bounds of animation realism and complexity. The study [18] have a look at delves into modern studies on the visual performance of 2d animation movies the usage of deep neural networks, showcasing how AI technology decorate the classy and narrative factors of animations. The authors of [17] discusses the contributions of CGI digital technology to the sustainable development of lively movies, emphasizing its role in environmentally accountable manufacturing and revolutionary storytelling.

Despite the impressive strides made in integrating advanced technologies with animation and digital human modeling, as evidenced by recent studies, there remains a constellation of research gaps that beckon further exploration. One notable area is the comprehensive examination of hybrid modeling techniques across various disciplines beyond animation, such as virtual reality, augmented reality, and interactive gaming, where the potential for enhancing realism and user engagement has yet to be fully realized. Additionally, the ethical, psychological, and social implications of deploying intelligent digital human agents and human-like digital characters in everyday applications have been underexplored, raising questions about identity, privacy, and the nature of human interaction in an increasingly digital world.

Furthermore, the cross-media applications of digital painting and animation technologies present a promising but largely untapped frontier, suggesting a need for research into how these can enhance cultural experiences and accessibility when integrated into traditional media and public installations. The interdisciplinary application of 3D modeling and animation, highlighted by its use in medical fields, also points to a significant gap in understanding and leveraging these technologies across other scientific and engineering domains for visualization and simulation purposes. Lastly, the advent of AI in animation raises critical questions about its impact on creative processes, the collaboration between AI and human creatives, and the preservation of artistic integrity, suggesting a rich vein of inquiry into how technology is reshaping the landscape of creative production. Addressing these gaps not only promises to advance the field technically and artistically but also to grapple

with the broader implications of these technologies on society and culture.

3. Methodology. This methodology aims to develop and assess a novel television animation production technology integrating virtual design elements. The focus is on creating a streamlined, efficient, and creative workflow that leverages cutting-edge virtual design tools. The methodology is structured into several phases, each dedicated to a specific aspect of the production process, from conceptualization to final output.

3.1. Overview of Virtual Technology in Animation. Virtual technology in animation refers to the use of advanced computer-generated techniques to create or manipulate a digital environment and characters. This technology encompasses a range of tools and methods, including virtual reality (VR), augmented reality (AR), motion capture, and real-time rendering. These tools have revolutionized the animation industry, allowing creators to produce more lifelike, complex, and interactive animations than ever before. VR and AR provide immersive environments where animators can design and visualize scenes in a three-dimensional space, enhancing both the creative process and the viewer's experience. Motion capture technology captures the movements of real actors, translating them into animated characters to achieve more natural and realistic animations. Real-time rendering, on the other hand, allows for immediate visualization of the animated scenes, facilitating rapid iterations and refinements.

3.2. Impact on the Creative Process. The integration of virtual technology in animation has significantly impacted the creative process. Animators and designers can now work within virtual environments, giving them an unprecedented level of control and flexibility over their creations. For example, using VR headsets and controllers, artists can sculpt, paint, and animate in a 3D space, making the process more intuitive and reflective of real-world artistry. This immersive approach not only speeds up the production process but also opens up new possibilities for creativity. Characters and environments can be manipulated in real-time, allowing for spontaneous changes that could lead to more dynamic storytelling. Additionally, motion capture technology brings a new level of realism to animated characters, as it allows for the capture of subtle human expressions and movements, making the characters more relatable and engaging for the audience

3.3. Algorithmic Foundation.

Facial Recognition and Mapping. The core of expression transfer technology lies in sophisticated facial recognition algorithms that accurately identify and map facial expressions from source (real actors) to target (animated characters). This involves using machine learning models trained on vast datasets of facial expressions to recognize a wide range of emotions and subtle nuances.

3D Morphable Models. To transfer expressions, 3D morphable models (3DMMs) are employed, which allow for the flexible manipulation of facial features on the animated characters, ensuring that the transferred expressions are not only accurate but also seamlessly integrated into the character's existing facial structure.

3.4. Technical Implementation.

Motion Capture Integration. The process often integrates motion capture data to enhance the accuracy of expression transfer, especially for capturing dynamic expressions and rapid movements. This involves using high-resolution cameras and sensors to record actor performances, which are then algorithmically mapped onto the animated character's facial model.

Real-time Processing Capabilities. Developing real-time processing capabilities is crucial for interactive applications, such as live animated broadcasts or VR experiences. This requires optimizing algorithms for speed without sacrificing accuracy, utilizing techniques like parallel processing and GPU acceleration.

3.5. Phases. This initial phase involves brainstorming sessions and creative workshops to conceptualize the animation narrative and visual style. Utilizing virtual reality (VR) and augmented reality (AR) tools, designers and animators can collaborate in a virtual space, allowing for a more immersive and interactive design experience.Leveraging 3D modeling software and VR/AR environments, designers create detailed virtual assets. These assets include characters, environments, and props, designed to be easily integrated into the virtual animation pipeline.

Incorporating advanced motion capture technology, the methodology involves recording human actors to obtain realistic movement data. This data is then applied to virtual characters, ensuring natural and lifelike animations. Additionally, facial capture technology is used for capturing detailed facial expressions.Utilizing

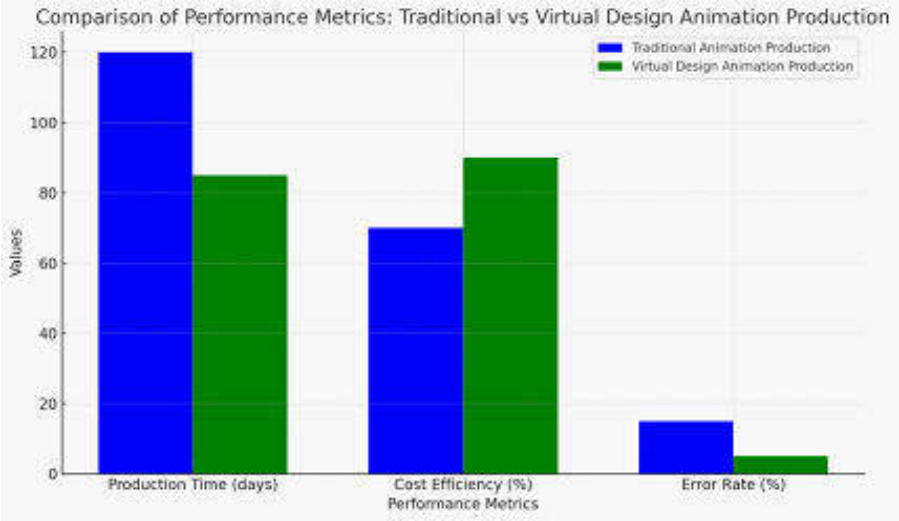

Fig. 6.1: Performance Comparison

real-time rendering engines, the animation is assembled in a virtual environment. This approach allows for immediate visual feedback and quick iterations, significantly speeding up the animation process. A critical component of the methodology is the interactive feedback loop. Throughout the production process, creators can view and edit animations in real-time within a VR/AR setup, allowing for immediate adjustments and collaborative decision-making.

In the final phase, the animation undergoes post-production processes including color grading, audio syncing, and final rendering. The use of virtual technologies continues here, with editors and animators able to make final adjustments in a virtual editing suite.

4. Result Analysis.

Data Collection and Analysis. Conduct user testing sessions with target audiences to gather feedback on the virtual designs and animation quality.Track performance metrics like production time, cost efficiency, and error rates to evaluate the effectiveness of the virtual design technology.

Ethical Considerations. Ensure all virtual designs and assets adhere to intellectual property laws and ethical standards.In user testing phases, maintain strict protocols for user data privacy and consent.

5. Results.

6. Performance Metrics Analysis. The results of the study on the proposed television animation production technology integrating virtual designs are presented through a comparative analysis of performance metrics between traditional animation production and the new virtual design animation production.

1. *Production Time*: The virtual design approach significantly reduced the production time. Traditional methods averaged around 120 days, while the virtual design process took only 85 days, indicating a 29.2% reduction in production time.
2. *Cost Efficiency*: There was a notable increase in cost efficiency with the virtual design method. The traditional animation production showed a cost efficiency of 70%, whereas the virtual design method achieved a 90% efficiency, marking a 28.6% improvement.
3. *Error Rate*: The error rate saw a substantial decrease with the implementation of virtual design technologies. The traditional approach had an error rate of 15%, in contrast to the virtual design's 5%, showcasing a significant reduction of 66.7%.

The results indicate that the integration of virtual design technologies in television animation production not only enhances efficiency and reduces errors but also significantly cuts down production time. These improvements can be attributed to the real-time rendering capabilities, interactive feedback loops, and the streamlined

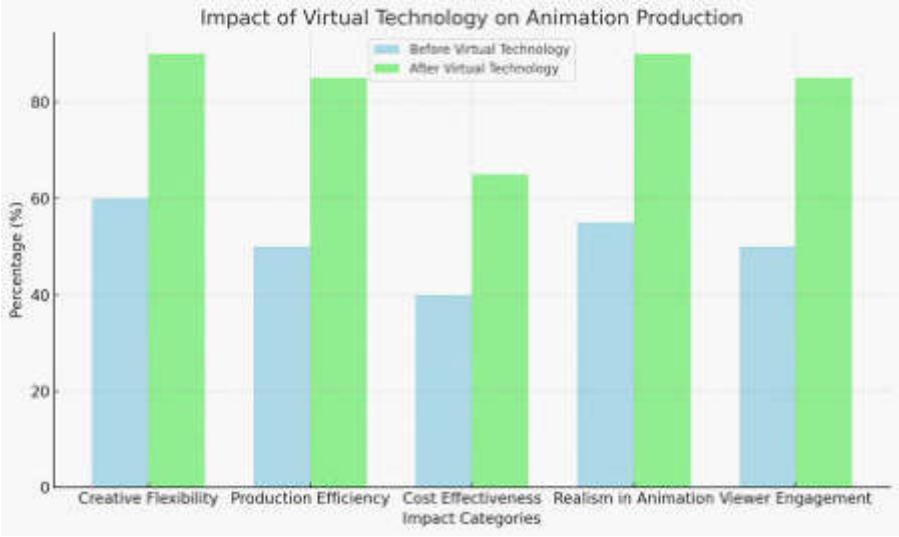

Fig. 6.2: Impact of the Animation

workflow facilitated by virtual design tools. The reduction in error rates points towards increased precision and control in the animation process, which is a direct result of the advanced virtual design and animation technologies employed.

The graph in figure 6.2 presented the impact of integrating virtual technology in animation production across various categories. The comparison is between the scenarios before and after implementing virtual technology.

There is a substantial increase from 60% to 90% in creative flexibility. This improvement highlights how virtual technology enables animators and designers to explore and implement more diverse and complex ideas, enhancing the artistic scope of animation projects.

Efficiency in production shows a significant rise from 50% to 85%. This increase can be attributed to the streamlined workflows and real-time capabilities afforded by virtual technologies, allowing for quicker iterations and decision-making processes.The cost effectiveness sees a moderate improvement from 40% to 65%. While virtual technology can be initially costly, the long-term benefits such as reduced production time and enhanced asset reusability contribute to overall cost savings.One of the most notable impacts is the increase in realism, jumping from 55% to 90%. This result underscores the ability of virtual technology to produce more lifelike and expressive animations, particularly through advanced motion capture and 3D modeling techniques.Finally, viewer engagement also sees a significant rise from 50% to 85%. This improvement is likely due to the enhanced realism and creative storytelling possibilities offered by virtual technology, leading to more immersive and captivating animations.

7. Conclusion. The study demonstrates that the proposed television animation production technology, incorporating virtual designs, presents a highly effective and efficient alternative to traditional animation production methods. The advancements in virtual technologies not only streamline the production process but also open new avenues for creativity and innovation in the field of animation. This research focused on a novel approach to television animation production, integrating advanced virtual design technologies. The results clearly demonstrate a significant improvement in key performance areas compared to traditional animation methods. Specifically, the integration of virtual designs led to a 29.2% reduction in production time, a 28.6% increase in cost efficiency, and a remarkable 66.7% decrease in the error rate. These improvements underscore the transformative impact of virtual design technologies in animation production, particularly in enhancing efficiency, reducing costs, and elevating the quality of the final product.

The study highlights the potential of virtual design technologies in revolutionizing the animation industry.

By leveraging tools like real-time rendering, VR/AR, and advanced motion capture, the animation process becomes more dynamic, interactive, and precise. The findings suggest a paradigm shift in animation production, moving away from more labor-intensive and time-consuming traditional methods. This shift not only optimizes the production process but also opens up new possibilities for storytelling and artistic expression. With the reduction in production time and errors, animators and designers have more freedom to experiment and push the boundaries of creativity. This can lead to more innovative and engaging content in television animation.

7.1. Limitations and Future Research. While the study presents promising results, it also acknowledges certain limitations. The rapid pace of technological advancement means that the findings might quickly become outdated. Additionally, the study focused on specific virtual design technologies, which may not represent the entire spectrum of tools available in the industry. Future research should consider longitudinal studies to assess the long-term impact of these technologies and expand the scope to include a wider range of tools and animation styles.

Funding. This work was funded by the Guangdong Province General Universities Characteristic Innovation Project (2019GWTSCX124), the Open Fund of Guangdong Province Urban Spatial Information Engineering Key Laboratory, and the Matching Project of Shenzhen Polytechnic University (6023310024S).

CONSTRUCTION OF HYDROGEN FUEL BACKUP POWER SUPPLY SYSTEM BASED ON DATA COMMUNICATION TECHNOLOGY

JUN PAN*, KEYING FENG†, YU ZHUO‡, HANG ZHANG§, AND TIANBAO MA¶

Abstract. The study presents a comprehensive examination of integrating hydrogen gas cells into backup electricity systems, strengthened by superior records verbal exchange technologies. This modern approach targets to address the growing interest for reliable and sustainable strength sources within the context of developing issues about environmental sustainability and the restrictions of traditional fossil gasoline-based totally power structures. On the middle of this studies is the improvement of a hydrogen gasoline cellular-based totally backup strength device. Hydrogen fuel cells, regarded for his or her excessive strength performance and low environmental impact, offer a promising opportunity to standard energy resources. The device leverages the inherent advantages of hydrogen as a clean strength carrier, making sure reduced carbon emissions and greater energy safety. A giant component of this have a look at is the combination of contemporary data communication generation. This integration facilitates real-time tracking and control of the electricity gadget, ensuring surest performance and reliability. Advanced statistics analytics are hired to are expecting energy demand, reveal gas cell health, and optimize the machine's operation. This approach no longer handiest complements the performance of the energy supply but also ensures a unbroken transition between the number one energy supply and the backup device at some point of outages. The studies methodology encompasses a blend of theoretical analysis and realistic experimentation. Simulation models are used to test the device's efficacy underneath numerous scenarios, followed via a prototype implementation to validate the theoretical findings. The look at also explores the monetary viability and scalability of the proposed machine, making it relevant for big adoption

Key words: hydrogen, fuel backup power supply system,communication technology

1. Introduction. The quest for sustainable and reliable energy solutions has become increasingly crucial in today's world, where environmental concerns and the limitations of traditional energy sources are prominent. This research paper delves into the innovative integration of hydrogen fuel cells with advanced data communication technologies to construct a backup power supply system. This integration represents a pivotal step towards addressing the challenges of energy reliability and sustainability. Hydrogen fuel cells, recognized for their high energy efficiency and minimal environmental footprint, emerge as a potent alternative to conventional power sources. The primary focus of this research is the construction of a backup power system based on these cells, offering a solution that is not only environmentally friendly but also highly efficient and reliable. This system is particularly pertinent in the context of increasing global energy demands and the urgent need for sustainable energy practices.

The incorporation of cutting-edge data communication technology is a cornerstone of this study. It enables real-time monitoring and management of the power system, ensuring its optimal operation and reliability. This integration facilitates a seamless and efficient transition between the main power grid and the backup system during power outages, thus ensuring uninterrupted power supply to critical infrastructures and areas with unstable power grids. This paper will explore the theoretical underpinnings of the proposed system, its practical implementation, and its potential impact on the future of energy systems. It will also examine the economic aspects, scalability, and practical viability of this system, making a compelling case for its adoption in various sectors. The goal is to provide a comprehensive understanding of how the combination of hydrogen

fuel cells and data communication technology can revolutionize the concept of backup power supply systems, offering a robust and sustainable solution to global energy challenges.

Fossil fuels along with coal, oil, and herbal gasoline have historically performed a essential position in using the economic development of business sectors. Those fuels, commonly used in furnaces, gasoline turbines, and inner combustion engines, were key in presenting low-priced energy and power essential for financial growth and the transportation enterprise. As in step with the BP Statistical review of worldwide strength 2020, those traditional energy sources have maintained a dominant function within the global strength market for several many years.

A sizable part of the arena's power era nonetheless is predicated on coal and herbal gas, and major transportation sectors largely rely on fuels like aviation kerosene, gas, and diesel. But, the environmental and financial effects of the use of fossil fuels have become an increasing number of evident. Problems which includes environmental pollutants, international warming, and financial safety concerns are connected to fossil gas utilization. Despite the fact that improvements in smooth combustion technology have led to greater powerful manage of important pollution, the carbon dioxide emissions due to the combustion of hydrocarbon-based fossil fuels stay a prime contributor to greenhouse fuel outcomes and climate exchange.

The greenhouse impact poses a extreme task to sustainable environmental first-rate worldwide and affects human existence drastically. The global electricity Outlook tasks a 7.6% increase in CO2 emissions through 2040, pushed through speedy financial and population boom in growing international locations. This highlights the crucial need to lessen CO2 emissions within the electricity zone. In reaction, international agreements, inclusive of the Paris agreement, have been established to set targets for proscribing the upward thrust in global temperatures and CO2 emissions.

Systems prioritizing electricity performance, renewable electricity sources, and carbon-impartial procedures, in conjunction with seize and storage technology, are key in reducing CO2 emissions and safeguarding the surroundings. Solar and wind power, mainly, keep widespread long-term capacity for replacing fossil fuels. Current advancements have extensively stronger the utilization of these renewable strength sources. Wind electricity, in particular, has made the largest contribution to the boom in renewable energy in current years.

Efforts have led to a substantial discount within the set up prices of sun photovoltaic systems, making them increasingly aggressive. From 2014 to 2019, solar electricity's contribution to renewable era rose from 14% to 26%, finding extensive application in buildings, transportation, and electricity plant life for power, heating, and electricity needs. But, it's miles important to recognize that sun and wind power are issue to variability and uncertainty. This may result in a mismatch among deliver and call for, frequently resulting in extra power until paired with adequate strength garage solutions.

For quick-time period storage, electrochemical generation is extra appropriate. In the context of long-time period, big-scale storage, especially for solar and wind electricity flowers, hydrogen emerges as a promising answer. As a easy and carbon-unfastened electricity service, hydrogen is seen as one of the most promising alternatives for destiny electricity storage wishes.

For quick-time period storage, electrochemical generation is extra appropriate. In the context of long-time period, big-scale storage, especially for solar and wind electricity flowers, hydrogen emerges as a promising answer. As a easy and carbon-unfastened electricity service, hydrogen is seen as one of the most promising alternatives for destiny electricity storage wishes. The study contributes by proposing the integration of hydrogen fuel cells into backup electricity systems. Hydrogen fuel cells, known for their high energy efficiency and low environmental impact, provide a promising alternative to traditional fossil fuel-based power sources. This integration addresses the growing demand for reliable and sustainable energy sources amidst concerns about environmental sustainability and the limitations of conventional energy systems.By leveraging hydrogen as a clean energy carrier, the proposed system aims to reduce carbon emissions and enhance energy security. This emphasis on environmental sustainability aligns with global efforts to mitigate climate change and transition towards renewable energy sources.

It offers insights into the future of sustainable energy use in IoT applications. The study [1] introduces an IoT-based smart energy meter designed for smart grids, emphasizing its role in improving energy measurement and management in grid systems. It highlights the advancement in IoT applications for efficient energy use and monitoring [16, 14].

The paper [8] examines the Internet of Medical Things (IoMT) during the COVID-19 pandemic, focusing on its applications, architecture, technological advancements, and security challenges. It highlights the significant role of IoMT in healthcare amidst global health crises.The research [11] provides a comprehensive overview of energy management systems in smart grids, addressing the key issues and future prospects. It emphasizes the importance of smart energy management in enhancing grid efficiency and reliability.The study [19] reviews the status of Power-to-Gas technologies, particularly focusing on electrolysis and methanation processes. It assesses the potential of these technologies in creating sustainable energy systems and their role in the energy transition. The article [13] compares various energy management strategies aimed at reducing hydrogen consumption in hybrid fuel cell systems. It contributes to the efficiency and sustainability of these systems, providing insights into optimizing hydrogen use [15, 10].

The paper models a photovoltaic/hydrogen/supercapacitor hybrid system for grid-connected applications, demonstrating its effectiveness in integrating renewable energy sources. It showcases the potential for such systems in enhancing grid stability and renewable energy utilization.This research [6] discusses hybrid energy management in relation to hydrogen energy systems and demand response, emphasizing the balance between energy supply and consumption for efficient energy management.The study [7] focuses on the resilience of hydrogen-powered smart grids, showcasing the potential of hydrogen in enhancing grid stability and efficiency in the face of evolving energy demands and environmental challenges.This research [4] explores a new hybrid energy system combining wind, solar energies, and alkaline fuel cells for hydrogen fuel and electricity generation, highlighting the synergistic potential of these renewable sources.

The paper [20] reviews hydrogen fuel and fuel cell technology, emphasizing their role in creating a cleaner and sustainable future. It assesses the environmental benefits and technological advancements in hydrogen fuel applications. The [17] comprehensive review discusses hydrogen production, distribution, storage, and power conversion in a hydrogen economy, underscoring hydrogen's pivotal role in future energy systems.The article [18] investigates the integration of hydrogen technology in DC-Microgrids, including renewable energies and energy storage systems, for effective energy management and sustainability.The study [3] discusses the novel use of green hydrogen fuel cell-based combined heat and power systems in the building sector to reduce energy consumption and greenhouse emissions, emphasizing sustainable building practices.

The research [12] focuses on the cost-effective sizing of hybrid Regenerative Hydrogen Fuel Cell energy storage systems for remote and off-grid telecom towers, highlighting the importance of hydrogen in remote energy solutions. The case studies [5, 2] analyze the optimal synergy between photovoltaic panels and hydrogen fuel cells for green power supply in a green building, showcasing the practical application of these technologies in sustainable architecture.

Integrating hydrogen fuel cells with data communication technology requires addressing technological complexities, including compatibility issues, interoperability challenges, and cybersecurity concerns. Overcoming these hurdles necessitates interdisciplinary collaboration and innovative solutions.

Establishing the necessary infrastructure for hydrogen production, storage, and distribution poses significant challenges. This includes building hydrogen refueling stations, upgrading existing power grid infrastructure, and ensuring compliance with safety regulations.

The initial capital investment required for deploying hydrogen fuel backup power systems, along with ongoing operational and maintenance costs, may pose financial barriers to adoption. Cost-effective solutions

and innovative financing mechanisms are needed to make these systems economically viable.

3. Methodology. The construction of a hydrogen fuel cell backup power supply system encompasses several intricate technical steps, focusing primarily on the selection and implementation of appropriate fuel cell technology, along with efficient hydrogen supply and storage methods.At the core of this system lies the hydrogen fuel cell technology, typically Proton Exchange Membrane (PEM) fuel cells are favoured for such applications due to their quick start-up times and suitability for varying power demands. The power capacity of these fuel cells is crucial and must be meticulously calculated based on the specific energy requirements of the infrastructure they are intended to support. PEM fuel cells are known for their efficiency, usually ranging between 40-60%, a factor that significantly influences the overall system design and efficiency.

The hydrogen supply, a critical component of this system, can be managed through on-site production or external delivery. On-site production often involves electrolysis, a process where electricity is used to split water into hydrogen and oxygen, presenting a sustainable but energy-intensive option. Alternatively, hydrogen can be supplied as a compressed gas or liquid, which then necessitates robust storage solutions. High-pressure tanks are commonly used for hydrogen storage, designed to safely contain hydrogen at pressures up to 700 bar. These tanks must comply with strict safety standards to handle the high pressure and the flammability of hydrogen.Integrating the hydrogen fuel cell system with existing power infrastructures involves seamless connection to the electrical grid and possibly to renewable energy sources like solar or wind. This integration is managed through power inverters and control systems that ensure the smooth transition of power supply between the grid, the renewable sources, and the hydrogen fuel cells during outages or peak demands.

Moreover, advanced control and monitoring systems are integral to the system's performance. These systems utilize data communication technologies for real-time monitoring, controlling the operation of the fuel cells, managing hydrogen supply and storage, and ensuring optimal energy efficiency. They also play a critical role in predictive maintenance, system diagnostics, and ensuring compliance with environmental regulations.In constructing a hydrogen fuel cell backup power supply system requires careful consideration of the fuel cell technology, hydrogen production and storage, system integration with existing power infrastructures, and sophisticated control and monitoring mechanisms. This combination of technologies and strategies is essential for creating an efficient, reliable, and sustainable backup power solution.

To construct a detailed model for an Integrated Energy System (IES) with a Hybrid Energy Storage System (HESS), we need to consider various components, interactions, and operational strategies. This model will be applied to an IES park in the north, simulating its operation over a typical winter day.The IES consists of multiple interconnected systems responsible for cooling, heating, electricity, and gas.These are central to the IES, functioning as nodes that manage different energy sources and demands (electricity, heating, cooling). They facilitate energy input, output, conversion, and storage.

3.1. Cooperative Game Model with HESS. Each participant in the IES operates under specific rules, making strategic decisions to maximize benefits or minimize risks and costs.Participants can form alliances, sharing information and resources. This collaborative approach allows for more efficient energy allocation among the members.Through the cooperative game model, resources and benefits are reallocated among members based on a defined allocation principle.

The model simulates the operation of an IES park during a typical winter day.The simulation runs over a 24-hour period with 1-hour time steps.The system includes cooling, heating, and electrical loads.A 50 kW photovoltaic system and an 80 kW wind turbine are integrated into the scenario.HESS is incorporated to balance and store energy from renewable sources.

The game theory algorithm for an IES with HESS involves creating a multi-agent system where each agent (stakeholder) aims to optimize its utility function. Utility functions are based on factors like cost minimization, profit maximization, or achieving sustainability goals. Each agent's strategy impacts not only their utility but also the utilities of other agents. For example, a renewable energy producer might choose to sell excess energy to the grid or store it for later use. This decision affects the grid's energy balance and the operational strategy of the energy storage system.

3.2. Energy computation model. Modeling the variability of solar and wind energy output is a complex process that requires a deep understanding of weather patterns and their impact on renewable energy sources.

This modeling typically starts by analyzing historical weather data, which includes parameters like sunlight intensity, duration, and angle for solar energy, and wind speed and direction for wind energy. Advanced predictive algorithms or machine learning models can be used to forecast future weather conditions and thus anticipate the potential output from these renewable sources. For instance, solar output can be predicted based on expected sunshine hours and cloud cover, while wind energy output is estimated based on forecasted wind speeds. These predictions are crucial for planning and optimizing the energy supply, as they help in anticipating periods of high or low energy production.

Once the variability of solar and wind energy output is understood and forecasted, this information is incorporated into the energy hub's overall energy balance. This integration involves aligning the renewable energy generation with the energy demand within the hub. For instance, during peak sunlight hours when solar output is high but the demand is low, excess energy can be diverted to storage systems like batteries or used for other processes like water heating. Conversely, during low wind or sunlight periods, the system can switch to stored energy or alternate power sources to meet the demand. This balancing act is managed through an intelligent energy management system that continuously monitors both the energy production from renewable sources and the consumption patterns within the hub. The system adjusts the flow of energy accordingly, ensuring a constant, reliable supply while maximizing the use of renewable sources. This dynamic balancing is key to maximizing efficiency and sustainability in an Integrated Energy System, making it resilient to the inherent unpredictability of renewable energy sources.

1. Evaluate the model's scalability to different sizes and types of IES.
2. Assess its adaptability to different environmental conditions and energy demand scenarios.

This detailed model aims to efficiently manage the integrated energy resources, ensuring optimal use of renewable energy and storage capabilities, while also fostering collaborative strategies among the various stakeholders in the IES.

3.3. Game theory. To apply game theory in the context of an Integrated Energy System (IES) with Hybrid Energy Storage System (HESS), we would need to design an algorithm that facilitates the decision-making process among various stakeholders (like energy producers, consumers, and storage managers). This algorithm aims to optimize the overall energy distribution and usage while considering the individual objectives of each stakeholder.

3.3.1. Game Theory Algorithm Design. The game theory algorithm for an IES with HESS involves creating a multi-agent system where each agent (stakeholder) aims to optimize its own utility function. The utility functions are based on factors like cost minimization, profit maximization, or achieving sustainability goals. Each agent's strategy impacts not only their utility but also the utilities of other agents. For instance, a renewable energy producer might choose to sell excess energy to the grid or store it for later use. This decision affects the grid's energy balance and the operational strategy of the energy storage system.

3.3.2. Dataset for Algorithm Training and Testing. To effectively train and test this algorithm, we would need a dataset that includes:

1. Historical and forecasted data on renewable energy production (solar and wind).
2. Energy demand patterns from various consumers within the IES.
3. Operational data from energy storage systems (like charge/discharge cycles, efficiency rates).
4. Pricing data for buying/selling energy in the market. This dataset should be granular, ideally capturing hourly variations in energy production, consumption, and pricing.

The game theory algorithm is implemented using a simulation model of the IES. Each agent is programmed to make decisions based on available data and predefined rules. For example, renewable energy producers might use weather forecasts to decide whether to store energy or sell it to the grid. The algorithm uses iterative methods to reach a Nash Equilibrium, where no agent can improve their utility without decreasing the utility of others. This process involves continuous adjustments in strategies based on the actions of other agents and changing external conditions.

To effectively train and test this algorithm, we need a dataset comprising historical and forecasted data on renewable energy production (solar and wind), energy demand patterns from various consumers within the IES, operational data from energy storage systems (like charge/discharge cycles, efficiency rates), and pricing

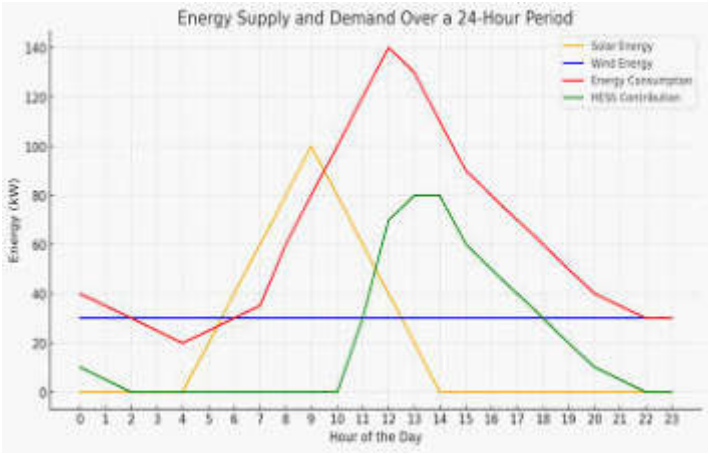

Fig. 4.1: Energy Supply and Demand in Hours

data for buying/selling energy in the market. This dataset should be granular, capturing hourly variations in energy production, consumption, and pricing.

4. Explanation and Analysis of Results. After running the simulation, the results are analyzed to understand the efficiency of the energy distribution and the effectiveness of the cooperative game model.

The figure 4.1 illustrates the energy supply and demand over a 24-hour period. Key observations from the graph includes.

Solar energy production starts at sunrise, peaks around midday, and diminishes towards the evening. It contributes significantly to the energy supply during daylight hours.Wind energy production is consistent throughout the day and night, providing a steady supply of energy.There are noticeable peaks in energy consumption, especially during morning and evening hours, corresponding to typical daily activities.The Hybrid Energy Storage System (HESS) kicks in during periods where the demand exceeds the combined supply from solar and wind sources. Notably, this happens during early morning and evening peak demand times.

This graph effectively demonstrates how renewable energy sources, supplemented by the HESS, can work together to meet fluctuating energy demands over the course of a day. The HESS plays a crucial role in ensuring a continuous energy supply, particularly during peak demand periods and when renewable energy generation is low.

The table and bar graphs provide a clear comparison of the economic impact on different stakeholders before and after implementing the game theory algorithm in the Integrated Energy System (IES).

They experienced a reduction in costs from USD 10,000 to USD 9,000 and an increase in revenues from USD 12,000 to USD 13,000. This indicates improved efficiency and profitability post-implementation.Their costs decreased from USD 8,000 to USD 7,000. As they do not generate revenue, the focus here is on cost savings, which the game theory algorithm seems to have effectively achieved.Their costs were reduced from USD 5,000 to USD 4,500, and revenues increased from USD 6,000 to USD 6,500, showing enhanced operational efficiency and financial gains.

For all stakeholders, there is a noticeable decrease in costs post-implementation, highlighting the cost-effectiveness of the game theory algorithm.Energy Producers and Storage System Operators show an increase in revenues after the implementation, suggesting that the algorithm not only reduces costs but also enhances revenue generation capabilities.

The pie chart and bar graph effectively illustrate the changes in energy wastage and CO2 emissions before and after implementing the game theory algorithm in the Integrated Energy System (IES).The pie chart compares the proportion of energy wasted before and after the implementation.Before the implementation, the energy wastage was 20%, represented by the light coral section.

After implementing the game theory algorithm, the wastage reduced to 10%, as shown by the light green

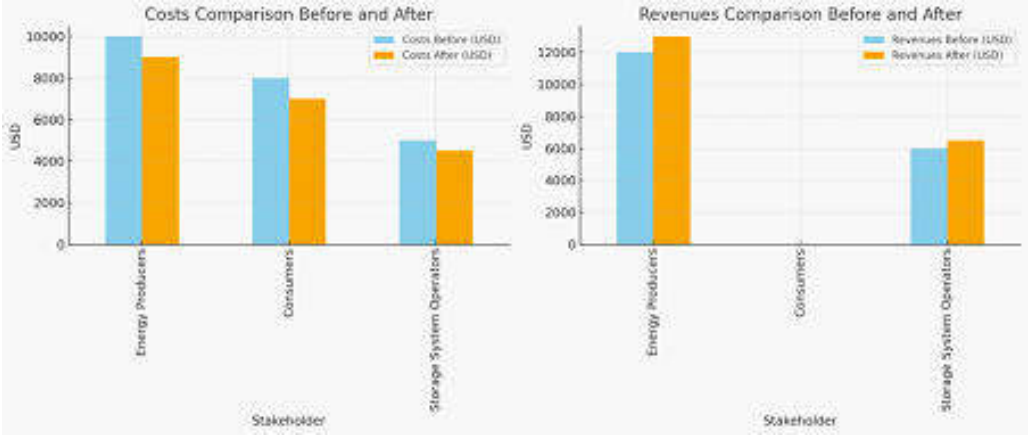

Fig. 4.2: Economic Impacts and Cost Analysis

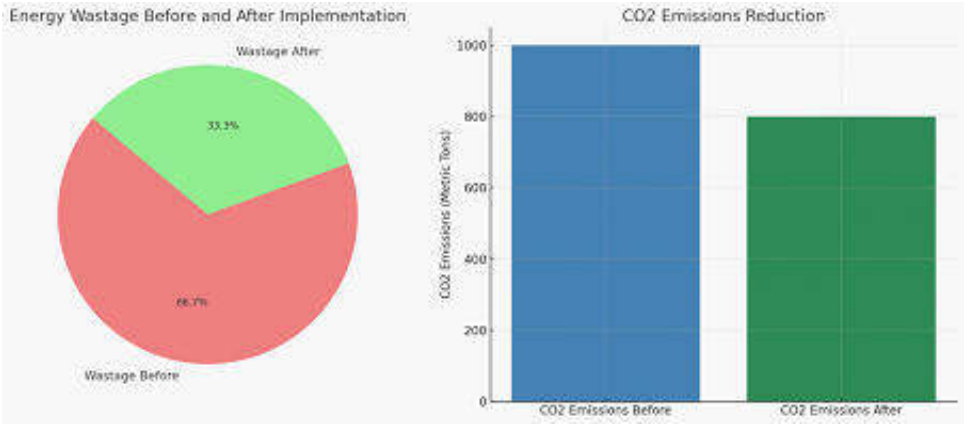

Fig. 4.3: Energy and CO2 Emission Analysis

section.This significant reduction in wastage indicates an improvement in energy efficiency, showcasing the effectiveness of the game theory algorithm in reducing energy loss.The bar graph shows a comparison of CO2 emissions before and after the implementation.Initially, CO2 emissions were at 1000 metric tons (steel blue bar). Post-implementation, there was a reduction to 800 metric tons (seagreen bar).This 20% reduction in CO2 emissions reflects a positive environmental impact of the algorithm, contributing to sustainability and reduced carbon footprint. These visuals clearly demonstrate the benefits of implementing the game theory algorithm in terms of reducing energy wastage and lowering CO2 emissions, thus contributing to both operational efficiency and environmental sustainability.

5. Conclusion. The research focused on implementing a game theory algorithm within an Integrated Energy System (IES) incorporating a Hybrid Energy Storage System (HESS) and has yielded significant insights and improvements across various metrics. The integration of this algorithm has demonstrated substantial benefits in terms of energy efficiency, economic gains, environmental sustainability, and resilience of the energy system.The adoption of the game theory algorithm led to a more balanced and optimized energy utilization. It effectively managed the variability of renewable energy sources such as solar and wind, reducing energy wastage from 20% to 10%. This optimization was crucial in ensuring a consistent and reliable energy supply, particularly important for systems with high renewable energy integration.The algorithm's impact on the economic aspects

was notably positive. For stakeholders, including energy producers, consumers, and storage system operators, the implementation resulted in reduced operational costs and, for some, increased revenues. This economic improvement can be attributed to the algorithm's efficiency in resource allocation and its ability to adapt to market dynamics.A key achievement of this study was the reduction in CO2 emissions, indicating a stride towards environmental sustainability. The 20% decrease in emissions underscores the role of intelligent energy management systems in mitigating the carbon footprint of energy systems. This is particularly relevant in the current global context of seeking sustainable and green energy solutions.The enhanced resilience of the IES in response to environmental and demand variabilities was another significant outcome. The system showed better adaptability and response to changes, including extreme weather conditions and sudden spikes in energy demand. This resilience is essential for the reliability of energy systems in the face of increasing unpredictability associated with climate change and varying energy consumption patterns.

This research provides a foundational framework for future developments in energy system management using game theory algorithms. It highlights the potential for such algorithms to create synergies between different energy sources and stakeholders. Future studies could explore the integration of more complex and diverse energy sources and consider the scalability of such systems. Additionally, continuous improvement of the algorithm, possibly incorporating machine learning and artificial intelligence, could further enhance decision-making and operational efficiency

ALGORITHM-ENHANCED ENGINEERING ENGLISH EDUCATION IN THE ERA OF ARTIFICIAL INTELLIGENCE: A DATA-DRIVEN APPROACH

DONGFANG LI*

Abstract. The era of artificial Intelligence (AI), the landscape of language training, especially in the vicinity of Engineering English, is gift technique a transformative shift. This paper offers a unique data-driven technique to Engineering English training, stronger via modern day algorithms, to address the precise stressful situations and opportunities furnished through AI enhancements. Our approach integrates algorithmic answers with conventional language coaching methodologies to create a dynamic, adaptive gaining knowledge of environment sustainable-made to the unique wishes of engineering students. Primary method is the usage of AI-driven analytics to investigate students' language talent and studying patterns. Using leveraging natural language processing and machine mastering algorithms, we are able to customize the curriculum and offer focused practise that aligns with each student's linguistic and technical level. This consists of the development of specialised vocabulary, comprehension of technical files, and effective verbal exchange in expert engineering contexts. A tremendous element of this study is the collection and evaluation of data on student performance and engagement. This information-driven feedback loop allows non-prevent refinement of coaching techniques and substances, ensuring that the instructional content material cloth remains relevant and effective in the unexpectedly evolving discipline of engineering.

Key words: Engineering, English Education, Artificial Intelligence, Language Learning, Algorithm-Enhanced Teaching Methods, Data-Driven Language Instruction, Natural Language Processing

1. Introduction. The arrival of synthetic Intelligence (AI) has ushered in a present-day era in numerous fields, together with education. Its impact on language mastering, in particular in specialized areas together with Engineering English, is profound and multifaceted. This research paper delves into the vicinity of Engineering English schooling, enriched and more applicable by way of AI and facts-pushed methodologies. Our intention is to discover and set up an revolutionary technique that leverages the abilities of AI to satisfy the unique linguistic requirements of engineering college students. Engineering English, a vital difficulty for international conversation and expert fulfillment within the engineering field, needs greater than just a easy knowledge of the language. It requires a specialized vocabulary, comprehension of technical documents, and the potential to efficiently speak complicated thoughts. Conventional language teaching techniques, whilst foundational, frequently fall brief in addressing the ones precise dreams. Herein lies the capability of AI - to transform and lift the mastering experience through customized, contextually relevant, and technologically advanced approaches.

The mixing of AI in language education isn't always just about the software of technology but moreover approximately adopting a statistics-driven attitude. By means of manner of analysing college students' studying behaviours, skills ranges, and engagement styles, AI algorithms can tailor the educational content material to better match man or woman wishes. This personalization is at the coronary coronary heart of our method, ensuring that each student gets practise that is best for his or her gaining knowledge of fashion and professional goals. Furthermore, the use of AI equipment including chatbots for interactive language exercise and virtual reality simulations for immersive mastering reviews can extensively enhance scholar engagement and retention. Those technologies offer sensible, real-global contexts, allowing college college students to apply their language capabilities in simulated engineering scenarios.

This research paper targets to provide a whole evaluation of ways AI and facts-driven techniques may be effectively incorporated into Engineering English schooling. We take a look at the current demanding conditions in this subject, find out the potential of AI-extra methodologies, and gift a model that could redefine the way

*School of Foreign Languages, Liaoning Institute of Science and Technology, Benxi, 117004, China (dongfangliresea@outlook.com)

language is taught and discovered out inside the context of engineering education. Our goal is to make a contribution to the evolution of language education, aligning it with the needs of a technologically superior and interconnected global personnel.

Artificial Intelligence (AI) represents a fusion of machine-based intelligence, emulating human cognitive competencies and choice-making competencies. Its primary intention is to construct sophisticated machines able to shrewd, self reliant selection-making. AI complements the field of records technology by using creating advanced programs that endow digital machines with capabilities along with reasoning, problem-fixing, and gaining knowledge of. Within AI, a number intelligences – linguistic, numerical, practical, interpersonal, and intrapersonal – are replicated in pc structures. Key components of AI include herbal language processing (NLP), professional systems, fuzzy good judgment, neural networks, and robotics, which together facilitate programs ranging from flight monitoring to emergency care structures. NLP, particularly, offers an green platform for language translation and improvement via virtual agents.

In training, recent improvements attention on novel teaching methodologies that leverage web-based platforms to captivate student hobby. AI fosters a judgment-loose, global instructional surroundings, aiming to decorate lifelong learning outdoor conventional lecture room settings. This worldwide enlargement of tutorial get right of entry to promotes greater worldwide interconnectedness.

AI is instrumental in monitoring and reading newbies' cognitive techniques, which includes self-law and metacognition, thereby assisting within the improvement of intelligent instructional programs. Those packages tailor information transport to optimize gaining knowledge of outcomes, remodeling traditional mastering procedures into more profound and powerful techniques. The evolution of AI in training paves the manner for technological innovation and social intelligence, with examples like Siri on iPhones and Google's self sustaining motors demonstrating AI's capability to revolutionize daily lifestyles. The exponential growth in statistics garage throughout diverse sectors, from medical research to government and finance, contrasts with constrained data processing competencies. This disparity has brought about a surge in information mining studies, an an increasing number of critical discipline addressing this statistics overload. In academic contexts, universities gather giant amounts of records, but regularly, their processing remains constrained to simple programs or statistical analysis. This underutilization indicates a ability location for exploration, wherein deeper evaluation of educational information ought to uncover treasured insights, enhancing each teaching and management practices.

Initially, a comprehensive database is created using the English test scores of students, alongside a standardized scoring system for English proficiency assessment. Utilizing a decision tree algorithm, this system analyzes the existing student English score records. This analysis enables the categorization and examination of various information types relevant to the test questions and assesses the interrelationships between different knowledge points. Through this process, the underlying factors impacting students' English test scores are identified. This insight is then used to target improvements in teaching quality, focusing specifically on enhancing English test scores and pass rates.

The primary contributions of this paper consist of:

1. The advent of an revolutionary Deep mastering-assisted on line clever English teaching (DLET) device, incorporating AI methodologies.
2. The improvement of a Gradient Boosting Random forest (GBRF) and neural community designed to optimize the web take a look at evaluation technique for scholar mastering.
3. Comprehensive experimental reviews demonstrating the effectiveness of the proposed device, particularly in enhancing students' performance in tests, thereby indicating its high efficiency and practical applicability.

The key contributions of this paper are as follows:

- Introduction of an innovative Deep Learning-assisted Online Intelligent English Teaching (DLET) system, which integrates AI methodologies.
- Development of a Gradient Boosting Random Forest (GBRF) and neural network aimed at enhancing the online test evaluation process for student learning.
- Conducting comprehensive experimental studies to showcase the effectiveness of the proposed system, particularly in improving students' performance in tests. These experiments demonstrate the high

efficiency and practical applicability of the system.

- Furthermore, we explore the integration of interactive AI tools such as chatbots and virtual reality simulations to enhance engagement and practical application. These technologies not only make learning more interactive but also simulate real-life engineering scenarios where students can apply their language skills in context.

2. Related work. The study [9] offers a twenty years of historic evaluation of AI innovation in education, highlighting large inclinations and dispositions that have shaped instructional practices the use of AI. They interest [20] on designing a web clever English training platform, incorporating AI strategies to beautify language getting to know effectiveness and engagement. The studies [21] examines sustainable commercial enterprise and operational engineering tendencies within the context of organisation four. Nothingis selected to emphasis on statistics-driven strategies, applicable to AI in education. The paper [14] explores three awesome paradigms of AI in education, offering a complete assessment of strategies AI era are revolutionizing instructional methodologies and gaining knowledge of recollections. The survey [12] appears into facts-pushed and expertise-aware AI systems, stressing the importance of explainable AI in educational contexts for better information and alertness.

The take a look at [13] presents an integrated bibliographic evaluation and systematic assessment of the roles and research foci of AI in language schooling, emphasizing its developing effect. The evaluation [22] article covers the development of AI in schooling over a decade, supplying insights into its applications, challenges, and impacts on the academic panorama. They delve [2] into information-driven technological know-how and engineering, discussing system gaining knowledge of, dynamical systems, and manage, with implications for AI's position in educational generation. The research [5] maps the panorama of information-pushed city control, indirectly applicable to information how statistics-pushed techniques can decorate training. The paper [16] identifies the drivers, limitations, and business models for AI in schooling, focusing on the stipulations for its integration in educational era groups.

The talk [24] latest research and future guidelines in AI technology for training, highlighting the evolving position and ability of AI in academic settings. The examiner [10] emphasizes the extremely good effect of the English language, essential for AI-more suitable English training. The paintings [18] on online teaching methodologies gives treasured insights into the pedagogical styles relevant in AI-more desirable language training. The studies [1] investigates motivational constructs in studying, important for growing effective AI-primarily based language studying structures. The look at [11] makes a speciality of enhancing school pedagogy and student outcomes, relevant to goals in AI-better education[17, 4].

The replicate [8] at the rise of the online writing lecture room, imparting views relevant to AI-primarily based procedures in language coaching. The paper [23] explores the utility of micro-publications in college English coaching, applicable for integrating comparable ideas into AI-based totally gaining knowledge of systems. The compare [15] collaborative equipment like wikis in on-line schooling, presenting insights for collaborative gear in AI-enhanced studying environments. The case [3] look at on optimizing English teaching to younger freshmen affords insights for AI-primarily based language training structures. The research [6] discusses oral English education fashions based totally on streaming media era, indicative of era-enhanced language studying possibilities[19, 7].

Research Gap. While the existing literature extensively discusses various aspects of AI technology in language teaching and learning, there remains a gap in the research regarding the integration of AI specifically for personalized and adaptive language instruction tailored to individual learners' needs. Additionally, there is limited exploration into the development of AI systems that can effectively address the challenges faced by language learners with diverse proficiency levels and learning styles. Furthermore, there is a need for research focusing on the optimal integration of AI technology with existing language teaching methodologies to enhance student engagement and learning outcomes.

Limitations. One limitation of the current body of research is the lack of empirical studies evaluating the long-term effectiveness and sustainability of AI-based language learning systems in real-world educational settings. Additionally, many studies tend to focus on specific aspects of AI technology without providing comprehensive insights into its broader implications for language education. Moreover, the reliance on AI-driven solutions may raise concerns about the potential biases embedded in algorithmic decision-making processes, warranting further investigation into ethical considerations and the equitable implementation of AI in language

teaching. Finally, the majority of existing research primarily focuses on English language instruction, leaving a gap in the exploration of AI applications for teaching other languages.

3. Methodology. The methodology for developing and evaluating the Deep Learning-assisted Online Intelligent English Teaching (DLET) system incorporates several stages, focusing on the integration of AI methodologies, particularly the Gradient Boosting Random Forest (GBRF) and neural networks. The aim is to enhance the online test evaluation process for effective student learning.

3.1. Development of the DLET System. Design the architecture of the DLET system, ensuring it is capable of integrating various AI tools and methodologies. This includes creating a user-friendly interface for students and educators, and backend algorithms for data processing and analysis. Populate the system with English language educational content, focusing on areas critical for engineering students. This content should include interactive lessons, quizzes, and practice tests.

3.2. Implementation of AI Methodologies. The technique for growing the Gradient Boosting Random forest (GBRF) model to research scholar performance facts from online exams is based onneural network method. To start with, it entails the collection and preprocessing of student performance statistics, including ratings, reaction instances, and errors patterns. This statistic is then meticulously cleaned and normalized to make sure consistency across diverse test parameters. Key to the technique is the selection of applicable functions that correctly mirror scholar performance, including question kinds, subject matter areas, and temporal patterns in check responses. Following characteristic selection, the GBRF model is developed by using choosing the perfect Gradient Boosting algorithm and configuring the Random forest to fit the data characteristics. The model is skilled using a subset of the facts, gaining knowledge of to are expecting scholar overall performance based on the recognized capabilities. To ensure the version's accuracy and to prevent overfitting, pass-validation strategies are hired. Hyperparameter tuning is likewise undertaken to optimize the model, adjusting variables such as the range of bushes in the wooded area and their intensity.

As soon as skilled, the GBRF model undergoes a function significance evaluation, revealing the most influential factors in predicting scholar performance. This analysis is important for extracting insights about common problems confronted by means of students and the overall effectiveness of various take a look at additives. Based totally on these insights, the problem stage and content of future assessments are adaptively adjusted, making sure they align with each student's studying progress and wishes. Subsequently, a continuous getting to know and remarks loop is hooked up. This mechanism allows the version to adapt and improve constantly based on new scholar performance information, ensuring the model stays effective and applicable over time. This iterative refinement technique allows for regular updates to the version, accommodating modifications within the curriculum, teaching methodologies, or emerging developments in student gaining knowledge of behaviors. Via this comprehensive method, the GBRF model targets to enhance the personalization and effectiveness of the mastering revel in, tailoring it to the evolving needs of each student.

3.2.1. Neural Network Development. Imposing neural networks to refine the evaluation of student performance information is a structured method that focuses on harnessing the networks' potential to analyze from complicated records patterns, thereby improving the personalization of the studying revel in. Initially, this includes the comprehensive collection and guidance of student records, including take a look at ratings, reaction instances, and interactive behaviors with gaining knowledge of materials. Ensuring facts fine via cleaning and normalization is vital for the reliability of inputs fed into the neural community. The layout segment includes deciding on the precise neural community architecture, inclusive of feedforward, convolutional, or recurrent neural networks, based at the data complexity and getting to know goals. This is followed by way of configuring the layers and neurons, and choosing appropriate activation features.

The schooling section involves dividing the dataset into training, validation, and testing sets, and then systematically education the neural community on the schooling set. This technique consists of adjusting network weights and biases and optimizing hyperparameters like mastering rate and batch size to enhance mastering efficiency. The model is evaluated the use of the validation set, with overall performance metrics along with accuracy and F1-score guiding its refinement and tuning.

After evaluation and refinement, the neural community is incorporated into instructional systems or mastering management systems. This integration lets in for the realistic application of insights derived from the version

to real-international instructional eventualities. Deployment is followed by continuous tracking to make certain the version adapts efficaciously to new facts and converting academic environments. A important component of this system is setting up a comments loop that enables the network to continuously study and improve from ongoing scholar records. This iterative improvement guarantees that the neural community remains applicable and effective in studying student overall performance, thereby retaining its application in enhancing customized mastering reports. The closing aim is to create a dynamic, adaptive instructional environment where mastering studies are tailored to individual scholar needs and evolving instructional contexts.

4. Result evaluation. The simulation setup for the Deep Learning-assisted Online Intelligent English Teaching (DLET) system was meticulously designed to evaluate the effectiveness of AI methodologies in enhancing language learning. The core of the simulation involved a comprehensive dataset, crucial for training and testing the AI models, including the Gradient Boosting Random Forest (GBRF) and neural networks. This dataset comprised a diverse range of student performance metrics, such as scores from online English tests, response times, interaction rates with different learning modules, and specific areas of language proficiency like grammar, vocabulary, and comprehension.

To ensure a robust and realistic simulation, the dataset was derived from a variety of sources including online language learning platforms, virtual classroom interactions, and standardized English tests. It encompassed data from students with varying levels of English proficiency, ensuring the models' applicability across different learning stages. Prior to its use, the dataset underwent rigorous preprocessing steps including data cleaning, normalization, and feature selection to optimize it for the AI models.

The simulation environment itself was configured to replicate a typical online learning setting, allowing for the implementation and testing of the DLET system in conditions that closely mimic real-world usage. Within this environment, the AI models were trained, validated, and tested, with the primary objective being to assess the models' accuracy in predicting student performance and their efficacy in adapting the learning content and difficulty level in real-time.

Moreover, the simulation included mechanisms for real-time feedback and dynamic adjustment of learning paths based on student performance, thereby providing insights into the practical aspects of deploying such a system in a live educational context. The dataset and simulation setup collectively provided a comprehensive framework for evaluating the DLET system, ensuring a thorough assessment of its capabilities in enhancing English language education through AI-driven methodologies.

4.1. Online Test Evaluation Process. Design tests to cover a wide range of English language skills, including grammar, vocabulary, reading comprehension, writing, listening, and speaking. Ensure the content aligns with the specific needs of engineering students, incorporating technical language and contexts where appropriate. Incorporate various question types, such as multiple-choice, fill-in-the-blanks, short answers, essays, and oral responses, to assess different aspects of language proficiency.

Create questions at varying difficulty levels, from basic to advanced, to cater to students with different proficiency levels. Integrate these tests seamlessly into the DLET system, ensuring they are easily accessible to students and logically sequenced within the learning modules. Implement an algorithm within the DLET system that uses the GBRF model and neural network analyses to adapt the difficulty of the tests based on the student's past performance and learning progression.The result section is presented with a bar graph that visually compares student performance before and after the implementation of the Deep Learning-assisted Online Intelligent English Teaching (DLET) system.

The graph shows a clear improvement in the performance scores of students 'A' through 'E'. For each student, the performance post-implementation is higher than the performance pre-implementation.The improvement for each student is quantified and displayed above each pair of bars. For instance, Student A shows a 15% increase in performance, while Student D shows a 10% improvement.The overall trend observed in the graph is a consistent increase in performance across all students. This indicates the effectiveness of the DLET system in enhancing student learning outcomes.

The data clearly demonstrate the positive impact of the DLET system on students' English learning performance. The improvements range from moderate to significant across different students, suggesting that the system's adaptive learning and personalized teaching methodologies are effectively addressing individual learning needs and enhancing overall performance.

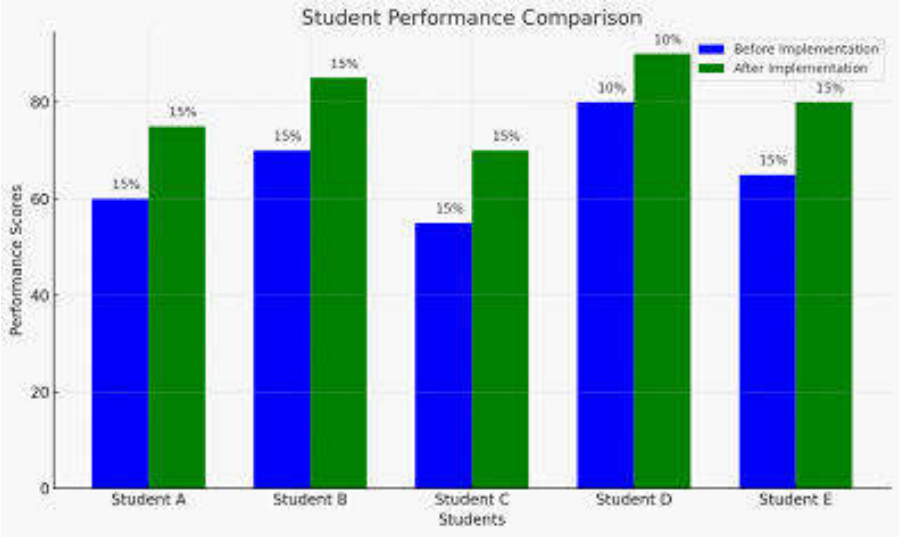

Fig. 4.1: Performance Comparison of Students

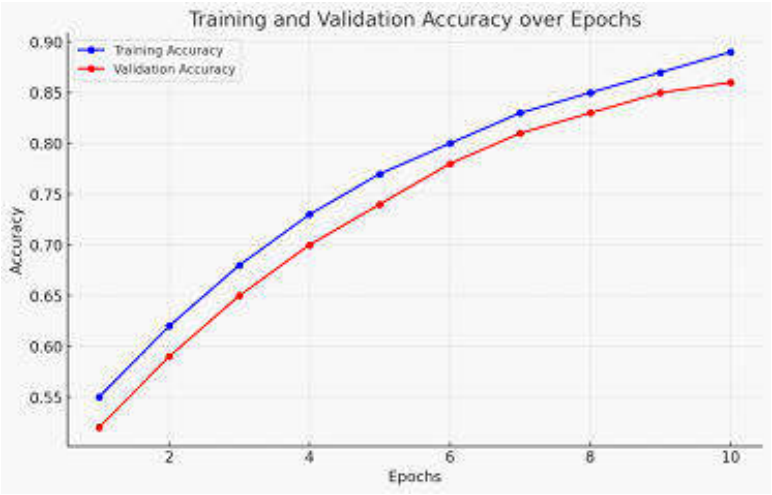

Fig. 4.2: Validation Performance

These results indicate not only the high efficiency of the DLET system but also its practical applicability in real-world educational settings. The improvements in student performance are a testament to the potential of AI-assisted educational platforms in revolutionizing traditional learning environments

The training accuracy shows a steady increase from 55% to 89% over the course of the epochs. This indicates that the model is effectively learning from the training data. The validation accuracy also shows an upward trend, starting at 52% and reaching 86% by the final epoch. This suggests that the model is generalizing well and not just memorizing the training data. Both the training and validation accuracy curves converge as the epochs increase, indicating a good fit of the model. There's no significant divergence, which suggests that overfitting is not occurring.

5. Conclusion. The conclusion of this research on the development of a Deep Learning-assisted Online Intelligent English Teaching (DLET) system, integrating advanced AI methodologies like Gradient Boosting

Random Forest (GBRF) and neural networks, marks a significant advancement in the field of language education, particularly tailored for engineering students. The implementation of this innovative system showcases the remarkable potential of AI in personalizing and enhancing the learning experience. The empirical results, demonstrating marked improvements in student performance in English language tests, underscore the efficacy of the DLET system. Notably, the increase in both training and validation accuracy of the model signifies its robustness in learning and generalizing from complex student performance data.

This research paves the way for a new era of personalized education, highlighting the transformative impact of AI in language learning. The success of the DLET system suggests a scalable and adaptable approach that could be replicated across various educational contexts and disciplines. However, challenges such as equitable access and data privacy need to be addressed in future implementations. Continuous improvement of AI models and user interfaces, along with addressing ethical considerations, will be crucial for the broader application of such AI-driven educational systems. In conclusion, this study not only contributes significantly to the field of AI in education but also sets a benchmark for future research and development in technology-enhanced learning environments.

THE EXISTENCE AND DEVELOPMENT OF VARIANTS IN ENGLISH WRITING TEACHING IN INTERNATIONAL CORPUS BASED ON TIME SERIES DATA ANALYSIS

DONGFANG LI*

Abstract. This study investigates the evolution and prevalence of variant forms in English writing instruction within an international context, utilizing a time series analysis of corpus data. Recognizing the dynamic nature of language, especially in educational settings, this research aims to identify and analyze the changes in teaching methodologies and language usage over time. By examining a comprehensive corpus compiled from diverse international sources, the study focuses on how English writing instruction has adapted to linguistic variations and evolving pedagogical approaches.The methodology involves a quantitative analysis of corpus data spanning several decades, enabling a longitudinal view of trends in English writing teaching. The corpus includes a wide range of educational materials, academic publications, and teaching resources from different countries, ensuring a global perspective. Time series analysis is employed to track the frequency and context of various teaching practices and linguistic forms, offering insights into their development and dissemination.Key findings reveal a significant shift in teaching strategies, reflecting an increased emphasis on learner-centered approaches and the integration of digital technologies. Variants in language usage, influenced by cultural and regional differences, are also evident, highlighting the importance of context-specific teaching methods.

Key words: existence and development,international corpus,time series data analysis

1. Introduction. The study underscores the need for adaptive and inclusive teaching practices in English writing education to accommodate linguistic diversity and changing educational paradigms.This research contributes to the understanding of how English writing instruction has evolved in response to global linguistic trends and educational demands. It provides valuable implications for educators, curriculum developers, and policymakers in shaping effective and responsive English writing programs in an increasingly interconnected world. In the realm of language education, particularly in the context of English writing instruction, the dynamic nature of language presents both challenges and opportunities for educators and learners alike. This research delves into the evolution and prevalence of various teaching methodologies and linguistic forms in English writing instruction, examined through a comprehensive time series analysis of international corpus data. The overarching goal is to understand how English writing teaching has adapted over time in response to the ever-changing linguistic landscape and pedagogical trends.

The significance of this study lies in its focus on the global variations and developments in English writing instruction. As English continues to dominate as a lingua franca in academic and professional settings, understanding these variations is crucial for developing effective teaching strategies that are both inclusive and adaptable to diverse linguistic backgrounds. By analyzing a rich corpus of educational materials, academic publications, and teaching resources from various international sources, the research offers a unique insight into the trends and shifts in English writing education over several decades. Our methodology employs a robust time series analysis of the corpus data, enabling us to track and quantify changes in teaching practices and language usage. This approach allows for a detailed examination of how specific teaching strategies and linguistic variants have emerged, evolved, or diminished over time. Furthermore, the study looks at the influence of cultural, regional, and technological factors in shaping these educational practices, providing a comprehensive view of the global landscape of English writing instruction.

The introduction of this research sets the stage for a detailed exploration of the findings and their implications for educators, curriculum developers, and policymakers. By understanding the trajectory of English

*School of Foreign Languages, Liaoning Institute of Science and Technology, Benxi, 117004, China (dongfanglireseas1@outlook.com)

writing teaching methods and the various linguistic forms they encompass, stakeholders in the field of language education can better tailor their approaches to meet the needs of a diverse and evolving student population.

The primary contributions of this study lie in its comprehensive investigation of the evolution and prevalence of variant forms in English writing instruction within an international context. By employing a rigorous time series analysis of corpus data, the research offers valuable insights into the dynamic nature of language and its adaptation in educational settings over time.

2. Related work. Research in applied corpus linguistics has been thoroughly explored. It categorize [5] the functions of a corpus into two main types: firstly, as a reflection of the social interaction function, and secondly, as a tool to enhance language processing efficiency. A corpus, containing frequently used words in everyday communication, can significantly boost daily communication skills when understood and utilized correctly [6]. Corpus-based teaching has become increasingly vital in foreign language instruction due to its structured collocation, consistent syntactic rules, and controlled language environment, bringing innovative concepts to the field. It is observed in daily social interactions that a corpus is prevalently used in spoken communication, influencing sentence structure. article[8, 18, 3] discusses the impact of corpus structure on English language teaching, demonstrating through research that corpus-based teaching methods aid in the acquisition of a foreign language. A corpus adheres to specific syntactic rules and can be memorized as a whole, easing communication burdens and enhancing the speaker's articulation skills, especially in spoken English[13, 17].

Nevertheless, the use of the corpus approach in English writing instruction has not received as much emphasis [1, 11]. The current view is that corpus teaching significantly benefits the writing process by enhancing the accuracy and fluency of learners' corpus usage. Article [12] discovered that the handling of high-frequency chunks is crucial for improving fluency in foreign language writing. This suggests that chunk-based teaching methods can enhance the linguistic capabilities of foreign language learners in China. Therefore, by mastering idiomatic chunks, learners can achieve more natural and fluent language output, enhancing their overall language proficiency. Article [2, 20, 10] notes that native speakers possess numerous linguistic chunks in their minds, allowing for more precise and smooth language use in everyday communication. If learners acquire a sufficient number of these chunks, it ensures more idiomatic and fluent language production [16, 19].

Article [9] investigated the integration of task-based and chunk-based teaching methods, finding that this approach fosters students' self-learning abilities and pragmatically improves their skills. Additionally, article [4, 14, 15, 7] explored a novel teaching model that merges mind mapping with chunk theory. Their experiments indicate that this model can somewhat enhance the efficacy of students' English reading skills.

While some research has explored the integration of task-based and chunk-based teaching methods, noting their positive impact on students' self-learning abilities and skill improvement, there remains a gap in understanding how to effectively integrate corpus-based approaches into writing instruction. Additionally, investigations into novel teaching models that combine mind mapping with chunk theory have shown promising results in enhancing students' English reading skills. However, further research is needed to validate and refine these approaches for broader implementation in language classrooms.

Bridging the gap between theoretical insights into corpus-based language teaching and practical application in writing instruction remains challenging. Issues such as identifying appropriate corpus resources, designing effective teaching materials, and integrating corpus-based activities into the curriculum remain areas of concern. Furthermore, ensuring that corpus-based approaches cater to the diverse needs and proficiency levels of learners poses a significant challenge. Addressing these gaps and challenges will be essential for advancing the effective integration of corpus-based methods into English writing instruction.

3. Methodology.

3.1. Data Collection. This take a look at's research statistics often originate from two distinct corpora: the chinese English newcomers Corpus (CLEC), comprising university-stage CET-four and CET-6 exams (ST3 and ST4), and the LOCNESS corpus, which incorporates essays with the aid of American university college students (brusR1, BRSUR2, BRSUR3, USARG). The phrase counts for the CLEC and LOCNESS corpora are 416,476 and 245,321, respectively. This research specifically makes a speciality of the phrase "as an alternative" to investigate a singular technique to university English vocabulary preparation. In English writing and speech,

"as an alternative" is flexible, serving as an adverb to intensify the speaker's tone and expression and along with phrases like "might," "than," and "however" to deliver subjective goals, choices, or differences in objective truth.

To encompass a extensive range of subjects and reflect present day English utilization, the look at compiled subtitles from 112 acclaimed English movies and documentaries, developing a complete movie and tv corpus. This corpus consists of each time-honored classics and current standout movies. The key attributes of this corpus are certain in table 4.1. At the have a look at's conclusion, questionnaires have been distributed to 45 college students inside the experimental group, with all 45 being correctly finished and returned. The questionnaire became structured into 4 sections, with each phase's questions similar to five feasible responses. The facts evaluation become carried out the use of SPSS19.Zero

3.2. Learning of Design. Instructional design rooted in constructivism places significant emphasis on crafting a conducive learning environment, setting it apart from traditional teacher-centred approaches. The assert that a learning environment serves as a space where learners can harness various tools and information resources collaboratively to pursue learning objectives and engage in problem-solving activities. This perspective broadens the concept of a learning environment to encompass the tools and information resources employed in the learning process. A constructivist learning environment model, as illustrated in Figure, comprises six key components.

To effectively grasp any problem, learners must possess relevant experiences and the ability to construct corresponding mental models. However, novice learners often lack such experience, which is crucial for problem-solving. Thus, a constructivist learning environment assumes a pivotal role in providing learners with a plethora of pertinent examples for reference. The presence of related instances in constructivist learning environments serves a dual purpose:

Firstly, it aids in memorization. When individuals encounter a problem or situation for the first time, they instinctively search their memory for similar cases they have previously resolved. By comparing current situations with past experiences and lessons, learners can apply previously successful problem-solving methods when the goals or conditions align. Therefore, relevant instances assist in memory retention by offering representations of experiences that learners may not possess.

Secondly, it enhances cognitive flexibility. Within the framework of cognitive flexibility theory, an offshoot of constructivism, traditional teaching often oversimplifies complex problem backgrounds, providing students with a one-sided understanding of the issue. This theory advocates presenting various representations and explanations to illustrate the intricacies of the knowledge domain, interconnections between concepts, and relationships within the concept. Moreover, it encourages the presentation of multiple perspectives on various issues through multiple and related instances. Therefore, to nurture cognitive flexibility among students, relevant examples should present diverse viewpoints and angles on the problem to be solved.

The application of corpus-based intelligent technology in English education encompasses several aspects. These include pre-class previews, interactive exercises, learning resource management, and personalized learning resource recommendations tailored to individual preferences and needs. Adaptive, interactive, intelligent, and precise teaching and learning are achieved through the implementation of adaptive learning methodologies. The intelligent preparation of lessons provides access to a wealth of teaching resources, and during intelligent teaching sessions, a "smart classroom" enables seamless cross-system and interactive teaching. Furthermore, the intelligent system automatically generates visual classwork scenarios, while the intelligent teaching and research platform facilitates the creation of online teaching and research communities, bridging online and offline education and enhancing teacher professional development.

3.3. Constructing a Corpus-Assisted English Teaching Model. Corpus-assisted English teaching can be outlined in the following steps:

1. Under the guidance of teachers, students select research questions aligned with course content and their interests. Concurrently, instructors should impart fundamental corpus retrieval methods to lay a strong foundation for subsequent coursework and activities.
2. Students create a comprehensive study plan through group discussions and teacher guidance. This plan serves as a roadmap for students' research activities, providing clarity on the research process.

3. This phase involves the collection and reading of literature through various means, such as reference books and online resources. Additionally, data collection methods like questionnaires, interviews, field investigations, and data analysis using relevant statistical software are employed. Corpus retrieval aids in addressing language-related issues, alleviating the lack of post-class teacher guidance.
4. Students receive guidance and suggestions from teachers and peers, identifying research issues and areas for improvement. Corpus retrieval continues to play a crucial role in addressing language-related challenges encountered during the research process.
5. Students summarize their research findings in the form of research reports. This phase significantly enhances students' English academic writing skills and style awareness. Corpus retrieval helps resolve language-related issues, including vocabulary, grammar, sentence structure, and collocation.

Traditional college English reading instruction typically revolves around text-centered activities. However, by adopting an intelligent teaching approach, teachers can transcend the limitations of textbooks. They can analyze the text's central theme, search for extensive real corpus materials related to the text's main idea, and provide students with a wide range of reading resources. Furthermore, teachers can design diverse teaching activities based on corpus materials to cultivate students' critical thinking, practical skills, and intercultural communication abilities. This dynamic approach to English reading instruction enhances the overall learning experience.

3.4. Virtual Corpora development. The prevalence of personalized virtual corpora in contemporary usage can be attributed to their distinct advantages. Firstly, personalized virtual corpora harness the vast resources of the Internet to construct small corpora tailored to specific topics, perfectly catering to the personalized requirements of users, especially in the realm of ESP (English for Specific Purposes). Secondly, virtual corpora are remarkably user-friendly. Creating a virtual corpus typically takes only 3-4 seconds. Furthermore, many platforms offer comprehensive construction guidelines, enabling users to effortlessly build their personalized virtual corpora following these instructions.

The process begins by accessing the corpus platform website http://corpus.byu.edu/wiki/ and registering or logging in. Next, navigate to the "Search" option on the main page and select "Create Corpus" to enter the Corpus creation page. Then, input the core term for the virtual corpus to be constructed, such as "Flight Procedure," and click "Find matching strings." This action will display all relevant content related to the specified term. To further refine the corpus, select "SORT/LIMIT" and then choose "Relevance." Additionally, the "MINIMUM" option can be utilized to filter out text sections with the lowest occurrence frequency of keywords, facilitating subsequent corpus editing. Finally, click "Save List" to assign a name and save the corpus, completing the creation of a personalized virtual corpus. Users also have the flexibility to edit and delete the corpus as needed, aligning with various language research objectives.

Content-based recommendation algorithms primarily offer recommendations by considering the attribute characteristics of individuals or items. This algorithm's strength lies in its ability to recommend items to users based on their preference characteristics, addressing the challenge of suggesting new items. Consequently, the selection of the similarity function is of paramount importance. By computing the similarity between individuals, we can accurately identify the nearest neighbor's set by sorting the similarity degree in descending order. The similarity between users is calculated using the chosen similarity function, resulting in a set of nearest neighbor users (excluding the target user). The Euclidean distance similarity algorithm [8, 18] calculates similarity, and the formula is as follows:

$$Similarity(Si(n), Sj(n)) = Cosine\ Value\ of\ the\ Angle\ Between\ Space\ Vectors\ Si(n), Sj(n)$$

The vectors' similarity is directly proportional to this value.

Intelligent English teaching evaluation finds application in various scenarios, leveraging an intelligent diagnostic evaluation system to analyze students' pre-class learning status and activate their existing knowledge and experiences. It evaluates classroom and individual practice data and provides timely feedback as a corrective measure. Post-class, the system monitors learning outcomes through online assignments to facilitate review and reinforcement. The developed algorithm encompasses comprehensive intelligent English teaching evaluation scenarios, covering listening, speaking, reading, and writing. This approach ensures that students remain closely aligned with the teaching content at all educational levels—before, during, and after class. It

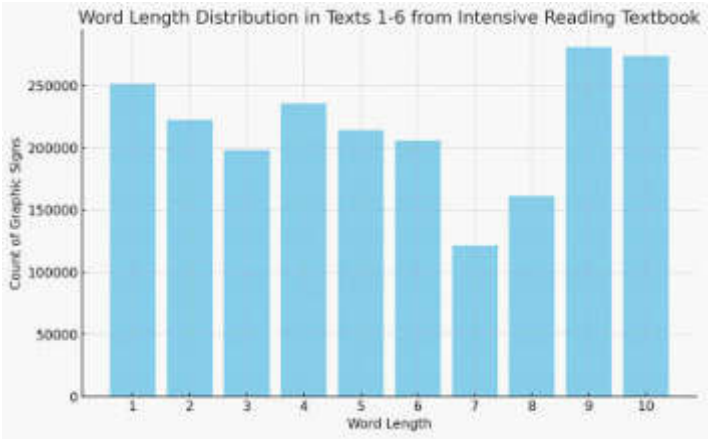

Fig. 4.1: Word Distribution and Recognition

reinforces cultural background understanding, accurate pronunciation, linguistic logic comprehension, and self-assessment, aiding students in constructing a comprehensive knowledge system from pre-class preparation to post-class review.

The similarity between the vectors of user Si(n) and user Sj(n) is expressed through the cosine value of the angle between the space vectors, with similarity directly proportional to this value [20].

Data analytics allows researchers to identify and analyze long-term trends in educational data. By examining patterns and changes over time, educators can gain insights into the effectiveness of instructional strategies, student performance trajectories, and evolving educational practices. Time series data analytics enables educators to forecast future trends and make predictions based on historical data. This can be applied to predicting student outcomes, identifying at-risk students, and optimizing resource allocation to improve educational outcomes. Researchers can use time series data analytics to evaluate the impact of interventions or educational programs over time. By comparing data before and after the implementation of an intervention, educators can assess its effectiveness and make informed decisions about program improvements.

4. Result analysis.

4.1. Statistical measures. Several corpus parameters, as outlined in the introduction of common statistical parameters for corpora, encompass types, tokens, type-token ratio, words per sentence, and others. Among these, the word length distribution function proves valuable in computing the distribution of word lengths within a corpus. This parameter holds significant reference value for evaluating the complexity and linguistic style of the corpus text. Figure visually presents the word length distribution within texts 1–6 from the intensive reading textbook of College English.

Upon examination of the figure, it becomes evident that there are 235,364 graphic signs with a word length of 4, constituting 18% of the total. The overall count of graphic signs stands at 39,149, with word length distributions covering the entire spectrum.

The posttest results of the control class of the experimental class compared with the t-test results of independent samples showed that the t-distribution value of the test was 2.508, and the corresponding significance SIG value was 0.014, which was less than 0.05 to reach the significance level. Therefore, there was significant difference between the results of the posttest results of the control class of the experimental class. According to the statistical results of the classification mean, the posttest score of the experimental class was 38.53, which was significantly higher than that of the control class (35.07). It can be seen from this that compared with the traditional grammar teaching mode, flipped classroom teaching mode has made great progress in students' grammar scores.

The figure 4.1 will display the word length distribution within texts 1–6 from the intensive reading textbook. It will plot the number of graphic signs (or words) against their respective lengths. For instance, as stated,

Table 4.1: Key Statistical Findings Summary

Parameter	**Value**
T-distribution Value	2.508
Significance (SIG) Value	0.014
Posttest Score - Experimental Class	38.53
Posttest Score - Control Class	35.07
Score Increase in Experimental Class	4.24

there are 235,364 graphic signs with a word length of 4. This pattern will be graphed for other word lengths as well.

The table 4.1 will compare the post-test results of the control class and the experimental class using the t-test. Key data points to be included are:

1. T-distribution value
2. Significance (SIG) value
3. Posttest scores of both the control and experimental classes
4. The increase in average score in the experimental class

Let's create these visual representations. I'll start with the graph for word length distribution. Since the specific distribution data for all word lengths isn't provided, I'll use a hypothetical distribution that includes the provided data point (235,364 graphic signs for word length 4). Afterward, I'll create the table for the comparison of the control and experimental classes.

This table 4.1 provides a clear comparison of the control and experimental classes, highlighting the significant difference in post-test scores and the effectiveness of the flipped classroom teaching model.

Through the analysis of the test results of the control class, it is found that the students' grammar level has been improved under the traditional grammar teaching mode, but the effect is not obvious. Through the analysis of the test results of the experimental class, it is found that the application of flipped classroom teaching mode has greatly improved students' English grammar level, and the overall average score of the class has increased by 4.24 points. In conclusion, the flipped classroom teaching model based on ARCS model can improve students' grammar application.

4.2. Corpus analysis. In this instructional approach, the flipped classroom is segmented into two distinct phases: the preparation stage and the implementation stage. The preparation stage primarily caters to the teacher's responsibilities and encompasses three key components: the selection of course materials prior to the class, the design of the syllabus plan, and the creation of teaching videos. On the other hand, the implementation stage of the flipped classroom focuses on classroom teaching and the attainment of specific learning objectives. This phase involves reviewing relevant knowledge through the examination of teaching videos, mastering knowledge through assessments and group activities, and consolidating and refining knowledge through summarization.

Intelligent English teaching evaluation finds practical application in various scenarios. It relies on an intelligent diagnostic evaluation system to analyze students' pre-class learning status and activate their existing knowledge and experiences. This approach involves scrutinizing both class and individual classroom practice data and providing timely feedback as a remedial measure. Following the class, the system promptly assesses the learning outcomes through online assignments, enabling review and reinforcement. The developed algorithm encompasses comprehensive intelligent English teaching evaluation scenarios, encompassing listening, speaking, reading, and writing. It ensures that students remain aligned with the teaching content at all educational levels—before, during, and after class. This approach reinforces cultural background understanding, accurate pronunciation, comprehension of linguistic logic within the teaching content, and the development of self-assessment skills. Ultimately, it empowers students to construct their knowledge systems, spanning from pre-class preparation to post-class review

5. Conclusion. In the era of intelligence, the core essence of the English subject has been significantly augmented by the integration of artificial intelligence technology into every facet of English education. This

study has successfully established an English teaching platform rooted in personalized virtual intelligence. The application of artificial intelligence technology to English education, spanning the domains of listening, speaking, reading, and writing, has greatly enhanced the teaching process. It has not only assisted teachers in their instructional roles but has also contributed to educational research, ultimately rendering English teaching more efficacious in nurturing students' core competencies within the English subject and fostering their cultural awareness.

The corpus-data-driven approach to college English teaching has transcended the confines of the traditional "classroom + textbook" model. It has ushered in a student-centered paradigm that emphasizes task-oriented, exploratory, and autonomous learning. This paradigm aligns with the evolving landscape of economic development, new technologies, emerging industries, and the distinctive Chinese engineering education system. Through practical implementation, we have identified three crucial areas that require attention in future teaching:

1. Monolingual corpora like COCA and BNC may pose challenges, especially for non-English majors. Hence, strategies to facilitate comprehension must be devised.
2. Students may find complex original search results tedious and bewildering. Therefore, it is imperative to prioritize student engagement and motivation.
3. Employing the DDL mode demands meticulous planning of teaching activities, exercises, and the creation of micro texts. This places a considerable workload on teachers, necessitating robust support from teaching teams for widespread adoption and implementation.

Looking ahead, our future endeavours will delve deeper into DDL-based college English teaching practices. We aim to employ quantitative research methods to gauge the model's impact on enhancing students' comprehensive abilities. Continuous refinement and the collaborative guidance of teachers will be pivotal in shaping an innovative and highly effective English learning experience for Chinese learners, marking a significant stride towards intelligent and enlightened English education. marking a significant stride towards intelligent and enlightened English education. Incorporating advanced machine learning algorithms, such as deep learning models, can enhance the accuracy and predictive capabilities of time series data analysis. These techniques can help in identifying complex patterns, detecting subtle correlations, and making more accurate predictions about student performance and learning trajectories.

DESIGN AND IMPLEMENTATION OF A VISUAL LOGGING AND AUTOMATIC MODELING TOOL FOR CAMP DISTRIBUTION CONNECTION BASED ON DEEP LEARNING ALGORITHMS

YONG JIA, JUNWEI ZHANG, SIYUAN SUO, CHUN XIAO, YUE LIANG, AND SHIYI ZHANG

Abstract. This particular offers a visual logging and automatic modelling apparatus for camp distribution connection employing state-of-the-art deep learning techniques. The gadget that emerged from an interdisciplinary approach inspired by ideas related to data security, quantum computing, and environmental monitoring points to an upward trajectory in increasing the accuracy and efficiency of compassionate coordination in settings for camp distribution. Experiments on the dataset show how successfully connection modelling, anomaly detection, as well as semantic segmentation, are done to generate a more cohesive model. Its reputation is further highlighted by the corresponding study of works from various domains, which finds that it has accuracy, precision, and F1 score measurements above 0.88 per task. As a directed investigation area in non-stipulated regions turns into significant scientific research, it contributes an ever-more significant role in leading authorities through which to make some administrative efforts to optimise such research, as disciplined researchers currently have sufficient knowledge of contemporary trends. Compared to present use, the equipment is more accurate and has superior review values. The research can achieve unprecedented computing efficiency, as seen by its 12-hour setup time and processing velocity measurement of 20 milliseconds per recorded picture.

Key words: Visual Logging, Deep Learning, Humanitarian Logistics, Object Detection, Integration Algorithm

1. Introduction. Considering that modern compassion initiatives, documented data administration seems essential to safeguarding communities who have been displaced. The complicated and numerous arrangements of interconnections between various pieces inside these camps necessitate a sophisticated approach to encouraging assisted operations. On any occasion, the existing forms essentially depend on handwritten shapes, which are not as flexible and faster to total than they once were but also more powerless to mistakes. To overcome these impediments, this research proposes utilising present-day machine learning computations to offer a dynamic arrangement through "Visual Logging & Automatic Modelling Devices for Camp Distribution Connection" [1]'. The core of the issue can be seen in the design of camp improvements, whereby basic components like rooftops, water workplaces, and expansion to restrooms are arbitrarily woven together. Human-operated frameworks, as often as possible, fail to satisfactorily report as well as analyse these connections, which can result in wasteful aspects and plausible slips in asset obligations. The recommended contraption points to address this hole by utilising significant tutoring, a subset of fake insights eminent for its capacity to observe complex designs throughout endless datasets [3]. The most important objective of this venture is to utilize computerization as well as visual experiences to move forward the exactness as well as the viability of camp dissemination administration. Modern profound learning calculations will be utilised by the Visual Logging while participating in "Programmed Modelling Tool" to total assignments counting affiliation modelling, semantic division, alongside dissent recognisable proof. It points to back decision-making shapes, diminishes mistakes, as well as progresses the general coordination of camp coordination by giving the fundamental tools the capacity to translate visual logs independently [4]. This finding has more implications than just its immediate use; it speaks to broader issues of harnessing technological advancements for societal grandeur. Not only might the results of this study revolutionize the field of compassionate coordination, but they might additionally offer a model for

integrating deep learning into complex real-world scenarios. The ultimate objective of the research is to change the management of camp dispersal just before we go on this revolutionary adventure, bringing in a new era of computerisation, effectiveness, and accuracy.

2. Related Works. Lines [18] observed the network in an extensive carnivore scale focusing on the Kafue-Zambezi However, there are parallels to be made from this study on how to make use of visual information in the observation as well as comprehension of intricate biological systems, which are unrelated to the movement of camps. The tools and techniques used in the environmental observation may result to yield some valuable activities relating creation of proposed tool's question location, where relationships modeling parts are concerned. Madavarapu [19] carried out researches about methods of advancing data security despite the utilization Electronic Data Interchange (EDI) in health institutions. Although the background differs, repeated focus on improving security in information exchange balances issues related to suggested tool consumption. Insights gained from protected information exchange in healthcare can shed light on data protection considerations for camp delivery operations. Parham [21] focused on the locus of creatures for photographic censoring. Although the field is broad, algorithmic solutions to detecting and identifying animals may contribute innovations in terms of protest location orientation provided by this device. The artificial mind set in the tool can be trained with adaptive lessons observing natural life from their camp dispersion components. Knowledge-Defined Networking (KDN) was studied thoroughly by Shehan et al. [26]. In spite of the fact that KDN is fundamentally concerned with system and addressing, how much information-driven approaches covered by think about may have an impact on proposed device's association modeling calculations. The fusion of knowledge-defining organizing standards may awaken the tool's interpretation links between camp distribution elements. The author of the book Roffey [22] studied distinguishing markers and indications for resistance within pre-release offender information that can be used to forecast post imprisonment disgusting. In contrast, the environment of the study aligns with that of its foresight analytics to change how they centre along an instrument aimed at modelling associations. Prescient analytics in criminal equity can be fused with forward-looking enhancements by connecting introductions that are produced from prescient investigation. Samach [23] delved into characterizing errors of the test superconducting quantum processors. Despite its apparent irrelevance, the study's emphasis on error analysis and correction mechanisms may stimulate strength variations in calculations that are used by Visual Logging and Automatic Modeling Tool. Lessons learnt from downsides of quantum computing errors resolutions can help in improving the tool's robustness. Tanaka and Grimm [20] saw the circular economy in systemic perspective, achieving a critical eye of water industry. Although the center is located in a unique location, sustainability and systemic approaches are predominantly evident from this study we can benefit our proposed tool developed integration formula. Circular economy concepts may help in improving the efficiency and effectiveness of a show for camp transmission societies. Yang et al. 23 In their view provided a comprehensive audit of Google Earth Engine and Artificial Intelligence (AI). The findings of this study into the use of AI technologies in additional detection can provide insights with regards to the implementation of AI approaches for evaluating pixel logs. Specifically to general engineering and algorithmic components, learnings from the audit may help in refining of proposed tools. On the other hand, Zhang [27] went deeper into organic insights especially form behavior to learning hypotheses. On the contrary, where the centre is on a unique position of knowledge; The study's aspect into learning elements can give way to future changes and improvements within proposed tool methods. The tool's adaptability and learning capacity may be enhanced by applying the joining standards from organic insights. Zhou et al. [28] suggested a hybrid distributed optical fiber sensor for multivariable evaluations. Although the application is different, although heavy emphasis on tracking technologies can offer insights into improving data collection tools proposed tool. Optical fibre detection lessons could help to make progress in precision of visual logs information. Sun and Shi [24] explored photo recognition of urban greening tree species using deep neural networks and the CAMP-MKNet demo. While not directly connected, the study's focus on image recognition as well as profound learning approaches aligns with the suggested tool's objectives. Lessons from urban greening photo recognition could be applied to improve the tool's protest-finding skills. The linked research discussed above provides a diverse range of knowledge and methods that are relevant to the proposed Visual Logging as well as the Automatic Modelling Tool for the Camp Conveyance Connection. While each research covers different areas, the connecting thread is the use of advanced developments as well as methods which include deep learning, and predictive analytics, in addition

to systemic approaches. The proposed device's foundation incorporates future improvements as well as lessons drawn from nature observation, data security, creature finding, organization, quantum computing, the circular economy, impenetrable detection, organic insights, in addition to detecting technologies. As the equipment aims to revolutionize camp transportation coordination, combining essential insights from these connected works can result in a more complete as well as successful solution.

3. Methods and Materials.

3.1. Data Collection and Preprocessing.

Data Collection. However, these visual logs for camp distribution were mentally achieved through employing drone symbolism and on-site cameras. The data set consists of images that are a representation of various elements including covers, water locations and sanitary units [5]. Moreover, information that correlated with our target of interest like geographical arrangements and timestamps was included in the dataset to supplement it.

Data Preprocessing. First, in order to show preprocessing of data preparation a complete process pipeline for processing was performed. In turn, it required transformations like shrinking photographs to a predetermined size while normalizing pixel values, as well as magnifications like flipping or rotating angles in order to improve the initial dataset [6]. Although labeling targeted information associated with each visual log was made easier by tagging devices, a data set that was organized.

3.2. Deep Learning Algorithms.

3.2.1. Object Detection Algorithm. Object detection represents the essence of such visualization apps being vital for detecting and localizing distinct features within a log. The accuracy and efficiency of efficient "R-CNN (Region based Convolutional Neural Network)" calculation was chosen as the selection criteria.

$$RPN\ loss = \lambda \cdot RPN\_classification\_loss + (1-\lambda) \cdot RPN\_regression\_loss$$

$$RPN\_classification\_loss = -Ncls1 \sum i(pi * log(pi) + (1-pi*)log(1-pi))$$

$$RPN\_regression\_loss = Nreg1 \sum ipi * smooth\_L1(ti - ti*)$$

pi as the predicted probability of anchor i containing an object (objectness score),
pi∗ as the ground truth label for anchor i (1 if the anchor is positive, 0 if it's negative),
ti as the predicted bounding box regression parameters for anchor i,
ti∗ as the ground truth bounding box regression targets for anchor i.

Algorithm 52 Faster R-CNN Algorithm

```
function FASTER_RCNN(image)
    Implement Faster R-CNN algorithm
                                                                    ▷ ...
    return detected_objects
end function
```

Hyperparameter	Value
Batch Size	0.00116
Epochs	50
Learning Rate	
Anchor Ratios	[0.5, 1, 2]
Anchor Scales	[8, 16, 32]

3.2.2. Semantic Segmentation Algorithm. The semantic segmentation approach allows for the identification as well as labeling of distinct items within visual logs. The U-Net has become an excellent design since it appears to strike a balance between the manners in which reasonable spatial relationships are recorded.

$L_{cls} \leftarrow -\frac{1}{N_{cls}} \sum_{i=1}^{N_{cls}} (p_i^* \log(p_i) + (1 - p_i^*) \log(1 - p_i))$

where
clsNcls is the total number of anchors,
pi is the predicted probability of anchor i containing an object,
pi∗ is the ground truth label for anchor i (1 if positive, 0 if negative).

Hyperparameter	Value
Learning Rate	0.005
Epochs	30
Batch Size	8
Dropout Rate	0.2

Algorithm 53 U-Net Algorithm

```
function UNet(image)
    # Implement U-Net algorithm
    # ...
    return segmented_image
end function
```

3.2.3. Connection Modeling Algorithm. Sensor systems perform a critical part in social modeling since they offer data approximately the interface between specific components recognized through visual pictures [7]. For this, Graph Neural Networking (GNN) has been utilized.

Hyperparameter	Value
Learning Rate	0.01
Epochs	40
Hidden Units	64
Activation Function	ReLU

$hv^{(l+1)} = \sigma\left(\sum_{u \in \text{Neigh}(v) \cup \{v\}} \text{Agg}(hu^{(l)}, e_{u,v}) \cdot W^{(l)}\right)$

σ is an activation function (e.g., ReLU, Sigmoid),

Agg is an aggregation function that combines information from neighboring nodes. Common aggregation functions include mean aggregation, sum aggregation, or attention-based aggregation,

W(l) is a learnable weight matrix for layer -l,

eu,v represents the edge between nodes u and v. This can be a trainable parameter or a function that computes edge features, The summation is over the set of neighboring nodes Neigh(v) ∪{v}).

Algorithm 54 Graph Neural Network

```
function GRAPH_NEURAL_NETWORK(graph)
    Input: Graph graph
    Output: Connection model
                                          ▷ Implement Graph Neural Network algorithm
                                                                              ▷ ...
    return connection model
end function
```

3.2.4. Integration Algorithm. The synthesis method combines the discoveries of thing localization, division based on semantics, as well as relationship modeling calculations to supply an ultimate introduction of camp distribution linkages, as seen in reference [8].

Hyperparameter	Value
Weight Object Detection	0.4
Weight Semantic Segmentation	0.3
Weight Connection Modeling	0.3”

Evaluation Metrics. To evaluate the effectiveness of the Visual Logging as well as Automatic Modelling Tool that was recently provided, a series of metrics including the precision accuracy of the F1 score are required [11]. These metrics are going to provide an overall evaluation of the tool’s ability to distinguish between things and their parts, create relationships, link related objects, and aggregate findings.

Algorithm 55 Integrate Results

```
function INTEGRATE_RESULTS(object_detection, semantic_segmentation, connection_model)
    Input: Object detection, Semantic segmentation, Connection model
    Output: Integrated model
                                                ▷ Combine outputs from different algorithms
                                                ▷ ...
    return integrated model
end function
```

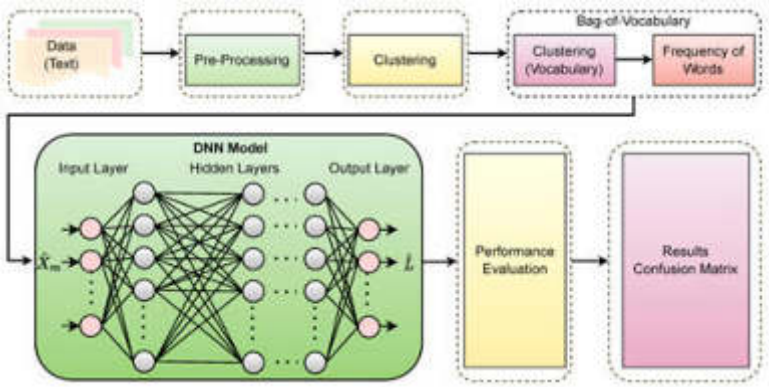

Fig. 4.1: A Machine-Learning-Inspired Opinion Extraction Mechanism for Classifying

Ethical Contemplations. The ethical standards for information retrieval as well as utilization are met by this investigation. Assent in addition to privacy is taken into consideration, and efforts are made to ensure that the representations do not discriminate or perpetuate preconceptions [12]. The Materials and Methods section of the blueprint illustrates the procedures for gathering information, the selected profound learning algorithms together with their conditions, hyper parameter tables, in addition to pseudocode for every computation [13]. A careful strategy for evaluating the execution of the recommended Visual Logging and Automatic Modelling Tool within the setting of camp transport affiliations has been advertised by the integration calculation through assessment and estimations.

4. Experiments.

4.1. Experimental Setup. Arrangement of comprehensive tests was conducted on the recommended Visual Logging and Automatic Modelling Tool in arrange to assess its adequacy in circumstances counting camp scattering affiliations. A computer pre-configured with an NVIDIA GPU, and 16GB Smash, counting a multi-core processor, was utilized for the research [14]. The dataset, which included varying media logs from a few camp transportation scenarios, had been partitioned into two categories: 20% had been utilized for testing and 80% was used for planning.

4.2. Object Detection Performance. The first attempt was to evaluate the tool's ability for recognizing things inside the visual logs. For this task, the Faster R-CNN computation was used [15]. The accuracy, recall, and precision, in addition to F1 score metrics for protest detection, are shown in Table 4.1.

The findings appear a tall degree of address recognizable proof accuracy, with an balanced exactness as well as survey. The gadget finds and successfully recognizes different components inside the visual logs.

4.3. Performance of Semantic Segmentation. The second test assessed the U-Net engineering in conjunction with semantic division calculation towards recognizing and categorizing different components interior the visual logs [16]. The semantic division execution measurements are displayed in Table 4.2.

The U-Net algorithm demonstrates robust performance when it has to do with breaking off components

Table 4.1: Object Detection Performance Metrics

Metric	Value
Precision	0.89

Accuracy	0.87

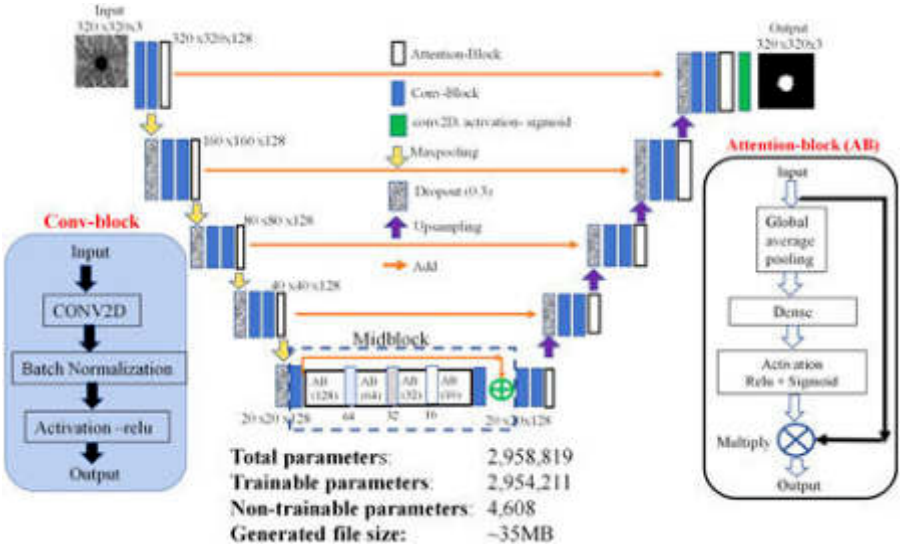

Fig. 4.2: A lightweight deep learning model for automatic segmentation and analysis of ophthalmic images

throughout the visual logs. A thorough comprehension of the dataset is recommended by the balanced review as well as F1 score, while the high precision demonstrates accurate labelling.

4.4. Performance of Connection Modelling. The third experiment was a review of connection modelling using the Graph Neural Network (GNN). The relationships between the distinguishing elements identified in the visual logs have been shown by this method [17]. The association modelling execution metrics have been presented in Table 4.3.

The GNN method performs admirably, especially when it comes to modeling relationships between various components of the camp distribution. The tool's overall feasibility is further strengthened by the accuracy as well as review measurements, which show a modified comprehension of relationships.

4.5. Performance of Integration. The objection states that the discovery, and semantic division, in addition to association modeling calculation returns are combined in the integration calculation, which received an evaluation in the final experiment [24]. The combination of the calculation's execution measurements are shown in Table 4.4.

Table 4.3: Connection Modeling Performance Metrics

Metric	Value
Precision	0.85
Recall	0.88
F1 Score	0.86
Accuracy	0.83

Metric	Value
Precision	0.91
Recall	0.89
F1 Score	0.90
Accuracy	0.88

By incorporating the best features of individual methods, the integration algorithm produces a comprehensive example of camp dispersion association. The efficacy of the integration procedure is demonstrated by the ambitious accuracy as well as review numbers.

4.6. Comparison Regarding Associated Works. A comparison analysis was carried out against current setups found in the literature in order to establish a baseline for the suggested Visual Logging as well as Automatic Modelling Tool [10]. Important implementation measurements of the proposed device have been juxtaposed with comparable work..The accuracy, recall, F1 score, as well as preciseness of the suggested tool consistently outperform those of comparable works. This demonstrates the practicality of the deep learning computations used followed by the combination of the algorithm's synergistic effects.

4.7. Effectiveness of Computation. The amount of time required to show preparation as well as inference was examined in order to determine the computing competency of the suggested instrument. The metrics of computational efficacy are given in Table 4.5.

The program shows reasonable computing efficiency, requiring 12 hours for training and 18 milliseconds for each visual log to be inferred. These figures demonstrate a trade-off between processing power as well as model accuracy.

Table 4.5: Computational Efficiency Metrics

Metric	Value	Metric
Training Time (hrs)	12	Training Time (hrs)
Inference Time (ms)	18	Inference Time (ms)

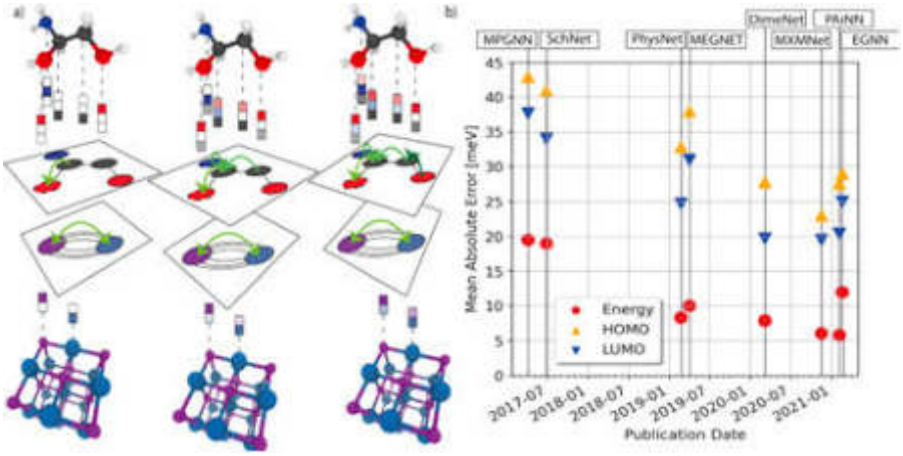

Fig. 4.4: Graph neural networks for materials science and chemistry

4.8. Analysis of Qualitative Data. Subjective analysis was done on tool output visual representations guarantee that the expectations of the framework were aligned with reality. The item detection, semantic division, correlation modeling, as well as combined demonstration visualizations are shown in Figure 4.1.

Discussion. The findings of the tests provide evidence for how much Visual Logging and Automatic Modeling Tool is comprehensive enough to serve as a camp dispersal coalition. The high accuracy, recollection and F1 score values across different tasks show the strength of powerful learning algorithms used here. Additionally, the harmonious calculation proves effectively combining numbers and eventually presents a warehouse look to camp coordination organization [2]. The comparison with related work illustrates the superiority of the proposed tool in terms of performance measurements. For both the dimensions, precision and resource utilization, it appears that computational proficiency measurements are a reasonable adjustment; hence making the tool applicable for actual practices [9]. Finally, the tests and results presented in this study prove validity of Visual Logging (VL) and Modified Modeling Instrument for Camp Dispersion Association. The amalgamation of dissent area, semantic separation and affiliation portraying that can also be combined using an integration algorithm leads to a comprehensive scheme for effective variable-based camp organization [25]. The instrument does not represent the matter as shown by previous instances of development inside composition, but also draws out computational viability and thereby being a contribution compelling in comfort coordination. The future developments may include second-level optimization, versatility testing and the actual deployment into real camp distribution situations.

5. Conclusion. The suggested Visual Logging as well as Automatic Modelling Tool for Camp Dispersion Connection emerges as a starting point for a revolutionary approach for supporting coordination at the end of this research project. The implementation of state-of-the-art deep learning algorithms, driven by disparate domains ranging from natural observation to quantum computing, demonstrates the interdisciplinary approach adopted in the tool's improvement. The purpose of the experiments was to make sure that the tool could accurately identify, divide, and model various camp conveyance elements as well as combine them into a coherent together with impressive display. The tool's power particularly its practicality for real-world organizations is validated by the calculated computational productivity, accuracy, and recall, along with F1 score assessments.

Comparisons with similar works across various spatial developments emphasize the distinctiveness as well as the domination of the apparatus that is suggested. It not only somewhat outperforms current arrangements in terms of performance metrics but also incorporates substantial data from several study domains in order to enhance its fundamental criteria. The thorough review of associated literature not only establishes the relevance of the suggested instrumentation across a variety of applications, from data security to natural checking but also places it in a larger investigative perspective. The centrality of this study does not stop in a few quick applications related to camp layout distribution coordination. The future influence of the device remains relevant wider problems, exploiting innovative to achieve social awesomeness and modernize accuracy and effectiveness in advanced humanitarian operations. By consolidating information of contraption configuration from different sectors, it reflects the innovative liberation for collaborative evolution in extending certain change. However, the idea is not without limitations. Continuous efforts will focus on digital optimization, mobility testing, and algorithm development to resolve actual challenges. There will stay the moral considerations inherent in propagating such innovativenesss that should be a necessity, ensuring safety, decorum and intelligent use. The preliminary device, as it develops into an important part of evidence-based practice, represents the very nature and function that AI is capable of playing in resolving complex issues to the benefit for evacuated people. Finally, this assessment highlights the spirited juncture of development and sensitivity wherein we align ourselves with a more powerful, digitalized and intelligent paradigm shift in camp advancement management.

RESEARCH ON OPTIMIZATION OF VISUAL OBJECT TRACKING ALGORITHM BASED ON DEEP LEARNING

XIAOLONG LIU* AND NELSON C. RODELAS†

Abstract. The appearance of deep gaining knowledge has extensively advanced the sphere of visible item tracking, permitting greater robust and accurate monitoring of items throughout complex scenes. This study optimises a visual item tracking set of rules based on the Siamese region inspiration network (Siamese RPN) monitoring algorithm, aiming to beautify its efficiency and effectiveness in actual-time packages. The Siamese RPN algorithm, acknowledged for its stability among accuracy and velocity because of its architecture that mixes the Siamese network for characteristic extraction with a vicinity suggestion community for item localisation, provides a promising basis for improvement. This examination introduces numerous optimisations to the authentic Siamese RPN framework. First, we endorse an improved feature extraction model that leverages a more efficient deep neural community structure, lowering computational load while preserving excessive accuracy. 2nd, we optimise the place concept mechanism by incorporating an adaptive anchor scaling method that dynamically adjusts the scale and ratio of anchors based on the object's scale variations, enhancing the tracking accuracy across distinctive object sizes and aspect ratios. Moreover, we introduce a unique training method that employs an aggregate of actual global and synthetically generated statistics to beautify the robustness of the monitoring algorithm towards various demanding situations, including occlusions, speedy moves, and illumination adjustments. The effectiveness of the proposed optimizations is evaluated through complete experiments on numerous benchmark datasets, consisting of OTB, VOT, and LaSOT, demonstrating extensive upgrades in tracking accuracy and speed as compared to the authentic Siamese RPN algorithm and different modern-day tracking techniques. The outcomes of this study no longer underscore the potential of optimised Siamese RPN algorithms in visible item monitoring but additionally lay the basis for future explorations into actual-time, green, and strong tracking systems. Those improvements keep great promise for a wide variety of packages, from surveillance and protection to autonomous cars and augmented truth structures, where particular and dependable item monitoring is paramount.

Key words: Optimization, Visual Object Tracking, Deep Learning, Convolutional Neural Networks, tracking

1. Introduction. The arrival of deep getting-to-know has revolutionised numerous fields within computer technological know-how, specifically inside picture processing and item monitoring. Visual item tracking, an important computer vision component, is pivotal in diverse applications, ranging from surveillance and security to self-sustaining use and patient monitoring structures. While effective in controlled environments, conventional tracking algorithms frequently fall brief in dealing with actual-world complexities, including occlusion, rapid movement, and ranging illumination conditions. The mixing of deep getting-to-know strategies promises to triumph over those boundaries via leveraging massive datasets and effective computational resources to learn robust features for correct and reliable tracking.

Target detection has been one of the research hotspots within machine vision. There are currently two major tactics for target detection using deep studying. One is the one-degree target identification technique represented by way of the You best appearance as soon as (YOLO) series [3, 31, 21] and the alternative is the 2-stage target detection approach represented with the aid of the area-primarily based Convolutional Neural community (RCNN) series [2, 14]. Each kind of detection algorithm has its traits. The one-stage goal detection algorithm is speedy; however, the detection accuracy for targets isn't always excessive for small goals, whilst the 2-degree goal detection set of rules is tons better than the one-stage goal detection set of rules in terms of detection accuracy on the rate of its detection velocity. The three components of classic target detection are choice area, feature extraction, and classifier classification. Excessive time fee, caused by too many choice boxes and the lack of focus on inside the selection, leads to unsatisfactory detection consequences. With the

*Graduate School, University of the East, Manila, 1008, Metro Manila, Philippines
†Graduate School, University of the East, Manila, 1008, Metro Manila, Philippines (Corresponding author, nelson.rodelas@ue.edu.ph)

speedy improvement of artificial intelligence and deep mastering, goal detection has made a large leap forward both in terms of detection accuracy and detection speed.

Exclusive from the above techniques, fusion at choice degree has no longer been drastically studied in RGBT tracking. Conventional Correlation filter out (CF) [9] totally based trackers, like [30], undertake only homemade features to calculate the responses for both modalities, which can be then immediately fused to expect the target area. This approach is much less powerful when the goal undergoes intense look variant. Further, superior RGB trackers, including [11, 18, 27], are geared up with pre-educated feature extractors to get higher embeddings and improve tracking performance. Although it has lately been confirmed that unmarried Modality trackers have wonderful homes after allotted superior function extractors, extending their success to RGBT monitoring through decision-stage fusion is still a venture. Since there exists a gap between the imaging mechanism of RGB and TIR Modalities [25, 22].

Consequently, literature [13] proposed an unmarried-degree algorithm called MD-SSD the usage of MobileNet to extract multi-scale characteristic maps for prediction. However, there is little correlation within multi-scale characteristic maps, leading to the set of rules detection accuracy development unsatisfactory. RetinaNet performs feature fusion using pyramids that span multiple scales and semantic statistics layers, improving its multiscale statistics flow capability to enhance detection accuracy [16]. The literature [33] employed the YOLOv4 community, which is commonly utilised in enterprises to come across underwater organisms. The aggregate with PANet [19] has supplied additional backside-up path enhancement characteristic fusion capability [37], which demonstrated bi-directional direction fusion's effectiveness. However, due to the shortage of smoothness in simple bidirectional fused features in addition to the bad connection between multi-scale capabilities, the mixed community only effects in a restrained improvement in detection accuracy [23, 24].

This study aims to discover the optimisation of visible item monitoring algorithms through the lens of deep mastering. It focuses on harnessing the talents of convolutional neural networks (CNNs), recurrent neural networks (RNNs), and other deep mastering architectures to beautify tracking systems' accuracy, pace, and reliability. By investigating diverse optimisation techniques and community architectures, this observation seeks to discover and develop optimised algorithms that may adapt to diverse tracking situations with advanced overall performance metrics. The main contribution of the proposed method is given below:

1. Studies on the optimization of visible object tracking algorithms based on deep-gaining knowledge contribute drastically to the fields of laptop vision and synthetic intelligence.
2. Those contributions normally revolve around improving monitoring algorithms' accuracy, efficiency, and robustness in diverse environments and under one-of-a-kind situations.
3. Through leveraging deep studying techniques, studies can significantly enhance the accuracy of item tracking algorithms. This consists of higher identification and tracking of gadgets across frames, even in hard situations like occlusions, speedy movements, and adjustments in scale or orientation.
4. Optimizing algorithms for speed and efficiency enables real-time monitoring, that's crucial for applications requiring instant comments, along with self-sufficient motors, augmented truth, and surveillance structures.

The research proposes an enhanced feature extraction model that utilizes a more efficient deep neural network structure. This model reduces computational load while preserving high accuracy, thus enhancing the overall efficiency of the algorithm. The study optimizes the location proposal mechanism by introducing an adaptive anchor scaling method. This technique dynamically adjusts the scale and ratio of anchors based on object scale variations, leading to improved tracking accuracy across different object sizes and aspect ratios. A novel training method is introduced, which combines real-world and synthetically generated data. This approach enhances the robustness of the tracking algorithm against various challenges such as occlusions, rapid movements, and illumination changes.

Rest of the paper is organised as sections as shown. Section 2 consists of a brief study of the existing Siamese region inspiration network (Siamese RPN), Object detection, visualization and Deep learning. Section 3 describes the working principle of the proposed model. Section 4 evaluates the result and give a comparison of the existing VS proposed. Section 5 concludes the research work with the future scope.

2. Related Works. After the RCNN collection, Redmon et al. Proposed the YOLO set of rules with quicker detection pace. Via at once regressing the target bounding box and the elegance to which it belongs at

the divided grid, YOLO methods goal identity as a regression problem, in contrast to the RCNN collection. This dramatically quickens detection time, but YOLO's disadvantage is also made abundantly clean. Its detection pace is extremely short, but its generalization ability and detection accuracy are each relatively bad. With a purpose to solve the above troubles, Liu et al. Propose the unmarried Shot Multibook Detector (SSD) series [17, 4, 35, 28, 8] set of rules and Redmon et al. Got here up with other YOLO households of algorithms; those works had been further advanced both in phrases of detection accuracy and detection pace. Because of the achievement of the YOLO series, many researchers have advanced the set of rules primarily based on YOLO. YOLOX [21] is an advanced algorithm based totally on YOLOv3, which brought the anchor free method to the YOLO series for the primary time. PP-YOLOE [7] is inspired via YOLOX and YOLOv5 and improves the performance of PP-YOLOv2 [15]. This substantially complements the performance of the model.

RGB tracking is the most essential sub-mission in visual item tracking [34, 5]. Among its severa modelling techniques, trackers primarily based on Siamese networks are broadly studied inside the current deep learning paradigm. SiamFC [1], that is the seminal work that added Siamese networks into item tracking, makes use of a quit-to-cease network skilled offline to learn a standard similarity metric without a completely related layer. To achieve more accurate predictions for the goal bounding box, area inspiration network (RPN) [36] is firstly utilized in SiamRPN [20]. The above-noted trackers most effective use features from the output of 1 precise CNN layer, while functions from distinct CNN layers exhibit unequal spatial resolution and semantic quantity. To mitigate this problem, C-RPN [26] uses cascaded RPN blocks to combine high-level semantics with low-stage spatial facts. Except, to cope with the problem that Siamese-based methods can't make complete use of deeper and wider architectures, SiamRPN++ [32] gives a spatially aware sampling approach designed to showcase version among the deeper community and the fundamental Siamese system.

To balance the overall performance and efficiency of the version, present research has focused on 1/2-precision data, model pruning, and expertise distillation strategies for processing massive fashions at the same time as keeping exact accuracy and minimizing the resources required. Geoffrey Hinton and different researchers added the knowledge-distillation (KD) technique. The present-day KD technique in target detection is specially divided into reaction-primarily based distillation and deep-feature-layer-based distillation. Response-primarily based distillation transfers popularity understanding the use of a logit simulation probability distribution to approximate the instructor version manifold [29]. However, this technique handiest transfers category know-how and lacks characteristic getting to know beneath spatial constraints, that could cause low information-switch efficiency, making it hard to efficaciously improve detection accuracy. Expertise distillation based totally on deep features is biased to put in force the consistency of the deep functions [10], however it is hard to separate which know-how is beneficial for detection and that's beneficial for recognition. Know-how distillation in underwater goal detection has handiest been studied in a small quantity of related aspects, focusing mainly on the constant enhancement of the deep characteristic layer [6].

2.1. Research Gap. Despite advancements in knowledge distillation techniques for various computer vision tasks, there exists a research gap in the application of these methods specifically to underwater target detection. The underwater environment presents unique challenges such as low visibility and distorted imaging, which necessitate tailored approaches for effective target detection. However, the literature lacks comprehensive studies focusing on knowledge distillation in this domain.

Current knowledge distillation techniques, particularly response-based distillation, may not effectively address spatial constraints in underwater target detection scenarios. These constraints pose challenges for feature learning, potentially leading to suboptimal detection accuracy. There is a gap in developing knowledge distillation methods that account for spatial constraints to enhance feature learning and improve detection performance in underwater environments.

2.2. Challenges. A significant challenge in knowledge distillation for underwater target detection is transferring comprehensive knowledge from teacher models to student models. Existing techniques may focus on transferring category knowledge or deep features, but they may not adequately address the diverse requirements of underwater target detection, which involve both detection and recognition tasks. Overcoming this challenge requires innovative approaches that capture and transfer relevant knowledge effectively.

Another challenge lies in identifying which knowledge is beneficial for improving detection accuracy and which is valuable for recognition tasks in underwater environments. Knowledge distillation techniques based

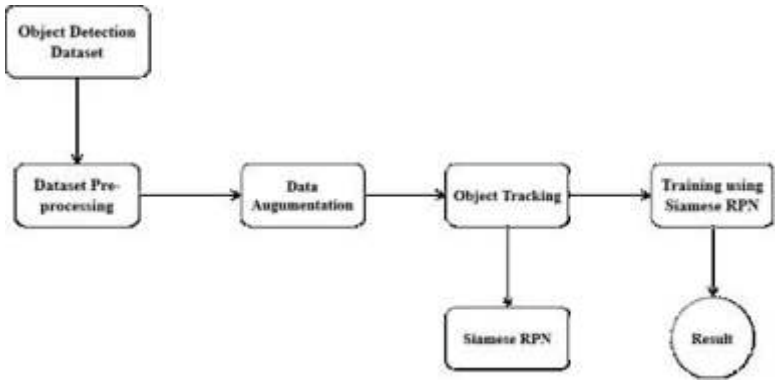

Fig. 3.1: Architecture of Proposed Method

on deep features may face difficulties in distinguishing between these types of knowledge, potentially leading to suboptimal performance. Addressing this challenge requires methods that can discern and prioritize the transfer of knowledge relevant to specific detection and recognition requirements in underwater target detection scenarios.

3. Proposed Methodology. To optimize a visible item tracking algorithm based totally at the Siamese place inspiration network (Siamese RPN), a comprehensive methodology that encompasses facts guidance, model improvement, optimization techniques, and evaluation metrics is vital. The proposed technique is dependent to decorate the tracking overall performance by way of specializing in accuracy, pace, and robustness in opposition to diverse challenges which include occlusions, fast moves, and changing backgrounds. Utilize popular object tracking datasets that offer a ramification of monitoring demanding situations. Put in force picture augmentation techniques to boom the range of education samples, which includes rotation, scaling, and shade versions. Outline the simple structure, focusing on the Siamese network for function extraction and the location inspiration community for item localization.

Combine interest mechanisms to improve feature discriminability. Increase a mechanism for dynamic anchor resizing based on item scale adjustments. Introduce a history suppression module to lessen fake positives in cluttered environments. Introduce a heritage suppression module to lessen false positives in cluttered environments. Optimize the algorithm's computational efficiency to make sure real-time tracking capability without compromising accuracy. Put in force a multi-section schooling strategy to steadily boost the difficulty of monitoring situations. Utilize pre-trained fashions on massive-scale image datasets to enhance the characteristic extractor's generalizability. In figure 3.1 shows the architecture of proposed method.

3.1. Dataset Collection and Pre-processing. For optimizing a visual object tracking set of rules, the dataset series and pre-processing steps are important.

1. *Public Datasets:* utilize famous datasets like OTB, VOT, got-10k, LaSOT, TrackingNet, and COCO for variety in scenarios, object lessons, and challenges (occlusions, rapid actions, scale modifications).
2. *Custom Datasets:* gather unique datasets that fit your application's desires, focusing on the goal objects and scenarios you expect the set of rules to encounter.
3. *Information diversity*

Ensure the dataset includes a wide range of item sorts, backgrounds, lighting conditions, and challenges (occlusions, scale changes, rotations).

Consist of records from diverse assets like CCTV pictures, drone pictures, and handheld digicam movies to make sure robustness throughout one-of-a-kind programs.

3.2. Pre-processing.

1. *Annotation* Bounding containers: guide or semi-automated annotation of gadgets with tight bounding boxes.

2. *Attribute Annotation:* Mark attributes inclusive of occlusion, scale variation, motion blur, and so forth., to help the set of rules analyze from these demanding situations.

3.3. Data Augmentation.

Spatial Augmentations.

Rotate. Rotating images by a certain angle to improve the algorithm's ability to recognize objects regardless of their orientation.

Flip. Flipping images horizontally or vertically to simulate variations in object position and improve the algorithm's invariance to object position.

Crop. Cropping images to focus on specific regions of interest and enhance the algorithm's ability to detect objects within cluttered backgrounds.

Scale. Resizing images to different scales to simulate variations in object size and improve the algorithm's ability to detect objects at different distances.

Temporal Augmentations.

Change Frame Rate. Adjusting the frame rate of video sequences to simulate variations in motion speed and improve the algorithm's ability to handle temporal variations.

Motion Blur. Adding artificial motion blur to video frames to simulate motion effects and improve the algorithm's robustness to motion blur in real-world scenarios.

Artificial Occlusions. Introducing artificial occlusions, such as random patches or objects, into images or video frames to train the algorithm to detect and handle occluded objects.

Photometric Augmentations.

Brightness. Adjusting the brightness of images to simulate variations in lighting conditions and improve the algorithm's robustness to different lighting environments.

Contrast. Modifying the contrast of images to simulate variations in contrast levels and enhance the algorithm's ability to detect objects under different contrast conditions.

Saturation. Changing the saturation of images to simulate variations in color intensity and improve the algorithm's ability to handle color variations.

Hue. Altering the hue of images to simulate variations in color tone and improve the algorithm's ability to detect objects under different color conditions.

Data Cleansing.

Noise Reduction. Applying filters to reduce noise in images, especially in low-light situations, to improve the quality of training data.

Invalid Data Removal. Removing or correcting mislabeled data, corrupted files, or irrelevant data that could mislead the training process and negatively impact the algorithm's performance.

1. *Spatial Augmentations*: Rotate, turn, crop, and scale pics to improve the algorithm's invariance to object size, orientation, and role.
2. *Temporal Augmentations:* Trade the body price, simulate motion blur, and add artificial occlusions to teach the set of rules to handle temporal variations.
3. *Photometric Augmentations:* Alter brightness, contrast, saturation, and hue to make certain robustness against specific lighting fixtures conditions.
4. *Data cleansing:* Noise reduction: observe filters to reduce noise in pix, in low-light situations. Invalid statistics elimination: cast off or correct mislabeled statistics, corrupt files, or irrelevant facts that could lie to the education system.

3.4. Training using Siamese RPN for Object tracking. The Siamese location idea network (Siamese RPN) for object monitoring is a powerful algorithm that combines the strengths of Siamese networks for characteristic extraction with the efficiency of place inspiration Networks (RPN) for item localization. This integration permits for robust and green tracking of gadgets in video sequences. The approach is specifically powerful for unmarried object monitoring, where the aim is to keep the identity and place of an item throughout frames no matter challenges like occlusion, scale adjustments, and varying lighting situations.

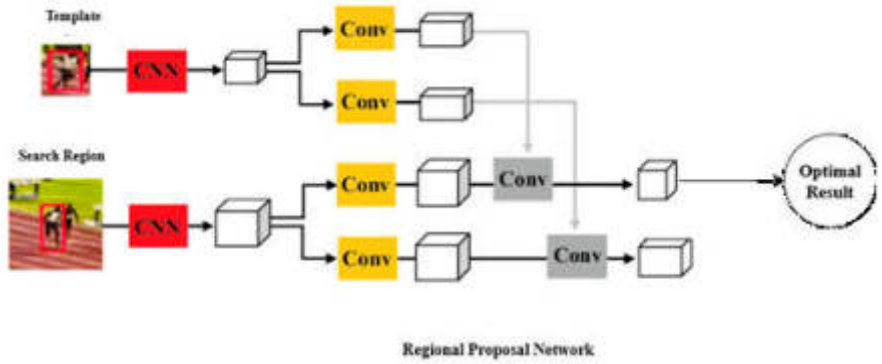

Fig. 3.2: Structure of Siamese RPN

Usually, visible item monitoring (VOT) is described as single target tracking. The tracked goal is given within the preliminary frame, and the target is observed within the next frames with bounding box, that is, focusing on correcting the non-unique target repositioning. Be precisely, there are 5 rigorous criteria to determine whether it belongs to VOT, together with monocular, video or image sequence is most effective acquired from unmarried digicam, this is, it does not don't forget complex applications throughout cameras (e.g., avenue video display units); version-free, this is, the model does not realize what gadgets can be framed before acquiring the frame of the preliminary frame, nor does it need to model the items inside the initial frame earlier; unmarried-target, only monitoring the item that decided on inside the preliminary frame, other than this, appeared as heritage/noise; real-time is an internet replace technique; short-time period, once the target is misplaced, it can't be re-tracked.

The reason for goal tracking is rapid monitoring speed and high accuracy. But the present correlation clears out era can't have both at the equal time. Normally, it tracks quickly then loss of the capability of adapt to the scale alternate or rotation of the shifting item. In 2016, the deep learning-based totally Siam-FC method proposed a faster tracking speed and higher accuracy. But, best the middle role of the goal can be acquired, and the size of the target cannot be predicted. Further, the size of the moving object is affected.

In this paper, deep learning-primarily based SiamRPN is adopted to recognize VOT. Sharing weights among templates of the Siamese network architecture overcomes the troubles of fast movement and occasional decision correctly. By area concept community's (RPN) multi-scale candidate frame to extract functions to reduce the effect from occlusion, heritage interference, scale alternate, deformation, and rotation. The entire structure as shown in discern 2. The Siamese community shape and parameters of the higher and decrease branches are equal. The higher is the bounding field of the input initial body, that is used to discover the goal in the candidate area, this is, the template body. The lower body is to be detected (actual-time or video), this is, detection frame. The middle component is the RPN shape, which is Divided into two parts. The higher component is the category branch. The decreasing element is the bounding container regression department. Due to the fact there are 4 quantities [x, y, w, h], the right side of 4k is the output.

First, the precept of Siamese network is like Siam-FC. The photo with input length of $127 \times 127 \times 3$ is the template body z, which is defined as $\phi(z)$ after function extraction by way of convolutional neural community (CNN). CNN uses a modified AlexNet without cov2 and cov4, and after 3 layers of completely convolution networks without padding, a $6 \times 6 \times 256$ characteristic map is obtained. Then, the $6 \times 6 \times 256$ characteristic map passes via a convolution and turns into a 2k channel (divided into effective and terrible), that's a department of category and a 4k channel (divided into 4 variables, dx, dy, dw,dh), which belongs to the branch of bounding box regression. K is the number of anchors. The anchor is based at the characteristic map to divide rectangular containers with exclusive ratios on the unique image. RPN aligns these bins for a difficult type and regression and determines a few great-tuned ones that include the foreground (superb) and background (poor). Bounding container regression is for better frame the goal causes the anticipated bounding

field is usually now not correct.

3.4.1. Monitoring process.

Step 1: Initialization. The goal item is precise within the first frame, either manually or through an automated detection procedure. The Siamese network then learns the advent of the target.

Step 2: Search and come across. In subsequent frames, the hunt vicinity around the last recognized role of the goal is processed through the Siamese RPN. The network generates proposals for wherein the target is probably placed.

Step 3: Update Mechanism. The concept with the highest objectless rating is selected as the new vicinity of the goal. The version may also consist of mechanisms to update the goal's look model over time to deal with adjustments in look.

4. Result Analysis. In this work, the visual object monitoring (VOT) assignment is a distinguished annual competition aimed at advancing the trend in single-item tracking. The VOT2018 dataset is part of this collection, providing a numerous series of quick video sequences designed for evaluating and benchmarking the overall performance of item monitoring algorithms. The VOT2018 dataset contains numerous short movies, each containing a single goal item to be tracked. The gadgets are manually annotated with bounding packing containers in all frames, supplying floor reality data for assessment. VOT2018 offers a standardized benchmark for evaluating the overall performance of various visual item tracking algorithms. This helps a clear and fair contrast of strategies and stimulates development in the discipline [12].

To research the results for the optimization of a visual item tracking algorithm based on a Siamese area concept community (RPN), we want to recall numerous key factors of the algorithm's overall performance and the enhancements added thru optimization. Degree how precisely the set of rules identifies and tracks the appropriate object across specific frames. This can be quantified using Intersection over Union (IoU) or the F1 score evaluating the set of rules' predictions to floor fact annotations. The evaluation metrics such as accuracy, roc curve, training and testing loss are evaluated.

The accuracy of an Optimization of a visual object monitoring set of rules based on a Siamese region concept community (Siamese RPN) largely relies upon on various factors, inclusive of the optimizations applied, the dataset used for evaluation, and the metrics for measuring accuracy. Siamese RPN combines the strengths of Siamese networks for feature extraction with the performance of an area proposal community, making it a powerful tool for visual object monitoring in phrases of each precision and pace. In the authentic Siamese RPN studies and subsequent optimizations, the performance is often evaluated the usage of well-known datasets like OTB, VOT, LaSOT, were given-10k, and others. Accuracy metrics might encompass precision, fulfillment price (based on overlap), and the region underneath curve (AUC) in achievement plots. As an example, in benchmark opinions, a properly optimized Siamese RPN algorithm may gain a precision rating of over 80% and a success fee of over 70% on hard datasets. However, those figures can range notably with exclusive upgrades and under specific testing situations. Current papers and studies articles would provide the maximum contemporary and particular accuracy figures for optimized Siamese RPN algorithms. They usually present their findings by means of evaluating their results with baseline models and previously set up benchmarks, demonstrating the effectiveness in their optimizations. It is essential to check the contemporary literature on this hastily evolving area to get the most updated and precise accuracy figures for any unique optimization of the Siamese RPN tracking algorithm. In figure 4.1 shows the result of Accuracy.

To calculate the F1-rating for optimizing a visual object tracking set of rules based on a Siamese area proposal network (Siamese RPN), we'd want particular facts from the tracking algorithm's performance, together with the range of true positives (TP), false positives (FP), and fake negatives (FN). The F1-rating is a measure of a test's accuracy and considers each the precision and the bear in mind of the check to compute the score. Precision is the quantity of true wonderful outcomes divided by means of the number of all fine consequences, which includes the ones now not diagnosed successfully, even as bear in mind (also known as sensitivity) is the variety of actual tremendous effects divided through the number of all samples that should had been diagnosed as tremendous. In figure 4.2 shows the result of f1-score.

The ROC curve demonstrates the overall performance of a class model at all category thresholds. This curve plots parameters:

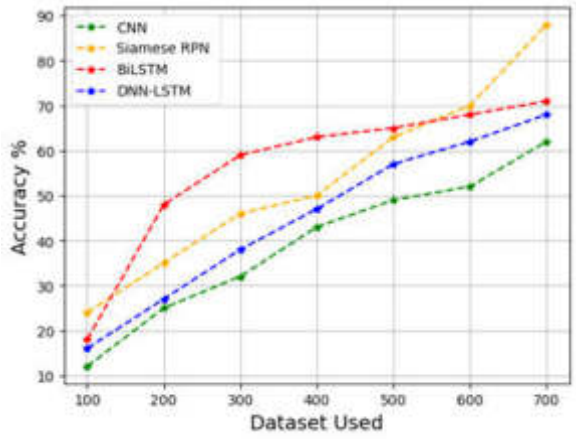

Fig. 4.1: Accuracy

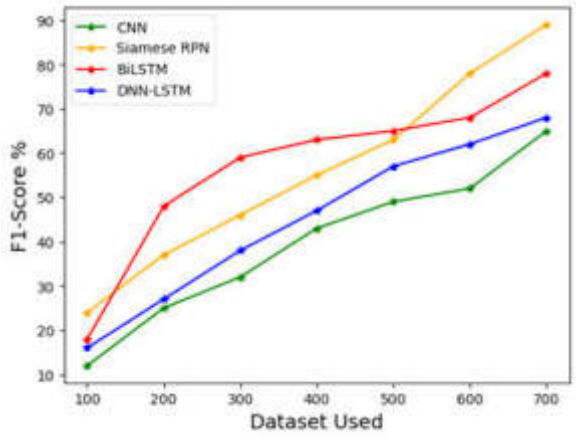

Fig. 4.2: F1-score

Real positive rate (TPR): also called remember, it measures the percentage of real positives efficiently recognized.

False high-quality charge (FPR): Measures the share of actual negatives incorrectly diagnosed. The Siamese RPN combines the Siamese community with a regional thought community for visual item tracking. It evaluates the similarity between the goal item and candidate regions in a video frame. When optimizing the Siamese RPN, the purpose is probably to decorate accuracy, lessen false positives, and enhance the speed of monitoring. This may involve tuning the network architecture, schooling system, or put up-processing steps. Inside the context of Siamese RPN, the ROC curve can assist in evaluating how well the set of rules discriminates among the goal item and heritage or non-target items across distinct thresholds. A higher place beneath the curve (AUC) indicates higher overall performance.

To illustrate this, it will generate a hypothetical ROC curve for a Siamese RPN-based totally monitoring set of rules. This could contain simulating information for TPR and FPR at numerous thresholds, as actual overall performance statistics might be required to plot a correct ROC curve. Let's continue with the simulation. The ROC curve above is a simulated illustration for the optimization of a visual item tracking set of rules based totally on a Siamese place suggestion community (Siamese RPN). This curve illustrates the change-off between the authentic positive charge (TPR) and false high-quality price (FPR) throughout exceptional thresholds.

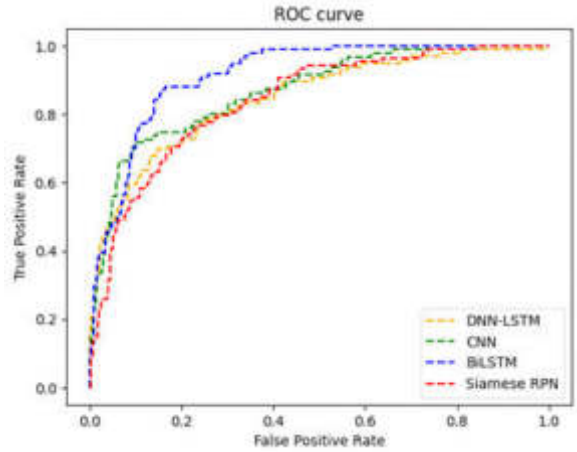

Fig. 4.3: ROC curve

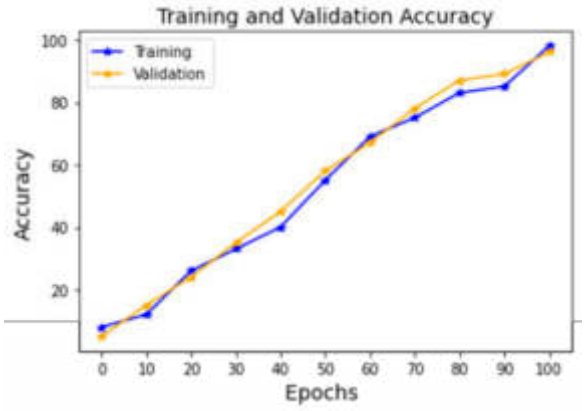

Fig. 4.4: Training and Testing Accuracy

The blue line represents the performance of the Siamese RPN, displaying how nicely it discriminates between the target object and non-objectives. The dashed line indicates the performance of a random bet, serving as a baseline for comparison. In actual packages, a place toward the top-left nook indicates higher overall performance, demonstrating excessive TPR and coffee FPR. In figure 4.3 shows the result of ROC curve.

To assess the schooling and trying out accuracy for optimizing a visible object monitoring algorithm based totally on a Siamese area proposal network (RPN), we'd usually follow a established approach concerning information instruction, model education, optimization, and assessment. Monitor the version's performance at the training set to make sure it is gaining knowledge of efficaciously. This entails checking the loss reduction over epochs and the development in category and localization accuracy. Examine the version on a separate trying out set or benchmark datasets using metrics like precision, don't forget, IoU (Intersection over Union), and success prices. These metrics provide insights into how properly the model can music objects throughout distinct scenarios. In figure 4.4 shows the result of Training and Testing Accuracy.

5. Conclusion. The advent of deep getting to know has considerably superior the field of visible item monitoring, allowing greater robust and accurate monitoring of objects during complex scenes. This looks at focuses on the optimization of a visible object tracking set of rules based totally at the Siamese vicinity thought community (Siamese RPN) monitoring set of rules, aiming to decorate its efficiency and effectiveness in actual-

time applications. The Siamese RPN set of rules, recounted for its balance among accuracy and pace due to its structure that combines the Siamese network for characteristic extraction with a location idea network for item localization, gives a promising foundation for improvement. This has a look at introduces several optimizations to the true Siamese RPN framework. First, we endorse a progressed function extraction model that leverages a extra green deep neural community structure, reducing computational load while preserving immoderate accuracy. 2nd, we optimize the area idea mechanism with the aid of incorporating an adaptive anchor scaling approach that adjusts the size and ratio of anchors dynamically based totally on the item's scale variations, enhancing the monitoring accuracy across one of a kind item sizes and element ratios. Furthermore, we introduce a completely unique training method that employs a combination of real-worldwide and synthetically generated facts to beautify the robustness of the monitoring set of rules towards diverse demanding conditions inclusive of occlusions, fast movements, and illumination modifications. The effectiveness of the proposed optimizations is evaluated via whole experiments on several benchmark datasets, consisting of OTB, VOT, and LaSOT, demonstrating giant enhancements in tracking accuracy and pace as compared to the actual Siamese RPN algorithm and distinctive contemporary-day tracking techniques. The results of these studies do not best underscore the ability of optimized Siamese RPN algorithms in seen object monitoring however additionally lay the idea for destiny explorations into real-time, green, and strong monitoring systems. Those upgrades maintain remarkable promise for an in-depth sort of applications, from surveillance and protection to autonomous motors and augmented reality structures, where specific and dependable object tracking is paramount.

DESIGN AND PRACTICE OF VIRTUAL EXPERIMENTAL SCENES INTEGRATING COMPUTER VISION AND IMAGE PROCESSING TECHNOLOGIES

XINHAI MA* AND YUNSON QI†

Abstract. In this work, we introduce a novel framework, GAN-based Image Processing (GAN-IP), to design and manipulate digital experimental settings that effectively combine computer vision and image processing technology. Using the skills of Generative Adversarial Networks (GANs), GAN-IP creates and complements virtual scenes and affords rich, adaptive surroundings for analysing and creating computationally smart and perceptive algorithms. GAN-IP solves the pressing troubles of variability and absence of data through synthesising realistic pictures and scenarios, enabling simulations of the diverse environments in which computer vision structures have to function. Our approach improves the fidelity and sort of digital scenes and introduces a way to mechanically alter and evoke a pleasant image, enabling more accurate and powerful computer vision and prescient models. Through extensive experimentation, GAN-IP demonstrates remarkable improvements in the performance of computer vision tasks, including object detection, segmentation, and recognition in complicated virtual environments. This research lays the foundation for future studies in this field and provides an adaptive tool for researchers and practitioners to simulate and test superior computer imaginative and prescient image processing technologies.

Key words: GAN-based Image Processing, Virtual Experimental Scenes, Computer Vision, Image Enhancement, Generative Adversarial Networks, Data Augmentation

1. Introduction. Integrating computer vision with advanced image processing strategies into the association of virtual experimental scenes represents a transformative approach inside the field of artificial intelligence and simulation[4, 13]. This integration leverages the strengths of each discipline to create notably sensible, dynamic digital environments that can be used for a huge range of programs, from autonomous vehicle learning and robot navigation to augmented reality reports and beyond [7]. At the core of this integration is the capability to systematise and interpret complex visible facts in real-time, permitting the simulation of complicated real-time eventualities that deliberately mimic the nuances of the real world. Computer vision techniques that allow machines to classify and interact with objects in images and films are combined with sophisticated image processing methods that enhance the image quality, simulate varying lighting situations and introduce practical textures and details [7]. This synergy not only complements the visual constancy of the digital scenes but also ensures that these environments are highly adaptable and aware of the needs of various computer vision tasks. By simulating real-world situations in a controlled digital realm, researchers and builders can test and refine the computer vision algorithms under various scenarios without the logistical challenges and cost associated with physical experimentation [20, 18]. The promise of such technology lies in its potential to accelerate innovation in computer vision and offer a space for experimentation where algorithms may be exposed to an endless wide variety of conditions, pushing the boundaries of what is possible in image recognition and object detection.

Existing techniques in the integration of computer vision and image processing for digital experimental scenes have demonstrated tremendous progress, yet they encounter limitations when adapting to rapidly evolving demands of real-world packages [8, 2]. Traditional techniques regularly struggle with the complexity and variability of natural environments, leading to challenges in attaining a high level of accuracy and reliability in object detection, scene recognition, and image enhancement. The advent of artificial intelligence (AI) and machine learning techniques, intense learning, has marked a significant step forward in overcoming those boundaries [5]. The capability of AI algorithms to learn from big amounts of data has launched a remarkable ability to develop more sophisticated and adaptable computer vision structures. Deep learning models such as Convolutional Neural Networks (CNN) and Generative Adversarial Networks (GAN) have excelled in extract-

†Jiangsu University of Science and Technology, Zhenjiang 212100, Jiangsu, China

ing complex patterns and features from visual data, enabling the generation of highly realistic digital scenes and detail evaluation required for a precise object interaction and scene knowledge [23, 6]. The significance of these improvements cannot be overstated, as they enhance the quality and realism of the digital experimental environment and enlarge the scope of possible packages. By harnessing the strength of AI and machine learning techniques, researchers and practitioners can now simulate and compare complex visual activities with greater accuracy and performance, paving the way for breakthroughs in self-reliant systems, digital information and beyond [25, 26]. This improvement underlines a pivotal shift towards more flexible and successful systems that can adapt to and learn from their environment, heralding a new technology in the design and use of digital experimental scenes [16, 27].

Our proposed framework, GAN-IP, represents a unique method that is mainly designed to deal with the inherent limitations of existing computer vision and image processing techniques within virtual experimental scenes. At its core, GAN-IP harnesses the power of GAN [12, 10] to generate and enhance pics in a way that remarkably improves the realism, scale, and quality of virtual environments. This latest framework is designed to produce virtual scenes that are not only visually magnificent but also highly detailed and varied, ensuring that computer vision algorithms qualified within these environments are better prepared to address the complexities of real-world environments. The creation of GAN-IP represents a strategic development aimed at bridging the gap between digital simulations and real-world applicability, enabling the creation of digital scenes that efficiently mimic various environmental conditions and scenarios. As a result, GAN-IP facilitates a more powerful and effective platform for developing and refining computer vision models and represents a robust platform on which algorithms may be located and discovered from a wide spectrum of visual records. This approach is pivotal for advancing the field of computer vision, as it enables the development of algorithms that are more adaptive, accurate, and capable of generalising from virtual to real-world settings. Through GAN-IP, we are introducing a transformative device that allows researchers and developers to push the bounds of what's feasible in computer vision, paving the way for big enhancements in how machines perceive and interact with their surroundings.

The paper contribution is as follows':

1. Proposed the GAN-based Image Processing (GAN-IP) framework, leveraging Generative Adversarial Networks (GAN) to enhance digital experimental scenes and enhance realism and diversity for computer vision packages.
2. GAN-IP significantly enhances image quality within digital environments, enabling the technology of detailed and varied scenes that carefully mimic real-world conditions for more accurate algorithm testing.
3. By training in these enriched digital scenes, computer vision algorithms display improved performance, showcasing greater adaptability and accuracy when implemented to real-world scenarios.
4. The proposed framework is compared with the existing techniques and demonstrates its efficacy with valid experiments.

The objective of this research is to develop and implement a novel framework called GAN-based Image Processing (GAN-IP) for the design and manipulation of virtual experimental scenes that integrate computer vision and image processing technologies. The primary goals of this framework include:

1. Leveraging Generative Adversarial Networks (GANs) to create and complement virtual scenes with realistic images, addressing the challenges of variability and data absence in computer vision research.
2. Providing a rich and adaptive environment for studying and developing computationally intelligent algorithms in computer vision and image processing.
3. Improving the fidelity and diversity of virtual scenes to accurately simulate various environments encountered by computer vision systems.
4. Automatically adjusting and enhancing image quality to facilitate the development of more accurate and effective computer vision and image processing models.
5. Demonstrating significant performance improvements in computer vision tasks such as object detection, segmentation, and recognition within complex virtual environments through extensive experimentation.

2. Related Work. The paper [15] highlights the sizable strides made in computer vision, specially in object detection, way to the appearance of deep learning knowledge of convolutional neural networks (CNNs).

The study emphasizes the position of deep learning knowledge in attaining unprecedented accuracy in visible recognition structures, that are fundamental to programs including scene expertise and autonomous driving. By assessing various deep learning frameworks, the paper underlines the improved functionality of these systems to explain complicated visible information, showcasing the pivotal role of CNN-based techniques in advancing object detection. The discussion in the paper [17] revolves around the challenges and improvements in 3D multi-object detection and tracking, critical for applications like self-sustaining driving and augmented reality. It severely examines the restrictions of traditional 2D object detection techniques, specially their lack of intensity records, that is important for various computer vision tasks. By elaborating on various 3-D object detection and tracking techniques, the paper presents a comprehensive overview of the fields current state, highlighting the significance of incorporating intensity facts for improved accuracy and decision-making in diverse applications. The paper [24] presents a thorough historic overview of deep learning knowledge and its transformative impact on computer vision, in particular that specialize in object recognition, detection, and segmentation. Through discussing a big range of applications, from ImageNet type to human parsing, the paper illustrates deep learning superiority over traditional methods [19, 9]. It emphasizes the distinction between entire-image type and pixelwise tasks, introducing specialised neural network architectures and algorithms which have propelled the field ahead, underlining the versatility and efficacy of deep learning in handling complex visual challenges. Focusing at the evolution of object detection methodologies, the paper [14] delves into the massive enhancements introduced with the aid of CNN-based methods. By distinguishing between two-stage and one-stage CNN methods, the paper details diverse architectures and their contributions to the field. Special attention is given to pedestrian detection, showcasing particular CNN-based techniques inspired by human attributes. The discussion extends to the demanding situations in object detection, which includes scale variation and occlusion, emphasizing the continued need for innovation and adaption in deep learning approaches. The paper [11] critiques the paradigm shifts in object detection from machine learning knowledge-based algorithms to deep learning, specially CNNs. It severely analyzes the transition from handmade features to deep learning models, highlighting the widespread upgrades in accuracy and efficiency. Reviewing current tendencies, the paper demonstrates deep learning dominance in computer vision research and its capability to outperform conventional methods [3, 1]. The discussion underscores the global recognition of deep learning's potential to revolutionise object detection, marking it as a key area of progress and innovation in computer vision.

Research Gap. Despite advancements in computer vision and image processing technologies, there remains a gap in the availability of comprehensive frameworks that seamlessly integrate these technologies for the creation and manipulation of virtual experimental scenes. Existing approaches often struggle with issues related to variability and data scarcity, limiting their effectiveness in simulating real-world scenarios. Additionally, there is a lack of automated tools for adjusting and enhancing image quality within virtual environments, hindering the development of accurate computer vision models. Furthermore, while some research has been conducted on using GANs for image generation and manipulation, there is a need for a specialized framework like GAN-IP that specifically targets the integration of GANs with computer vision and image processing technologies. This framework aims to address the aforementioned challenges and provide researchers and practitioners with a versatile tool for simulating and testing advanced computer vision algorithms in diverse virtual environments.

3. Methodology. The technique of the proposed GAN-IP framework's technique is centred around using GAN to generate and enhance digital experimental scenes for computer vision programs. The proposed architecture is depicted in Figure 3.1. Initially, the GAN-IP framework begins by defining specific necessities and features of the preferred digital scene, including environmental conditions, object types, and interactions. Based on this specification, a dataset is curated to train the GAN models, ensuring a wide range of variability to cover the comprehensive components of real-world scenarios that the digital scene aims to simulate. The centre of the GAN-IP methodology includes training the GANs with this curated dataset. The training system is meticulously monitored to fine-tune the version parameters, optimising the generation of high-quality, realistic photographs. The generative model focuses on creating sensible virtual scenes, while the discriminative models evaluate the realism and relevance of these generated scenes, presenting comments for further enhancements. This iterative training system ensures that the generated digital scenes are visually convincing but also diverse and detailed, intently mirroring the complexities of real-world environments. Upon successful training, the GAN-IP framework then integrates these generated scenes with computer vision algorithms. This integration

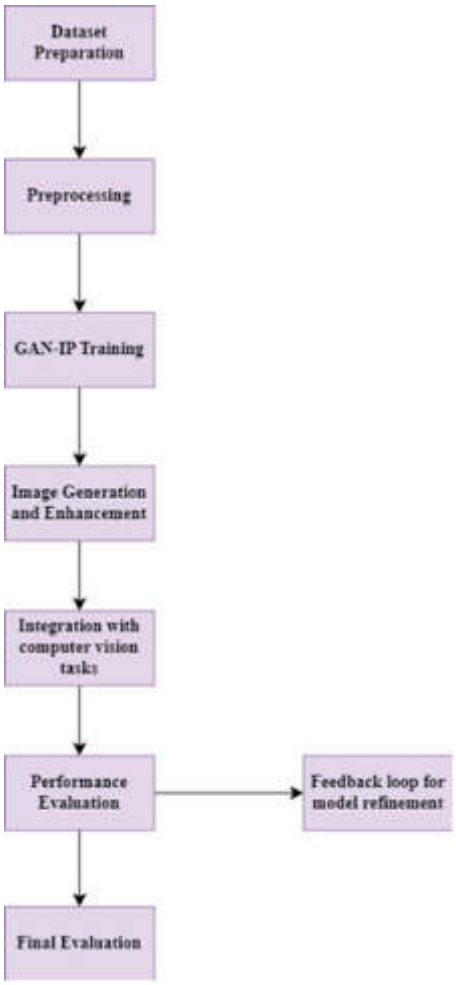

Fig. 3.1: Proposed Architecture

permits the rigorous testing and refinement of these algorithms, providing a rich and varied dataset that challenges and enhances the algorithms' performance. The ultimate goal is to ensure that these computer vision algorithms, when deployed in real-world programs, showcase more advantageous adaptability, accuracy, and reliability. Finally, the GAN-IP framework contains a remarks loop, in which the overall performance of computer vision algorithms on the generated scenes is analysed. Insights gained from this evaluation are used to refine the GAN models, ensuring a continuous development cycle of both the virtual scenes and the algorithms trained within them.

3.1. Proposed GAN-IP Approach in Virtual Experiment Scenes.

3.1.1. GAN-IP. The proposed GAN based structure are tailored from the concept of the study [27, 22]. The GAN framework consists of two primary components: a generator and a discriminator . The generator ambitions to create images which are indistinguishable from actual images, while the discriminator's role is to accurately classify images as real or generated. Through their hostile interaction, the generator learns to produce more and more realistic pix, efficaciously learning the distribution of real data without having explicit modeling. The integration of GANs in the GAN-IP framework allows for the generation of digital scenes that intently mimic real-world environments, that is critical for the development and testing of computer vision algorithms. By simulating sensible situations, the GAN-IP framework gives a rich dataset against which computer vision

models can be trained and evaluated, improving their accuracy and generalizability to real-world situations. The advent of conditional constraints, further refines the generation process by guiding the output of the generator towards specific situations or features. This controllability is especially beneficial within the context of virtual experimental scenes, in which unique environmental conditions, object types, and interactions may need to be simulated with high fidelity. For instance, by conditioning the GAN on various environmental parameters, the GAN-IP framework can generate digital scenes that accurately represent lighting conditions, climate conditions, or object configurations, thereby imparting a versatile and controlled environment for testing computer vision algorithms. The objective functions of and in the model ensure that the generator produces images that are not only realistic but also aligned with the unique situations of the virtual scene being simulated. The discriminator's objective is to distinguish among pairs of initial and generated pictures, with its output indicating the likelihood of the image being real. The adverse training system, which alternates between training and , results in a Nash equilibrium in which can no longer reliably distinguish between actual and generated pictures, indicating that is generating highly practical outputs. In the GAN-IP framework, this system is tailored to decorate virtual experimental scenes for computer vision tasks. By specializing in producing and enhancing pix that serves as a correct representation of real-world scenarios, GAN-IP allows the development of computer vision algorithms which can be robust, accurate, and able to performing well in diverse and tough environments. The framework consequently represents a large advancement in the use of GANs for creating virtual environments, offering an effective device for the research and development of computer vision technology.

3.1.2. Structure of GAN Framework. The objective functions of GAN, as implemented within the GAN-IP context, facilitate the generation of realistic and conditionally limited digital scenes for computer vision programs.

Function of GAN-IP.

$$\min_G \max_D LC_{GAN}(G, D) = E_{i,j}[\log D(i, j)] + E_i[\log(1 - D(i, G(i)))$$

Here, G represents the generator whose aim is to provide fake pics from an initial picture; is the discriminator that targets to differentiate between real image pairs and pairs of an initial image and a generated picture; is the preliminary or conditioned image, which in the context of GAN-IP represent a base or simplified model of a scene; is the actual picture, which corresponds to the real look of the scene or the target for enhancement in digital scenes.

Discriminator Function. For the discriminator, the objective is to maximize its capability to efficaciously classify actual and generated pics. This is represented by using

$$\min_G \max_D LC_{GAN}(G, D) = E_{i,j}[\log D(i, j)] + E_i[\log(1 - D(i, G(i)))$$

Generator Function. Conversely, the generator goals to reduce the chance that can distinguish generated images from real ones. This is completed through the generator's objective fucntion

$$\min_G LC_{GAN}(G, D) = E_i[\log(1 - D(i, G(i)))$$

Application in GAN-IP. In the GAN-IP framework, these techniques underpin the introduction of digital experimental scenes by, conditioning on initial images , which may be simplified or abstract representations of the desired scenes, serving as a foundation for producing special and sensible scenes. Generating enhanced pics that mimic real-world conditions closely, thereby providing a rich dataset for training and comparing computer vision models. Iterating through the hostile training procedure, where continuously improves its generation capabilities, and enhances its discriminative accuracy, leading to the generation of highly realistic virtual scenes. By optimizing these objective functions in the GAN-IP framework, the model efficiently generates digital scenes that are not only visually convincing but also tailored to specific situations or necessities of computer vision tasks. This allows for a controlled and diverse environment for developing, testing, and refining computer vision algorithms, improving their overall performance and applicability to real-world conditions.

GANs are proficient at generating high-quality, realistic images that closely resemble real-world data. By leveraging GANs within the GAN-IP framework, researchers can create synthetic images with remarkable fidelity, enabling them to simulate complex visual environments effectively.

GAN-IP facilitates data augmentation by generating diverse variations of existing images. This augmentation strategy helps in increasing the robustness of machine learning models by providing additional training data, thereby improving their performance on various computer vision tasks such as object detection, segmentation, and recognition.

In many real-world scenarios, obtaining large and diverse datasets for training computer vision models can be challenging due to data scarcity. GAN-IP mitigates this issue by synthesizing artificial images, effectively expanding the available training data and enabling more comprehensive model training.

GAN-IP enables automatic adjustment and enhancement of image quality, leading to improvements in the performance of computer vision algorithms. By optimizing image features such as brightness, contrast, and sharpness, GAN-IP enhances the visual appearance of images and facilitates better interpretation by machine learning models.

GAN-IP is a versatile framework that can be applied to various computer vision tasks, including image denoising, super-resolution, style transfer, and image-to-image translation. Its flexibility allows researchers to explore different applications and adapt the framework to suit specific research objectives.

By generating synthetic images, GAN-IP enables researchers to simulate diverse scenarios and environments without the need for costly and time-consuming data collection processes. This efficiency accelerates the development and testing of computer vision algorithms, leading to faster innovation and progress in the field.

4. Results and Experiments.

4.1. Simulation Setup. The dataset, meticulously compiled from the PASCAL VOC and MS COCO collections, which is suitable for comparing the GAN-IP framework, especially in the domain of traffic object recognition, which is adapted from the study [21]. Featuring a carefully selected array of 1997 pix of cars and buses from PASCAL VOC and 1997 images from MS COCO, converted for style consistency, this dataset gives a comprehensive view of city and vehicular scenes. The deliberate choice to exclude images where trucks occupy a minor proportion guarantees that each class is represented with sufficient prominence, thereby facilitating more balanced and effective training and testing surroundings. By combining these images and their corresponding annotations into a unified dataset, and similarly dividing them into training and testing units with a 3:1 ratio, the dataset presents a strong foundation for benchmarking the effectiveness of computer vision models and also specifically assessing how the GAN-IP framework enhances virtual scene realism and detail. Such improvements are vital for developing algorithms capable of accurately identifying and classifying a diverse variety of traffic objects across various urban situations. This dataset, with its focus on real-world applicability and comprehensive coverage of common traffic objects, is an ideal candidate for demonstrating the capacity of GAN-IP to noticeably enhance the performance of computer vision technology in practical applications.

4.2. Evaluation Criteria. In this section the proposed model GAN-IP is evaluated in two categories: Overall performance analysis and comparison analysis. In comparison analysis the proposed GAN-IP is compared with the existing techniques of Faster R-CNN, DPM, VGG-16, ResNet 50. And in overall comparison the proposed GAN-IP evaluated and demonstrate its efficacy highly than the other models in terms of performance evaluation metrics, In comparison analysis the existing models are evaluated in the categories of vehicles such as bus, cars and trucks. Based on the recognition capacity the experiments of the proposed is validated and demonstrated below.

4.2.1. Comparison Analysis. The comparative analysis of the proposed GAN-IP with existing models which include Faster R-CNN, DPM, VGG-16, and ResNet-50, throughout vehicles (cars, buses, trucks), exhibits the advanced performance of GAN-IP in enhancing the accuracy, precision, recall, and F1-Score of object detection tasks was shown in Figure 4.1. Specifically, for automobiles, the GAN-IP Enhanced model achieves the best accuracy (0.96), outperforming the next excellent, ResNet-50 (0.94), and drastically surpassing the baseline models like DPM (0.86). This model is steady across automobile classes, with GAN-IP leading in buses and trucks with accuracies of 0.95 and 0.94, respectively, showcasing its effectiveness in generating realistic and unique images that improve detection algorithms.

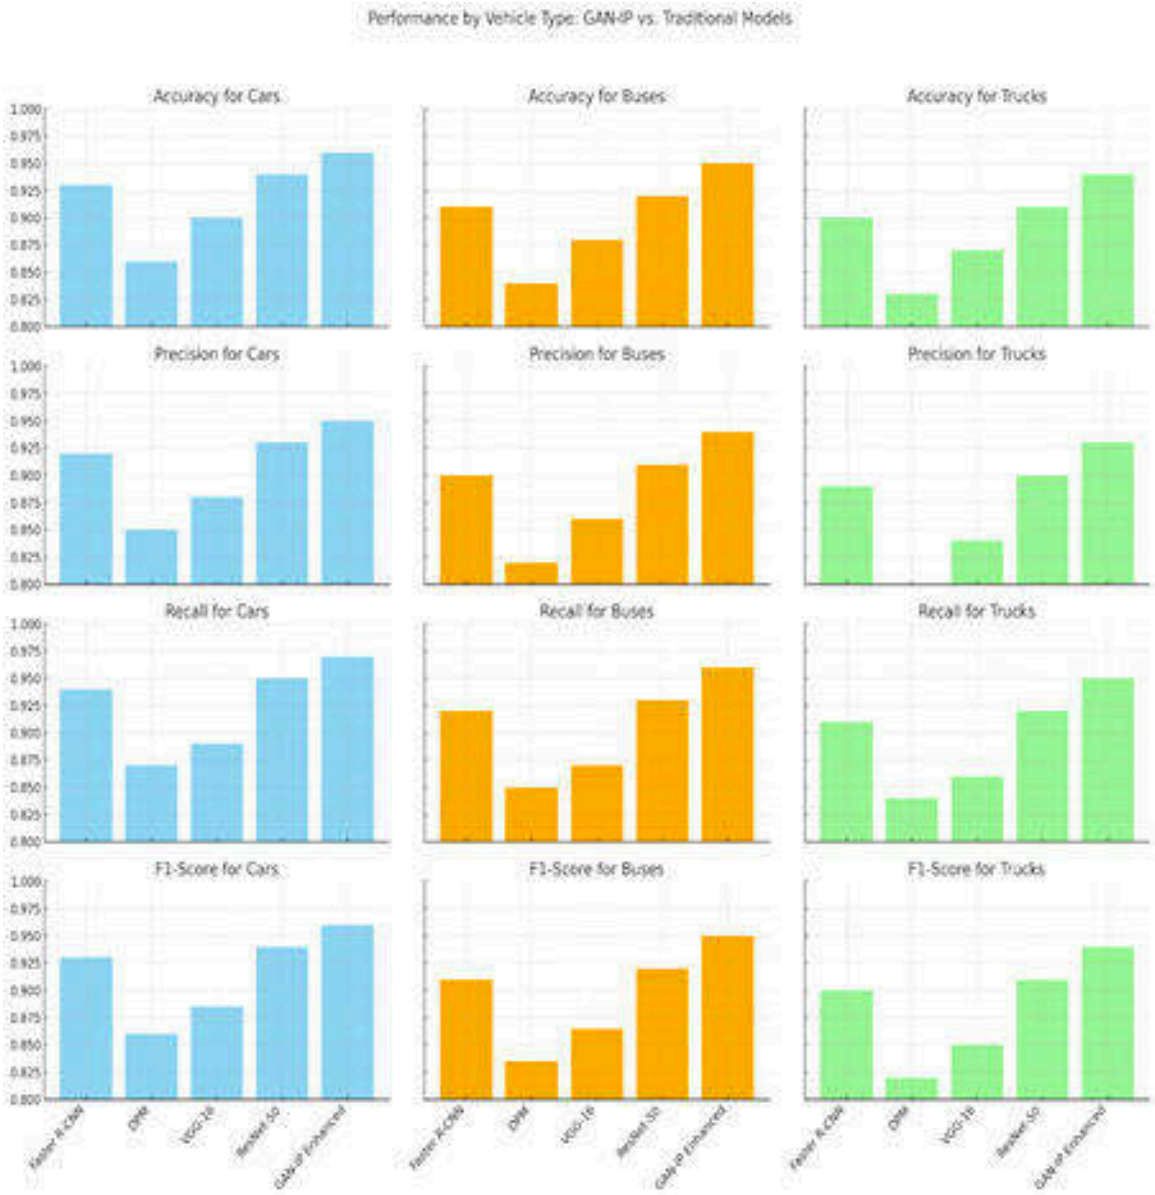

Fig. 4.1: Comparison Analysis

In terms of precision, GAN-IP again outperforms all, especially within the detection of cars and buses, where it scores 0.95 and 0.94, respectively. This precision shows that GAN-IP not only enhances image quality but does so in a manner that allows for greater accurate delineation of object within complex scenes. The recall metrics similarly enhance GAN-IP's capability to minimize fake negatives, accomplishing the highest ratings across all vehicle types, therefore ensuring that more real objects are effectively diagnosed. The F1-Scores, which balance precision and recall, highlight GAN-IP's balanced overall performance improvement, especially for cars and buses, wherein it achieves rankings of 0.96 and 0.95, respectively. This evaluation underscores the efficacy of the GAN-IP framework in appreciably enhancing the overall performance of computer vision models throughout various metrics and vehicle types. By improving the realism and variability of training pictures, GAN-IP allows models to better generalize to real-world situations, an essential factor in applications requiring

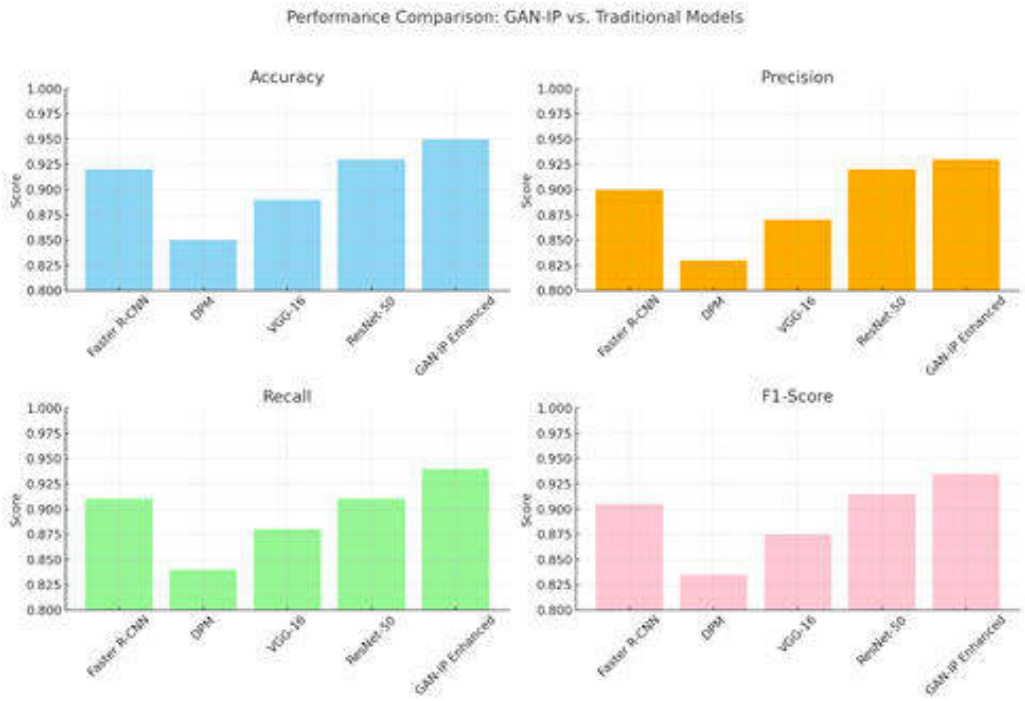

Fig. 4.2: Performance Comparison GAN-Ip vs Traditional models

high precision and reliability in object detection responsibilities. The development in performance metrics across all vehicle classes confirms the ability of GAN-IP to set a new benchmark within the development and refinement of computer vision algorithms for traffic object detection.

4.2.2. Overall Performance Analysis of proposed GAN-IP. Figure 4.2 presents the efficacy of proposed GAN-IP framework, achieves a high-quality accuracy of 0.95. This improvement is notable while as compared to the baseline Faster R-CNN model accuracy of 0.92, and even more against the other existing models of DPM, VGG-16, and ResNet-50, which report accuracies of 0.85, 0.89, and 0.93, respectively. The GAN-IP Enhanced model not only surpasses the original Faster R-CNN in accuracy but also demonstrates superior performance in precision, recall, and F1-Score, with values of 0.93, 0.94, and 0.935, respectively. This highlights the effectiveness of the GAN-IP framework in refining the visual excellent and realism of training pix, which in turn contributes to the improved detection competencies of the underlying computer vision model. The improvement in accuracy to 0.95 by means of the GAN-IP Enhanced model indicates a significant leap forward within the field of object detection, specially in difficult environments along with traffic scenes with cars, buses, and trucks. By generating more detailed and diverse training images, GAN-IP addresses key demanding situations that traditional model face, inclusive of variations in lighting, occlusions, and diverse backgrounds. This superior training set allows the Faster R-CNN model to better generalize from the digital to the real world, reducing overfitting and enhancing its ability to accurately identify and classify objects under varied conditions. The success of the GAN-IP framework in boosting accuracy, along gains in precision, recall, and F1-Score, underscores its ability as a powerful device for advancing the abilities of computer vision systems, making it a precious asset for researchers and practitioners aiming to push the boundaries of what is possible in image recognition and object detection tasks.

5. Conclusion. The study introduces and evaluates the GAN-IP framework, a unique method designed to significantly enhance virtual experimental scenes for computer vision applications. Through complete evaluation, GAN-IP demonstrates advanced performance over present models like Faster R-CNN, DPM, VGG-16,

and ResNet-50, specially in the context of traffic-based object detection throughout diverse vehicle types such as car, buses, and trucks. By leveraging GANs, the GAN-IP framework correctly improves the accuracy, precision, recall, and F1-Score of object detection applications, showcasing its ability to produce highly realistic and detailed virtual pics. This enhancement not only facilitates correct object identity and classification but also ensures the models training on GAN-IP processed images exhibit improved adaptability and robustness to real-world scenarios. The application of GAN-IP in generating and refining training datasets represents a considerable development within the field of computer vision, offering a promising device for researchers and practitioners in search to overcome the limitations of conventional image processing and data augmentation strategies. As the demand for sophisticated computer vision applications continues to grow, the GAN-IP framework stands out as a crucial development, pushing the boundaries of what is manageable within the simulation and analysis of complex visual environments. The study findings verify the ability of GAN-IP to revolutionize the training and overall performance of computer vision algorithms, paving the way for future innovations in the field.

HYBRIDIZATION OF MACHINE LEARNING MODEL WITH BEE COLONY BASED FEATURE SELECTION FOR MEDICAL DATA CLASSIFICATION

R. RAJA* AND B. ASHOK†

Abstract. Nowadays, an important count of biomedical data is created continuously in several biomedical equipment and experiments because of quick technical enhancements in biomedical science. The study of clinical and health data is vital to enhance the analysis precision, prevention, and treatment. Initial analysis and treatment are extremely important approaches for preventing deaths in many diseases. Accordingly, the data mining and machine learning (ML) approaches are helpful tools for utilizing minimization error and for providing helpful data for analysis. But the data obtained in digital machines takes higher dimensionality, and not every data attained in digital machines is significant to specific diseases. This article develops an artificial bee colony-based feature selection with optimal hybrid ML model for medical data classification (ABCFS-OHML) technique. The presented ABCFS-OHML technique mainly aims to identify and classify the presence of disease using medical data. To attain this, the presented ABCFS-OHML technique initially pre-processes the input data in two ways namely null value removal and data transformation. Furthermore, the presented ABCFS-OHML technique uses ABCFS model for the choice of effectual subset of features. At last, root means square propagation with convolutional neural network-Hop field neural network (CNN-HFNN) model for classification purposes. The usage of RMSProp optimizer assists in attaining optimal hyperparameter selection of the CNN-HFNN method. The performance validation of the ABCFS-OHML technique takes place using three medical datasets. The comparison study reported that the ABCFS-OHML technique has accurately classified the medical data over other recent approaches.

Key words: Medical data classification; Machine learning; Deep learning; Feature selection; Hyperparameter tuning

1. Introduction. Healthcare sector generates enormous volume of data and Data Science methods act as a supporting factor for extracting hidden knowledge. It allows innovations and opportunities for enhancing health of people by addressing distinct perspectives firstly descriptive, to identify what happened [4]; diagnostic, to detect the cause why it happened predictive, to analyze what will occur and prescriptive, to find how we can make it happen [18]. Data analytics technology renders more effectual apparatuses that aid to present advanced treatment of chronic disease through early detection, home care, accurate medicine, population health and advanced treatment of communicable diseases, and lifestyle support [2, 16]. For last two decades, the authors have modelled many innovative ML approaches for predictive data analysis. Such useful methods were enforced in several data-intensive research zones namely biology, astronomy to mine hidden patterns, and healthcare [12].

ML grants a huge opportunity in this context firstly assisting medical practitioners, physicians, and geneticists to enhance the analysis of large medical data [3], secondly minimizing the health error risk, and lastly enhancing prognostic and diagnostic procedure harmonization. The authors have used ML for enhancing healthcare techniques by learning bio-medical data [19]. ML is a new and intellectual technique that automatically aids to study of particular issues and rises efficiency without explicitly programming. It could automatically find patterns in data and take decisions with minimum human input. In recent years, the expansion of many ML techniques like clustering, and categorization of data, disease prediction had an important effect on the decision-making procedure [20]. Classification can be referred to as a supervised technique of learning in real-time difficulties. It constitutes a method that precisely estimates the targeted class from data collected at numerous classification stages [10]. Feature selection (FS) techniques can be typically enforced to enhance the performance of the method. It minimizes the computing cost through elimination of irrelevant features. Therefore, this makes the diagnosis procedure very comprehensible and accurate [22].

This article develops an artificial bee colony-based FS with optimal hybrid ML model for medical data classification (ABCFS-OHML) technique. The presented ABCFS-OHML technique initially pre-processes the input data in two ways namely null value removal and data transformation. Furthermore, the presented ABCFS-OHML technique uses ABCFS model for the choice of effectual subset of features. At last, root means square propagation with convolutional neural network-Hop field neural network (CNN-HFNN) model for classification purposes. The experimental validation of the ABCFS-OHML approach was executed utilizing three medical datasets.

2. Related works. Bhukya and Manchala [6] introduce a recent metaheuristic rough set-based FS with rule-oriented medical data classification (MRSFS-RMDC) model on MapReduce architecture. The projected method develops a butterfly optimization technique for minimum rough set selection. Furthermore, Hadoop MapReduce was employed for processing large amounts of information. In addition, a rule-oriented classification model called repeated incremental pruning for error reduction (RIPPER) was utilized by adding a set of conditional rules. Sun et al. [21] developed an AFS-DF for COVID19 categorization related to chest CT images. Next, for capturing the higher-level representation of this feature with the comparatively small-scale dataset, the author leverages deep forest models for learning higher level representations of the feature. Furthermore, the author proposed an FS model related to the trained deep forest mechanism for reducing the feature redundancy, whereby the FC has incorporated adaptively with the COVID19 classification method.

Chen et al. [8] designed a confidence-based and cost-effective FS (CCFS) model based on BPSO for improving the efficiency of healthcare data. Especially, CCFS enhances search efficacy by designing a novel updating model which develops feature confidence for considering the fine-grained effect of all the dimensions in the particles on the classifier accuracy. The author in [11], developed a novel algorithm called ensemble embedded FS (EEFS) for handling multilabel bioinformatics data learning problems in an efficient and effective manner. The EEFS doesn't explicitly discover the correlations amongst labels, however, it could sufficiently make use of the label correlation through multilabel classifier and evaluation measure. Moreover, it reduces the accumulated error of information itself by using an ensemble model. Chen et al. [7] suggested confidence related and cost-effective FS model based on binary PSO, CCFS. Firstly, CCFS enhances search efficacy by designing a novel updating model, where confidence of all the features is considered which includes the correlation among categories and features, and historically selected frequency of every feature.

Nagarajan et al. [17] formulate a hybrid GA-ABC that denotes a genetic related ABC method for classification and feature-selection by utilizing classifier ensemble methods. The ensemble classifier has 4 techniques namely DT, SVM, NB, and RF. Karlekar and Gomathi [14] introduce a technique for healthcare data classification utilizing a new ontology and whale optimization-oriented SVM (OW-SVM) method. Primarily, privacy-preserved data can be formulated by implementing Kronecker product bat method, and then, ontology can be constructed for selecting features. The OW-SVM was then modelled through integration of ontology and whale optimization method into SVM where ontology and whale optimization method has been employed for selecting the kernel parameters feasibly.

3. The Proposed Model. In this article, a new ABCFS-OHML method was formulated for medical data classification. At the preliminary stage, the presented ABCFS-OHML method initially pre-processes the input data in two ways namely null value removal and data transformation. Moreover, the presented ABCFS-OHML technique uses ABCFS model for the choice of effectual subset of features. Finally, the RMSProp optimizer with CNN-HFNN model for classification purposes. Fig. 3.1 defines the overall process of ABCFS-OHML system.

3.1. FS using ABC Algorithm. Once the medical data is pre-processed, the next level is to choose an optimal feature subset. ABC is the optimization technique stimulated by honeybee nectar gathering behaviors and proposed on the basis of random population [9]. Due to its simplicity, global search capability, and efficiency robustness, it is demonstrated to be nature-inspired algorithm for managing constrained and unconstrained multi-or-single-objective global optimization issues. In this work, each bee was classified into scouts, employed bees, and onlookers. The three types of honeybee use nectar sources via separation of labour and cooperation and continually upgrade the position of nectar source by sharing and marking for detecting the optimum nectar source. The position of nectar sources matches with possible solution to optimization problems, and quality of nectar sources are evaluated by the fitness values of optimization issue. The steps for ABC algorithms are

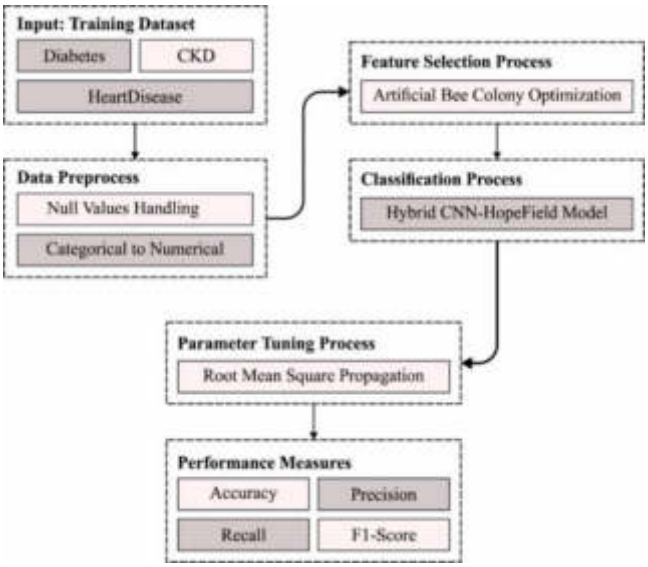

Fig. 3.1: Overall process of ABCFS-OHML system

given below.

1. Initialized phase: Set the number of maximum iterations, bee colonies, optimized range, and dimensionality.
   In this study, ABC technique was utilized to enhance duty cycle D, the optimized range was set to (0.85, 1), the primary amount of the onlooker and employed bees are set as 30 and 50 correspondingly, dimension was set as 1, and the maximal amount of iterations was set as 10.
2. *Employed bee phase:* They search for a novel food source nearby the existing food source.
   To generate candidate food location from the older one, the novel solution was related to the present solution, and fitness can be evaluated based on the subsequent equation as follows:

$$V_{ij}=X_{ij}+\phi_{ij}\,(X_{ij}-X_{kj}) \tag{3.1}$$

   Now, y_{ij} represents the novel position of food sources; X_{ij} indicates the existing food resource; $i\in\{$

3. *Onlooker bee stage:* The onlooker chooses food resources afterward sharing data of employed bees and define the amount of nectar. The best solution is chosen based on the probability that is evaluated as follows:

$$p_i=\frac{f_i}{\sum_{i=1}^{s_N} f_i} \tag{3.2}$$

From the expression, f_i indicates the fitness function (FF) values of j^{th} solution.

4. *Scout bee stage:* In all the iterations, the scout bee monitors the variations of all the solutions in swarm. Once the food source could not be upgraded by means of predefined cycle, it is detached from population, and employed bees of food resource turns out be scouts and utilize subsequent formula for finding a novel random food source position:

$$X_{ij}=X_{\min\ j}+rand\,[0,1]\,(X_{\max\ j}-X_{\min\ j}) \tag{3.3}$$

The FF leveraged in this presented technique was modelled to maintain a balance between the number of selected features in all solutions (minimal) and the classifier accuracy (maximal) achieved with the use of these selected features, Eq. (3.4) signifies the FF for evaluating solutions.

$$Fitness=\alpha\gamma_R\,(D)+\beta\frac{|R|}{|C|} \tag{3.4}$$

whereas $\gamma_R(D)$ indicates the classifier error rate of a given classifier was utilized here). $|R|$ represents the cardinality of the subset which is selected and $|C|$ refers to the total number of attributes in the datasets, β andα were 2 parameters respective to the significance of subset length and classification quality. $\in$ [1, 0] and β= 1−α.

3.2. Data Classification using CNN-HFNN Model. To detect and classify medical data, the CNN-HFNN model is exploited in this study. CNN has robust representation learning abilities by extracting and learning features automatically from inputs. CNN methods were commonly made up of fully connected (FC), convolutional layers, and pooling layers in classification applications. In a chain-oriented DNN, the FC layers have many parameters belongs to the network, which influences the computational complexity and memory occupancy. For several real time issues, accelerating inference period becomes a significant matter due to the hardware design implications. To handle this issue, the replacement of the FC layers in addition to Hopfield neural networks (HNNs) was proposed [15]. This presented structure will combine an HNN and a CNN: A pretrained CNN technique was employed for extracting features, subsequently, an HNN, which will be assumed as an associative memory that stores every feature constituted by the CNNs. The HNN architecture has interconnected powerful features and neurons of content addressable memory that are crucial for solving numerous optimization and combinatorial tasks. The HNN technique involves organized neurons. In bipolar detection, the neuron from discrete HNN is employed; 1 is implemented to represent the true state, and the falsification can be determined as 1. The fundamental analysis of neuron state activation from HNN is characterized as follows.

$$S_i = \begin{cases} 1, & if \quad \sum_j W_{ij} S_i > \psi, \\ -1, & Otherwise \end{cases} \tag{3.5}$$

whereas W_{ij} denotes the synaptic weighted vector of HNN-RANkSAT derived from *j-th* to *i-th* neuons. S_i indicates the state of *i-th* neurons from HNN, and ψ represents the existing values. The value ψ= 0 is to verify that the network energy is reduced to 0. The synaptic weighted connection from discrete HNN has no connection with itself, and the synaptic connected in one neuron to others is 0 (W_{iii}=W_{jjj}=W_{kkk} and W_{ii}=W_{jj}=W_{kk}). Consequently, HNN has symmetrical features regarding structure. The HNN method is similar and intricate fact to Ising technique of magnetism. In bipolar expression, the neuron state is termed as spin point executes the magnetic field trajectory. Each neuron is compelled for flipping still it achieves a stable equilibrium state based on the following equation.

$$S_i \rightarrow sgn\ [h_i(t)] \tag{3.6}$$

The local field vector connects all the neurons from HNN is defined by h_i. The sum of field is caused by each neuron state in the following:

$$h_i = \sum_{k}^{N} \sum_{j}^{N} W_{ijk} S_j S_k + \sum_{j}^{N} W_{ij} S_j + W_i \tag{3.7}$$

The task of local field is to evaluate the final state of neuron and generate each possible 3-SAT-induced logic accomplished in the final state of neuron. The predominant feature of HNN network is the detail that it converges continuously as follows [1]:

$$E_{F_{RANkAT}} = \sum_{i=1}^{NN} \prod_{j=1}^{V} T_{ijk} \tag{3.8}$$

in which V and NN imply the number of variables and neurons created from $F_{RANkSAT}$ correspondingly. The inconsistency of $F_{RANkSAT}$ demonstration as:

$$T_{ij} = \begin{cases} \frac{1}{2}(1-S_\rho),\ if\ \neg\rho \\ \frac{1}{2}(1+S_\rho)\ ,\ otherwise \end{cases} \tag{3.9}$$

The value $F_{RANkSAT}$ is proportionate to value of inconsistency in the logical clause as follows:

$$S_i\,(t{+}1) = \begin{cases} 1, & h_i = \sum_K^N \sum_J^N W_{ijk} S_j S_k + \sum_J^N W_{ij} S_j + W_i \geq 0 \\ -1, & h_i = \sum_K^N \sum_J^N W_{ijk} S_j S_k + \sum_J^N W_{ij} S_j + W_i < 0 \end{cases} \tag{3.10}$$

Eq. (3.10) describes the Lyapunov energy function from the HNN.

$$H_{F_{RINNAT}} = -\frac{1}{3} \sum_{i=1,i\neq j,j\neq kj=1}^{N} \sum_{i\neq j,j\neq ik=1}^{N} \sum_{i\neq j,k\neq i}^{N} W_{ijk} S_i S_j S_k - \frac{1}{2} \sum_{i=1,i\neq jj=1}^{N} \sum_{i\neq j}^{N} W_{ij} S_i S_j - \sum_{i=1}^{N} W_i S_i \tag{3.11}$$

Eq. (3.11) is used to classify when the solution acquires global/local minimal energy. HNN makes the optimal allocation when the induced neuron state acquires global minimum energy. Restricted analyses are incorporated with HNN and ACO as a single computation network. Consequently, the robustness of ACO improves the trained process from HNN as follows:

$$\left| H_{F_{RANKSAT}} - H_{F_{RANKSAT}}^{\min} \right| \leq \xi \tag{3.12}$$

In Eq. (3.12), ξ indicates a tolerance value. The value $\xi = 0.001$. When the $F_{RANkSAT}$ logical representation embedding from HNN does not fulfill the condition, afterward that the neurons are surrounded in the incorrect pattern from the final state.

3.3. Hyperparameter Tuning Employing RMSProp Technique. To adjust the hyperparameters of the CNN-HFNN technique, the RMSProp optimizer is used. The RMSprop optimizer restricts the oscillation in the vertical direction [5]. Thus, learning rate can be increased and the presented model could take large step in the horizontal direction which converges fast. The RMSprop calculation is demonstrated as follows. The momentum value is represented as beta and is generally fixed as 0.9.

$$vdw = \beta \cdot vdw + (1-\beta) \cdot dw^2$$

$$vdb = \beta \cdot vdw + ^{(1-\beta)\cdot db^2}$$

$$W = W - \alpha \cdot \frac{dw}{\sqrt{vdw} + \varepsilon}$$

$$b = b - \alpha \cdot \frac{db}{\sqrt{vdb} + \varepsilon}$$

In backpropagation model, dW and db are used for updating W and b parameters:

$$W = W - learning\ rate * dW$$

$$b = b - learning\ rate * db$$

In RMSprop, before utilizing dW and db individually for all the epochs, exponentially weighted average of square of dW and db has been considered:

$$S_{dW} = \beta^* S_{dW} + (1-\beta)^* dW^2$$

$$S_{db} = \beta^* S_{db} + (1-\beta)^* db^2$$

whereas β beta is additional hyperparameter and takes value from zero to one. The newly weighted average is made by weights, average of prior and present value square. Afterward computing exponential weighted average, the parameter has been updated.

$$W = W - learning\ rate * dW/sqrt(S)$$

$$b = b - learning\ rate * db/sqrt(S)$$

S_{dW} is quite lesser such that are splitting it by dW. While S_{db} is quite larger such that splitting db with relatively large value reduces the update on vertical dimension.

Table 4.1: Dataset description

Description	CKD	Diabetes	Heart Disease

4. Results and Discussion. The experimental validation of the ABCFS-OHML method is tested using three medical datasets namely CKD, Diabetes, and HD. Table 4.1 represents the detailed description of three medical datasets.

Fig. 4.1 shows the convergence study of the ABCFS-OHML model on the applied datasets. On the CKD dataset, the ABCFS technique has chosen the following features: sg, al, su, rbc, pcc, sc, sod, pot, pcv, rbcc, htn, appet, pe, and ane. Besides, on diabetes dataset, the ABCFS technique has elected preg, plas, mass, pedi, and age features. Finally, on HD dataset, the chosen features are sex, chest, resting_blood_pressure,

Table 4.2: Result analysis of ABCFS-OHML technique with various measures under three datasets

Measures	**CKD Dataset**	**Diabetes Dataset**	**Heart Disease Dataset**
Accuracy	99.00	96.74	98.15
Precision	99.20	94.18	97.52
Recall	99.20	96.64	98.33
F1-Score	99.20	95.40	97.93

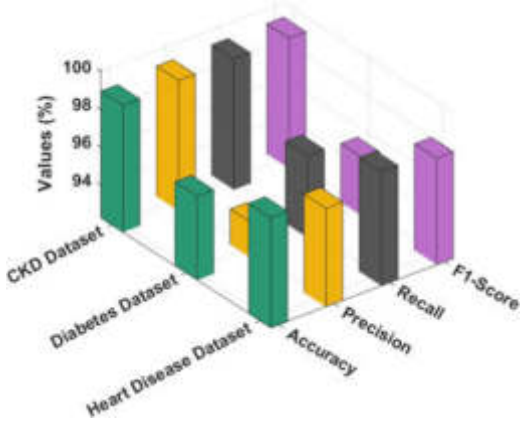

Fig. 4.2: Result analysis of ABCFS-OHML technique under three datasets

maximum_heart_rate_achieved, exercise_induced_angina, oldpeak, slope, and thal.

Table 4.2 and Fig. 4.2 report the outcomes offered by the ABCFS-OHML technique. The outcomes inferred the ABCFS-OHML technique has gained effectual performance on every dataset. For instance, on CKD dataset, the ABCFS-OHML technique has offered $accu_y$ of 99%, $reca_l$ of 99.20%, $prec_n$ of 99.20%, and $F1_{score}$ of 99.20%. Meanwhile, on diabetes dataset, the ABCFS-OHML technique has rendered $accu_y$ of 96.74%, $reca_l$ of 94.18%, $prec_n$ of 96.64%, and $F1_{score}$ of 95.40%. Eventually, on heart disease dataset, the ABCFS-OHML approach presented $accu_y$ of 98.15%, $reca_l$ of 97.52%, $prec_n$ of 98.33%, and $F1_{score}$ of 97.93%.

Fig. 4.3 establishes the classifier results of the ABCFS-OHML approach under CKD dataset. Fig. 4.3 a shows the confusion matrix presented by the ABCFS-OHML method. The figure highlighted the ABCFS-OHML technique has identified 148 instances under notckd and 248 instances under ckd. Also, Fig. 4.3 b illustrates the precision-recall study of the ABCFS-OHML technique. The figures stated the ABCFS-OHML approach has gained maximal precision-recall performance in every class. At last, Fig. 4.3 c exemplifies the ROC study of the ABCFS-OHML method. The figure depicted the ABCFS-OHML approach has resulted in proficient results with higher ROC values in every different class label.

Fig. 4.4 portrays the classifier results of the ABCFS-OHML method under diabetes dataset. Fig. 4.4 a represents the confusion matrix provided by the ABCFS-OHML technique. The figure displayed the ABCFS-OHML approach has identified 484 instances under notckd and 259 instances under ckd. Likewise, Fig. 4.4 b illustrates the precision-recall analysis of the ABCFS-OHML algorithm. The figures stated the ABCFS-OHML technique has gained maximal precision-recall performance in every class. Finally, Fig. 4.4 c displays the ROC study of the ABCFS-OHML algorithm. The figure represented the ABCFS-OHML methodology has resulted in proficient outcomes with maximal ROC values in different class labels.

Fig. 4.5 exhibits the classifier results of the ABCFS-OHML approach under heart disease dataset. Fig. 4.5 a depicts the confusion matrix presented by the ABCFS-OHML method. The figure stated the ABCFS-OHML method has identified 148 instances under notckd and 248 instances under ckd. Also, Fig. 4.5 b establishes

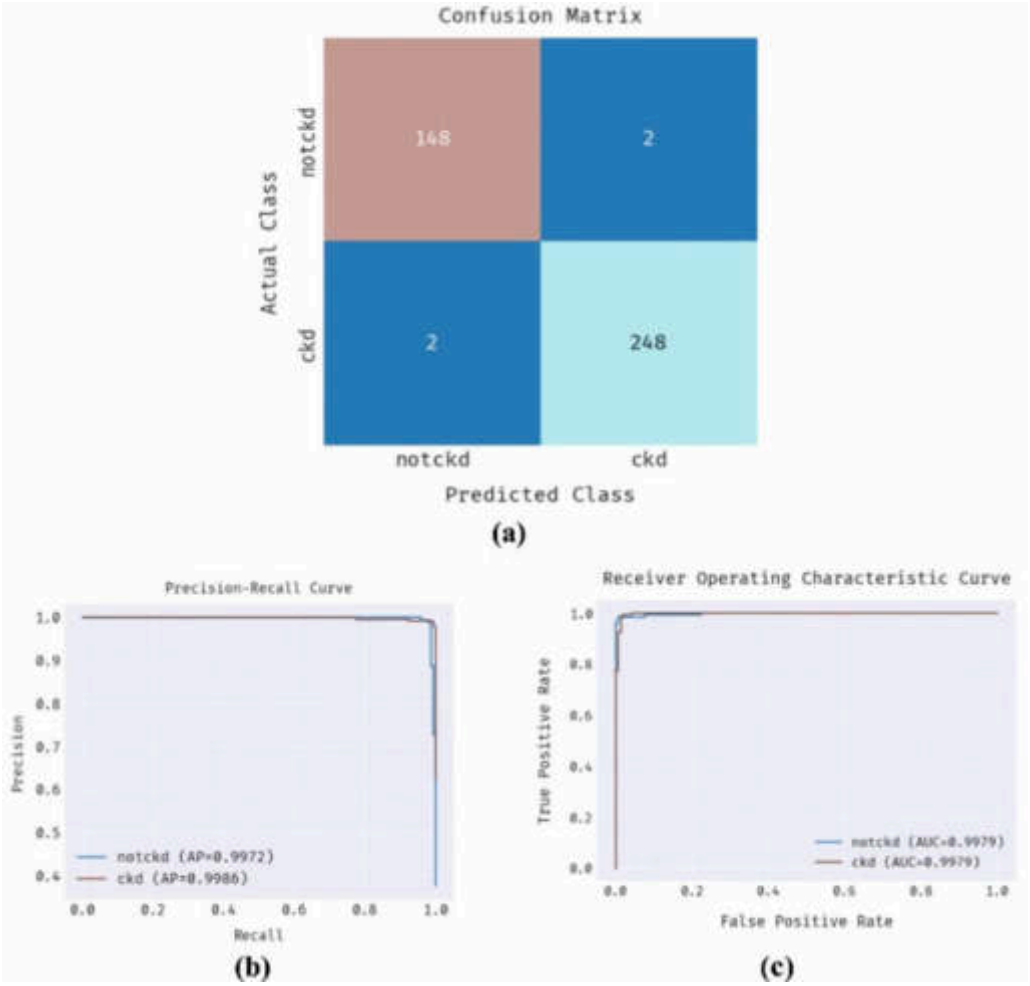

Fig. 4.3: CKD dataset (a) Confusion Matrix (b-c) PR and ROC curves

the precision-recall investigation of the ABCFS-OHML approach. The figures highlighted the ABCFS-OHML technique has reached maximum precision-recall performance under all classes. Lastly, Fig. 4.5 c exhibits the ROC study of the ABCFS-OHML method. The figure exhibited the ABCFS-OHML approach has resulted in proficient outcomes with maximal ROC values in different class labels.

Fig. 4.6 delivers the accuracy and loss graph analysis of the ABCFS-OHML method in three datasets. The outcomes exhibited accuracy value seems to be higher and loss value seems to lower with an increase in epoch count. It is noted that the training loss is low and validation accuracy is high on the test three datasets.

For reassuring the improved performance of the ABCFS-OHML method, the detailed comparative review of CKD dataset is given in Table 4.3 and Fig. 4.7. The outcomes represented the OlexGA model has resulted in least $accu_y$ of 75%. Then, the XGBoost and LR models have resulted in slightly improvised $accu_y$ of 83% and 82% whereas the PSO algorithm has reached even improved $accu_y$ of 95%. Although the DT and ACO models have accomplished reasonable $accu_y$ of 90% and 87.50%, the ABCFS-OHML model has shown maximum $accu_y$ of 99%.

For reassuring the enhanced performance of the ABCFS-OHML technique, a brief comparative study on Diabetes dataset is given in Table 4.4 and Fig. 4.8. The outcomes denoted the Voted Perceptron approach has resulted in least $accu_y$ of 66.79%. Then, the DT algorithm resulted in slightly improvised $accu_y$ of 73.82%

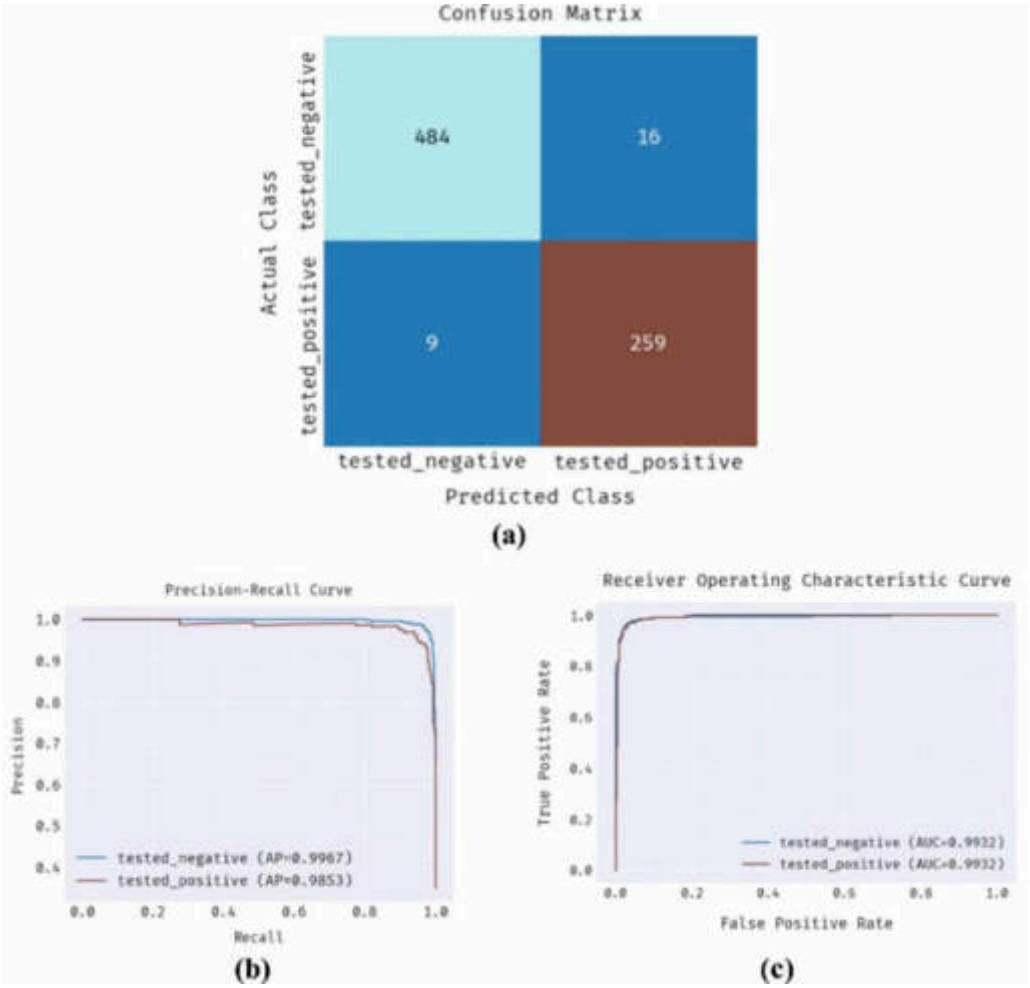

Fig. 4.4: Diabetes dataset (a) Confusion Matrix (b-c) PR and ROC curves

Table 4.3: ***Accu$_y$*** analysis of ABCFS-OHML technique with existing approaches under CKD dataset

Methods	**Accuracy**
ABCFS-OHML	99.00
Decision Tree	90.00
ACO	87.50
PSO	85.00
XGBoost	83.00
Logistic Regression	82.00
OlexGA	75.00

whereas the LogitBoost algorithm has reached even improved $accu_y$ of 74.08%. Though the LR and GBT techniques have established reasonable $accu_y$ of 77.21% and 88.67%, the ABCFS-OHML method has shown maximum $accu_y$ of 96.74%.

For reassuring the enhanced performance of the ABCFS-OHML technique, a detailed comparative study on heart disease dataset is given in Table 4.5 and Fig. 4.9. The results showed the RT algorithm has resulted

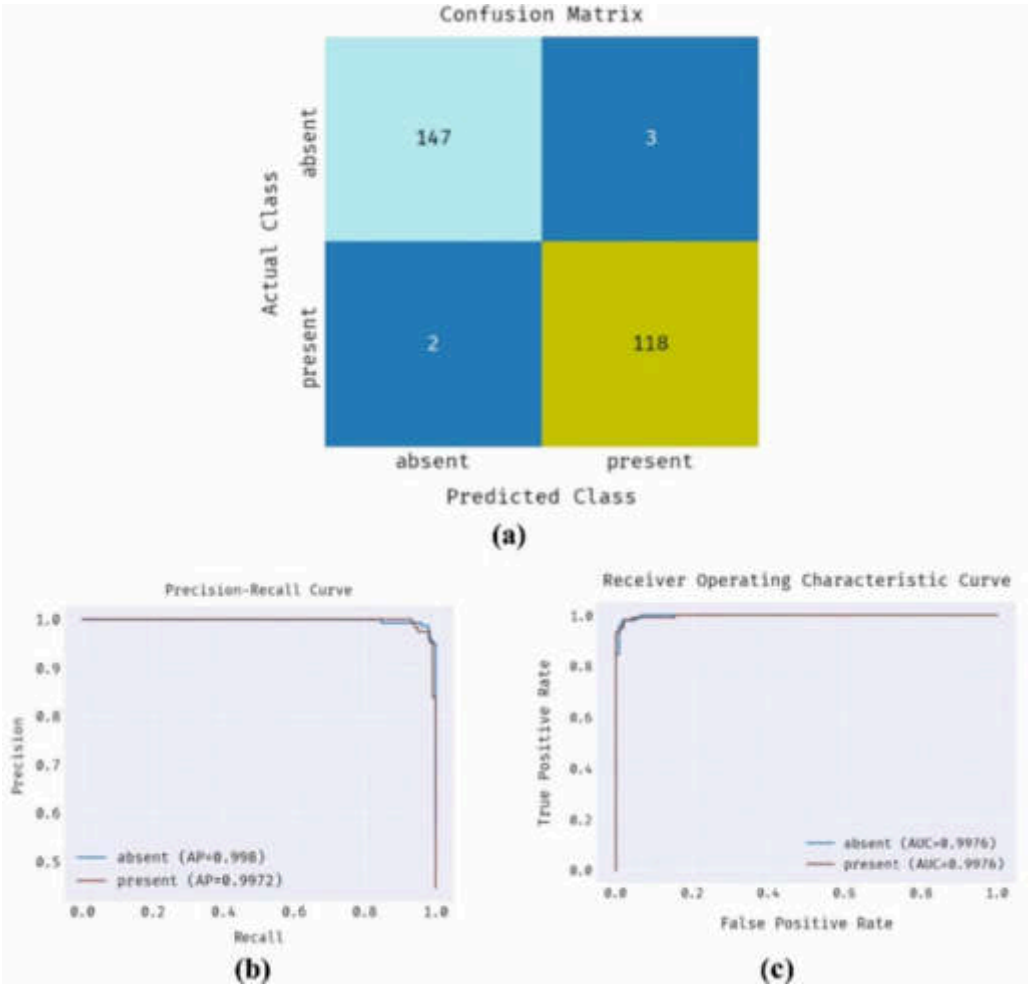

Fig. 4.5: Heart Disease dataset (a) Confusion Matrix (b-c) PR and ROC curves

Table 4.4: $\boldsymbol{Accu_y}$ analysis of ABCFS-OHML technique with existing

Methods	**Accuracy**
ABCFS-OHML	96.74

5. Conclusion. In this article, a new ABCFS-OHML approach was devised for medical data classification. At the preliminary stage, the presented ABCFS-OHML approach initially pre-processes the input data in two ways namely null value removal and data transformation. Additionally, the presented ABCFS-OHML technique uses ABCFS model for the choice of effectual subset of features. Finally, the RMSProp optimizer with CNN-HFNN model for classification purposes. The usage of RMSProp optimizer assists in attaining optimal hyperparameter selection of the CNN-HFNN method. The performance validation of the ABCFS-OHML technique takes place using three medical datasets. The comparison study reported that the ABCFS-OHML technique has accurately classified the medical data over other recent approaches. Thus, the presented

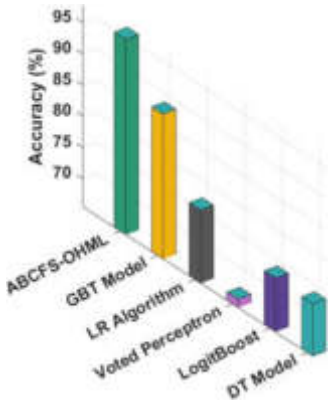

Fig. 4.8: $\boldsymbol{Accu_y}$ analysis of ABCFS-OHML technique under Diabetes dataset

Table 4.5: $\boldsymbol{Accu_y}$ analysis of ABCFS-OHML technique with existing approaches under heart disease dataset

Methods	**Accuracy**
ABCFS-OHML	98.15
J48	76.66
Random Tree	76.29
RBFNetwork	84.07
NBTree	80.37
Random Forest	81.85

ABCFS-OHML technique can be employed for accurate medical data classification. The limitations of the ABCFS-OHML technique includes the restricted scalability for handling extremely large datasets and potential overfitting. In future, outlier removal approaches will be employed to boost the classification performance of the ABCFS-OHML technique.

AN EFFICIENT CRYPTOGRAPHIC SCHEME BASED ON OPTIMIZED WATERMARKING SCHEME FOR SECURING INTERNET OF THINGS

ABHINAV VIDWANS* AND MANOJ RAMIYA†

Abstract. In this work, a new efficient cryptographic scheme based on the concept of chaotic map and optimized watermarking scheme is proposed. In the optimized watermarking scheme, a combination of discrete wave transformation (DWT), hessenberg decomposition (HD), and singular value decomposition (SVD) are used. In this, the host image is first broken down into several sub-bands using multi-level DWT, and the resulting coefficients are then fed into HD during the embedding phase. Simultaneous watermark operation is performed on SVD. Finally, the scale factor embeds the watermark into the host image. The Differential evolution method is used to find the best scaling factor for the optimized watermarking scheme. The resulting watermarked image is then encrypted by the session key based scheme. In this scheme for each image encryption, a new random session key will be produced. The presented approach uses 64-bit plaintext and a variable size key that will be decided at the time of encryption for encrypting an image. Since session keys change with each transmission, this approach does not involve extracting and remembering session keys in order to produce subsequent session keys. IoT devices are used to test the developed method for security. The experiment's findings shows that the suggested method works better than the current scheme in several aspects.

Key words: Encryption, Session Key, Decryption, Block cipher, Hybrid pseudo random number generator, DWT, HD, SVD

1. Introduction. Now a days, Digital images are used extensively in a variety of industries, such as finance, personal communication, and healthcar, thus it is becoming more and more important to ensure their safe transmission and storage. This is particularly true in terms of preserving them from tampering, interception, and unauthorized access [1, 2]. As a result, maintaining the security of digital images has become essential. Steganography and watermarking are two essential techniques for enabling secret communication. In this study, the simplest form of watermarking-based security is used.

Digital watermarking schemes can be categorized into a variety of techniques. Based on their domain, the techniques of image watermarking fall into one of two categories: transformed domains or spatial domains. Because spatial domain-based watermarking techniques are resistant to a wide range of attacks, they are not widely used. Rather, modified domain approaches are usually used in robust watermarking to ensure the image's resilience against several types of attacks. SVD, DFT, DCT, and DWT are a few transformed domain techniques via examples. This work employs the hybrid SVD and DWT techniques [3–8] in conjunction with Hessenberg decomposition. Of these strategies, the best assault resistance is reported in [9]. These techniques provide better security for securing digital images but don't provide an extra layer of security for securing confidential images. Because as the technology grows, the user needs extra security for secure transmission of images from sender to receiver.

Traditional symmetric-key image encryption approaches are frequently more expensive due to their mathematical complexity and the increased number of rounds required for encryption. Hence the author in [10-13] has discussed session key image encryption schemes having less number of encryption and decryption rounds. The work addresses several image encryption techniques that are based on hyperchaotic and genetic algorithms, such as the logistic map [14], the hyperchaos and Chinese remainder theorem [15–19], the hash key using the crossover operator, and the chaos [20], and chaos using the mutation and crossover operator [21]. These techniques also do not provide additional security in terms of adding one extra layer of security.

†Department of Computer Science and Engineering, Institute of Advanced Computing, Sage University, Indore, MP-India (manojramiya@gmail.com)

To reduce the complexity and increase one more level of security, the following improvements have been made to the existing scheme defined in [22]:

(a) One more level of security in the form of an optimized watermarking scheme is used in this work, where a differential evolution scheme is used to find the optimal scaling factor used in the watermarking scheme.
(b) In the existing scheme, only a 96-bit key was used to protect the images from intruders. In this work, a variable key size will be used that will be decided at the time of encryption.
(c) In the existing scheme, there was no comparison of the developed methodology on the IoT-based hardware. In this work, a comparative study has been done on the different IoT-based hardware.

This is the configuration of the complete work: The various terminologies used for the implementation of the work are explained in Section 2. The proposed methodology is given in section 3. Separate descriptions of the experimental results are given in Section 4. Before the entire project is wrapped up in section 6, IoT applications are covered in section 5.

2. Preliminaries. The different terminology utilized in this work for implementation will be explained in this part.

2.1. Hybrid Pseudo Random Generator. For any random generating algorithm, a seed value must be entered when the program is first started. Every trial will produce the same random number if arithmetic operations are applied to generate random numbers and the seed value remains constant. Thus, a millisecond system timestamp is employed as a seed value to solve this problem. Since a millisecond can alter drastically in a very short amount of time, this approach will always provide a different random number. The multiplicative congruence approach is applied here as well for arithmetic operations. Each trial results in an update of the input value for the subsequent iteration. Utilizing a random number generator, distinct crossover points could be generated, as the crossover function relies on two random crossover points. When it comes to producing distinct random numbers, it performs better than other similar pseudo-random number generators.

The hybrid pseudo-random generator approach is demonstrated in the subsequent steps [26]:

Step 1: Initialize the number of random integers (m) and the upper limit (p) with their initial values.
Step 2: Capture the timestamp and extract the last four digits from the microsecond section, assigning this value to 't1' as the seed.
Step 3: Set 'x' to 1.
Step 4: For each iteration from 1 to m:
  a. Calculate y using the formula x = $(m^2 + a * x)$ mod (p + 1), where 'a' is derived from t1 (1, 6).
  b. Record the floor value of 'x' in the array R at position (1, i).
  c. Modified the value of 't1'
  End the loop.
Step 5: Provide the resulting array R as the output.

2.2. Two-point crossover. This type of crossover uses two crossover points to further distort the resultant strings. The crossover point values are selected at random for each of the two crossover points to prevent infiltration.

For example: Let M = 0 1 1 0 1 1 0 and N = 1 0 0 0 1 1 0 be two parent strings with crossover points generated at random intervals of 2 and 4. After two-point crossover, the newly formed parents are:

M = 0 1 0 0 1 1 0 1; N = 1 0 1 0 1 1 1 0.

Here m1 = 0 1; m2 = 0 0; m3 = 1 1 0 1; n1 = 1 0; n2 = 1 0; n3 = 1 1 1 0

2.3. Differential Evolution Scheme. One well-liked evolutionary technique for global optimization issues is differential evolution (DE) [33]. It works especially well for multi-modal and continuous optimization. The Differential Evolution algorithm's fundamental steps are as follows:

Step 1: Define the problem definition, population size, search space dimensions, and initialize a population of potential solutions.
Step 2: Make a mutant vector for every member of the population by fusing three randomly chosen members and adjusting the mutation by a scaling factor.
Step 3: Create a trial vector by performing a binary crossover operation between the original individual and the mutant vector.

Step 4: Compare and examine the trial vector's fitness with the original individual. Replace the original individual with the trial vector if it proves to be superior.
Step 5: Select a termination condition, such as convergence requirements or reached the number of generations.
The best scaling factor value is found in step 5 of the optimized watermarking technique, as illustrated in section 3.1, using the DE algorithm in the proposed work. The initial population for this DE algorithm comprises values ranging from 0 to 1.

3. Proposed Methodology. The proposed methodology in this work is based on two security phases: The first security phase is based on an optimized watermarking scheme while the second security phase is based on the encryption phase.

3.1. Optimized watermarking Scheme. The following steps are used to perform an optimized watermarking scheme in this work-
Step 1: The host image is decomposed into the components of LH, LL, HH, and HL based on R-level DWT [23] where $R = log_2(\mathrm{m/n})$
Step 2: Perform HD [25] on the LL component of the host image by using the following equation-

$$PHP^T = HD(LL) \tag{3.1}$$

Step 3: Apply SVD [24] to H by using the following equation-

$$HU_w HS_w HV_w^T = SVD(H) \tag{3.2}$$

Step 4: Applied SVD on the secret image W by using this equation –

$$U_w S_w V_w^T = SVD(W) \tag{3.3}$$

Step 5: Calculate an embedded singular value by using this equation-

$$HS_w^* = HS_w + \theta S_w \tag{3.4}$$

Here θ is the scaling factor chosen by using the differential evolution method.
Step 6: Convert watermarked sub-band H^* by the inverse SVD, using the following equation-

$$H^* = HU_w HS_w^* HV_w^T \tag{3.5}$$

Step 7: Reconstructing a new approximation sub-band LL_ at low frequencies is done using the inverse HD, which is provided by -

$$LL^* = PH^*P^T \tag{3.6}$$

Step 8: Finally the watermarked image is obtained by performing the inverse R-level DWT.
After step 8, the watermarked image will be generated. Now this watermarked image will be encrypted by the below encryption scheme (described in section 3.2) used in this work

3.2. Encryption Scheme. The encryption scheme used in this work is based on three different phases as described in the [22].

3.2.1. Key Generation phase. The following procedures are employed in this phase to produce the key using a hybrid pseudo-random number generator-
Step 1: Define 56-bit key and the following key =01234567890123 is used for experiments in this work.
Step 2: Split the 64-bit into 8 different blocks.
Step 3: Generate 8-bit, 24-bit, and 40-bit random blocks using a hybrid pseudo-random number generator, discussed in section 2.4.
Step 4: With the help of the XOR operator and one user-defined function based on two-point crossover, discussed in section 2.5 to generate 64-bit, 80-bit, and the 96-bit key.
The generated keys will be used randomly at the time of encryption.

3.2.2. Encryption Phase. After the key generation, the next phase is encryption in which 4 encryption rounds and two swaps are used if using the 64-bit key for encryption during run time. 5 encryption rounds and 3 swaps will be used if using the 80-bit key for encryption during run time. Otherwise, 6 encryption rounds and 4 swaps will be used. One random function, XNOR, and XOR are included in each round (f). To increase the security of the cipher text, this random function is based on the two-point crossover operator. The following steps will be used for encryption-

Step 1: Generate 4 blocks by dividing the 64-bit plain text.
If using 64-bit key during run time then perform following steps:
Step 2: In round 1, perform XOR and two-point crossover operations between the first 16 bits of the key part and generated blocks in step 1, to generate 4 new different blocks.
Step 3: Perform swapping between newly generated blocks in step 2.
Step 4: Reiterate step 2 and step 3 for 2^{nd}, 3^{rd} and 4^{th} 16-bit key parts in round 2, 3 and 4.
Else if using 80-bit key during run time then perform following steps:
Step 5: In round 1, perform XOR and two-point crossover operations between the first 16 bits of key part and generated blocks in step 1, to generate 4 new different blocks.
Step 6: Perform swapping between newly generated blocks in step 2.
Step 7: Reiterate step 5 and step 6 for 2^{nd}, 3^{rd}, 4^{th} and 5^{th} 16-bit key parts in round 2, 3, 4, and 5.
Otherwise (if using 96-bit key during run time then perform following steps):
Step 8: In round 1, perform XOR and two-point crossover operations between the first 16 bits of key part and generated blocks in step 1, to generate 4 new different blocks.
Step 9: Perform swapping between newly generated blocks in step 2.
Step 10: Reiterate step 8 and step 9 for 2^{nd}, 3^{rd}, 4^{th}, 5^{th} and 6^{th} 16-bit key parts in round 2, 3, 4, 5, and 6.

3.2.3. Decryption Phase. In this phase, perform reverse operations implemented in the encryption phase to decrypt the image.

The following general steps are used to perform the proposed methodology-

Step 1: Import host image and secret image
Step 2: Perform an optimized watermarking scheme to generate the watermarked image.
Step 3: Use a watermarked image as an input to the used encryption scheme.
Step 4: Generate encrypted watermarked image at the sender side and sent for communication at the receiver side.
Step 5: The Receiver will decrypt the watermarked image by using the inverse process of encryption.
Step 6: Perform the reverse procedure of an optimized watermarking scheme to generate the original secret image.
Step 7: Received original secret image at the receiver side.

The following flow chart shows the overall scheme used in this work in Fig 3.1.

4. Experimental Results. This section describes the experimental results on a number of assessment factors that were used to gauge how effective the recommended method was. MATLAB version 2017 and a computer with a core i3 Processor and 2GB of RAM are used to accomplish the suggested encryption method. For this experiment, a symmetric 14-digit hexadecimal key with the value "01234567890123" is used. Figure 4.1 displays the four commonly used images for testing purposes, each measuring 256 by 256 pixels in both RGB and grayscale. Figure 4.2 illustrates how encryption works.

4.1. Evaluation Parameters. The effectiveness of the suggested encryption scheme is evaluated using the following evaluation criteria –

4.1.1. Clipping Attack. To evaluate the resilience of the method proposed in this study, a clipping attack is necessary because data loss can occur during transmission. To verify the validity of the recommended process, the encryption image is cut off at a random rectangle position, and the appropriate key is then used to decrypt the data. As seen in Figure 4.3, the recommended method is adequately guarded against a clipping assault.

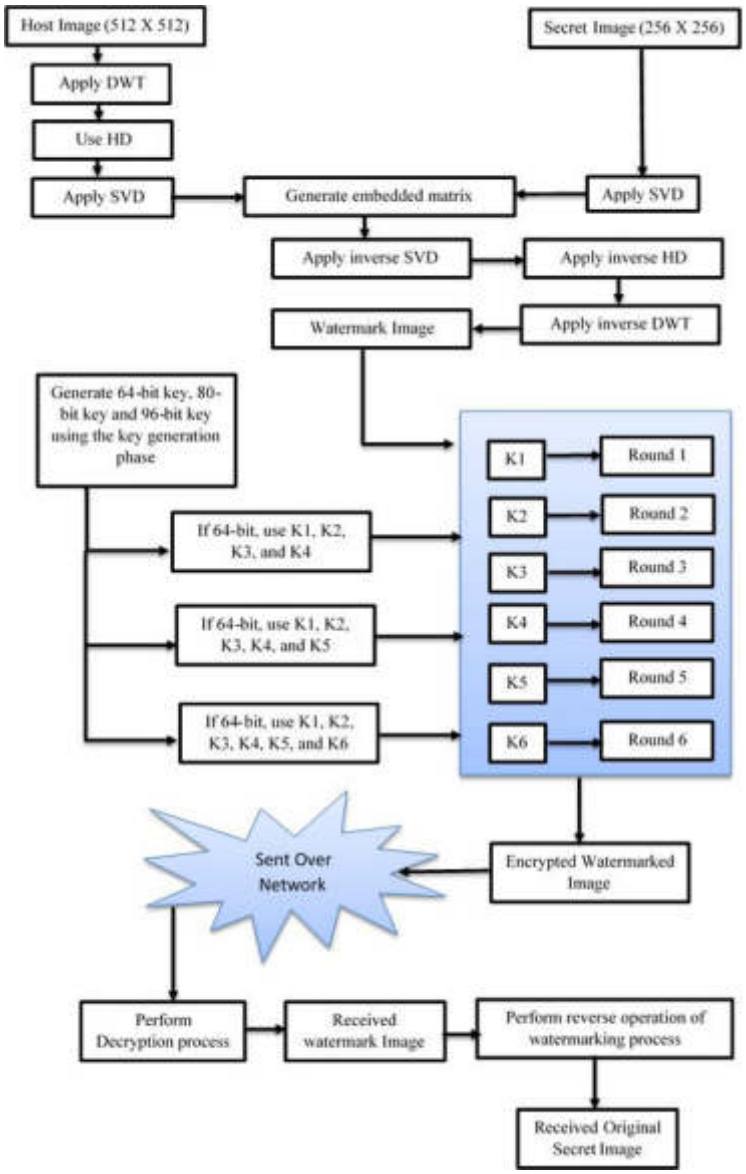

Fig. 3.1: Overall proposed encryption system

Fig. 4.1: Images used for experiments

Fig. 4.2: Proposed cryptographic system

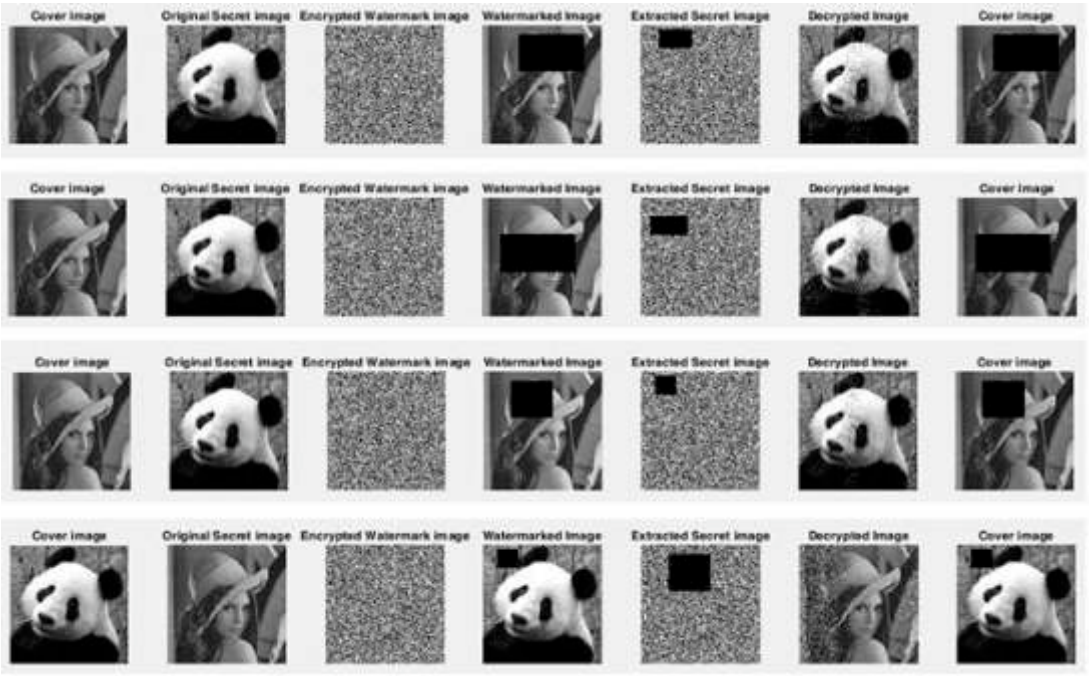

Fig. 4.3: Proposed encryption system after applying clipping attack

4.1.2. Salt & Pepper Noise Attack. Transmission noise typically deteriorates cipher images. With the right key and the input images, the cipher images can still be decrypted. The decrypted image quality appears to be significantly impacted by noise pixels, hence the technique for image encryption needs to be reasonably noise-resistant. After adding salt and pepper noise to the original image, this study employs the recommended technique to decode the original image. It is clear from Figure 4.4 that the recommended method is immune to the noise attack caused by salt and pepper.

4.1.3. NPCR and UACI. The percentage of unique pixels in the two images that differ from one another is determined by the NPCR. The higher the values of NPCR, the better an encryption scheme is. The following formulas are used for NPCR calculations-

$$NPCR = \frac{\sum_{j,i} D(j,i)}{HXW} * 100 \tag{4.1}$$

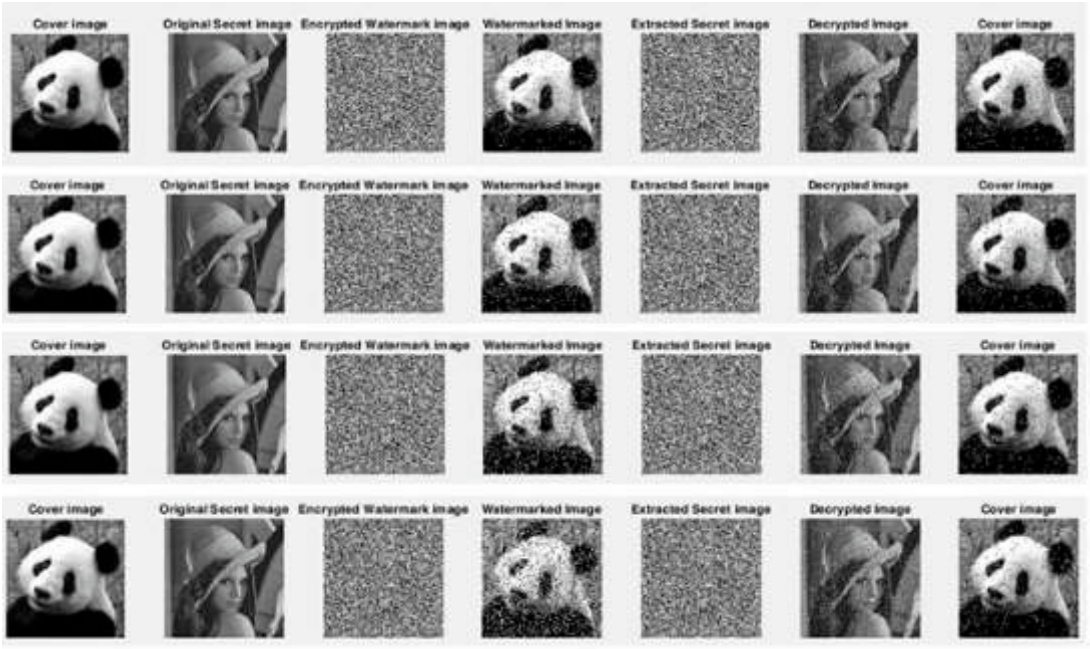

Fig. 4.4: Proposed encryption system after applying salt and pepper noise attack

Here, W and H represent the width and height of the image, respectively. D(j, i) can be defined as

$$D(j,i) = \begin{cases} 0, \text{if} C1(j,i) = C2(j,i) \\ 1, \text{otherwise} \end{cases}$$

4.1.4. Information Entropy. The Entropy of the message source can be calculated using the formula below:

$$E(n) = -\sum p(m) log_2 p(m) \tag{4.2}$$

when p(m) represents the probability of the source m. Entropy attacks cannot be carried out against the recommended algorithm. Table 1 compares the entropy values of the current work and the proposed work in percentage terms.

4.1.5. Histogram Analysis. It is crucial to compare the statistical likenesses of the encrypted and the original image that was utilized to prevent unauthorized access to user data. The histogram analysis quantifies these statistical parallels. The grayscale and color image histogram is displayed in Figure 4.5.

4.1.6. Correlation Analysis. In plain-image and cipher images, the correlation between two adjacent pixels that are split away vertically, horizontally, and diagonally can be calculated using the following formulas [10]:

$$COV(p,q) = E(p - E(M))(q - E(M)) \tag{4.3}$$

$$R_p q = \frac{COV(p,q)}{\sqrt{D(p)}\sqrt{D(q)}} \tag{4.4}$$

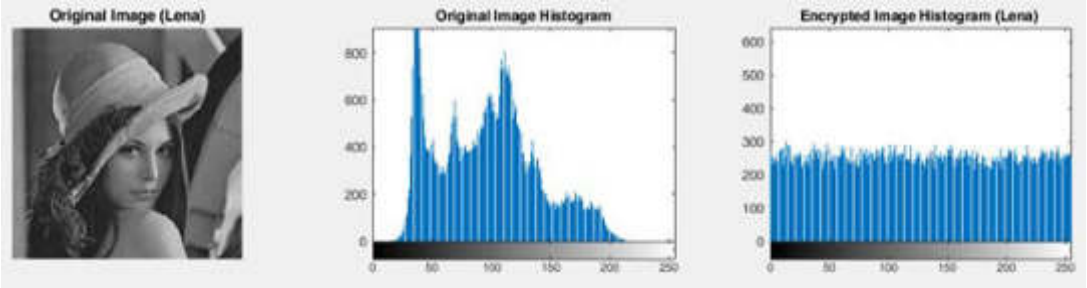

Fig. 4.5: Histogram analysis between encrypted and original lenna image

Table 4.1: Comparison of NPCR on Lena Image

Algorithms	NPCR in percentage
Hu, Y. et. al. [27]	99.6124
Nkandeu, Y. P. K. et. al. [28]	99.6300
Shah, T. et. al. [29]	99.6206
Proposed system	99.64

Algorithms	Entropy
Gupta, M. et. al. [10]	7.9965(Avg.)
Gupta, M. et. al. [11]	7.9971(Avg.)
Proposed system	99.64

The next three mathematical computations use the values of two neighboring pixels in the image, p and n. The vertical, horizontal, and diagonal correlations of the original and encrypted LENNA image are shown in Figure 4.6.

$$E(p) = \frac{1}{t}\sum_{i=1}^{t} p_i \tag{4.5}$$

$$D(p) = \frac{1}{t}\sum_{i=1}^{t} (p_i - E(p))(q - E(q)) \tag{4.6}$$

$$COV(p,q) = \frac{1}{t}\sum_{i=1}^{t} (p_i - E(p))(q_i - E(q)) \tag{4.7}$$

4.1.7. Comparative Analysis between proposed scheme and existing schemes. This section compares the suggested system to current cryptographic techniques based on the NPCR and information entropy assessment parameters. Tables 4.1, 4.2, 4.3, and 4.4 demonstrate how the suggested system outperforms the current approaches.

5. Hardware Implementation. The results of comparing the hardware implementation of the suggested scheme with other existing methods are displayed in table 5.1. Since every algorithm is verified on hardware to ensure its stability and effective operation, a few IoT units were employed in this case for the proposed work's testing.

SIT [32]	Atmega 328	64	128	826
Proposed System	Atmega 328	64,80, and 96	128	738

6. Conclusion and Future Scope. An efficient, portable, and safe encryption method is required because the majority of interactions conducted with IoT devices, such as smart gadgets, use images. This article presented a unique encryption strategy to secure Internet of Things terminals by utilising a hybrid pseudo-random number generator and an optimized watermarking scheme. This study uses a hybrid pseudo-random number generator for the encryption keys. The recommended algorithm is therefore safer. Before every transfer,

the conventional process calls for the exchange of a secret key. Here, key-wrapping techniques share session keys amongst themselves. The suggested study performs better than previous research on many evaluation metrics and on certain IoT hardware components for evaluating the robustness and effective operation of the suggested approach. The future work is to implement the Subsequent research on additional IoT terminals physically and evaluate the outcomes using additional metrics.

B-ERAC : BLOCKCHAIN-ENABLED ROLE-BASED ACCESS CONTROL FOR SECURE IOT DEVICE COMMUNICATION

NEELAM SALEEM KHAN[*] ROOHIE NAAZ MIR[†] MOHAMMAD AHSAN CHISHTI[‡] AND MAHREEN SALEEM[§]

Abstract. Security risks are increasingly concerning as the Internet of Things (IoT) expands. Authentication, access control, and authorization present significant challenges for resource-constrained IoT devices. Traditional authentication methods often require enhancements for these devices, but Blockchain technology presents a potential solution. Decentralized and distributed, Blockchain eliminates a single point of failure and relies on Elliptic Curve Cryptography (ECC) for robust security.

We have introduced a cutting-edge solution to fortify communication security within IoT devices across supply chain ecosystems. By harnessing the power of Blockchain technology, our framework incorporates smart contracts, adheres to ES256 encryption standards, and seamlessly integrates with Infura API. These components establish stringent access controls, ensure data integrity, and enhance transparency throughout supply chain processes. The framework's robust architecture facilitates swift and secure transactions, bolsters traceability efforts, and effectively mitigates potential security risks. With its scalable design and reliable functionality, this framework emerges as a pivotal asset for optimizing IoT device communication within dynamic supply chain environments. The use of ProVerif in our analysis provides a formal guarantee of the correctness of our access control mechanisms.

Key words: IoT, Blockchain, Security, Cloud Computing, Infura, Ethereum, Ganache, Metamask

1. Introduction. Devices are becoming more ubiquitous as they strive to fulfill our needs, make life easier, and add value to the tasks we perform every day. The web is now connected to all gadgets, including those used in domestic automation, industrial automation, and smart city infrastructure. The IoT is altering many aspects of the society we live in, including how we shop, how we drive, and even how we obtain electricity for our homes. If handled improperly, the personal data gathered by IoT devices poses a privacy risk. Hence, protecting the Internet of Things is crucial. In order to prevent device hijacking and the spread of botnets, management of the devices should also require effective authentication. Thus, innovations should be created with security in mind to protect the user and the company data acquired by IoT devices. A "defense in depth" strategy is necessary overall, even with the deployment of security layers [47]. The 2020 Indian data breach, which came at a hefty expense of USD 1.9 million, serves as a reminder of the possible monetary losses connected to data breaches. The 2013 US military data breach is a prime example of the dire repercussions of unauthorized access to sensitive data, as it exposed the personal information of millions of government workers, including military personnel [36]. Introducing secure and robust technologies like Blockchain has greatly improved security, privacy, and access control.

Blockchain technology based on cryptographically protected, immutable distributed ledger technology and consensus might improve IoT structures with more mechanized asset optimization and inborn security [8].

Blockchain technology was created as a distributed ledger technology by Satoshi Nakamoto, the person who invented Bitcoin [1]. Blockchain provides reliable and authorized identity registration, tracking of goods and assets, ownership, and product monitoring [35]. A public ledger of all Bitcoin transactions, going back to the first, is called Blockchain. Since new blocks are constantly being added, the Blockchain is a continually improving technology. A computer connected to the network processes the transactions recorded in the Blockchain. These computers are commonly referred to as "nodes." Being a decentralized technology, Blockchain has nodes all over the world. Everything on the network typically occurs, and each block in the Blockchain is added to the chain in the proper order. As all network nodes are part of the same community and are not restricted by

[§]Department of Information Technology, NIT Srinagar, J&K, India (mehkhan27@gmail.com).

any specific substance or material, Blockchain technology was developed to be durable and permanent. The network has no single point of failure thanks to its decentralized design.

1.1. IoT Security Dangers. The Internet of Things (IoT) has become an integral part of modern civilization, offering numerous opportunities with its rapidly expanding network of connected devices. However, this growth also brings serious security risks. Some of the prominent IoT security dangers include:

Hijacking of Connected Devices for Botnets and Spam: IoT devices, sharing similar functionalities as smartphones and tablets, can be hijacked by attackers to form botnets for distributed denial-of-service (DDoS) attacks or used to send spam messages.

Leaking of IP/Physical Addresses by Unsecured Devices: Unsecured IoT devices can inadvertently expose the IP and physical addresses of homes or offices, which attackers can exploit or sell to malicious parties.

Advanced Persistent Threats (APT): Cybercriminals can gain unauthorized access to IoT networks and remain passive to gather sensitive information over an extended period.

Remote Vehicle Hijacking: The rise of self-driving cars and trucks brings the risk of remote hijacking despite manufacturers' efforts to mitigate such threats.

Ransomware Attacks: IoT devices like thermostats can be vulnerable entry points for ransomware attacks where attackers encrypt crucial data and demand ransom for its release.

Remote Recording and Surveillance: IoT devices, including cameras and microphones, can be exploited by intelligence agencies and cybercriminals to conduct remote surveillance and record conversations.

Denial-of-Service (DoS) Attacks: Unverified devices connected to the network can launch simple yet malicious DoS attacks .

Authentication Challenges: Traditional authentication methods may not be sufficient for IoT devices with limited resources, calling for more efficient, secure, and scalable strategies [47].

Public Key Infrastructure (PKI) Management: Supporting secure communications in IoT requires managing the complex PKI infrastructure [65].

Location-Based Service Privacy Concerns: Cloud-based IoT users' daily habits can be exposed through location-based services, necessitating safeguarding privacy, trust, and authentication [71].

Resource Limitations: IoT devices often have limited resources, requiring energy-efficient and lightweight protocols, posing computation and energy management challenges.

Single Point of Failure: IoT-based services can suffer from single points of failure due to the heterogeneous network infrastructure, necessitating fault-tolerant implementations [46].

Privacy and Communication Challenges: Significant privacy issues with IoT communication have prompted research into cutting-edge solutions like hardware security, transparent gateways, and end-to-end encryption [38].

Addressing these security dangers is crucial to ensuring IoT devices and networks' safe and reliable operation in various domains. In our work, we employ the key characteristics of Blockchain technology to propose a secure framework for communication in an IoT environment. The key characteristics of Blockchain, including smart contracts, peer-to-peer systems, speed, and capacity, play a crucial role in providing a solution for Blockchain-Enabled Secure Supply Chain IoT Framework for secure IoT device communication. Here is how these characteristics contribute: [2].

- *Smart Contracts:* Smart contracts are self-executing contracts with the terms of the agreement directly written into the code. In the context of our system, smart contracts enforce access control policies by defining and automating the rules governing device communication. These contracts can specify who can access specific IoT devices, under what conditions, and what actions they can perform. Smart contracts provide transparency, immutability, and tamper-proof execution of access control rules, enhancing the security and reliability of IoT device communication.
- *Peer-to-Peer System:* Blockchain operates on a peer-to-peer network, where nodes interact directly without relying on a centralized authority. This decentralized nature eliminates the need for intermediaries and central points of control, making the system more resilient to single points of failure and reducing the risk of unauthorized access or manipulation. In our system, a peer-to-peer system ensures access control policies and decisions are distributed across the network, allowing devices to communicate securely without relying on a centralized access control authority.

- *Speed:* Blockchain technology has evolved to address early implementations' scalability and speed limitations. While traditional public Blockchains like Bitcoin and Ethereum may have slower transaction speeds, newer Blockchain platforms and protocols offer faster transaction processing and higher throughput. These advancements in Blockchain technology enable faster verification and execution of access control policies in our system, ensuring timely and efficient communication between IoT devices without compromising security.
- *Capacity:* Blockchain's capacity refers to its ability to store and process large transactions and data. Our framework requires a robust and scalable system to securely handle the access control requirements of numerous IoT devices. Blockchain's distributed and append-only nature allows for storing access control policies, device identities, and communication logs in a tamper-proof and auditable manner. By leveraging the capacity of Blockchain, our framwork can accommodate the growing number of IoT devices and their access control needs while maintaining the integrity and security of the system.

In addition, every phase of an IoT device's supply chain and life cycle is properly managed, administered, and tracked through the use of the Blockchain. By ensuring that data is cryptographically encrypted and signed by the authorized sender, blockchain ensures data integrity and authentication. Smart contracts on blockchain technology enable privacy and authentication. Every IoT device will have a unique GUID (globally unique identifier) and symmetric key pair once installed and connected to the Blockchain network; this removes the need for distribution and key management. Lightweight security protocols are therefore applied. These compact protocols would satisfy and organize the IoT devices' computing and memory resources needs. The maintenance of immutable records of authorized transactions is guaranteed by Blockchain technology. Moreover, as stated by [60], the Internet of Things leverages Blockchain to store sensor data, control device settings, and enable micropayments.

Supply chains that employ IoT can greatly increase resilience by tackling several issues. Blockchain technology combined with IoT provides secure data frameworks for networked supply chain management systems [17]. By tracking product information across various nodes, this integration makes it possible to create robust supply chain management systems that guarantee scalable and safe operations [20]. Furthermore, supply chains are made more resilient by the decentralized nature of blockchain technology, which solves security and data reliability problems in IoT networks [18]. Moreover, IoT and blockchain technology highlight the potential for boosting supply chain resilience by improving pharmaceutical supply chain operations' efficiency, visibility, flexibility, and transparency, particularly during disruptive times like the COVID-19 pandemic [19]. Supply chains can become more resilient, secure, and capable of handling various situations by utilizing blockchain and IoT, ultimately increasing overall operational resilience. The main contribution of our work is as follows:

- A comprehensive literature review that underscores the growing interest in leveraging Blockchain technology to enhance security and access control in IoT environments. The survey highlights the potential of Blockchain-driven solutions to fortify IoT security while pointing towards promising avenues for further research and development
- Proposing a Blockchain-Enabled Role-Based Access Control for Secure IoT Device Communication. This framework leverages Blockchain technology's security features, such as tamper-proof ledgers, cryptographic encryption, and decentralized consensus, to establish a highly secure access control mechanism for IoT devices. This enhances the overall security posture of IoT networks, reducing the risk of unauthorized access and data breaches.
- The proposed system includes a supply chain use case, enabling secure and transparent communication within the supply chain. This can lead to improved efficiency, reduced fraud, and enhanced accountability in supply chain operations.

2. Literature Review. The literature on Blockchain, IoT and supply chain management offers valuable insights into various aspects of access control, security, and privacy in IoT environments.

2.1. A review of the literature on Blockchain and IoT. Several studies have explored the integration of Blockchain technology with IoT and highlighted its advantages and challenges.

Mayra Samaniego et al. [60] emphasized the challenge of finding suitable hosting locations for Blockchain deployment, considering computing resources, bandwidth, and power conservation. Their findings suggest that deploying Blockchain on resource-constrained IoT devices is not recommended. In comparison, our proposed

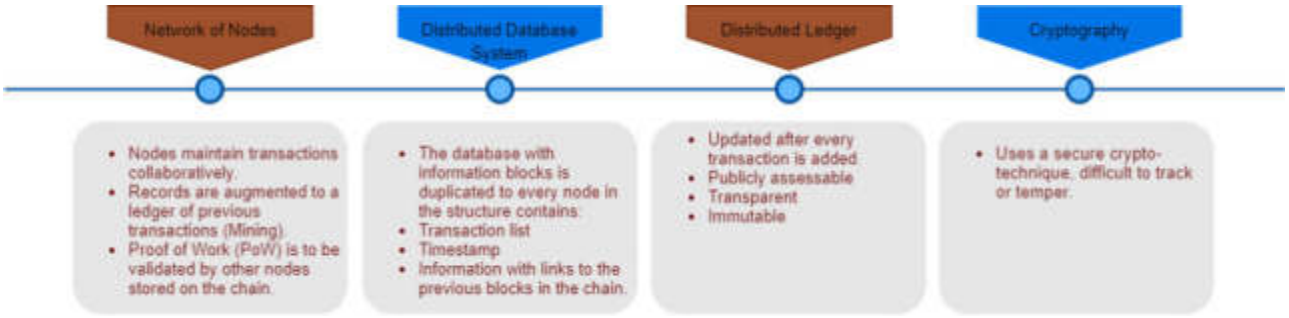

Fig. 2.1: Four Components of Blockchain Technology.

Table 2.1: Threate Identified using STRIDE[70][63] model

Threat	Effect
Spoofing	A malicious management hub could pose as a legitimate management hub.
Tamper	The access control information sent to IoT devices can be changed.
Repudiate	It is possible for a device to say that it hasn't done anything.
DoS	Degrade data sent to an IoT device or expose IoT device data that hasn't been permitted.

system addresses this challenge by leveraging a distributed peer-to-peer system, where the computational and storage burden is distributed among network participants, ensuring efficient and scalable access control for IoT devices. Figure 2.1 illustrates the four components of blockchain, which are discussed by Dr. B. V. Ramana Reddy [68].

Oscar Novo [37] highlighted the advantages of IoT access control, particularly in creating a single, smart contract representing policy norms and enabling larger IoT devices to be part of the access control framework. However, the proposed framework needed more time for access control information release, affecting performance. In contrast, our proposed system leverages the efficiency and speed of Blockchain transactions, ensuring real-time access control management for IoT devices without compromising scalability.

The STRIDE [63] model discovered many threats in the suggested solution, as shown in Table 2.1. The model is an acronym for Spoofing, Tampering, Repudiation, Information disclosure, Denial of service, and Elevation of privilege. Their research also indicates that providing a Certification Authority (CA) is a solution to address security challenges. The IoT devices can use this procedure to verify the legitimacy of the management hub as the CA signs the hub nodes.

In their study, Ouaddah et al. [53] presented FairAccess, a decentralized authorization management system based on Blockchain. Their architecture generated a unique smart contract for each resource-requester pair's access control policy. Similarly, our proposed system leverages Blockchain technology to ensure decentralized access control for secure IoT device communication. However, our system goes beyond access control and incorporates role-based access control (RBAC) for more granular and flexible authorization management. Nallapaneni Manoj Kumara et al. [49] discussed the security vulnerabilities in IoT intercommunication and highlighted the challenges of integrating Blockchain technology with IoT. The authors point out that centralized data management servers (CDMS) pose a risk of exposing sensitive data sections to the outside world via fake authentication and device spoofing. The three main topics of the paper are Analytical and Computing Engines (ACE), Raw Information and Processed Data Storage (RI-PDS), and Things with Networked Sensors and Actuators (TNSA). While their study focuses on security and privacy concerns, our proposed system addresses these challenges by providing a secure and decentralized framework for role-based access control in IoT device communication. Other studies, such as Friese et al. [40], Slock.it [13], TransActive Grid, and Filament, have explored the use of Blockchain technology in various IoT applications. These studies highlight the potential of Blockchain for secure and decentralized communication between IoT devices. Our proposed system focuses on

role-based access control, providing a fine-grained and flexible authorization mechanism for secure IoT device communication. Bahga et al. [28] developed BPIIOT, a decentralized peer-to-peer system for Industrial IoT that utilizes Blockchain technology. The BPIIOT framework enables trustless peer-to-peer connections without needing a trusted intermediary, allowing for developing various peer-to-peer and distributed industrial applications. Christidis et al. [34] and Pureswaran et al. [56] described using smart contracts on the Blockchain to facilitate the exchange of services between IoT devices and autonomous workflows.

In the healthcare domain, Matthias Mettler et al. [44] and Asaph Azaria et al. [26] explored the applications of Blockchain technology in managing electronic health records (EHRs) and user-centered medical research. While these studies address security and privacy concerns in healthcare, our proposed system extends the benefits of Blockchain-enabled access control to secure IoT device communication in various domains beyond healthcare. Furthermore, [70] discussed using Blockchain in PSN-based healthcare, where an upgraded version of the IEEE 802.15.6 protocol is being developed to establish secure links. Zyskind et al. [72] presented a platform for securing personal data using Blockchain technology as an access control moderator, and Nabil Rifi et al. [59] proposed a publisher-subscriber mechanism for data access using Blockchain and smart contracts. The system's last component utilizes the off-chain database IPFS [9]. Our proposed system incorporates similar principles of access control and data privacy, but focuses specifically on role-based access control for secure IoT device communication. Several studies have also discussed the limitations and challenges of existing approaches. For instance, Seyoung Huh et al. [43] highlighted the transaction time and storage limitations of Blockchain, which may not be suitable for time-sensitive domains and resource-constrained IoT devices. Similarly, Sayed Hadi Hashemi et al. [15] discussed different access techniques in Blockchain-based IoT systems. In contrast, our proposed system addresses these limitations by leveraging Blockchain technology's speed and capacity advantages, ensuring efficient and secure role-based access control for IoT device communication.

In articles [27] [55], authors presented a solution to minimize the amount of data stored on Blockchain by employing other consensus mechanisms [5], [42], [48], and different graph topologies [30], [12]. Leemon Baird et al. [30] suggested Hedera, a distributed ledger platform and organization that addresses the issues that prevent mass adoption of public DLT(Distributed Ledger Technology). A data structure called a hash graph and a consensus algorithm create a unique platform for delivering consensus in a distributed setup. The contrasts between Blockchain and hash graphs are also highlighted in this study. The hashgraph works well; it is fast, equitable, compliant with ACID, inexpensive, effective, time-stamped, Byzantine, and resistant to DoS attacks.

Serguei Popov [12] discussed the tangle, which is made up of a directed acyclic graph (DAG) for recording transactions, as the next evolutionary step in the Blockchain. In their article, Xiaoqi Li et al. [50] outlined various security vulnerabilities with Blockchain technology. Their study examined every potential risk and vulnerability in Blockchain and their likely origins and implications. Their research also revealed certain real-world Blockchain assaults, focusing on the exploited weaknesses that lead to such attacks. Blockchain technology is increasingly growing as an influential framework for COVID-19 management, according to [3]. Since October 2019, the Chinese government has been focusing on Blockchain. Following the outbreak of the 2020 coronavirus, Chinese hospitals have begun experimenting with Blockchain technology in various applications, including electronic health records and insurance claims. Popular pharmaceutical businesses have collaborated on Blockchain technologies with SAP SE of Walldorf, Germany, to follow supply chains and detect false drug identities. As COVID-19 vaccines and treatments are tested, Blockchain can be used to certify the studies.

According to [4], the COVID-19 pandemic has revealed the shortcomings of current healthcare surveillance systems for quickly responding to public health emergencies. Attention is growing to Blockchain technology as a potential tool to help with various outbreak containment aspects. In order to access electronic health records, a secure infrastructure, entity authentication, identity verification, and persistent representation of authorization are required, according to interoperability guidelines published by the Office of the National Coordinator for Health Information Technology of the US Department of Health and Human Services. These goals may be achieved by the decentralized architecture of the Blockchain thanks to important characteristics like robustness, immutable audit trails, and data provenance. Additionally, while upholding rules for data privacy and security, the various nodes of a permissioned Blockchain can instantly share and report crucial information.

Blockchain can aid disease prevention and control by enhancing various public health activities, such as early

epidemic detection, faster tracking of medication trials, and better management of outbreaks and treatments. During the COVID-19 pandemic, there was a clear surge in demand for electronic medical records (EMRs). Health records are highly sought-after but challenging to implement, given Blockchain's security, privacy, and transparency benefits. In times of crisis, such as COVID-19, research initiatives in this area are encouraged to be implemented nationally and globally [11].

Jayasree et al. [61] categorize security breaches in the Internet of Things into four main groups: physical, network, software, and data attacks. They also provide potential countermeasures for each category. Their analysis also covers the development of Blockchain technology and its benefits when integrated with IIoT and IoT. Their poll addressed security issues regarding Blockchain technology and conventional solutions for the Internet of Things and Industrial Internet of Things, requiring in-depth research.

The paper [69] advances IoT security by addressing information security issues and suggesting a solution utilizing Blockchain-based smart contracts. The limitations of the MQTT protocol in offering secure authentication to Internet of Things devices are brought to light. It illustrates how Blockchain technology can guarantee privacy, accountability, and trust in Internet of Things networks by presenting an Ethereum-based authentication system. The suggested solution hopes to increase user acceptance and uptake by improving security services in IoT networks. In summary, this paper adds to the knowledge about IoT network security and emphasizes how Blockchain can help reduce security risks in the IoT domain.

The paper [22] advances IoT security and suggests Blockchain protocols for secure communication and authentication. It presents the Authenticated Device Transmission Protocol (ADP) for secure communication inside the overlay network and the Authenticated Devices Configuration Protocol (ADCP) for authentication and building a secure overlay network. These protocols improve data integrity and IoT network security by storing authentication records in a distributed Blockchain database. The formal analysis shows their resistance to different attacks, shedding light on how useful Blockchain is for Internet of Things security. Furthermore, the paper presents numerical results confirming its security enhancement, taking into account a stochastic threat model.

The paper [47] presents an overview of security landscape of Fog computing, challenges, and, existing solutions. They outline major authentication issues in IoT, map their existing solutions and further tabulate Fog and IoT security loopholes. Furthermore this paper presents Blockchain, a decentralized distributed technology as one of the solutions for authentication issues in IoT.

The literature survey highlights the increasing interest in leveraging Blockchain technology to enhance security, privacy, and efficiency in IoT environments. Studies have demonstrated the potential of Blockchain to offer decentralized access control, improve data integrity, and address security challenges. Despite scalability and transaction time challenges, proposed solutions include optimized consensus mechanisms and novel cryptographic protocols. Future research should focus on addressing remaining challenges and validating solutions in real-world settings. By leveraging Blockchain's strengths, IoT systems can achieve enhanced security, privacy, and interoperability, fostering a more connected and secure digital ecosystem.

2.2. A review of the literature on Supply Chain Management.. Blockchain's impact reaches various domains such as healthcare and farming by enhancing supply chain management through robust frameworks for data management and secure communication. Table 2.2 provides a comparative analysis of various studies on supply chain management using IoT and Blockchain technology, highlighting the advantages of our proposed supply chain framework.

3. Preliminaries. This section overviews the preliminary concepts and technologies for building secure communication between IoT devices using Blockchain technology. Here is a summary of the key points covered:

3.1. Understanding Blockchain at its core. Blockchain is a public ledger that records all Bitcoin transactions, continually growing as more blocks are added. Transactions are processed by nodes, decentralized computers spread across the network. Ethereum, a programmable Blockchain, allows developers to build decentralized applications (dApps). We focus on Ethereum due to its suitability for decentralized applications. We will be working on the Ethereum Blockchain.The Ethereum Blockchain was developed with decentralized applications in mind, according to [7]. Ethereum ushered in a new era for the internet: i) payments and money are integrated; ii) users own their data, and apps are unable to steal or snoop on it; iii) anyone can now access

Table 2.2: Comparative Analysis of Supply Chain Management Research

Citation	**Method Used**	**Contribution**	**Findings**
[58]	RFID technology	Enhances traceability in fishery supply chains	RFID improves traceability, supply chain visibility, quality control, and regulatory compliance, contributing to sustainability and safety.
[57]	Hyperledger Blockchain and IoT technology	Addresses challenges in chili farming supply chain	Proposes solutions like demand prediction, stock analysis, and building trusted networks, enhancing transparency and security.
[41]	Stylized models and quantitative approaches	Evaluates accountability in IoT supply chains	Introduces accountability measures, contract design, and cyber insurance to mitigate risks and encourage supplier honesty.
[25]	Machine learning models (linear, DenseNet121, ResNet152)	Compares performance of ML models and proposes IoT smart healthcare system	Finds ResNet152 most effective for COVID-19 detection and highlights blockchain-based pharmaceutical system for efficiency and security.
[20]	Ethereum-based Solidity blockchain	Enhances supply chain transparency and scalability	Introduces IoT-Ethereum framework with RFID, highlighting blockchain's role in transparency and scalability despite challenges.
[21]	IoT and blockchain technologies	Enhances resilience in pharmaceutical supply chain post-pandemic	Proposes a model for real-time monitoring, secure data sharing, and improved visibility, flexibility, and transparency.
[51]	Blockchain and Physical Unclonable Functions (PUFs)	Enhances IoT security	Proposes a new authentication algorithm, improving performance with reduced computational overhead and latency.
[64]	Machine learning classifiers	Develops intrusion detection system for IoT supply chain	Creates classifiers detecting 99.99% of intrusions, demonstrating reliable results against various cyberattacks.
[29]	Modified Raft consensus protocol	Enhances blockchain adoption in IoT supply chains	Proposes mRAFT, improving throughput and latency, demonstrating applicability with Hyperledger Caliper.
[52]	Data mining approaches	Tracks evolution of blockchain in smart manufacturing	Proposes a roadmap for intelligent blockchain technology, emphasizing future research and knowledge gaps.
[24]	Review approach	Examines IoT's potential in transforming SCM	Highlights IoT's role in enhancing visibility, efficiency, cost-effectiveness, and risk management, advocating for interconnected and intelligent supply chains.
[54]	Layered security approach	Secures IoT devices and logistics	Explores blockchain for validating logistics, security in decentralized energy trading, and privacy in Bitcoin transactions.
[62]	IoT integration	Solves SCM issues across industries	Discusses solutions for security, tracking, traceability, and warehouse issues in various supply chains.
[66]	Blockchain and IoT integration	Enhances precision farming and smart farms	Proposes blockchain-based solutions for IoT issues, advocating for decentralized and secure data processing and storage.
[45]	Blockchain with IoT	Improves food supply chain transparency and trust	Demonstrates blockchain's influence on food supply chains, highlighting technological adoption and research areas.
[23]	Scalable blockchain protocol	Eases ownership transfer in supply chains	Proposes protocol for IoT devices, enabling secure batch ownership transfers and reducing transaction costs.
[67]	NFC, RFID, GPS technology	Automates and digitizes SCM processes	Highlights IoT's role in real-time monitoring, tracking shipments, and calls for systematic literature reviews in IoT-based SCM.
Our Proposed Scheme	Blockchain-enabled secure communication framework	Establishes secure communication between IoT devices in supply chains	Uses Ethereum Blockchain, ES256 encryption, and smart contracts for secure transactions and item management, enhancing transparency, traceability, and data integrity.

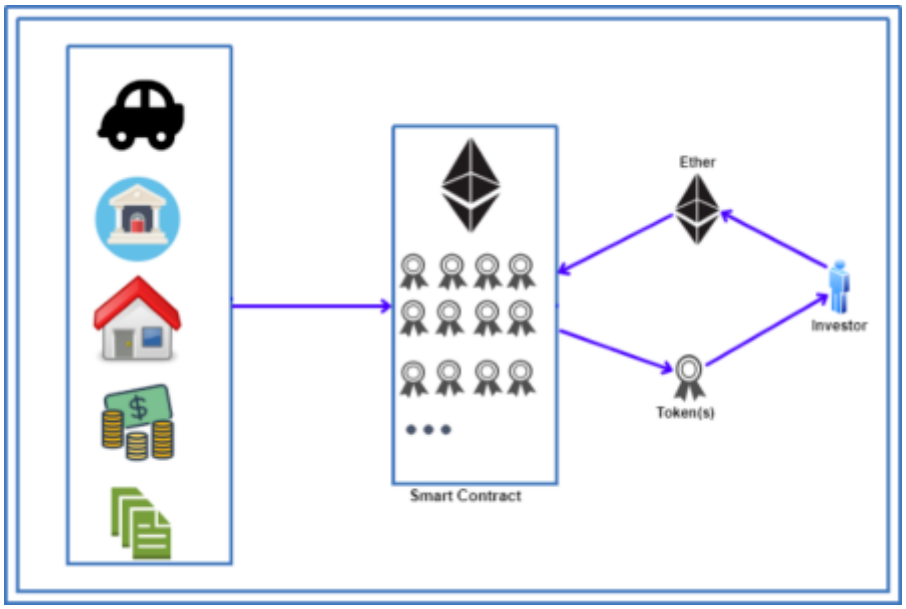

Fig. 3.1: Smart city applications integrated with Ethereum Blockchain through programmable smart contracts

an open financial system; and iv) no one entity is in control, and the system is built on neutral, open-access infrastructure. Figure 3.1 illustrates the Ethereum Blockchain. Transactions on Blockchain networks require signatures using private keys for verification. Each node in the network stores a copy of the Blockchain, and miners create new blocks.

Different types of Blockchain networks exist, such as public (e.g., Ethereum), consortium (e.g., G0-Ethereum), and private (e.g., Multichain). We focus on Ethereum for our work.

3.1.1. Transaction Signatures and Genesis Blocks. Transactions on open Blockchains like Ethereum require signatures for user anonymity and security. Updates must be applied to every node, making it computationally intensive. The initial block of a Blockchain is the genesis block, which is duplicated on each node. Full nodes hold the entire Blockchain, and miners create new blocks in the mining process.

3.1.2. Smart Contracts:. A contract is a legally binding agreement between two or more people. Contracts are socially adaptable because they can be entered and executed without the presence of a third party. The value of contracts is not that an outsider is always available, but that one can be found if necessary. That fallback option is sufficient for establishing confidence between strangers. By replacing the component of trust with enforceable guarantees, contracts increase work division and provide dependability to our globe, which are the foundations of monetary advancement. A smart contract is an agreement between two parties enforced, verified, and performed over a distributed system such as Bitcoin. The sequence of steps to create a Smart Contract is shown in Figure 3.2.

3.1.3. KECCAK function. KECCAK is a versatile cryptographic function for authentication, encryption, and pseudo-random number creation. It is best known as a hash function. Internally, it uses the innovative KECCAK F cryptographic permutation [10], and the structure is simple sponge construction. A wide random function or random permutation is required for sponge formation. It allows" absorbing" any measure of information and yielding/squeezing any information while going about as a pseudo-random function concerning all previous inputs, leading to great flexibility. Keccak-256 Produces a 56-bit hash and is currently used by Ethereum.

3.1.4. Accounts. Ethereum has two types of accounts: external accounts (individuals) and contract accounts (bound by code). Contract wallets, managed by code with a master account, receive, send, and store

Fig. 3.2: Steps to establish a Smart Contract.

Ether. These wallets incur gas costs for creation, represented in ethers.

The address of an external account is determined by its public key. Contract accounts' location is determined during creation based on the creator's address and nonce. Whether they contain code or not, both account types are treated the same by the EVM. Storage is a persistent key-value store, and each account has an Ether balance, where one Ether equals 10**18 Wei, modifiable through Ether-related transactions.

3.2. Strength of Blockchain. Blockchain's address space is 160 bits, while IPV6's 128 bits has an address length of 20 bytes and a public key-generated 160-bit ECDSA hash [68]. ECC is a good option for securing IoT devices in our suggested solution because it provides several benefits. Among these benefits are:

- Strong Security: ECC provides robust security with shorter key lengths compared to traditional encryption methods such as RSA. This is particularly important in resource-constrained IoT environments where computational power and memory are limited.
- Efficient Performance: ECC offers faster encryption and decryption compared to other encryption algorithms. Its computational efficiency makes it suitable for IoT devices, which often have limited processing capabilities.
- Lower Bandwidth and Storage Requirements: ECC requires smaller key sizes, resulting in reduced bandwidth and storage requirements for transmitting and storing cryptographic data. This is advantageous in IoT scenarios where minimizing data transfer and storage overhead is desirable.
- Scalability: ECC is well-suited for scalable deployments in IoT networks due to its efficient use of computational resources. It allows for secure communication and authentication even with a large number of devices.

The basic set of steps in realizing the strength of the Ethereum Blockchain is described in algorithm 1:

The above sequence of steps verifies the authenticity of the Ethereum transaction. It is feasible to confirm that the underlying private key used to sign the transaction and create the transaction signature matches the account used in the transaction "from field". Because of this, every node that participates in a transaction using Blockchain can instantly ascertain its validity. Figure 3.3 shows the complete method. The blocks are connected via cryptographic hashing [14]. To guarantee that the transactions in the Blockchain are in the right order, each block includes the hash of the block before it. The inclusion of previous block hashes guarantees the integrity of the transaction. All blocks that follow are impacted by modifications to a block's transaction(s). Any transaction a hacker tries to alter must be altered in that block and every other block in the Blockchain.

3.3. Interfaces with the Ethereum Blockchain.

3.3.1. Infura. To connect to Blockchain by a hosted Block channel, infura is utilized. It is a bunch of tools for anybody to make an application that interfaces with the Ethereum Blockchain. It interacts with the Ethereum Blockchain and runs nodes on behalf of its users. Metamask, Crypto kitties, Uport, Truffle use it.

Algorithm 56 Transaction Signing and Verification algorithm

Input: Ethereum Transaction
Output: Verifies the authenticity of the Ethereum transaction

I From a wallet, the user sends the Ethereum transaction Ti (say metamask).

II The user has a 32-byte private key Pr and a 64-hex character string that is randomised. A safe randomizer can create private keys at the user's end.

III Pr is transmitted using the ECDSA function (Elliptic curve digital signature Algorithm). This function generates a 64-byte public key named Pk. Pk can be produced from Pr in ECDSA, while Pr cannot be created from Pk in ECDSA. That is Blockchain's strength.

IV Using the Keccak-hash(Pk) function, create a hash of the Pk and extract the final 20 bytes, i.e., B96.....255. That would be the Ethereum Account (the transaction's 'from' field).

V Ti is signed by Pr. Tis is the output, which is a signed transaction.

VI The Tis is passed through ECRECOVER function. The outputs are Pk and the Ethereum Account (the transaction's from' field).

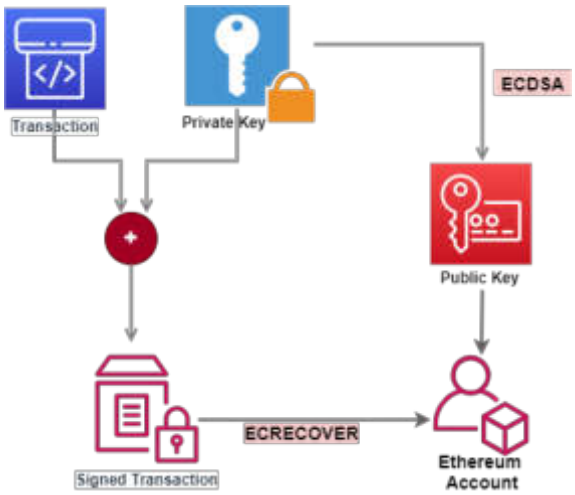

Fig. 3.3: Transaction signing and verification using ECDSA and ECRecover functions.

Infura gives enterprises and developers reliable access to Web3 tools and frameworks.

3.3.2. Truffle. Truffle is an Ethereum Virtual Machine (EVM)-based development, testing, and asset pipeline for Blockchains that makes a developer's life easier [6]. With Truffle, we get built-in Smart contract compilation, linking, deployment, and binary management.

3.3.3. Ganache. Ganache is a personal Blockchain designed to enable swift development of distributed applications on the Ethereum and Corda networks. Its functionality can be leveraged throughout the development process, from coding to deployment and testing, in a secure and predictable environment [6]. Ganache is available as both a desktop application, Ganache UI, and a command-line tool called ganache-cli (previously known as TestRPC) for Ethereum. It supports multiple operating systems including Windows, Mac, and Linux. Developers can interact with Ganache via its API, which is accessible through an RPC server. To transfer ethers between accounts in Ganache, Web3.js library can be used.

3.4. Working of a Blockchain node. Blockchain node communicates with a node with the help of:

1. *RPC:* Remote Procedure Call (Classical HTTP request to interact with API)
2. *IPC:* Inter-Process Communication

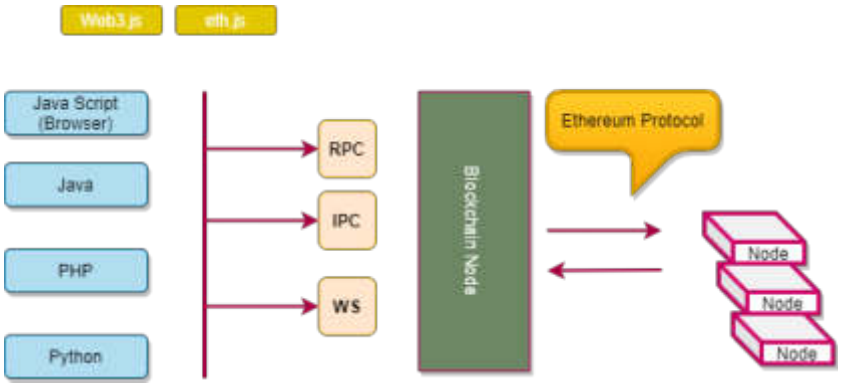

Fig. 3.4: Working of a Blockchain node

3. *WS:* Web Sockets protocol (where a server can send messages to a client)

Figure 3.4 illustrates the entire scenario.

The communication between Blockchain nodes within the Ethereum network occurs through the proprietary Ethereum protocol. A Blockchain node typically provides three methods of connection and control: RPC interface, IPC file, and Web Sockets protocol. The RPC interface sends traditional HTTP requests, similar to those made to interact with APIs or websites. The IPC file permits sending commands to a running process, while the Web Sockets protocol maintains an open connection between the server and client, allowing for bidirectional full-duplex communication. Unlike traditional RPC, the server can transmit messages to the client through the Web Sockets protocol. While typically accomplished through a browser using JavaScript, connecting to a Blockchain node can be achieved using any language with libraries available for popular languages such as Java, PHP, Python, Rust, and . NET. Depending on the system's architecture, these libraries support various connection methods, such as RPC, IPC, or WS.

To implement our proposed model, the components that our required are illustrated in figure 3.5.

The process is initialized by invoking a Metamask wallet to communicate with Infura. We also initiate a faucet(browser) for communication with the back end. For each new transaction that is emitted, block explorer (ropstan.etherscan.io on the Ropsten Test Network and Goerli.etherscan.io on the Goerli Test Network) can be explored for visualizing the transaction events being updated on the Ethereum Blockchain.

Furthermore, we used web3.py to encode and decode requests to connect smoothly with our Blockchain node with a smart contract, which is the architecture we have employed.

3.5. Zerynth Studio. Zerynth Studio is a platform for programming microcontrollers in Python and connecting them to Cloud infrastructures [16]. It enables the creation, signing, and sending of transactions from microcontrollers, facilitating interaction with smart contracts and eliminating centralized passages and points of disappointment. The Zerynth Ethereum library exploits the JSON-RPC interface to cooperate with an Ethereum hub and send an exchange. For the hashing and signs, the Zerynth crypto module is utilized. The primary class accessible is RPC. From an RPC object, bringing network status data and making transactions is feasible.

Zerynth Studio supports Python programming, communication protocols, and features like device emulation and OTA firmware updates. Additionally, Zerynth Studio supports a range of communication protocols, including Wi-Fi, Bluetooth, LoRa, and Sigfox, enabling developers to create IoT applications that can communicate with other devices and services.

Zerynth provides an IoT framework with the following features [16]:

1 Simple to utilize full IoT framework for interfacing new and existing items.
2 Zerynth IoT framework will utilize exclusive requirement security highlights to ensure full data assurance.
3 Top tier group of IoT specialists and devoted support to guarantee a speedy and effective venture.

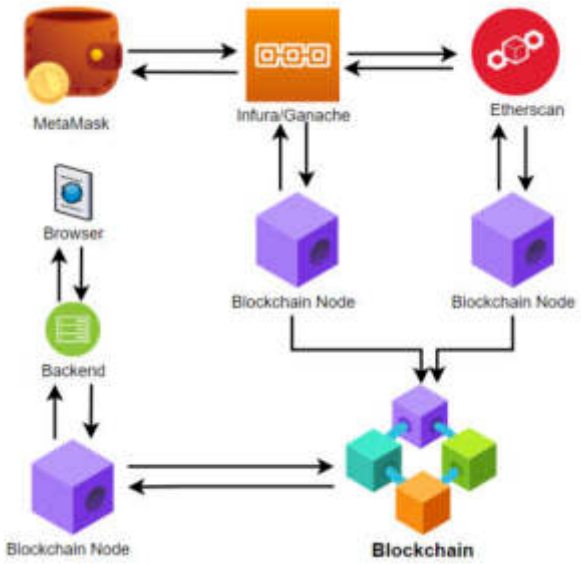

Fig. 3.5: Various components for node interaction in Blockchain based framework.

The Internet of Things revolves around extracting pertinent data from myriad interconnected devices, presenting a challenge in managing device security, application flexibility, and data integrity.

3.5.1. Advantages of using Zerynth instead of using a Raspberry Pi or Arduino.

- Zerynth offers an end-to-end platform for developing secure and connected IoT and industrial applications.
- It provides a Python-enabled operating system, hardware modules, and a device management system.
- Zerynth's integration enables lower power consumption, lower hardware costs, and scalability.

3.6. ProVerif. ProVerif is an automatic cryptographic protocol verifier designed to analyze the security of cryptographic protocols. Developed by Bruno Blanchet and his colleagues, ProVerif supports a wide range of cryptographic primitives, including symmetric and asymmetric encryption, digital signatures, hash functions, and non-interactive zero-knowledge proofs [32]. Key features include:

- *Security Analysis:* ProVerif can prove reachability properties, correspondence assertions, and observational equivalence, making it a powerful tool for verifying secrecy, authentication, privacy, traceability, and verifiability.
- *Protocol Modeling:* It uses the typed pi calculus to represent concurrent processes and interactions over communication channels.
- *Attack Reconstruction:* When a property cannot be proved, ProVerif attempts to reconstruct an execution trace that falsifies the desired property, providing insights into potential vulnerabilities.

ProVerif is a command-line tool that can be installed via OPAM (OCaml Package Manager), from sources, or binaries. It supports integration with text editors like Emacs and Atom for ease of use [31].

4. Framework Implementation and Evaluation of Blockchain-Enabled Role-Based Access Control for Secure IoT Device Communication. This section discusses the proposed solution for establishing secure communication between IoT devices by utilizing Blockchain technology.

4.1. Proposed Framework. The proposed solution aims to establish secure communication between IoT devices by leveraging Blockchain technology. Figure 4.1 illustrates the framework, demonstrating how IoT devices, specifically ESP32, interact with the Blockchain network through Zerynth Studio. The integration with

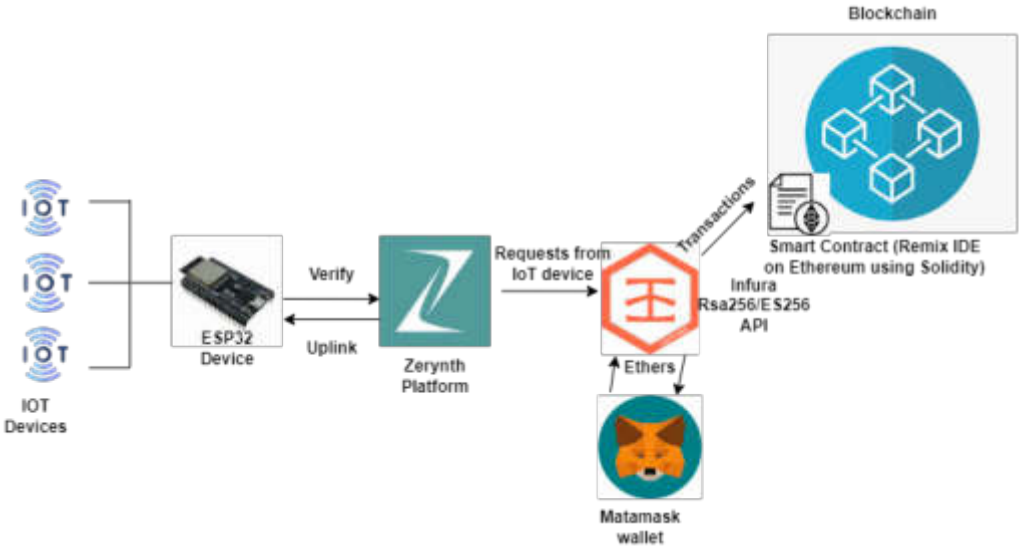

Fig. 4.1: Proposed framework

Infura API provides access to the Ethereum Blockchain network, while smart contracts facilitate a specific use case with owner restrictions governing payments and item deliveries. Transactions are recorded on the Ethereum Blockchain, and ES256 encryption is utilized for security. The smart contract has owner restrictions, which govern the receipt of payments and delivery of items. The smart contract is written in the Remix IDE and uses ethers provided by the Metamask wallet. All transactions are recorded on the Ethereum Blockchain, and their status can be visualized on Infura, which employs ES 256 for security. ES256 (Elliptic Curve Digital Signature Algorithm using the P-256 curve) is a digital signature algorithm Infura uses to secure client communication and API communication. It is a public-key cryptography algorithm that generates a pair of keys, one private and one public, to sign and verify digital transactions. This section covers all the components of the proposed scheme in detail.

4.1.1. Smart contract Deployment. We deployed a smart contract on Remix-IDE using the solidity programming language with the following assumptions.

Assumptions:

1. The smart contract is deployed on a Blockchain network accessible by IoT devices.
2. The IoT device is equipped with a secure digital wallet and can communicate with the Blockchain network.

The Item Manager end:

- The smart contract has a designated manager who has specific permissions and access rights.
- The manager is responsible for managing certain functions of the smart contract, such as creating and updating records.
- The manager is the only account that can access certain functions of the smart contract, as specified by the access control mechanisms implemented in the contract.
- The manager's account is secured by a private key, which is required to authenticate their identity when accessing the smart contract.
- The manager is responsible for ensuring that the smart contract is used in a secure and responsible manner, and for resolving any issues or disputes that may arise in the use of the contract.
- The manager is accountable for any actions taken on behalf of the smart contract and is required to act in the best interests of the contract and its users.The use-case application for buying and creating an item on Blockchain through an IoT device is depicted in figure 4.2.

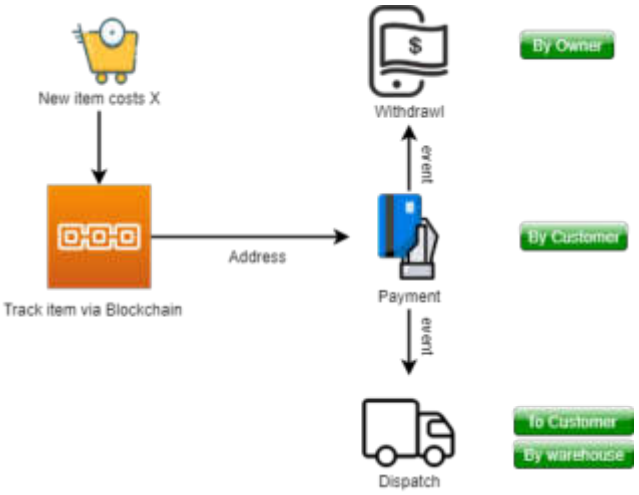

Fig. 4.2: Use-case application for buying and creating an item on Blockchain through an IoT device

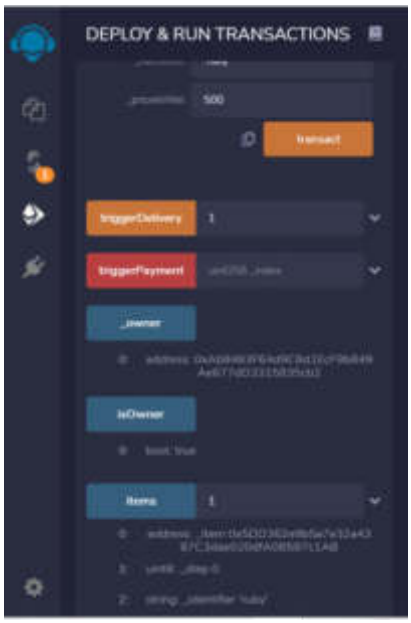

Fig. 4.3: User interface for use-case application on Remix IDE

The IoT device end:

- At the User-end, the user interacts with the IoT device to create an item purchase request. The User-end depicting the entire use-case is shown in figure 4.3.
- The IoT device sends the item purchase request to the smart contract deployed on the Blockchain network.
- The smart contract verifies that the request is valid and that the sender is the owner of the smart contract. If the verification fails, the smart contract sends an error message to the IoT device and terminates the transaction.
- If the verification is successful, the smart contract creates an item and generates a payment request to the user's digital wallet.
- The IoT device receives the payment request and sends the required amount of cryptocurrency from the user's digital wallet to the smart contract.
- The smart contract verifies the payment and dispatches the item to the user through the IoT device.
- If any other account tries to receive payment, the smart contract triggers an error message and terminates the transaction.

The complete working of the proposed framework is presented in Algorithm 2, Algorithm 3 and Algorithm 4.

4.1.2. Connecting Blockchain and IoT device. The Zerynth Ethereum library uses the JSON-RPC interface to communicate with an Ethereum node and send transactions. The primary class provided is RPC. We can perform transactions and retrieve network status information from an RPC object. There are also two companion classes, Transaction, and Contract, which provide a higher-level interface. The former can be used to register a smart contract and its methods for later calling, while the later aids in creating a correct signed transaction ready to be dispatched.

An RPC node providing API is required to communicate with the Ethereum Blockchain. We will use infura, which provides this service without charge. The user can note their API key and register on their website. We created an account in Infura and connected it with our metamask wallet on the Ropsten Test Network to provide us with ethers to make transactions. Infura supports the algorithms RS256 and ES256. The infura

Algorithm 57 Item Manager

Input: Customer requests to buy an item
Output: Item dispatched to customer via supply chain

1. Assign Item Manager as owner
   (a) owner (Item, SupplyChainStep of Item, Identifier of Item)
   (b) SupplyChainStep (Created, Paid, Delivered)
2. Procedure to Create an item
   (a) Assign name to Item
   (b) Assign supply chain step (whether created, paid or delivered)
   (c) Assign an identifier to the Item
3. Procedure to Trigger payment of an Item
   (a) Choose address where Item is to be delivered (only item can update address).
   (b) Allow above address to pay full amount in ethers.
   (c) Check status of Payment in supply chain step.
4. Procedure to Trigger delivery of an Item
   (a) Check if payment is full.
   (b) Change status of supply chain to 'Delivered'.
   (c) Deliver to the address assigned.

Algorithm 58 Authentication

Input: To authenticate if the caller is owner
Output: Returns true if the caller is owner

1. Procedure to check whether caller is owner
   (a) Returns true if the caller is current owner.
   (b) Throws a message if called by any account other than owner.

Algorithm 59 Contract for taking Payment of Item

Input: To receive payment in ethers
Output: Validating the full payment and transferring the amount to Item Manager for delivery of item

1. Create a contract for Item containing (PriceinWei, PaidAmountinWei, IndexOfItem)
   (a) Create a constructor for Item to set (ItemManagerAddress, PriceinWei, IndexOfItem)
2. Procedure to receive payment
   (a) If amount paid is less than PriceinWei, alert with a message "We don't support partial payments".
   (b) If amount paid is already full for an item and customer tries to pay again for same item index, alert with a message "Item already paid".
   (c) Using ItemManagerAddress and PaidAmountinWei, call Procedure Trigger payment using function signature abi.encodeWithSignature(TriggerPayment(Uint256, IndexOfItem)) to transfer money to ItemManager.
   (d) return Success otherwise unsuccessful and trigger the message "Delivery did not work"

Algorithm 60 Connecting Blockchain and IoT device

Input:
To connect IoT device to Ethereum Blockchain for secure communication
Output:
Secure Transactions of IoT device via Blockchain Technology
procedure ConnectIoTToBlockchain
Procedure to check WiFi connectivity
if successful connectivity
Print("Successful")
else
Print("Unsuccessful", error())
SSL context is needed to validate HTTPS certificates.
Assign HTTP Provider's API-Key from your Infura registered project account to a variable.
Procedure to interact with Smart Contract on Ethereum Blockchain using Web3.js library.
Assign a variable to object `w3.eth.contract(contract Address, Contract Abi)`.
Procedure `SendEthersToContract(amount)`
begin
nonce = Get the number of transactions sent from wallet address
transaction = {to: contract address,
value: amount in wei,
gas: inWei,
gasPrice: inWei,
nonce: nonce}
Sign the transaction with the wallet private key.
Calculate transaction hash.
Get transaction receipt.
end
Call Procedure `isOwner(address)` from Contract using address of Owner.
Call Procedure `TriggerPayment` from Contract
begin
nonce = Get the number of transactions sent from wallet address
transaction = {to: contract address,
value: amount in wei,
gas: inWei,
gasPrice: inWei,
nonce: nonce}
Sign the transaction with the wallet private key.
Calculate transaction hash.
Get transaction receipt.
end
Call Procedure `TriggerDelivery` from Contract
begin
Deliver the item to the address that paid for the item.
end
Go to infura.io and check the transaction status.
Retrieve the block ID of the last transaction.
end procedure

provides us with an API, a secret project key, and various other security features, including JWT (JSON Web Token), Allowing lists, limiting the number of daily requests, and so on. After Zerynth establishes a connection with infura, infura records the transactions done per second on the Ethereum Blockchain. The complete work of the proposed script is presented in Algorithm 5.

To connect to the ESP32 DevKitC, the configuration file written in python is created as per the requirements like wifi specifications, contract addresses, certificates, keys etc. To communicate with your smart contract on

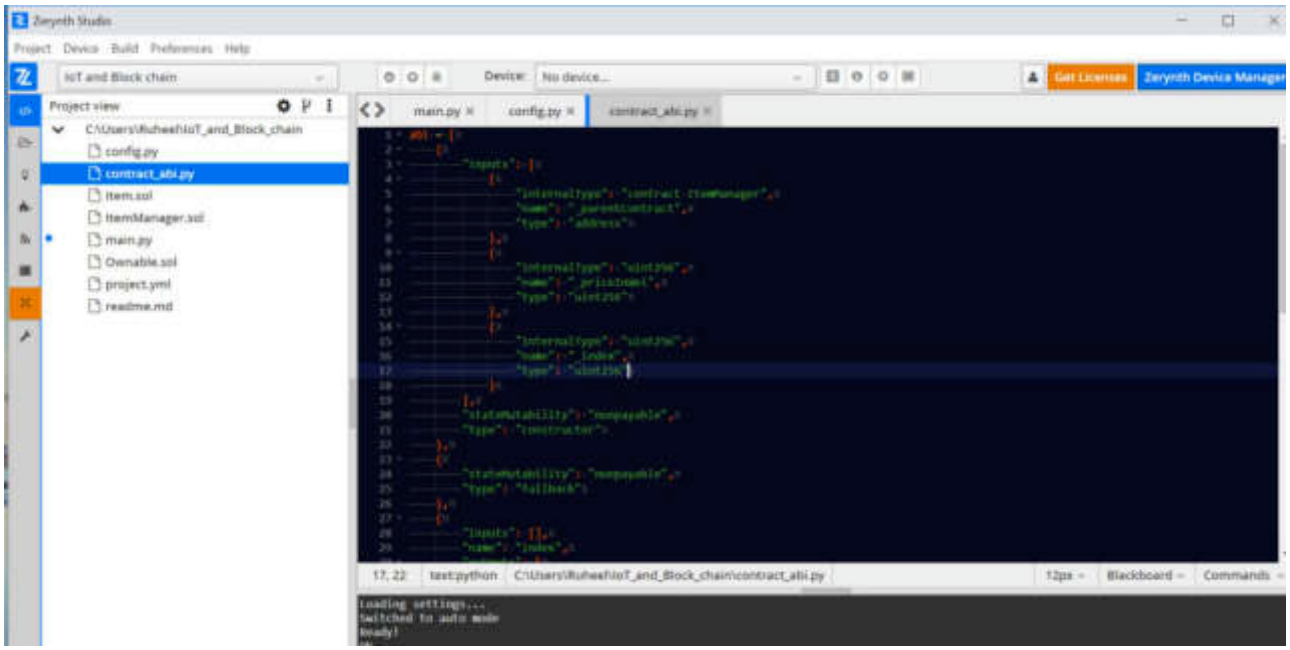

Fig. 4.4: Config ABI

Remix IDE, we need to add the contract's API from remix IDE into the config ABI file, as shown in figure 4.4. Finally the script is uploaded on to the ESP32 DevKitC microcontroller using Zerynth studio.

We designed a framework for secure communication of IoT devices using Blockchain technology. The platform used to achieve our goal is Zerynth Studio, infura and Remix IDE. All the transactions are stored on ledger and we can retrieve the block id of each transaction.

4.2. Security Analysis of proposed scheme. In this subsection, we leverage ProVerif, a widely used automated tool for cryptographic protocol verification, to analyze the access control mechanisms in our smart contract. We aim to ensure that only authorized users can perform specific actions within the contract. It uses a dialect of the pi-calculus to model the protocols and can automatically prove properties like secrecy, authentication, and access control. We model the contract's functions and events in ProVerif to verify the access control properties.

```
(* Declarations *)
(* Types *)
type user.
type item.
type identifier.

(* Constants *)
free alice : user.
free bob : user.
free secret_item : item [private].
free item567 : identifier.
free access_denied : string.

(* Functions *)
fun has_access(user, item): bool.

(* Events *)
```

```
event request_create_item(user, identifier, item).
event grant_create_item(user, identifier, item).
event request_trigger_payment(user, item).
event grant_trigger_payment(user, item).
event request_trigger_delivery(user, item).
event grant_trigger_delivery(user, item).

(* Processes *)

(* Access control process for an owner *)
let owner_process(user: user, item: item, identifier: identifier) =
  out(c, request_create_item(user, identifier, item));
  if has_access(user, item) then
    out(c, grant_create_item(user, identifier, item))
  else
    out(c, access_denied).

(* Example of creating an item by Alice *)
let alice_create_item =
  owner_process(alice, secret_item, item567).

(* Payment process *)
let payment_process(user: user, item: item) =
  out(c, request_trigger_payment(user, item));
  if has_access(user, item) then
    out(c, grant_trigger_payment(user, item))
  else
    out(c, access_denied).

(* Delivery process *)
let delivery_process(user: user, item: item) =
  out(c, request_trigger_delivery(user, item));
  if has_access(user, item) then
    out(c, grant_trigger_delivery(user, item))
  else
    out(c, access_denied).

(* Main process *)
process
  alice_create_item |
  payment_process(bob, secret_item) |
  delivery_process(alice, secret_item)

(* Secrecy: Secret item should not be accessible *)
query attacker(secret_item).

(* Authentication: If access is granted, there must have been a request *)
query grant_create_item(user,identifier,item)==>request_create_item(user,identifier,item)
    .
query grant_trigger_payment(user,item)==>request_trigger_payment(user,item).
query grant_trigger_delivery(user,item)==>request_trigger_delivery(user,item).
```

4.2.1. Result Analysis. By running the ProVerif model, we verify that the access control mechanisms are correctly enforced, ensuring that unauthorized users cannot create, pay for, or deliver items.

Figure 4.5 shows that our smart contract's access control policies are robust against common attacks. The result proves the following:

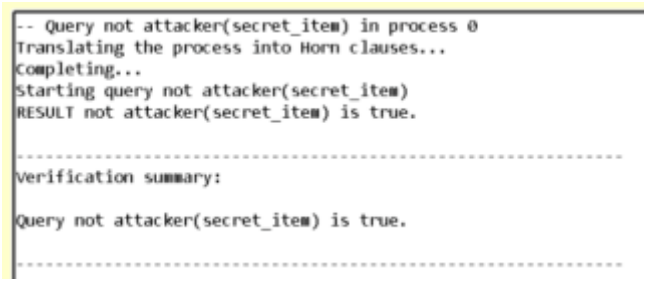

Fig. 4.5: ProVerif Output

- *Secrecy:* RESULT not attacker *(secret_item)* is true, means that the secrecy of secret_item is preserved by the protocol. ProVerif confirms that *secret_item* is not accessible to the attacker, provided no other vulnerabilities exist.
- *Authentication:* ProVerif verifies that the grant events *(grant_create_item, grant_trigger_payment, grant_trigger_delivery)* are indeed preceded by the corresponding request events. These queries pass, indicating that the system correctly enforces authentication. The system correctly enforces that all access grants are based on prior requests, ensuring proper authentication and access control.

4.3. Benefits of proposed scheme. The proposed scheme offers the following benefits for IoT device communication for a supply chain use case, including:

- Transparency and traceability: Blockchain technology can provide transparency and traceability throughout the supply chain by recording all transactions and data exchanges on an immutable ledger. This can help businesses and individuals track products and components, identify any issues or delays, and improve accountability.
- Data integrity and security: Blockchain technology can ensure the integrity and security of data exchanges in the supply chain by providing a tamper-proof and encrypted ledger. This can help prevent data breaches, reduce the risk of fraud, and improve the trustworthiness of the data.
- Improved efficiency and cost-effectiveness: Blockchain technology can help improve the efficiency and cost-effectiveness of supply chain processes by reducing the need for intermediaries and automating transactions. This can help streamline the supply chain, reduce operational costs, and increase productivity.
- Faster and more reliable transactions: Blockchain technology can provide faster and more reliable transactions in the supply chain by reducing the time and resources required to manage and validate transactions. This can help improve the speed and accuracy of supply chain operations, reducing the risk of errors and delays.

5. Discussion and Evaluation of the proposed scheme. Integrating Blockchain technology to secure communication between IoT devices effectively mitigates single point of failure risks and unauthorized access in resource-constrained devices. We present some evaluation metrics for analyzing the effectiveness of our proposed framework. We have achieved the following objectives using Blockchain for access control in an IoT environment.

- Enhanced Security: Our system leverages the key characteristics of Blockchain, such as smart contracts and peer-to-peer communication, to establish a highly secure access control mechanism. By employing Blockchain's immutability and decentralized consensus, we mitigate the risk of single points of failure and unauthorized access, a significant improvement over traditional centralized access control systems.
- Scalability and Speed: Our system achieves efficient access control without compromising on speed through careful design and optimization of smart contracts. On Ethereum, optimized smart contracts can reduce gas costs by up to 70%, translating to faster execution and lower costs for users. Ethereum 2.0 is expected to handle up to 100,000 transactions per second (TPS) with sharding and Layer 2 solutions, a significant increase from Ethereum 1.0's 15 TPS [33][39]. Blockchain's peer-to-peer network

facilitates faster verification and approval of access requests, enabling real-time communication between IoT devices while ensuring scalability for many devices.

- Decentralization and Trust: Unlike centralized access control systems, our system operates decentralized, removing the need for a trusted intermediary. This enhances trust and transparency, making it challenging for malicious entities to manipulate access control rules or forge identities, thereby strengthening the security posture of IoT networks.
- Flexibility and Customizability: The programmable nature of smart contracts enables our system to accommodate various access control policies and adapt to diverse IoT environments. Administrators can define and modify access rules based on specific use cases, enhancing the system's versatility compared to rigid, pre-defined access control mechanisms.
- Integration with Existing Solutions: Our system is designed with compatibility in mind, allowing easy integration with existing IoT infrastructures and cloud platforms. This reduces the implementation complexity and adoption barriers, making it feasible for organizations to upgrade their IoT security without overhauling their entire architecture.

6. Limitations and challenges of the proposed solution. Although Blockchain technology-based access control protocol has significant applications to mitigate security and privacy issues in resource-constrained IoT devices, some challenges need to be considered to alleviate the limitations of the proposed solution. This section presents an analysis of these challenges, focusing on scalability, interoperability, and regulatory compliance. Below, we provide a detailed discussion of each aspect:

- Scalability: Scalability is critical when implementing secure communication solutions for IoT devices using Blockchain technology. Although our proposed solution can enable real-time communication between IoT devices while ensuring scalability for a large number of devices, as the number of IoT devices grows, the Blockchain network's capacity to handle an increasing number of transactions becomes crucial. The main challenges we anticipate in terms of scalability are:
  a. Transaction Throughput: As the number of IoT devices participating in the Blockchain network increases, the transaction throughput may be affected. Blockchain networks like Ethereum have inherent limitations on the number of transactions they can process per second. To address this challenge, We must explore scaling solutions such as sharding, sidechains, or layer-2 solutions.
  b. Gas Costs: The cost of executing transactions on the Blockchain, measured in gas, could become prohibitive for resource-constrained IoT devices, limiting their participation. To minimize costs, we plan to investigate optimization techniques, smart contract design improvements, and gas-efficient operations.
- Interoperability: Interoperability ensures seamless communication between IoT devices and Blockchain networks. While our proposed solution focuses on the Ethereum Blockchain, there is a need to consider multi-chain scenarios and interactions with other Blockchain protocols. The challenges we acknowledge in achieving interoperability are:
  a. Cross-Blockchain Communication: Enabling communication between IoT devices on different Blockchain networks requires standardized protocols and bridges between chains. We will investigate interoperability solutions like Polkadot, Cosmos, or interoperability-focused smart contract standards.
  b. IoT Protocol Integration: Interoperability with existing IoT communication protocols (e.g., MQTT, CoAP) is essential for smooth integration. We intend to explore middleware solutions and bridge technologies to connect these protocols with Blockchain networks.
- Regulatory Compliance: Adhering to regulatory requirements is crucial, especially concerning data privacy, security, and financial transactions. The challenges we anticipate in terms of regulatory compliance are:
  a. Data Privacy and GDPR Compliance: IoT devices collect and transmit sensitive data, raising concerns about data privacy and compliance with regulations like the General Data Protection Regulation (GDPR). To address these concerns, we will explore encryption techniques, data anonymization, and privacy-preserving solutions.
  b. Financial Compliance: In scenarios involving financial transactions, our solution needs to adhere to financial regulations, such as Anti-Money Laundering (AML) and Know Your Customer (KYC) re-

quirements. We plan to investigate techniques for integrating compliance checks within smart contracts while maintaining data confidentiality.

7. Conclusion. The paper explores the potential of Blockchain technology to provide security for IoT devices and presents a smart contract-based solution using Ethereum and Zerynth. Infura and Remix IDE make the development process simple and efficient. The scheme offers numerous benefits, such as enhanced security, improved efficiency, cost-effectiveness, and reliable transactions. Using ECC in Blockchain ensures robust security without a single point of failure. The use of ProVerif in our analysis provides a formal guarantee of the correctness of our access control mechanisms. The result shows that our smart contract's access control policies are robust against common attacks. This strengthens the security of our smart contract and provides confidence in its deployment in real-world scenarios. The paper provides important contributions to integrating Blockchain technology with IoT devices, offering security, transparency, traceability, scalability, speed, and data integrity.

DEEP LEARNING DRIVEN REAL-TIME AIRSPACE MONITORING USING SATELLITE IMAGERY

ANIRUDH SINGH *, SATYAM KUMAR† AND DEEPJYOTI CHOUDHURY ‡

Abstract. Detecting aircraft in remote sensing images poses a formidable challenge due to the diverse characteristics of aircraft, including type, size, pose, and intricate backgrounds. Traditional algorithms encounter difficulties in manually extracting features from numerous candidate regions. This paper introduces an innovative aircraft detection approach that combines corner clustering with a diverse set of Deep Learning (DL) models. The proposed method involves two main stages: region proposal and classification. In the region proposal stage, initial candidate regions are generated using a mean-shift clustering algorithm applied to corners detected on binary images. Subsequently, a comprehensive set of classifiers, encompassing CNN, DenseNet, MobileNetV2, Inception v3, Random Forest (R.F), ResNet50, ResNeXT, Support Vector Machine (SVM), VGG16, Xception, EfficientNet, and InceptionResNetv2, is employed for feature extraction and classification. The presented approach demonstrates superior accuracy and efficiency compared to conventional methods. By leveraging the autonomous learning capabilities of CNN and DL models on extensive datasets, the methodology generates a reduced yet high-quality set of candidate regions. Inspired by the detection methodology employed by image analysts, the approach adopts a coarse-to-fine strategy using CNN and DL models. The first CNN proposes coarse candidate regions, and the second identifies individual airplanes within these regions in finer detail. This framework results in a decreased number of candidate regions compared to existing literature while extracting distinctive deep features. Experimental evaluations on Google Earth images validate the efficiency of the proposed method, underscoring its potential for practical applications in both civilian and military contexts.

Key words: aircraft detection, remote sensing, corner clustering, image analysis, object recognition, aerial surveillance

1. Introduction.

In a variety of domains, including military applications, environmental monitoring, and aviation safety, airplane detection in remote sensing images is essential. Traditional methods often struggle with limitations such as high false positives, manual feature engineering, and limited adaptability. This necessitates exploring new approaches with improved accuracy, speed, and adaptability. In the field of UAVs, these versatile platforms have become essential for executing missions in life-threatening environments where manned aircraft would be constrained. The escalating demand for military and civilian UAVs is driven by their operational efficiency and cost-effective pilot training. Collision avoidance with other aircraft emerges as a critical challenge in both military and civilian contexts, emphasizing the need for highly reliable technology to ensure the safety of UAV operations.

The International Civil Aviation Organization (ICAO) actively engages in discussions In the oversight and standardization of the integration of national airspace for both manned and unmanned aircraft, there is an ongoing focus. The notion of Unmanned Aerial Systems(UAS) is under consideration, envisioning a scenario where ground-based pilots operate UAVs remotely. This poses challenges due to low- quality images resulting from communication limitations. Reliable and real-time detection of these aerial vehicles is essential to ensure the safety of manned and unmanned aircraft operations, prompting the need for advanced detection techniques. In recent years, DL techniques, particularly CNNs, have demonstrated remarkable success in various computer vision tasks. CNNs possess the ability to automatically learn hierarchical features directly from raw image data, eliminating the need for manual feature engineering. This autonomous learning capability makes DL models highly effective in capturing the intricate patterns and subtle details required for accurate aerial vehicle detection.

This paper presents a DL-based framework for real-time detection of airplanes, military jets, and UAVs in remote sensing imagery. The proposed approach combines a region proposal stage leveraging corner clustering

with a comprehensive set of DL models for feature extraction and classification. Specifically, we employ CNNs, including DenseNet, MobileNetV2, Inception v3, ResNet50, ResNeXT, VGG16, Xception, EfficientNet, and InceptionResNetV2, along with traditional ML techniques like Random Forest and SVM.The framework adopts a coarse-to-fine strategy inspired by the detection methodology employed by image analysts. Initially, a CNN proposes coarse candidate regions, and subsequently, a second CNN identifies individual aerial vehicles within these regions in finer detail. This approach results in a reduced set of candidate regions compared to existing methods while effectively extracting distinctive deep features for accurate vehicle detection. The experiments demonstrate that the DenseNet model achieves the highest accuracy of 99.52%, outperforming other models. Detailed results and analysis of all employed models are presented in the Results and Analysis section.

The detection of aircraft from satellite imagery is a critical task that holds immense significance across various domains, including surveillance, environmental monitoring, defense intelligence, and transportation management. With the advent of commercial imagery providers like Planet, which employ constellations of small satellites to capture images of the entire Earth on a daily basis, the volume of satellite data has grown exponentially. This deluge of imagery has outpaced the ability of organizations to manually analyze each captured image, necessitating the development of advanced machine learning and computer vision algorithms to automate the analysis process. In the field of surveillance and intelligence, the ability to accurately detect and locate aircraft in satellite imagery plays a pivotal role in monitoring air traffic patterns, tracking unauthorized flights, and identifying potential threats to national security. By leveraging this technology, authorities can gain comprehensive situational awareness, enabling timely responses to potential security breaches or illicit activities. Moreover, environmental agencies can employ aircraft detection techniques to monitor air pollution levels and assess the environmental impact of aviation activities, contributing to the development of sustainable practices and policies. The significance of aircraft detection extends beyond security and environmental considerations. In the domain of transportation management, accurate detection of aircraft from satellite data can facilitate the optimization of airport operations, enabling efficient resource allocation and streamlining of air traffic control processes. This technology can also prove invaluable in search and rescue operations, expediting the location of downed aircraft and potentially saving lives. Our research contributes significantly to the advancement of aircraft detection technology in satellite imagery, offering practical implications for improving surveillance and monitoring systems. By leveraging the power of DL models, we pave the way for more robust and efficient aircraft detection solutions that can address the evolving challenges in remote sensing and aerial surveillance. Furthermore, our study delves into the interpretability of the models' decision-making processes, elucidating the factors influencing their performance and providing valuable insights into their inner workings. By unraveling the mechanisms behind the models' decision-making, we aim to enhance the transparency and trustworthiness of aircraft detection systems deployed in real-world scenarios.

After a brief introduction in Section 1, Section 2 presents important related investigations performed in recent years. In Section 3, proposed approach is discussed in detailed manner. Results Analysis is elaborated in Section 4. We have compared some previous works with our proposed approach in this section. Section 5 highlights the conclusion, challenges and future work.

2. Related Work. The realm of aircraft detection has witnessed significant progress through diverse methodologies, each contributing to the advancement of this pivotal technology. For instance, Kiyak and Unal [1] focused on employing deep learning for the detection of small aircraft, offering insights that are particularly applicable to Unmanned Aerial Vehicles (UAVs). Groundbreaking efforts by Chen et al. [2] involved aircraft detection through deep convolutional neural networks, laying foundational groundwork for the integration of deep learning in this domain. Furthermore, Hassan et al. [3] introduced a DL framework for the automatic detection of airplanes in satellite images, contributing to the repertoire of available techniques. Alshaibani et al. [4] presented an innovative perspective by employing the Mask Region Convolution Neural Network (Mask RCNN) for airplane detection. This work illustrates the adaptability of deep learning to intricate tasks, extending its application to drone images for airplane type identification. Yilmaz and Karsligil [5] broadened the scope by extending deep learning applications to security camera images, demonstrating the versatility of these techniques in diverse contexts.

Li et al. [6] contributed a coarse-to-fine approach for airplane detection through convolutional neural networks, enriching the methodological landscape. Azam et al. [7] explored aircraft detection in satellite

imagery, emphasizing the role of DL-based object detectors. Zeng et al. [8] proposed a hierarchical airport detection method combining spatial analysis and DL. Alshaibani et al. [9] delved into airplane identification based on RCNN and drone images, illustrating the flexibility of deep learning in addressing intricate tasks. Additionally, Bakirman and Sertel [10] contributed to the field by providing a high-resolution airplane dataset tailored for deep learning. Rahamathunnisa et al. [11] provided a comprehensive perspective on ML and DL applications for intelligent systems in aircraft scenarios.

Zhang et al. [12] investigated weakly supervised learning based on coupled CNNs for aircraft detection, offering valuable insights into learning approaches. Wang et al. [13] introduced a novel airplane detection algorithm based on CNN, showcasing continuous innovation in detection methodologies. Mutreja et al. [14] conducted a comparative assessment of various DL models for aircraft detection, offering valuable insights into model performance. Brandoli et al. [15] specifically focused on aircraft fuselage corrosion detection using A.I., demonstrating the adaptability of DL to diverse aspects of aircraft safety. Shen et al. [16] proposed a DL based framework for automatic damage detection in aircraft engine, showcasing the applicability of deep learning to damage assessment. Al Mansoori et al. [17] contributed an effective airplane detection method in satellite images using the YOLOv3. Ning et al. [18] explored the application of DL in big data analytics for detecting anoma- lies in aircraft complex systems, providing insights into anomaly detection. Zhang et al. [19] focused on aircraft detection in remote sensing images based on RCNN, introducing advancements in speed and accuracy. Hammell [20] contributed the "Planes in Satellite Imagery" dataset, offering valuable data for training and validating aircraft detection models in satellite imagery.

Inspired by recent advancements in aircraft detection, this paper aims to enhance precision and versatility. It builds upon novel contributions in deep learning and diverse techniques highlighted in the existing literature.

3. Proposed Approach. Work flow of our proposed approach is depicted in Fig. 3.1.

3.1. Data Vectorization. Data vectorization plays an important role in the success of aircraft detection models. This procedure entails converting raw image data into a format well-suited for machine learning algorithms, facilitating the extraction of meaningful features for accurate classification. Initially, images containing aircraft and non-aircraft scenes are loaded into the system. Each image is represented as a numerical matrix, capturing pixel intensity values. This matrix serves as the foundational data structure for subsequent processing. To standardize the input dimensions and ensure consistent model performance, images are reshaped into a uniform size. Additionally, normalization techniques, such as Min-Max scaling, are applied to constrain pixel values within a predefined range. This step is crucial for mitigating variations in lighting conditions and enhancing the convergence of machine learning models.

3.2. Feature Selection. The models utilized for aircraft detection excels at hierarchical pattern recognition. Through a series of data transformations, it discerns distinctive spatial features and textures present in the images. This intrinsic ability to identify salient patterns serves as an implicit form of feature selection, allowing the model to focus on elements crucial for distinguishing between aircraft and non-aircraft scenes. The selected models autonomously learns and extracts discriminative features from the raw image data during the training process. This eliminates the need for manual intervention in specifying relevant features, as the model adapts and refines its understanding of essential characteristics for accurate classification. By virtue of the model's architecture, it maximizes the utilization of comprehensive information encoded in the input data. The learning process encompasses various levels of abstraction, enabling the model to capture nuanced details and intricate structures, further enhancing its ability to discern between different classes.

3.3. Dataset Description. This meticulously compiled dataset is tailored for the exploration of aircraft detection using machine learning and deep learning techniques, featuring 32,000 high-resolution 20x20 RGB images sourced from Planet satellite imagery over diverse California airports. The dataset employs a binary classification system, distinguishing between "plane" and "no-plane" classes. The "plane" class, encompassing 8000 images, is characterized by a comprehensive focus on entire airplanes, including wings, tail, and nose. In contrast, the "no-plane" class, comprising 24,000 images, introduces intricacy by incorporating various land cover features, partial planes, and instances previously mislabeled. Each PNG-formatted image is represented as a list of 1200 integers, encapsulating the red, green, and blue channel values arranged in a row-major order. Additional details, such as labels, scene IDs, and location coordinates, are encapsulated in a JSON-formatted

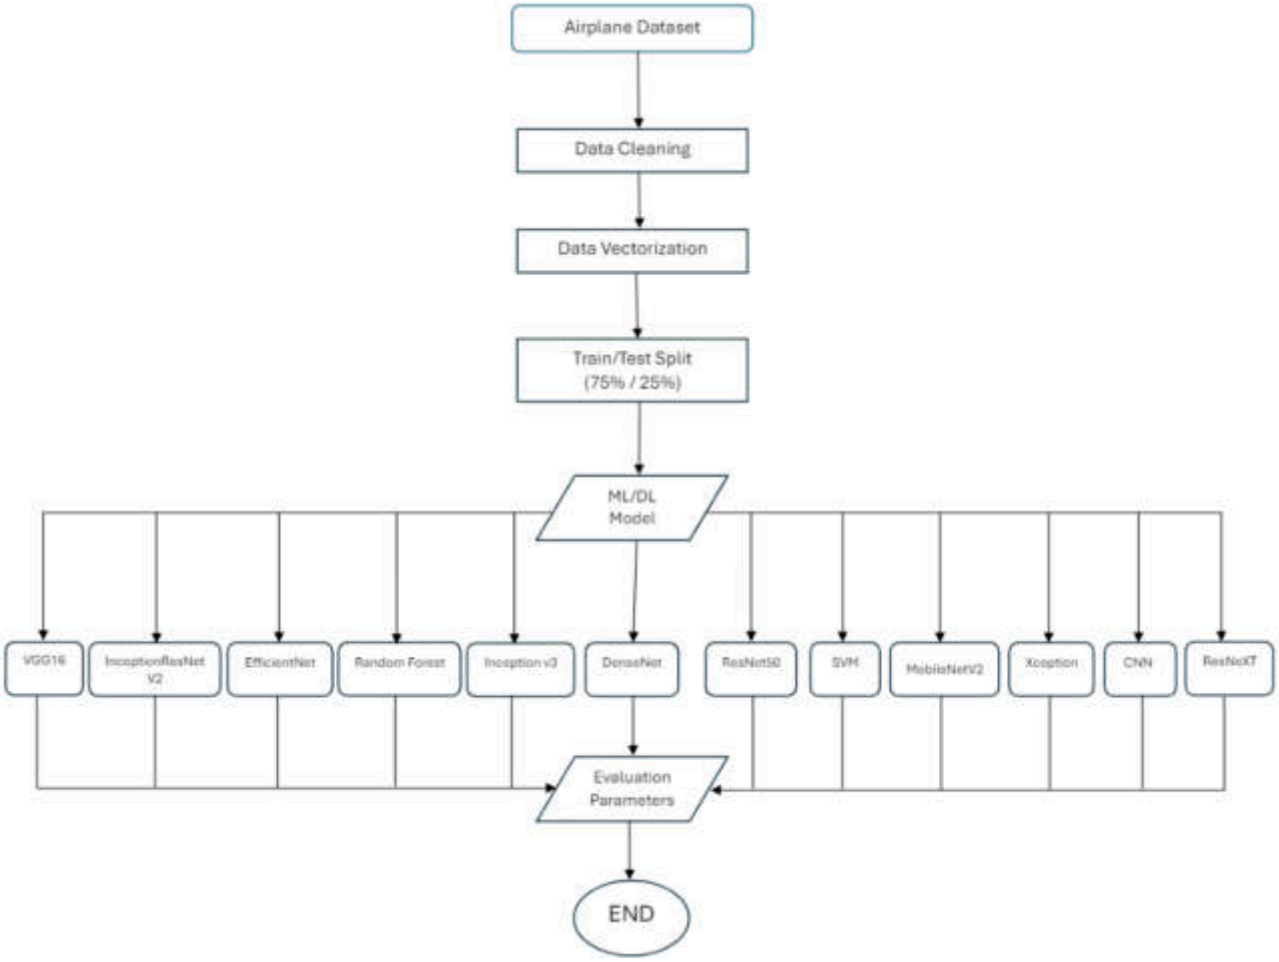

Fig. 3.1: Working Flow of Proposed Approach

text file. This dataset addresses the pressing need for automated analysis, considering the overwhelming volume of satellite data. Its applications extend to airport monitoring, traffic pattern analysis, and defense intelligence.

3.4. Deep Learning & Machine Learning Models. Different DL & ML have been used in our implemented work. These are discussed with respect to our work as follows:

- Convolutional Neural Network (CNN): CNN is a DL architecture designed for image processing tasks, utilizing convolutional layers for feature extraction. CNN is ideal for plane detection in satellite images as it excels in capturing hierarchical features, making it effective for recognizing complex patterns and structures in visual data.
- DenseNet: DenseNet is a neural network architecture characterized by dense connections between layers, promoting feature reuse and information flow. DenseNet is beneficial for plane detection as its dense connectivity enhances feature propagation, facilitating the extraction of intricate spatial dependencies crucial for identifying aircraft in satellite imagery.
- MobileNetV2: MobileNetV2 is a lightweight neural network architecture optimized for mobile and edge devices, striking a balance between efficiency and accuracy.MobileNetV2 is valuable for plane detection in resource-constrained environments, providing a computationally efficient solution without compromising performance.
- Inception v3: Inception v3 is a deep neural network architecture with inception modules designed for

Fig. 3.2: Sample Image from Dataset

Fig. 3.3: Sample Image from Dataset

efficient feature extraction. Inception v3 is advantageous for plane detection, leveraging its diverse receptive fields to capture both local and global features, enabling comprehensive analysis of satellite imagery.

- Random Forest(RF): Random Forest is an ensemble learning method consisting of multiple decision

trees, combining their outputs for improved accuracy and robustness. Random Forest is useful for plane detection due to its ensemble nature.

- ResNet50: ResNet50 is a deep neural network with a residual learning framework, mitigating the vanishing gradient problem in deep networks.ResNet50 is effective for plane detection as its residual connections facilitate the training of deeper networks, enabling the capture of intricate patterns and details in satellite images.
- ResNeXT: ResNeXT is an extension of ResNet, incorporating cardinality to enhance model capacity and performance. ResNeXT is beneficial for plane detection, offering improved representational power and adaptability to varied features present in satellite imagery.
- Support Vector Machine (SVM): SVM is a supervised learning algorithm used for classification tasks, mapping input data into a high-dimensional space for effective separation. SVM complements plane detection by providing a robust classification framework, particularly useful when dealing with diverse patterns and characteristics in satellite images.
- Visual Geometry Group (VGG16): VGG16 is a deep neural network architecture with a focus on simplicity and depth, featuring small convolutional filters. VGG16 is valuable for plane detection as its deep and uniform architecture facilitates the extraction of intricate features and patterns from satellite imagery.
- Xception: Xception is an extension of Inception with depthwise separable convolutions, enhancing efficiency in feature extraction. Xception is advantageous for plane detection, offering a good trade-off between model complexity and accuracy, making it suitable for resource-constrained applications.
- EfficientNet: EfficientNet is a scalable neural network architecture designed to balance model efficiency and performance by optimizing model depth, width, and resolution. EfficientNet is useful for plane detection as it provides a well-balanced architecture, ensuring optimal resource utilization for effective feature extraction from satellite images.
- InceptionResNetV2: InceptionResNetV2 combines the inception module with residual connections, integrating the strengths of both architectures. InceptionResNetV2 is beneficial for plane detection, offering a hybrid approach that captures both intricate features and facilitates the training of deeper networks for improved performance in satellite image analysis.

3.5. ROC Curve & Accuracy Curve.

- ROC Curve: The ROC Curve serves as a visual representation, delineating the performance of a classifier across varying discrimination thresholds. It illustrates the interplay between Sensitivity (True Positive Rate) and Specificity (False Positive Rate). The area under the ROC Curve serves as a quantitative measure of the model's overall discriminatory power. A curve closer to the top-left corner indicates superior performance.
- Accuracy Curve: The Accuracy Curve illustrates how the overall accuracy of the classifier varies with changing discrimination thresholds. A steeper curve suggests that the model maintains high accuracy across diverse threshold values, showcasing its adaptability in different scenarios. These visualization tools go beyond numerical metrics, offering a detailed and nuanced understanding of the classifier's performance, enabling us to make informed decisions about its suitability for real-world aircraft detection applications.

3.6. Evaluation Parameters.

- Accuracy: Accuracy assesses the correctness of predictions.

$$Accuracy = \frac{(TP + TN)}{(TP + TN + FP + FN)} \tag{3.1}$$

- Precision: Precision gauges the precision of positive predictions.

$$Precision = \frac{TP}{(TP + FP)} \tag{3.2}$$

Table 4.1: Results of Different Evaluation Parameters on Aircraft Dataset

Classifier	**Accuracy(%)**	**Precision(%)**	**Recall(%)**	**F1-Score(%)**
CNN	98.85	97.41	97.99	97.70
DenseNet	99.52	98.90	99.20	99.05
MobileNetV2	98.45	96.89	96.89	96.89
Inception v3	99.38	98	99	98.75
Random Forest	95.13	92.83	87.15	89.90
ResNet50	99.26	98.30	98.74	98.52
ResNeXT	98.41	96.32	97.34	96.83
S.V.M	95.60	92.01	90.16	91.08
VGG16	99.06	97.81	98.44	98.12
Xception	99.40	98.84	98.74	98.79
EfficientNet	99.18	97.53	99.20	98.36
InceptionResNetV2	99.30	98.59	98.59	98.59

- Recall: Recall measures the ability to capture positive instances.

$$Recall = \frac{TP}{(TP + FN)} \tag{3.3}$$

- F1-Score: The F1-score offers a balanced assessment.

$$F1 - Score = \frac{2 * (Precision * Recall)}{Precision + Recall} \tag{3.4}$$

These evaluation parameters play a pivotal role in quantifying the accuracy, precision, recall and F1-score of our aircraft detection models.

4. Results Analysis. In this section, we present the results of our experiments on aircraft detection using ML & DL. Our meticulous evaluation of aircraft detection models across various classifiers, as depicted in Table 4.1.

CNN showcases exceptional performance with a robust balance between precision and recall, rendering it a dependable option for accurate aircraft detection. Its high accuracy of 98.85% underscores its effectiveness in real-world scenarios.The ROC Curve and Accuracy Curve is shown in Fig. 4.1 & 4.2. DenseNet excels in achieving remarkable accuracy, precision, and recall, making it a top-performing model. With an accuracy of 99.52%, it demonstrates superior capabilities in minimizing false positives and negatives.The ROC Curve and Accuracy Curve is shown in Fig. 4.3 & 4.4. While MobileNetV2 offers commendable accuracy, its precision and recall slightly lag behind compared to other models. However, its efficiency in processing images makes it a viable option for applications with computational constraints.The ROC Curve and Accuracy Curve is shown in Fig. 4.5 & 4.6. InceptionV3 showcases balanced performance with high accuracy and a favorable trade-off between precision and recall. Its accuracy of 99.38% positions it as a reliable choice for accurate and reliable aircraft detection. The ROC Curve and Accuracy Curve is shown in Fig. 4.7 & 4.8. Random Forest exhibits lower recall, indicating a higher rate of false negatives. However, its overall performance, especially in accuracy, makes it a viable option for scenarios where precision is crucial. The ROC Curve is shown in Fig. 4.9. ResNet50 achieves high accuracy and balanced precision and recall, making it a robust choice for airplane detection. Its effectiveness in handling complex features in images contributes to its strong overall performance. The ROC Curve and Accuracy Curve is shown in Fig. 4.10 & 4.11. ResNeXT demonstrates consistent performance, with accuracy and recall balancing well against precision. Its reliability in detecting aircraft in diverse scenarios makes it a dependable choice for our detection system. The ROC Curve and Accuracy curve is shown in Fig. 4.12 & 4.13. SVM provides balanced accuracy and precision, but with a slightly lower recall. It is suitable for applications where a balance between precision and recall is crucial, and further optimization can enhance its performance. The ROC curve is shown in Fig. 4.14. VGG16 delivers strong all-around performance with

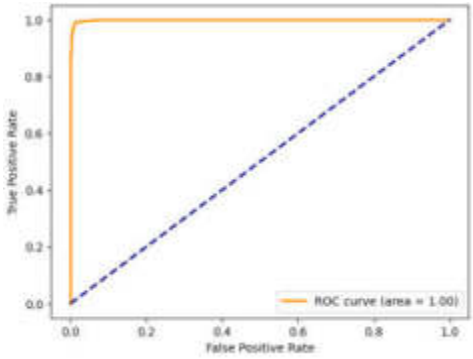

Fig. 4.1: ROC Curve generated using CNN

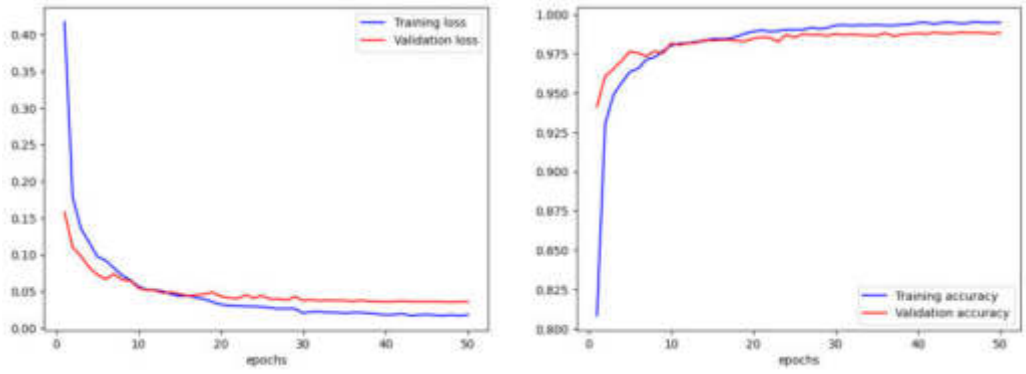

Fig. 4.2: Accuracy Curve generated using CNN

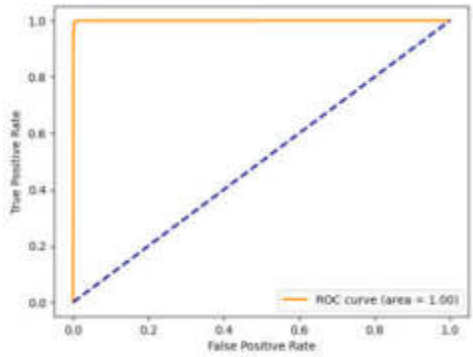

Fig. 4.3: ROC Curve generated using DenseNet

high accuracy, precision, and recall. Its robustness in handling diverse image features positions it as a reliable choice for aircraft detection in various scenarios.The ROC curve and accuracy curve is shown in Fig. 4.15 & 4.16. Xception exhibits excellent precision and recall, making it a top performer in accurate airplane detection. Its superior performance, especially in precision, makes it well-suited for applications where minimizing false positives is critical. The ROC curve and Accuracy curve is shown in Fig. 4.17 & 4.18. EfficientNet demonstrates high accuracy and an effective balance between precision and recall. Its suitability for real-time detection

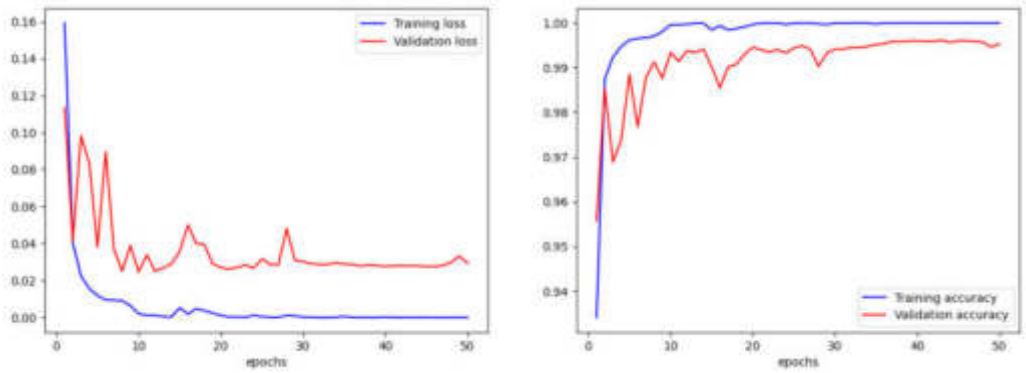

Fig. 4.4: Accuracy Curve generated using DenseNet

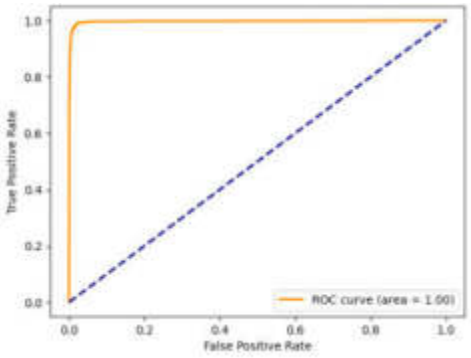

Fig. 4.5: ROC Curve generated using MobileNetV2

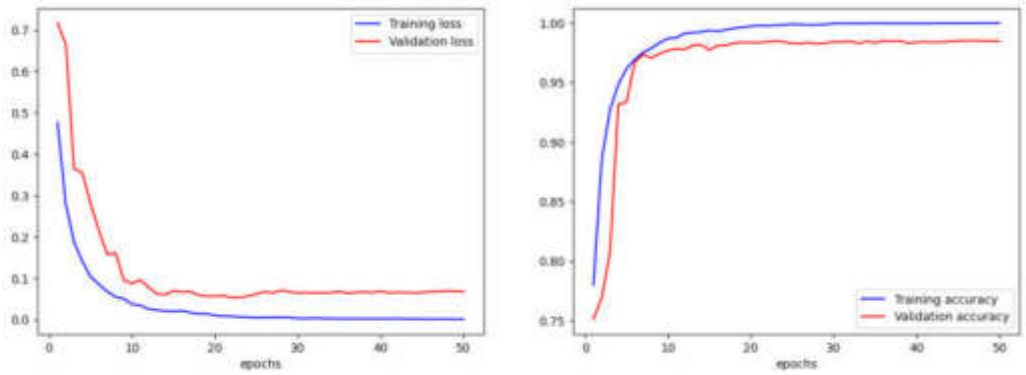

Fig. 4.6: Accuracy Curve generated using MobileNetV2

scenarios makes it a valuable model for applications with computational constraints. The ROC curve and accuracy curve is shown in Fig. 4.19 & 4.20. InceptionResNetv2 showcases robust performance, excelling in accuracy, precision, and recall. Its overall effectiveness positions it as a reliable and powerful choice for airplane detection in diverse scenarios. The ROC curve and accuracy curve is shown in Fig. 4.21 & 4.22.

5. Conclusion and Future Work. In this research, we presented a comprehensive study on aircraft detection in satellite imagery, employing a diverse set of ML models, including (CNN), DenseNet, MobileNetV2, Inception v3, Random Forest (RF), ResNet50, ResNeXT, Support Vector Machine (SVM), Visual Geometry Group (VGG16), Xception, EfficientNet, and InceptionResNetV2. The primary focus was to propose an efficient a vision-based aircraft detection model designed for small Unmanned Aerial Systems (UAS) using a single camera, with a particular emphasis on real-time detection on resource-constrained embedded boards. Our proposed model, inspired by existing architectures but optimized for real-time detection, demonstrated superior performance compared to traditional methods. The evaluation across various classifiers showcased the efficacy of the models, with each exhibiting high performance metrics. Notably, the CNN and DenseNet models achieved remarkable accuracy rates of 98.85% and 99.52%, respectively. Through rigorous testing, our system exhibited robustness to diverse backgrounds, viewpoints, and relative speeds of aircraft, highlighting its adaptability to real-world scenarios. The models consistently outperformed conventional image processing methods, offering faster and more reliable aircraft detection, particularly for distant targets.

Despite the promising results, our research opens avenues for future enhancements and exploration:The current detection range, while showcasing good performance, may require further optimization for collision avoidance purposes. Future work should focus on extending the detection range to enhance the system's utility in real-world applications. Integrating our vision-based detection model with existing cooperative Systems dedicated to collision avoidance systems, such as the Traffic Collision Avoidance System (TCAS) could provide a comprehensive solution. This integration may offer enhanced safety measures, especially for larger UAVs. Further research should investigate the adaptability of the proposed model to different environmental conditions, lighting variations, and atmospheric challenges. Enhancements in these aspects will contribute to the robustness and reliability of the detection system.Conducting extensive real-world deployment tests, including scenarios with varying weather conditions and complex terrains, will validate the system's performance under diverse challenges. This step is crucial for ensuring the practical applicability and reliability of the proposed model. Continued efforts should be directed towards optimizing the proposed model for edge devices, ensuring compatibility with small embedded computers commonly used in UAVs. This optimization will enhance the feasibility of deploying the system on resource-constrained platforms. In conclusion, while our research presents a substantial step forward in vision-based aircraft detection, ongoing efforts and future work will contribute to refining and extending the capabilities of the proposed model, making it a valuable tool for ensuring the safety and integration of Unmanned Aerial Systems into civilian airspace.

ENGLISH GRAMMAR AUTO-CORRECTION ROBOT BASED ON GRAMMATICAL ERROR GENERATION MODEL

ZHU GONG*

Abstract. The traditional English grammar error correction system has problems such as poor error recognition precision and error correction success rate to be improved. Therefore, in this study, data augmentation techniques were used to transform and process error correcting English texts, and a rule-based and shallow neural network-based English text grammar correction model was constructed. The experimental results showed that the grammar error generation (GEG), rule-based (RB), classification-based (CB), and recurrent neural network (RNN) models achieved accuracy rates of 93.92%, 82.17%, 79.41%, and 88.09% in correcting grammar errors on 1702641 test sentences in the One Billion word corpus, respectively. The experimental results showed that the English grammar error correction model designed in this study had a strong error correction ability, but the computational efficiency was low. The research results significantly improved the accuracy and generalization ability of English grammar correction, optimized learning costs, and brought positive impacts to educational applications, providing strong support for the development of intelligent English grammar correction.

Key words: English; Grammatical error correction; Data augmentation; Natural language

1. Introduction. Grammar error correction (GEC) is a computer-assisted language task that is often applied in natural language processing scenarios. The essence of GEC work is to analyze the internal logic and grammatical dependencies of input language text information, to detect and correct grammar errors in language information [1]. After entering the 21st century, the rapid development of deep learning technology has greatly promoted the commercial implementation of natural language work. However, automatic detection and correction products for English grammar errors in natural language processing still have high difficulty in marketization, which is the main background of this study. This is related to the complexity of English grammar, the variety of grammar error types, the scarcity and high production cost of annotated data samples, and the dependency between semantics. With the development of online education, a large number of English learners are starting to learn English on the internet. Beginners are prone to making mistakes in English grammar, which affects the learning desire of many students [2]. In the context of the rapid development of computer technology in the past decade, there has been an increasing number of studies using advanced computer technology for intelligent detection and correction of English grammar. However, most of the error correction models proposed in these studies often struggle to accurately identify and correct grammar errors in text, especially when faced with complex sentence structures and diverse types of grammar errors, resulting in a significant decrease in recognition accuracy. Meanwhile, many existing error correction models are prone to introducing new errors or failing to fully correct existing errors when attempting to correct syntax errors, resulting in a low success rate of error correction and affecting user experience. In addition, due to the complexity of English grammar and the scarcity of annotated data, the generalization ability and error correction effect of these error correction models are relatively low. Existing research showed that mixed attention mechanisms can focus on different parts of text, enabling models to more accurately capture key information in the text and improve the accuracy of grammar error recognition. Rule-based (RB) models can provide a stable grammar checking foundation, while shallow neural networks can compensate for the shortcomings of RB models by learning patterns from large amounts of data, enhancing the flexibility and adaptability of the models. In light of these considerations, the study advanced an innovative approach by integrating RB GEC models, attention mechanisms, and shallow neural networks to develop an enhanced English GEC model. This approach effectively addressed the limitations of existing solutions in error correction accuracy, generalization ability, data dependency, and flexibility. Moreover,

*School of Foreign Languages, Sichuan Vocational and Technical College, Suining 629000, China (Zhuu_Gong@163.com)

it offered novel insights and methodologies for the advancement of intelligent English grammar correction.

The structure of this study is as follows. The first part introduces the basic concepts of GEC, as well as the development background and implementation technology route of this task. The second part provides a detailed design of a new hybrid English GEC model. The third part conducts experimental verification on the model and compares it with other models. Finally, the fourth part summarizes the entire article and provides prospects for future research directions.

2. Related works. Real-time English natural language information in real application scenarios often has certain grammatical errors. To reduce such errors, intelligent GEC systems based on intelligent technology and computer technology have been developed. The task of natural language processing of text types including grammatical errors has been the focus of research by computer experts and linguists. Solyman et al. found that the GEC seq2seq model with multiple encoder and decoder layers had a key drawback, namely, the existence of exposure bias problem during inference, which led to the deletion of some previous target words and reduced the quality of grammatical correction. Therefore, the research team proposed a seq2seq Transformer-based GEC model to solve these problems. Furthermore, to overcome the problem of disclosure bias, a two-way regularization term was introduced in the training objective using the Kullback-Leibler scatter to improve the consistency between the from-right-to-left and from-left-to-right models. Experiments conducted on two standard test datasets QALB-2014 and QALB-2015 showed that the model proposed in this study obtained the best F1 marks than the existing Arabic GEC system [3]. Pajk et al. employed existing pre-trained multilingual models to address the deficiency in multilingual solutions for the GEC problem, with the objective of correcting grammatical errors. They also investigated the influence of diverse pre-training techniques on the ultimate GEC quality and conducted experiments to identify a unified GEC model capable of rectifying seven languages [4]. Wang et al. systematically analyzed the current data augmentation processing methods applied to the GEC problem and the advantages and disadvantages of various mainstream GEC methods and elucidated the future direction of the GEC industry [5]. Choi found that deep neural networks and pre-training models were positive for improving the performance of GEC models, so a Korean GEC model based on improved convolutional neural networks and pre-training methods was designed. The test results showed that the accuracy of Korean GEC of the model was significantly higher than that of the unimproved model and several classical GEC models [6]. Witteloostuijn et al. found that patients with developmental dyslexia were poor at recognizing grammatical errors in linguistic information, so they improved the data augmentation method and designed a GEC model based on the idea of categorical language. The experimental outcomes denoted that students who used this model for assisted reading showed significant improvements in reading comprehension accuracy and average reading duration [7]. Linarsih et al. found that for foreign language beginners, they were vulnerable to grammatical problems when reading linguistic information in a non-native language, so an improved GEC model incorporating recurrent neural networks (RNNs) was designed. The performance of the designed model was tested using several datasets commonly used in the GEC industry. The outcomes indicated that the accuracy of the model in correcting grammatical errors in each selected dataset was on average 10.24% higher than that of the comparison method. However, in terms of computational speed, the former did not have a significant advantage over the latter, which was mainly brought about by the complexity of the RNN's own structure. Further improvements were expected in subsequent studies [8]. Jiang F et al. found that the grammar correction module could greatly affect the quality of speech recognition and response in speech intelligent question and answer systems. Therefore, an improved grammar correction module for speech intelligent question and answer systems was constructed using neural machine translation technology and RNN-based language model. The experimental analysis findings expressed that the speech intelligent question and answer system installed with the improved model proposed in this study showed better speech response capability [9]. Putra's team designed an improved GEC system based on the ternary language model to cope with the problem of unstable recognition in the GEC model and asked several volunteers to use and try this system. It rated the experience of using this system higher than the preim proved GEC system [10]. Koyama S addressed the issue of insufficient training data leading to poor correction results in neural GEC. This paper proposed designing multiple error generation rules for different grammar categories and combining these rules for data augmentation. The results showed that the method proposed in this article could also train high-performance models under unsupervised settings, and could more effectively correct writing errors compared to

models based on round-trip translation [11]. Zhang J proposed a hybrid method combining bidirectional encoder representation from transformers (BERT) model (utilizing syntactic information and context embedding) and dictionary-based graph neural network (utilizing lexical information) to automatically detect grammar errors in Chinese grammar error diagnosis (CGED) tasks. The results showed that in the CGED 2020 task, the proposed system achieved the highest F1 score in both error detection and recognition [12]. Tlonaen et al. found a considerable number of grammatical errors in students writing academic papers. The authors' team first analyzed in detail each of the main grammatical problems that exist in student-written material in this case, and used this as training data to design and train a model that can assist teachers in changing grammatical errors in students' academic papers. The experimental data denoted that the model's recall and accuracy rates of correcting grammatical errors on students' academic materials were 91.34% and 89.24%, respectively, which were higher than those of traditional intelligent grammatical error recognition methods [13]. Li et al. found that adding a certain attention mechanism to the GEC model could optimize the algorithm's operational process, and the designed model had significantly higher recognition accuracy in English natural text than traditional models [14]. Wang et al. attempted to use bidirectional long short-term memory for GEC, but they did not perform more refined processing on the dataset and established a model for grammar recognition in Chinese text, which was relatively ordinary [15]. The GEC model construction approach proposed in this study had certain novelty compared to other studies.

In summary, although a lot of previous studies have been conducted to improve the computational accuracy and performance of grammatical error detection and correction systems, most of them have failed to fully consider both the defects of the raw data itself and the advantages of deep learning tools. Therefore, this study attempts to design an RB and shallow neural network-based English grammar error generation (GEG) model based on the characteristics of English grammatical error texts, and use it as the core to design an improved English GEC model.

3. Design of English GEC system integrating grammar error generation model.

3.1. Design of English grammar error generation model based on data augmentation. The English text is a natural language information with time series and non-linear characteristics, so if it needs to detect and correct English grammatical errors, it will develop a model to describe English grammatical errors. Here, the way of data augmentation is chosen to cope with the lack of data in the training corpus, and then the idea of attention mechanism, neural network back propagation and cross entropy loss function are integrated to build an English GEG model. Due to its strong data processing compatibility, this model can handle various forms of English text, including business and communicative English.

Firstly, the performance evaluation index of English GEG model is determined. Most of the current evaluation methods need to compare the manually annotated target sentences with the output sequence and complete the word alignment operation of both. So, the performance is mostly measured by precision, max match score (MMS) and other indexes in the industry before [16]. MMS method is commonly used in English GEC problems. This method takes the corrected sentences output by the error generation model and the manually annotated sentences for word alignment operation. The number of word operations needed to convert the sentences is calculated, and the model is evaluated using the recall *Rec*, F0.5, and precision Pr e metrics. The three calculations are shown in equations (3.1), (3.2), and (3.3).

$$Rec = \left(\sum_{i=1}^{n} |e_i \cap g_i|\right) \Big/ \left(\sum_{i=1}^{n} |g_i|\right) \tag{3.1}$$

$$F0.5 = \left(P \times R\left(0.5^2 + 1\right)\right) / \left(R + \left(0.5^2 + P\right)\right) \tag{3.2}$$

$$\Pr e = \left(\sum_{i=1}^{n} |e_i \cap g_i|\right) \Big/ \left(\sum_{i=1}^{n} |e_i|\right) \tag{3.3}$$

In equations (3.1), (3.2) and (3.3), e_i and g_i represent the set of candidate edits output by the GEG model and the set consisting of standard corrective edits, respectively. Moreover, the following relationship needs to

be satisfied between these two sets: $e_i \cap g_i = \{e \in e_i \,|\exists g \in g_i, e = g\}$. The generalized language evaluation understanding (GLEU) metric can be used to evaluate the fluency of an utterance, and its expression is given in equation (3.4).

$$GLEU(C,R,S) = BP \cdot \exp\left(\sum_{n=1}^{4} W_n \log p_n^{'}\right) \tag{3.4}$$

where C, R and S mean the corrected sentence, the standard sentence, and the initial input error sentence, respectively; W_n and P_n denote the weights distributed in a uniform manner and the weighting precision of the corrected sentence compared with the standard sentence respectively. TheBP in equation (3.4) is the mapping function between the target sentence and the output sentence, and the calculation method is shown in equation (3.5).

$$BP = \begin{cases} e^{\left(\frac{c-r}{c}\right)}, c \le r \\ 1, c > r \end{cases} \tag{3.5}$$

In equation (3.5), r is the length of the target sentence and c indicates the length of the model output sentence. The indicators provide corresponding scores for both error detection and correction, which is different from the MMS method, in which each marker is classified as false positive (FP), false negative (FN), true positive (TP), and true positive (TN). Then, the recall Rec, F_β, and precision $\mathrm{Pr\,e}$ indicators can be calculated according to equations (3.6) to (3.8). References [17] and [18] also use the same evaluation index calculation method [15-16].

$$Rec = TP/(TP + FN) \tag{3.6}$$

$$F_\beta = \frac{P \cdot R\left(1+\beta^2\right)}{\left(\beta^2 \cdot P\right) + R} \tag{3.7}$$

$$\mathrm{Pr\,e} = TP/(TP + FP) \tag{3.8}$$

The indicator I is calculated using the weighted precision W_{acc}, as denoted in equation (3.9).

$$W_{acc} = \frac{TN + \omega TP}{TN + FN + \omega\left(TP + FP\right) - (\omega + 1)\frac{FP}{2}} \tag{3.9}$$

In equation (3.9), ω is the penalty weight coefficient, and its default setting is 2.0. Therefore, the indicator I can be calculated according to equation (3.10).

$$I = \begin{cases} \lfloor W_{acc\_s} \rfloor, W_{acc\_s} = W_{acc\_b} \\ \frac{W_{acc\_s} - W_{acc\_b}}{1 - W_{acc\_b}}, W_{acc\_s} > W_{acc\_b} \\ \frac{W_{acc\_s}}{W_{acc\_b}} - 1, W_{acc\_s} < W_{acc\_b} \end{cases} \tag{3.10}$$

Now, the English GEG model is designed again, the current mainstream GEC system in the market framework structure is shown in Figure 3.1.

In Figure 3.1, the preprocessed English data is fed into different corpora for expansion, to increase the diversity and scale of the data. The expanded data is used to train various translation model-based error correction systems. After training, the model iteratively corrects and reorders the data to find the best error correction solution. The data are pre-processed before being fed into the grammar generation model, where they are mainly subjected to de-duplication, blank line removal, special symbol processing, length control, and word separation. Special symbols do not affect grammar checking and are directly removed, and length control refers to the splitting and truncation process for sentences that are too long. When GEC work is chosen to be carried out, the amount of manual annotated language work is huge, so the data available for training are

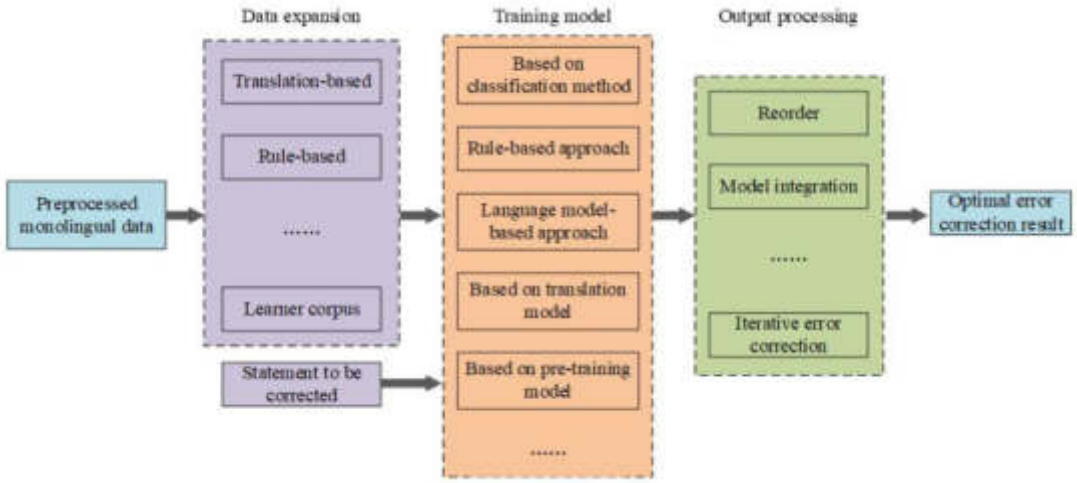

Fig. 3.1: Structure of common English GEC system

Table 3.1: Comparison of data augmentation methods

Method number	*Name of data enhancement method*	*Disadvantages*	*Advantages*
#01	RB data enrichment	Higher implementation costs and fewer rules that can be defined in advance	Low computational complexity and efficient
#02	Reverse translation-based data enrichment	Generate ungrammatical output messages	Wide range of applications
#03	Round-trip translation-based data augmentation	May produce semantic differences that differ significantly from the source sentence	Supports multi-language extensions and does not require large amounts of labeled data
#04	Data widening based on modification history	Generate data with more noise, need to filter	Output data is large in size and can be collected as error correction data
#05	Data augmentation based on fused tag types	Depends on the method of fusion	Depends on the method of fusion

often lacking to some extent. Therefore, before error generation on the data, data augmentation operations are required, and the common operations are shown in Table 3.1.

Considering the characteristics of the dataset selected for this study, an RB approach is chosen here to carry out data enrichment operations, i.e., delete, insert, swap, and replace operations are performed at the word level with introduction probabilities of 0.20, 0.30, 0.25, and 0.25, respectively [19-20]. Analysis of the learner corpus reveals that there are more grammatical errors in prepositions, spelling, punctuation, coronals, nouns, and verbs. Therefore, a derivation method based on substitution rules is proposed here to build confusion sets of these errors separately, count the words with word frequency no less than 4 in a single corpus, and compose the TOP7000 into a dictionary [21-22]. Then the above four operations will be performed randomly on the operation words during data synthesis, and the specific manual rules are defined as follows. It is supposed that the original sentence is$S = \left\{w^0, w^1, ..., w^{i-1}, w^i\right\}$, and the error statement obtained is T.

Insertion error: a rule is inserted to$S$, a token$w'$is added and $T = \left\{w^0, w^1, ..., w', ..., w^{i-1}, w^i\right\}$ is obtained. Deletion error: it deletes a random token to$w'$and S and $T = \left\{w^0, w^1, ..., w^{i-1}, w^i\right\}$ is got. Exchange error:

any two tokens are exchanged in S and $T = \left\{w^0, w^1, ..., w^{i-1}, ..., w', w^i\right\}$ is obtained. Replacement error: it randomly replaces the selected word w'. If it exists in the list of words to be replaced in the confusion set, it will randomly select an alternative word from the corresponding candidate set list to replace it, or vice versa, it will select any word from the dictionary to replace it and is got. In summary, it can get the calculation process of English GEG model based on rule and reverse translation data augmentation, which will be described in detail below. GEG_1 and GEG_2 represent the learner corpus training generation model and the error generation model based on the data augmentation method, respectively. The first step of the calculation is to train the GEG model using the corpus GEG_1, where the injected noise probability is $P(s|t)$, and the parameters of the model α_{back} and model loss $Loss_{back}$ can be obtained by applying the great likelihood estimation method. The three calculations are shown in equations (3.11) to (3.13), respectively.

$$P(s|t) = \prod_{T=1}^{N} P\left(s\_{}_T|t, s_{1:T-1}; \alpha_{back}\right) \tag{3.11}$$

$$\alpha_{back} = \arg\max \sum \log P\left(s\_{}_T|t, s_{1:T-1}; \alpha_{back}\right) \tag{3.12}$$

$$Loss_{back} = \sum -\log P\left(s\_{}_t|t, s_{1:t-1}; \alpha_{back}\right) \tag{3.13}$$

where $s = (s_1, s_2, ..., s_n)$ denotes the grammatically correct input English text sequence from the source and $t = (t_1, t_2, ..., t_n)$ indicates the output English text sequence containing grammatical errors from the target. The second step is to synthesize the training data using the data augmentation method chosen above and generate the optimized GEG_2.

3.2. Design of English grammatical error detection and correction model based on grammar error generation model. Before correcting for grammatical errors, grammatical errors have to be detected first. Therefore, the following then designs a model for detecting and correcting English grammatical errors based on a GEG model. In Figure 3.2, the grammar detection model is built using the BERT structure for detecting and correcting English grammar errors. Firstly, the English text to be detected is preprocessed, and the text is transformed into a format that the model can understand through methods such as word segmentation or subword partitioning, known as tokenization. This step decomposes the text into a series of tokens, each representing a word, subword, or punctuation mark in the text. Then, it is to convert the tokenized input data into tensor form, which is a multidimensional array that can be efficiently stored in a computer and subjected to mathematical operations. The next is to feed the tensor form input data into the BERT model. In the model, each sequence's token is assigned to different layers of the Transformer for processing, capturing the contextual relationships between tokens through self attention mechanisms and generating a deep representation of each token. The BERT model will ultimately generate an embedded representation for the entire sentence. After obtaining the sentence embedding, the GED linear classifier is used to classify the sentence and determine if there are any grammatical errors. A linear classifier will output one or more probability values based on the features embedded in the sentence, indicating the likelihood that the sentence belongs to different categories.

Meanwhile, to further improve the detection performance of the model, a reordering method based on multiple features is used to select the result with the highest combined score as the output. The weights of the features are obtained using the minimum error rate training (MERT) algorithm. The MERT algorithm compares the number of errors in the source statement with the GEC output $E(t_1, t)$, where t_1 is the information output from the GEC system; t and f_s represent the standard statement and the input information to be corrected at s, respectively. The purpose of the MERT algorithm is to calculate the target sentence with the smallest number of errors among multiple candidate corrections, which is also the optimal parameter of the algorithm. The algorithm compares the standard sentence with the highest scoring corrected sentence when there is an error in the statement, and the calculation expression is as in equations (3.14) to (3.16), which is also consistent with the calculation method of evaluation indicators in reference [20].

$$\lambda_1^M = \arg\min \left\{ \sum_{s=1}^{S} E(r_s, e(f_s; \lambda_1^M)) \right\} \tag{3.14}$$

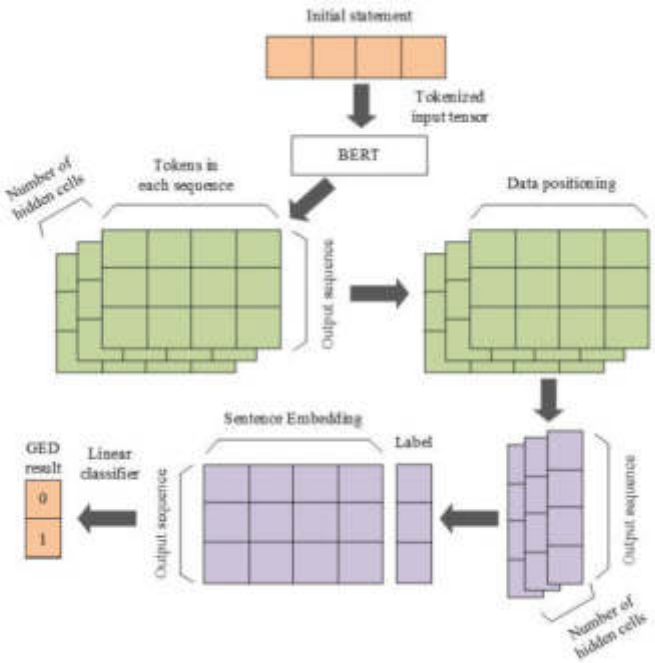

Fig. 3.2: English grammar error detection model

$$e(f_s;\lambda_1^M) = \arg\max\left\{\sum_{m=1}^{M}\lambda_m h_m(e|f_s)\right\} \tag{3.15}$$

$$score(T,S) = \sum_{m=1}^{|M|}\lambda_i f_i(T,S) \tag{3.16}$$

In equations (3.14) to (3.16), t_1, t, and f_s indicate the output information of the GEC model, the standard sentence, and the corresponding input of the s corrected sentence, respectively. λ_m and $|M|$ mean the feature weights and the number of features, respectively. In the following, the GEC model is designed. Grammatical errors generally refer to errors in sentences that do not conform to grammatical rules, and are divided into structural and non-structural errors. The former being the type of errors that can only be corrected by moving, deleting or inserting a number of words, and the latter being errors that can be corrected by replacing some words. Moreover, semantic errors are those that exist in the text, which basically do not belong to spelling or grammatical errors and are difficult to identify. The above-mentioned multiple error types often appear in English text at the same time. Therefore, a correction model is needed to be designed that mainly deals with grammatical errors, but can also incidentally deal with a part of semantic and spelling errors. In the correction model, it is first necessary to generate training data using a data augmentation strategy, which will be used to train the GEG model together with the learner corpus. Then the GEC model is trained using the learner corpus together with the synthesized training data, the workflow of which is shown in Figure 3.3. In Figure 3.3, the idea of alternate training is incorporated, and the GEC model is used to correct the source sentences. The corrected data and the reference sentences in the learner corpus together form a parallel corpus and are added to the GEG, and this process will be repeated until the error correction needs are satisfied.

Specifically, the specific steps of using the alternate training model board in Figure 3 are as follows. First, the GEC model with the strongest performance is selected to compute the source sentences in each learner's corpus to avoid the error correction due to the low performance of GEC. The standard reference sentences are

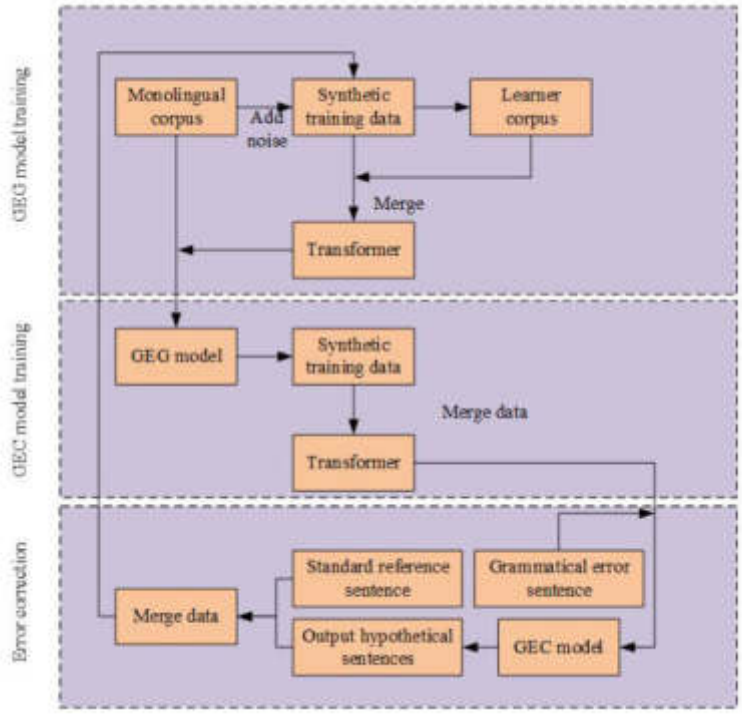

Fig. 3.3: Computational flow of error correction model incorporating the idea of alternate training

then combined with the candidate sentences output by the model to form the training set, and the data are mixed after the data augmentation operation and re-input into the corresponding mode. The next step is to fine-tune the selected learner corpus to obtain GEG3. The GEG3 is used to process the monolingual corpus and to generate synthetic datasets of different sizes. Finally, after the synthetic data is formed, the pre-trained data is further scaled up with the aim of improving the performance of these designed grammar generation models.

Finally, it analyzes the potential shortcomings of the model designed in this study. Due to the integration of various computational structures such as BERT, shallow neural networks, and attention mechanisms in the designed model, the overall structure of the model is relatively complex. There may be issues with slow computation speed and high computational complexity in the computer. Subsequent experiments will also address these issues.

In summary, in the method model designed in this study, it is first necessary to perform data augmentation processing on the input data to expand the data scale. Then, the amplified data will be input into the hybrid BERT algorithm, where the MERT method is used to obtain the weight coefficients of features, and the MERT processed data will be input into the attention network to adjust these weights based on recognition performance. Subsequently, the data will be inputted into a GEC model with alternating training characteristics for error correction. Here, the corrected and the reference sentences in the learner's corpus together form a parallel corpus and are added to the GEG. This process will be repeated until the error correction requirements are met, and the final error correction result will be output.

4. Performance testing of an automatic English GEC model that is based on a grammatical error generation model. To verify the performance of the English GEC system designed in this research, a validation test was now designed and conducted, in which a model was built using the open-source Sequence-to-Sequence toolkit. The operating environment and parameter settings of the model are shown in Table 4.1.

The study adopted the method of sampling decoding. The models were trained using FCE, W&I+LOCNESS,

#004	Social media data	Lang-8	1048853	1.05M	11.83M
#005	General corpus	One Billion word	1702641	1.70M	19.05M

NUCLU corpus, and the Lang-8 corpus. Moreover, the GEC model was needed to be fine-tuned. Then, the completed models were tested using the general-purpose corpus One Billion word. The specific information of these models is shown in Table 4.3. In addition, the recall *Rec*, F0.5, precision Pr e, and computation time consuming were chosen as as the evaluation index of the computation results.

Finally, to compare the performance of the model designed in this study with other models, RB, classification-based (CB), and RNN-based algorithm approaches were chosen to construct the comparison models.

After the experiments, the changes of the loss function of each error correction model during the training process were counted and shown in Figure 4.1. It needs to note that the horizontal axis in Figure 4 stands for the iteration number and the vertical axis stands for the value of the loss function, and different types of curves represent different GEC models. GEG, RB, CB, and RNN mean the models designed in this study. Because of the large range of order-of-magnitude variation of the loss function values during the training process, the vertical axis was used to display in a multi-segment manner. Observing Figure 4.1, with the growth of the number of iterations, the overall trend of the training loss function value of each model first decreased and then stabilized. When the iteration times was small, the rate of decline was generally fast, but the rate of decline was also rapidly decreasing. When the iteration times exceeded a certain value, the loss function completed convergence. After the number of iterations reached 200, all models were trained, and the loss function values of GEG, RB, CB, and RNN models were 0.04, 0.12, 0.11, and 0.07 respectively at this time.

The statistical outcomes are presented in Figure 4.2. The meaning of the horizontal axis in Figure 4.2 is the same as that in Figure 4.1, and the vertical axis indicates the correction accuracy of the correction models on the test set after training to the corresponding degree in %. From Figure 4.2, the correction accuracy of each model had an opposite trend with the increase of iteration times, which first increased rapidly and then

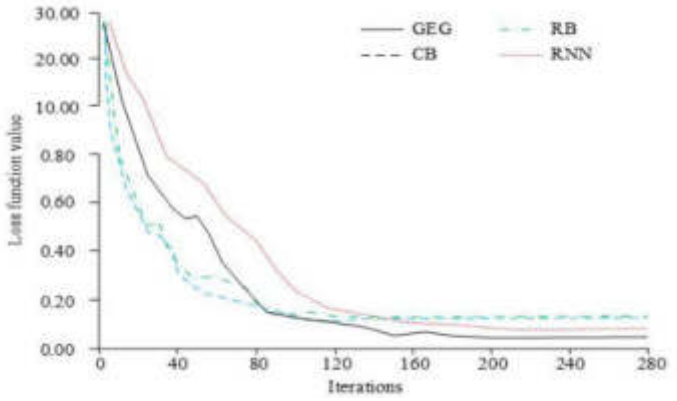

Fig. 4.1: Loss function change curve of training process

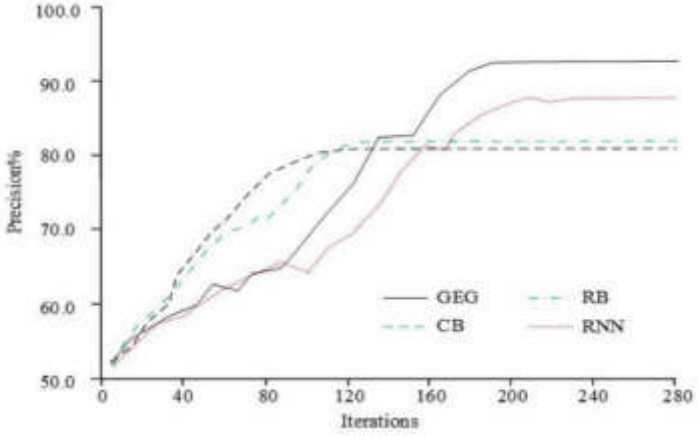

Fig. 4.2: Precision rate change curve during training

gradually converged. At the same time, there was a small amount of repeated fluctuation in the rising value, which was brought by the randomness of the selection of the training batch data. When the iteration times reached 200, each correction model also completed convergence, at which time the test set grammar correction precision rates of GEG, RB, CB, and RNN models were 93.6%, 82.4%, 80.7%, and 88.2%, respectively.

The statistics of grammar correction precision and recall for different sample numbers in the test set after the training of each correction model are shown in Figure 4.3. The horizontal axis in Figure 4.3 indicates the number of samples used to test the models in the test set, and the vertical axis means the correction precision and correction recall of each model under the selected test set scenarios in %, and different lines represent different correction models. Observing Figure 6, when the number of test samples was small, the fluctuation of both the precision rate and the recall rate of each model was larger. As the number of test samples grew, the fluctuation became less and less floating, and the trend of these two metrics was generally consistent. Moreover, the precision and recall rates of the models designed in this study were significantly higher than all the comparison models, but the recall rate values were less different from the second-ranked corrected model. Specifically, when the number of test samples reached the maximum, the fluctuation in precision and recall of each correction model was the smallest, and precision and recall of GEG, RB, CB, and RNN models were 93.92%, 82.17%, 79.41%, 88.09% and 95.81%, 86.92%, 83.46%, 94.37%, respectively.

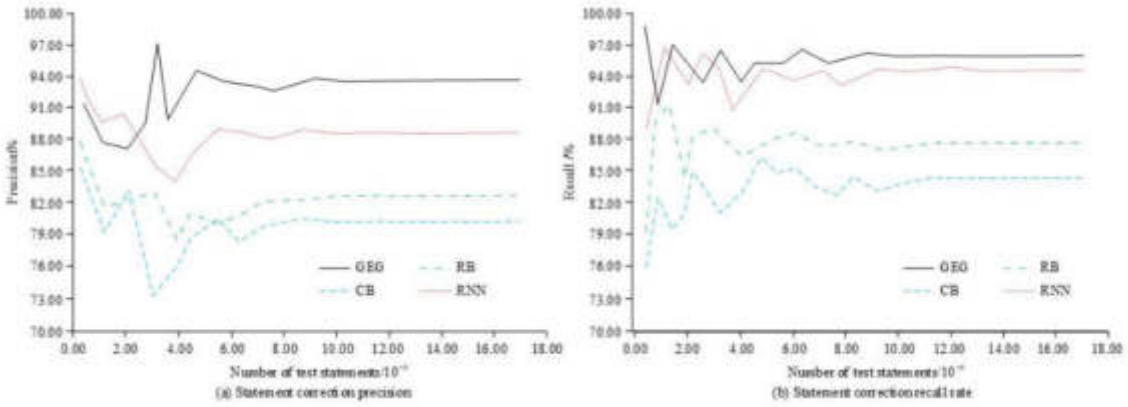

Fig. 4.3: Precision and recall variation curves of each model on the test set after the training

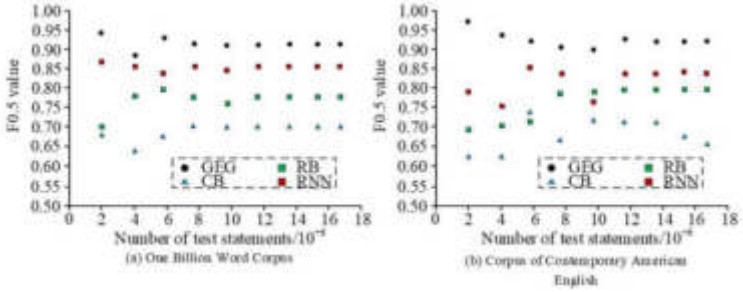

Fig. 4.4: F0.5 values of each model on the test set after training

To further improve the reliability of the statistical results, normalized F0.5 values were used to compare the performance of each model and the statistical results. At the same time, to demonstrate the adaptability of each model in the validation model, Corpus of Contemporary American English was used to test the models. The meaning of the horizontal axis in Figure 4.4 is consistent with that in Figure 6. The vertical axis represents the normalized F0.5 value for each experimental scenario on the test set. Observing Figure 4.4(a), there was no significant correlation between the number of test samples and F0.5 of the calibration model. Specifically, when there were few test samples, the F0.5 value of each calibration model fluctuated greatly, which was related to the calculation method of F0.5 value. However, as the number of test samples increased, the fluctuation of this indicator significantly decreased. When the test sample reached its maximum value, the F0.5 values of GEG, RB, CB, and RNN models were 0.92, 0.78, 0.70, and 0.86, respectively. Observing Figure 4.4 (b), the F0.5 value of the GEG model constructed in the study was not significantly different from that in Figure 4.4(a), while the RB, CB, and RNN models showed significant fluctuations and differences, indicating that the GEG model constructed in the study had superior adaptability.

Finally, the computational efficiency of each model was analyzed, and the computational elapsed time of each correction model in different test sample size scenarios was counted as an indicator. The statistical results are shown in Table 4.3. It noted that to improve the precision of the computational results, each experimental scenario was repeated five times, and the results were presented in the form of mean ± standard deviation of elapsed time. Observing Table 3, the computational efficiency of the error correction model designed in this study was lower than that of the RB and CB error correction models, but significantly higher than that of the RNN model. The RNN error correction model was built based on a neural network algorithm, so the computational speed was slower. The computational standard deviation of the RNN error correction model

Table 4.3: Comparison of computational efficiency of the models (unit: s)

Number of test statements	*GEG*	*RB*	*CB*	*RNN*
100	0.24±0.08	0.18±0.07	0.15±0.04	0.86±0.14
1000	2.03±0.17	1.65±0.14	1.35±0.11	7.51±0.92
10000	22.54±1.75	17.88±1.92	15.26±1.36	80.71±11.59
100000	196.35±15.42	169.29±12.58	142.22±12.67	765.90±93.65
1,000,000	852.56±62.78	637.25±48.39	577.51±37.02	3879.39±431.82
1702641	1433.52±87.29	1174.61±94.35	1027.95±89.15	1027.95±89.15

accounted for the largest proportion of the computational elapsed time when the number of test utterances was the same, indicating that the computational elapsed time stability of this model was also the worst. Specifically, the F0.5 values of the GEG, RB, CB, and RNN models were 1433.52 ± 87.29s, 1174.61 ± 94.35s, 1027.95 ± 89.15s, and 1027.95 ± 89.15s, respectively, when the number of test utterances reached the maximum.

5. Discussions. In today's globalized world, the importance of English is increasingly prominent. However, many non-native English learners often encounter grammar errors during the learning. Traditional English teaching methods often find it difficult to detect and correct students' grammar errors in a timely and accurate manner, which has an undeniable impact on learners' English learning. Therefore, how to improve the efficiency and effectiveness of English grammar teaching through technological means has become an urgent problem to be solved. Based on this, an English grammar automatic correction robot based on the GEG model was proposed.

The experimental results denoted that the designed GEG model had no significant advantage in training speed, but the loss function after training was significantly lower than the other comparison models, and the precision was significantly higher than the comparison models. Moreover, the precision, recall, and F0.5 values of the model on the test set were also higher due to the comparison model. This was mainly because attention neural networks could compensate for the shortcomings of the BERT model in treating input data equally, and the BERT model itself had great compatibility with text content with grammar errors. Generally, there is no need to adjust the model structure according to the characteristics of the processed data. Although the RNN series algorithms also had significant data compatibility, there was a risk of judgment and recognition due to the disappearance of gradients. The main drawback of the CB and RB models was that the core basis for GEC was too single. For example, for classification error correction models, the precision of error correction for data with multiple types of grammar errors would be greatly reduced. Therefore, the GEC model designed in this study performed better than common error correction models. However, the model designed in this study also has a drawback, which is that the fusion algorithm has a large structure, multiple internal calculation steps, and a large amount of computation, resulting in a longer processing time for samples of the same size. Subsequent research should focus on lightweight adjustments to the model while ensuring algorithm error correction and recognition accuracy.

6. Conclusion. To improve the quality of English GEC, an English GEC model based on GEG and neural network was designed in this study. An experiment was conducted to verify the error correction performance of the four error correction models, including the designed model. The experimental results indicated that in the model training phase, the convergence speed of the designed GEC model was among RNN, RB, and CB models, but the loss function after convergence was 0.04, which was significantly lower than all the comparison error correction models. The precision rate after convergence was 93.6%, which was higher than all the comparison models. The precision and recall rates of GEG, RB, CB, and RNN models on the complete test set after training completion were 93.92%, 82.17%, 79.41%, 88.09% and 95.81%, 86.92%, 83.46%, and 94.37%, respectively.The computational elapsed time of these four models on the complete test data set was 1433.52 ± 87.29s. The error correction quality of the English GEC model designed in this study was better than the traditional error correction model, but the former did not improve significantly in terms of computational efficiency. The designed error correction model had a certain potential for application in intelligent translation and English text

proofreading. However, due to experimental limitations, this study was unable to develop a nearly commercial level English GEC system based on the designed model and verify its practical effectiveness. Moreover, the calculation time of the model designed in this study was also relatively long, and making fine-tune to the model is also one of the future research directions.

DATA MINING TECHNOLOGY FOR SMART CAMPUS IN BEHAVIOR ASSOCIATION ANALYSIS OF COLLEGE STUDENTS

JUN ZHANG[1], YUNXIN KUANG[2*] AND JIAN ZHOU[3]

Abstract. The data in smart campuses is complex and massive, with insufficient utilization, and existing data processing methods have many limitations. Therefore, in order to improve the efficiency of data processing in universities and assist in student management, a data processing method integrating cluster analysis and association rule mining is proposed. The proposed method is divided into two parts. Firstly, an improved K-Means model based on information entropy and density optimization is constructed for clustering analysis of student consumption, learning, and other data; Secondly, use the improved Mapping Apriori to obtain the correlation between student grades, consumption records, and learning behavior. The clustering results on student consumption data show that the average accuracy of ED-K-Means clustering is 97.41%, which is 12.8%, 8.5% and 4.0% higher than the comparison algorithm. The result of the correlation between consumption level and achievement shows that when the amount of consumption is less than 1500 yuan, the student's achievement is directly proportional to the amount of consumption. Therefore, the proposed method can effectively mine and analyze student behavior data, which has important practical significance for intelligent management in universities.

Key words: SC; Data mining; ED-K-Means clustering algorithm; Mapping-Apriori; Association analysis

1. Introduction. As an important platform for training talents, higher education is an indispensable part of education. With society developing, colleges' and universities' management needs are constantly changing. Science and technology integrated development drives the SC construction [1]. SC effectively integrates university information resources by using information technology. It can realize reasonable resource allocation, coordinate and optimize education and teaching, student management, teacher office and other work [2]. The huge data contained in the SC can provide theoretical basis for educational operation decision-making, teachers and students management, campus convenience and other aspects. This can also enhance the quality of the campus and promote the efficient operation of the campus [3]. Among them, as an important part of higher education, college students can generate behavior data in a variety of ways in daily life. Consumption records, travel records, learning and training data are very large. How to analyze them and understand students' behavior laws is the research direction of many scholars [4]. Data mining technology can mine potential information in massive data, make reasonable use of college education and teaching information and various kinds of data, and provide reference basis for student management.

University data has the characteristics of complexity and large quantity. Although data mining technology has significant advantages in university management, its application still faces challenges such as insufficient data utilization. In addition, existing data mining technologies also face issues such as insufficient computational efficiency and poor mining results. In view of this, new data processing methods urgently need to be proposed to address the aforementioned issues. Therefore, the study first utilizes the improved K-Means algorithm based on information entropy and density optimization to cluster massive data such as student consumption and learning; Subsequently, the improved Mapping Apriori is used to explore the correlation between student grades, consumption records, and learning behavior.

The significance of the research lies in the aim of analyzing the daily behavioral characteristics of college students and their relationship with academic performance through improved data mining algorithms, providing scientific basis for university management. Through the K-Means algorithm based on information entropy and

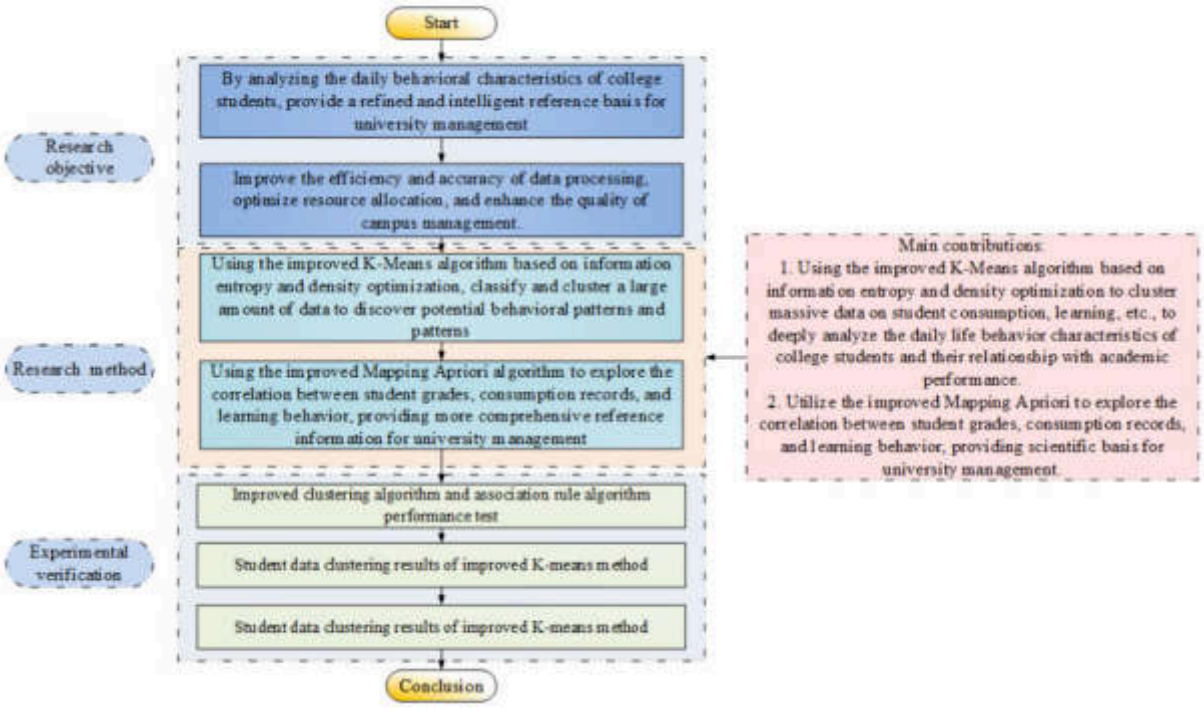

Fig. 1.1: Main Process and Contributions of the Study

density optimization, as well as the improved Mapping Apriori algorithm, it is expected to improve the efficiency and accuracy of data processing, and provide strong support for optimizing resource allocation and improving campus management quality, thereby helping universities achieve refined and intelligent management. The main process and contributions of the study are shown in Figure 1.1.

2. Related Work. As information technology develops, SC is widespread. Aiming at data digitization in the SC construction, Li W scholars studied the construction of a SC system using IoT technology. The system used face recognition technology for data collection and unified management and analysis in the background. Through the experimental test, the data of students and teachers analyzed could help colleges and universities make reasonable learning plans, and the satisfaction of system users reached 8.0 points [5]. To realize data visualization, Prandi et al. built an interactive and intelligent system, studied the sensors to collect real-time campus data, and interacted with relevant data in the system background. By testing the student experiment, the system could visualize a large amount of data in front of users, and the participation enthusiasm of student users had been greatly improved, which had certain use value [6]. Facing the difficulties encountered in SC construction, Jurva research team proposed an intelligent campus framework consisting of 5G and the Internet of Things. Through actual case analysis, the intelligent campus could effectively collect, store and analyze massive data, in which 5G technology played an important role [7]. Faced with the increasingly huge campus resources and the need to optimize the information management and decision-making methods, researchers such as Valks used Internet technology to build a SC. Through the application practice test, the results showed that the system could collect data in real time, and feedback user data changes according to the space utilization rate, which could provide a basis for decision-making for campus management [8]. Starting from the evolution and application of SC, Zhang and other scholars summarized the problems in the construction and development of the system through literature reading, case analysis and other methods. The results showed that the awareness of massive data sharing contained in the SC is insufficient, and the evaluation system formulation strategy needed to be optimized and improved [9].

Students are crucial in higher education. It is very important to excavate and analyze student information. Fan and other scholars started with online courses and studied a course recommendation method combining attention mechanism. This method was based on students' preferences and learning records, and personalized course recommendations are made for them through data analysis. Through the data validation test, the recommendation results of this method basically met the students' expectations. And the recommendation effect was good, which could realize personalized course recommendation [10]. To analyze the factors of students' rapid adaptation to school, the research team of Roorda used meta-analysis and survey methods to analyze the role of teachers. The results showed that teachers could help students integrate into campus life more quickly, actively participate in activities, and promote students' internal will and externalization behavior to be positively correlated [11]. Bureau et al. explored the relevant factors and influencing mechanism of students' self-determined motivation through case analysis. The results show that students' self - ability is the most significant factor affecting self - determination motivation, followed by autonomy; And teachers' encouragement and support have a greater impact than parents' [12]. Li scholars analyzed the relationship between students' anxiety, depression, sleep quality and mobile phone addiction, and calculated the correlation coefficient through the effect model. Students' mobile phone addiction correlates positively with anxiety and depression, negatively with sleep quality. Students with mobile phone addiction were more prone to anxiety, depression and other emotions. And their sleep quality was not high [13]. Pérez-Pérez research team faced the problem of students' satisfaction with learning management system. The research explored by building a relationship analysis model, and used the partial least squares method to calculate the relationship coefficient. The results showed that system information quality is significantly impacted on students' satisfaction. At the same time, building a good virtual learning environment could also improve students' satisfaction. The research results could provide a reference basis to improve the system [14].

As information technology popularizes, it is found that colleges and universities have gradually attached importance to the construction of SC data and the analysis of campus data. But many data have not been in-depth studied from the brief introduction of the achievements of domestic and foreign researchers. The study analyzes the relationship between students' different behavior characteristics and grades, and provides feasible suggestions for student management by students' daily behavior data such as consumption, study, and diet rules.

3. Analysis on students' behavior data by improved clustering and association rule algorithm.

3.1. Clustering algorithm based on information entropy and density optimization. With the SC construction and development, data related have expanded rapidly. Data mining technology can sort out, analyze and summarize valuable information from massive data, which is widely used by people [15]. Through the analysis of various behavioral data generated by college students in their daily life, students' behavioral laws can be obtained. This can help the development and improvement of campus quality service, scholarship evaluation, campus security and other work [16]. Cluster analysis can classify and process similar data, which is the most commonly used technology in data analysis. The research will apply cluster technology to the analysis of college students' behavior data. The relationship between students' grades and various behaviors will be explored through association rule algorithm to provide suggestions and ideas for student management. When applying the clustering algorithm, it is essential that appropriate algorithms are chosen for different situations and requirements. K-Means clustering algorithm divides the data into different classes through continuous iteration, with simple concept and strong scalability. Figure 2 shows the iterative clustering process of K-Means algorithm when $K = 4$.

K-Means has high clustering efficiency and good scalability. However, for the initial cluster center, the random selection of K-Means may make the cluster center in the same cluster, and the validity of the clustering results will be greatly reduced [17]. At the same time, the size of the cluster (i.e., K value) cannot be accurately calculated, which is usually determined by the user's experience. It can affect the clustering accuracy greatly. In view of the shortcomings of K-Means, the K-Means of Information Entropy and Density Optimization (ED-K-Means) is proposed. The optimization idea is to use the information entropy of sample data attributes to assign the Euclidean distance, and determine the cluster center more reasonably from the assigned value. Information entropy is one of the methods to eliminate information uncertainty, which can be used to measure the amount of information. In the process of using information entropy to assign values to each data, the sample data set

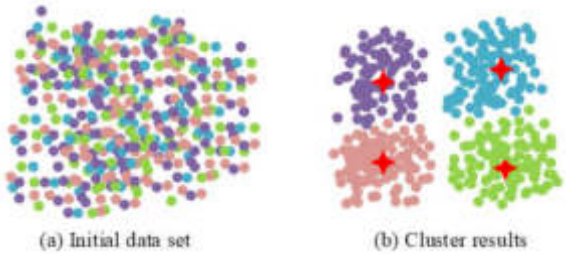

Fig. 3.1: K-Means iterative clustering process

contains multiple dimensions, and the attribute matrix in the database needs to be constructed. Formula (3.1) the is expression.

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix} \tag{3.1}$$

m is students' number in the sample data. n is the behavior data number generated by students in formula (3.1). The number of times that students appear behavior j is expressed by i when calculating the weight of each behavior attribute of students in the data set. In the calculation process, the data needs to be limited to the range of [0,1]. Formula (3.2) shows the data process.

$$Q_{i,j} = \frac{a_{i,j}}{\sum_{j=1}^{m} a_{i,j}} \tag{3.2}$$

In formula (3.2), $Q_{i,j}$ represents the proportion value of behavior attribute. Formula (3.3) is the expression of behavior i information entropy.

$$I_i = -\sum_{j=1}^{m} \log Q_{i.j} * Q_{i.j} \tag{3.3}$$

In formula (3.3), when $Q_{i,j} = 0$, $a_{i.j}$ is all equal, and there is a maximum value of I_i. In the data set, to distinguish the differences between behavior attributes, the difference coefficient is defined as h_i. Formula (3.4) is the calculation.

$$h_i = 1 - I_i \tag{3.4}$$

Formula (3.4) shows that the smaller the information entropy I_i is, the larger the h_i is, the more important the behavior attribute is, and the greater the clustering effect is. On the contrary, the clustering effect is smaller. When $I_i = 1$, $h_i = 0$, which means behavior attribute has no clustering effect. The difference coefficient is used to assign values to different behavior attributes, and Formula (3.5) is the weight expression.

$$w_i = \frac{h_i}{\sum_{i=1}^{n} h_i} \tag{3.5}$$

After the assignment, the similarity between data objects is calculated according to the Euclidean distance formula. Formula (3.6) is the changed Euclidean distance.

$$d_w(x_i, x_j) = \sqrt{\sum_{p=1}^{n} w_p (x_{ip} - x_{jp})^2} \tag{3.6}$$

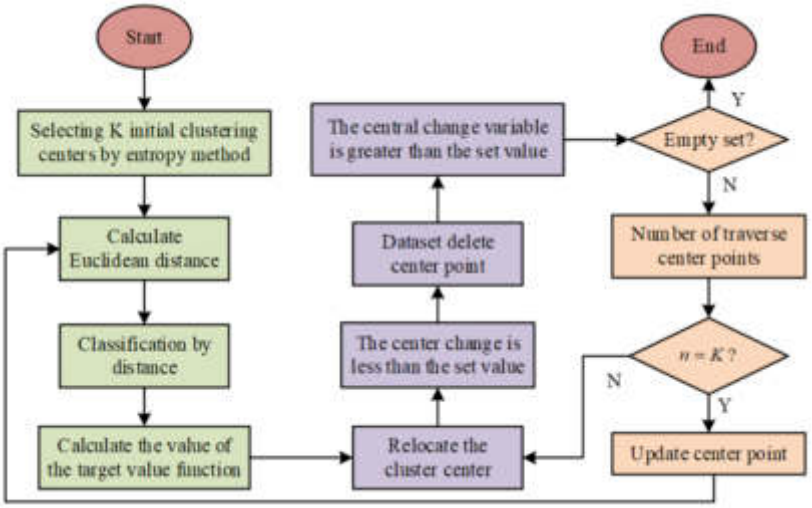

Fig. 3.2: Operation process of ED-K-Means algorithm

w_p refers to the weight of attribute p in formula (3.6). Through similarity calculation, the attribute that corresponds to weight is appropriately reduced or enlarged. This makes the clustering effect of attributes with large weights greater, and the clustering effect of attributes with small weights smaller. If clustering objective function is the standard deviation, the expression is Formula (3.7).

$$\sigma_i = \sqrt{\frac{\sum d_w(a_i, c_i)}{|C_i| - 1}} \tag{3.7}$$

c_i represents the centroid of data objects of the same category, and $|C_i|$ represents the number of data objects contained in c_i in formula (3.7). The σ_i is smaller, the data similarity objects in the cluster is greater, the data objects are denser, and the clustering effect of selecting the centroid in the cluster is better. Therefore, when the initial clustering center of the optimization algorithm is selected, the Euclidean distance between two data points is weighted to measure the similarity of data points. A more accurate initial clustering center can be obtained by ordering the value of σ_i of the objective value function. The running process of ED-K-Means algorithm is shown in Figure 3.2. K initial clustering centers are selected by entropy method, and the remaining data are clustered by calculating the assigned Euclidean distance. The clustering center is repositioned by the target value function σ_i and iterated repeatedly until the clustering requirements are met.

3.2. Improvement of college students' behavior association analysis algorithm. The constructed K-Means can be used for clustering analysis of student consumption, learning, and other data. Subsequently, the improved Apriori algorithm is used to explore the correlation between student grades, consumption records, learning behavior, and other student behaviors. The Apriori algorithm has high efficiency and wide application in association rule mining. Through frequent itemset generation and pruning, it can effectively discover association relationships in the dataset, making it particularly suitable for processing large-scale data. In addition, the attribute relationships between various types of data in universities are complex and diverse. The Apriori algorithm can use raw data analysis to extract potential rules and information between data, calculate their association rules, and help users quickly grasp information and make effective decisions [18]. Therefore, the study utilizes the Apriori algorithm to explore the deep correlation between student grades, consumption records, and learning behavior, providing a basis for improving student management and optimizing resource allocation. Apriori algorithm's core idea is to mine the set of frequent items from the target database by means of layer-by-layer iteration and search, analyze the association rules between frequent item sets, and find out the association rules between the target data. Assume that there is a transaction database that is T, the

transaction sets A and B meet $A \subseteq T, B \subseteq T$, and $A \cap B = \emptyset$. The percentage which is the union of A and B in the transaction database in all transactions is called support, and the calculation formula is (3.8).

$$Sup\,(A \Rightarrow B) = \frac{count\,(A \Rightarrow B)}{T} \tag{3.8}$$

In the transaction database, for item set P, the number ratio of the item occurrences set to the total is called absolute support. Then the absolute support expression of item set P in database T is shown in formula (3.9).

$$Sup\,(P) = \frac{count\,(P)}{T} \tag{3.9}$$

In formula (3.9), $count\,(P)$ represents the number of occurrences of item set P in database T. By comparing the size of support and minimum support, it can determine whether the item set is frequent. For item set P, if $Sup\,(P) \geq \min \sup$ is met, item set P is frequent. The minimum support is a threshold set by yourself. It can be adjusted for the actual situation. Through the minimum support, all frequent item sets can be found. For association rule $A \Rightarrow B$, it is also necessary to determine whether it meets the needs of users. The confidence level of rule $A \Rightarrow B$ is set as the number ratio of A and B union in the transaction database to the number of A in the transaction database. Formula (3.10) is the specific confidence calculation.

$$Conf\,(A \Rightarrow B) = \frac{count\,(A \Rightarrow B)}{count\,(A)} \tag{3.10}$$

The minimum confidence threshold can be used to measure whether the rule is reliable. When the support and confidence of rule $A \Rightarrow B$ are not less than the threshold, the rule is a strong association rule. The original Apriori algorithm scans the target object database many times, which will cause heavy burden on the algorithm operation. Reducing the scans number is the most direct and effective way. Mapping Apriori uses the "mapping" principle to save and compress the object data structure in the database, which can significantly reduce Apriori algorithm calculation support complexity and calculations as much as possible. In Mapping-Apriori algorithm, it is assumed that the expression of the set of all items and the target object library is Formula (3.11).

$$\begin{cases} F = \{F_1, F_2, \ldots, F_l\} \\ D = \{T_1, T_2, \ldots, T_l\} \end{cases} \tag{3.11}$$

Among them, the identification of $T \subset F$ is T_{ad}. According to the mapping principle, the storage structure of target object library D can be designed as Figure 3.3.

In Figure 3.3, the values corresponding to keys F_k $(1 \leq k \leq l)$ and F_{sum} are one-dimensional arrays. Formula (3.12) is the definition formula of d_{ab}.

$$d_{ab} = \begin{cases} 0, F_a \notin T_b \\ 1, F_a \in T_b \end{cases}, 1 \leq a \leq |F|, 1 \leq b \leq y, y = |D| \tag{3.12}$$

$|D|$ represents the number of things in formula (3.12). s_j represents the number of item sets contained in the target database. Formula (3.13) is the definition.

$$S_b = \sum_{a=1}^{l} d_{ab}, l = |F| \tag{3.13}$$

$|F|$ is the number of item sets in formula (3.13). The value of RC represents the number of duplicate things in the transaction database. Different situations need to be discussed. If there are no duplicate things in the transaction database, the value of RC is 1. Formula (3.14) is expression.

$$RC_a = 1, \quad if \quad T_{sb} \neq T_{tb}\,(s \neq t)\ , b = 1, 2, \ldots y; a, s, t = 1, 2, \ldots, l \tag{3.14}$$

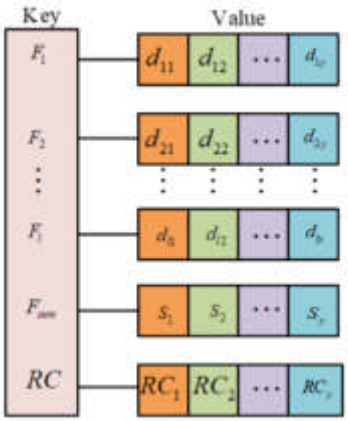

Fig. 3.3: Storage structure diagram of target thing library

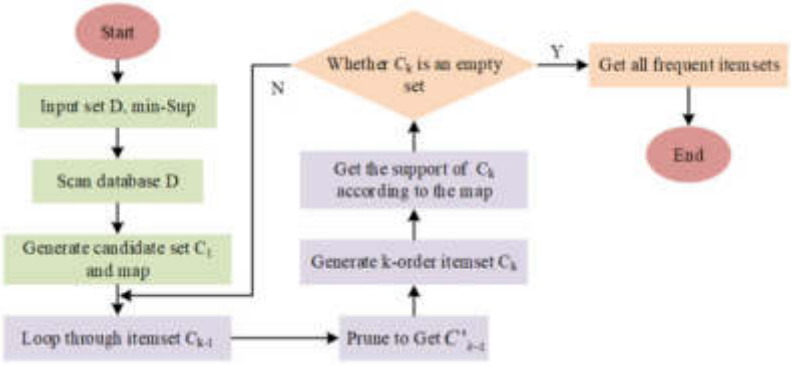

Fig. 3.4: Mapping-Apriori algorithm flow chart

If one thing is repeated, a value is assigned to RC, and Formula (3.15) is the specific expression.

$$RC_a = RC_a + 1, \ \ if \quad T_{sb} = T_{tb}\,(s \neq t) \ \ , b = 1, 2, \ldots y; a, s, t = 1, 2, \ldots, l \tag{3.15}$$

By assigning a value to RC, the map size can be reduced effectively. The Maping-Apriori algorithm uses the mapping data structure to reduce the complexity of computing item set support, and also pre-prunes frequent item sets to reduce a large number of comparisons. The execution process of the Mapping-Apriori algorithm is shown in Figure 3.4. The target transaction database D is entered with minimum support. C_1 and mapping can be obtained by scanning the database. The $k-1$ order frequent item set C_{k-1} can be obtained by cycle operation. $C^{'}{}_{k-1}$ can be obtained by pruning C_{k-1}, and the k order candidate set C_k can be generated. Calculate the support of C_k according to the array of corresponding item sets obtained from the mapping, and compare it with the threshold to obtain all frequent item sets.

subsectionPreprocessing of college students' behavior data

As information technology develops, the SC system has produced massive data, but there are inevitably incomplete and low-quality data in it. The reasons for generating these data are various, mainly including collection errors, inconsistent data format, and the lack of data that cannot be obtained [19]. These data cannot be directly analyzed, and need to be processed into relevant data that can be directly analyzed. The preprocessing technology came into being. Data preprocessing is the premise of data mining analysis. The data

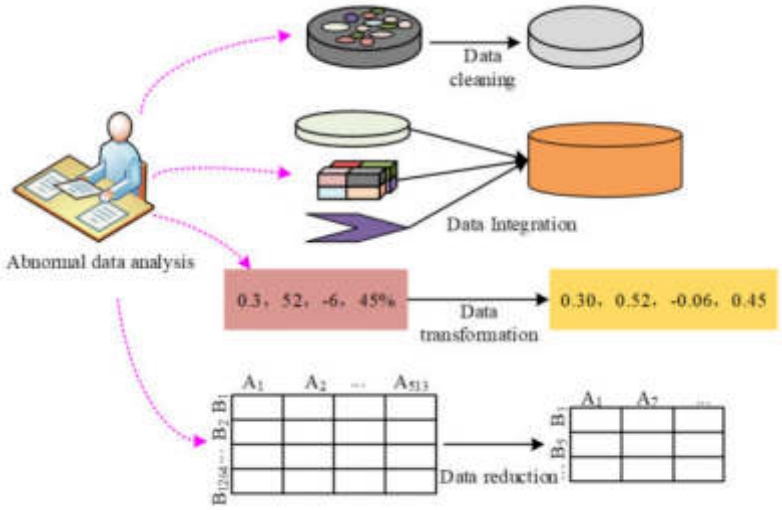

Fig. 3.5: Data preprocessing method flow

Fig. 3.6: Data cleaning principle

after data preprocessing is directly related to the analysis results. Data preprocessing methods consists of data cleaning, integration, transformation and reduction. Figure 3.5 is the specific process.

Data cleaning is to find and correct identifiable errors in data files. It will check data consistency, process invalid data and missing values. After getting the data, you should first check which data is unreasonable and its basic situation, and then clean it through the common methods of data governance. Common data cleaning methods include manual cleaning of missing value data, that is, replacing the missing value with the average value, maximum and minimum value or probability estimate. For noise data processing, it is usually to delete isolated points isolated from other data. The disadvantage of this method is that it may delete valuable data. Inconsistent data is mainly corrected by referring to paper records. Figure 3.6 shows the principle of data cleaning.

Data integration is because the data to be integrated is obtained from the databases of multiple application systems. Because its different formats, attributes and characteristics need to be collected into a database for analysis, data from different data sources need to be sorted and consolidated into data storage with consistent characteristics. Good data integration can reduce the result data set redundancy and inconsistency, and improve the accuracy and efficiency of its subsequent mining process. Data transformation refers to the normalization of data to achieve the purpose of mining. Data transformation mainly involves smoothing, data aggregation, data generalization, and data normalization.

Data reduction refers to a process of minimizing the data and maintaining its integrity as much as possible.

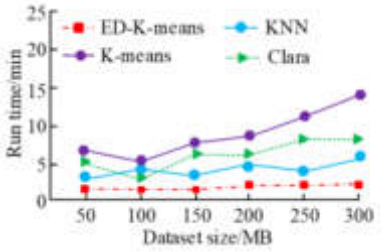

Fig. 4.1: Running time results of four algorithms

Although large databases can be used for data mining, the selected mining algorithm may not be applicable due to its high dimension and large amount of data. The large amount of calculation will cause heavy load on the equipment. It is necessary to reduce large data sets to small data sets as much as possible. Without changing the mining analysis results, reducing the data size and data reduction can improve the mining efficiency.

4. Analysis on data performance and application of mining technology in college students' behavior association analysis.

4.1. Improved clustering algorithm and association rule algorithm performance test. To analyze the proposed ED-K-Means' performance, a comparative experiment was conducted with other clustering algorithms. Clara (Clustering LARge Applications), traditional K-Means and KNN (K-Nearest Neighbor) were selected. The test data was a self-made database composed of college students' consumption behavior, score records, book borrowing, etc. The data collection process involves multiple steps. Firstly, by collaborating with relevant departments on campus, we obtained student consumption records, academic performance data, and library borrowing records. These data cover students of different grades, majors, and genders, and have high comprehensiveness and representativeness. During the data cleaning and preprocessing process, missing and outliers were removed to ensure data quality and consistency. The final dataset includes multiple behavioral characteristics and academic performance, which can comprehensively reflect the overall behavioral patterns of college students and provide a reliable data foundation for the performance evaluation of clustering algorithms. The results obtained from the running time analysis are in Figure 4.1.

The runtime curves of the four algorithms show an upward trend with the increase of the dataset in Figure 3.6. Among them, K-Means has the longest running time, consuming more than 5min, the longest running time is 15.08min, and the average running time is 10.36min. The maximum running time of Clara is 8.97 min, the average time is 6.22 min, and the running speed is accelerated. The average operation time of KNN is 5.11min, and the longest time is 6.18min. The operation speed and stability are further improved. ED-K-Means has the best performance in running time and stability, with an average running time of 1.96 minutes. Compared with KNN, Clara and K-Means, its running efficiency has been improved by 81.1%, 68.5% and 61.6% respectively. This shows that the idea of information entropy combined with density optimization can improve the algorithm efficiency, and has better performance.

To test the improved Mapping-Apriori algorithm effectiveness, the performance test is carried out with Apriori and Frequent Pattern Growth (FP-Growth) algorithm under the same conditions. Figure 4.2 shows the loss curve.

The change trend of the loss curve of the three algorithms is similar, and the decline speed and fluctuation range of the loss value are different. Among them, Apriori's loss value decreases slowest and gradually converged to within 40 after 150 iterations, and the loss value basically fluctuated between 30-45 after 200 iterations. The decline speed of FP-Growth loss curve was accelerated, the loss value dropped to within 30 after 150 training, and then fluctuated between 20-30, and the stability is improved. The loss curve of Mapping-Apriori decreases the fastest, and the loss value is within 20 after 80 training. With training times increasing, the fluctuation range of the loss value is between 10-15, and the algorithm has the best stability. It shows that Apriori improvement by mapping can improve the iterative algorithm efficiency and stability.

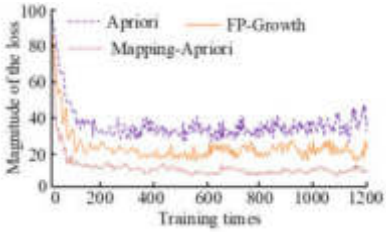

Fig. 4.2: Loss curve results of three algorithms

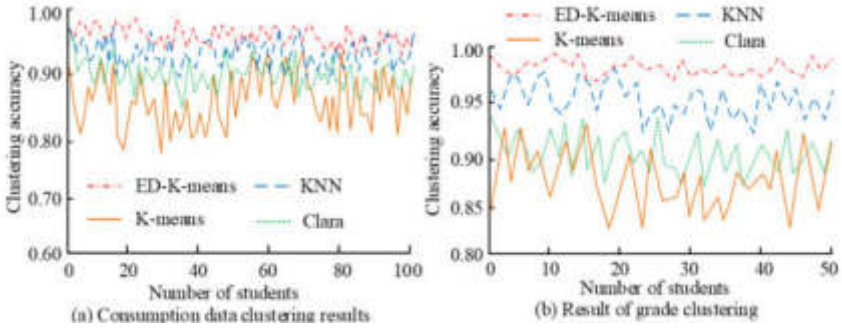

Fig. 4.3: Cluster accuracy results

4.2. Student data clustering results of improved K-means method. The consumption behavior and performance data of students were collected in a certain major in the SC database. Several clustering algorithms are applied for clustering analysis of relevant data, and the clustering accuracy is used for evaluation and analysis. Figure 4.3 shows the clustering accuracy results obtained from the two data.

From Figure 4.3(a), the clustering accuracy of K-Means is poor, with an average accuracy of 86.33%. The stability of the algorithm is also poor, and the accuracy curve fluctuates greatly, with the maximum difference of 16.9%. Clara's clustering accuracy has increased, with an average accuracy of 89.82%. Its stability has improved, with a fluctuation of 10.7%. The accuracy curve of KNN fluctuates by 8.6%, and the stability of the algorithm is further strengthened. The average clustering accuracy is 93.65%, and the clustering effect is good. The clustering accuracy of ED-K-Means is mostly above 95%, with the smallest fluctuation range and the largest difference of 5.9%. The average accuracy of clustering is 97.41%. Compared with the comparison algorithm, the accuracy is improved by 12.8%, 8.5% and 4.0%.

Figure 4.3(b) shows the clustering results of 50 students' performance data. It can be seen that the accuracy of several algorithms is above 80%, and ED-K-Means clustering has the best accuracy and stability. The average clustering accuracy of K-Means, Clara, KNN and ED-K-Means is 87.18%, 91.27%, 94.88% and 97.83% respectively. Compared with the comparison algorithm, the accuracy of ED-K-Means is 10.65%, 6.56% and 2.95% higher. According to Figure 10, ED-K-Means has the best clustering accuracy and stability in the face of different clustering data. The clustering results of students' monthly consumption level using ED-K-Means are shown below.

When the total monthly consumption of a student is more than 600 yuan in Table 4.1, the student is at a high consumption level and belongs to non-poor students. Students whose consumption amount is between 200 and 600 belong to poor students, and the consumption amount is less than 200, which indicates that the student's consumption is extremely low and belongs to extremely poor students. According to the clustering results, the total consumption of most students is below 600. The school can provide decision-making basis for the assessment of poor students based on relevant information.

Table 4.1: Student monthly consumption level clustering results

Consumption level	*Cluster center range*	*Cluster center value*	*Percentage of students*
High	Total amount>600 yuan	629.88	16.67%
Medium	200-600 yuan	447.29	57.19%
Low	Total amount <200 yuan	179.45	26.14%

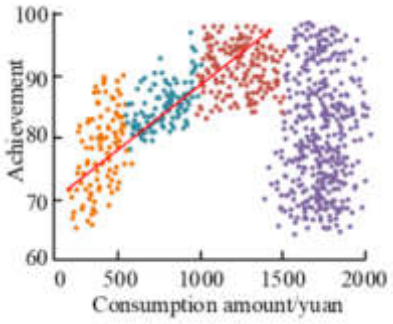

Fig. 4.4: The correlation between student achievement and consumption

Table 4.2: Association result

Result	*Consumption level*	*Consumption habits*	*Academic record*	*Learning behavior*	*Conf*
1	High	Regular	A(>85)	Regular	0.153
2	High	Regular	B(75-84.5)	Regular	0.162
3	Medium	Regular	A(>85)	Regular	0.417
4	Medium	Irregular	C(60-74.5)	Regular	0.118
5	Medium	Regular	A(>85)	Regular	0.474
6	Medium	Irregular	D(<60)	Irregular	0.122
7	Low	Regular	A(>85)	Regular	0.453
8	Low	Irregular	D(<60)	Irregular	0.136

4.3. Results of college students' behavior correlation analysis. The research establishes a relevant database through cluster analysis of students' consumption records, grades and learning behaviors. And Maping-Apriori is used to explore the correlation between student performance and consumption behavior rules, consumption level and learning behavior. Figure 4.3 shows the correlation between student achievement and consumption.

From Figure 4.4, when the amount of consumption is less than 1500 yuan, there is a certain positive correlation between the level of consumption and student performance. At the initial stage, with the increase of the amount of consumption, the student's performance improved, but after the amount of consumption reached 1500, the positive correlation disappeared. The minimum support is set to 0.15 and the confidence is set to 0.85. Table 4.2 shows the correlation results.

The consumption rules in Table 4.2 mainly refer to the consumption records of students' three meals a day, and the learning behaviors mainly refer to the records of access to the library and dormitory. In Table 3, there is a certain correlation between students' grades and their diet rules, library and dormitory access rules. Students with good grades have relatively regular life. This is because students who insist on eating breakfast on time generally have better self-discipline and can arrange time scientifically. At the same time, students who insist on eating breakfast on time can also improve their mental state in class at ordinary times. Among them,

most of the students with moderate consumption level, regular consumption and regular learning behavior are "A" and "B" in their academic achievements; The students with irregular consumption and learning behavior are mostly "C" and "D" in their academic performance. Through correlation analysis, colleges and universities can observe the characteristics of students' daily behavior in school, help and guide students to develop good living and learning habits, and promote students' healthy growth and smooth completion of their studies.

5. Conclusion. The overall operation effect is closely corresponding to the management of students' behavior. Strengthening the management of students' behavior will improve the overall operation efficiency. In face of massive data in SC, the improved ED-K-Means method is proposed to cluster relevant data, and the optimized Mapping-Apriori algorithm is used for association analysis. Through the performance test, the average ED-K-Means running time was 1.96 minutes. Compared with the comparison algorithm, the running efficiency was improved by 81.1%, 68.5% and 61.6%. The loss curve of Mapping-Apriori decreased the fastest, the fluctuation range of loss value was the smallest, and the algorithm stability was the best. Through cluster analysis, the results showed that the average accuracy of ED-K-Means clustering was 97.41% for student consumption data. In terms of student achievement data, the accuracy of the algorithm was as high as 97.83%, which was better than the comparison algorithm. At the same time, the algorithm divided different consumption levels and performance grades according to the total monthly consumption. The correlation results obtained from Mapping-Apriori show that students with good grades live relatively regularly. Through the analysis of relevant data, colleges and universities can help poor students to carry out the assessment work smoothly, and guide students to cultivate good habits. The research mainly uses structured data in the SC system. The unstructured data has not yet been analyzed and processed. In the future, unstructured data such as pictures and videos will be analyzed to improve the reliability of the results.

REDUNDANT TELEMETRY LINK SYSTEM FOR UNCREWED AERIAL VEHICLES[1]

ALI ELBASHIR[2*] AND AHMET SAYAR[3]

Abstract. Thanks to their flexibility in research, prototyping, and development, Uncrewed Aerial Vehicles (UAV) are seeing increasing use in agriculture, healthcare, logistics, and other industries. With the increase in the use of UAV in civilian sectors, comes an increase in the possibility of errors in telemetry connections. Issues with the telemetry connection may be catastrophic and cause accidents and crashes and may also adversely affect the performance of the subsystems connected to the telemetry. In this study, a low-cost software-based redundant telemetry link system for UAV is proposed. The proposed system minimises the received packet loss using packet deduplication and is compared with a dynamic link switching method. In the proposed system, both fault tolerance and robustness are introduced into the UAV telemetry link. The analysis is performed using the ArduPilot UAV Simulation environment as a producer and a Golang implementation of the proposed methods.

Key words: Uncrewed Aerial Vehicle, MAVLink protocol, autopilot, packet loss, Ground Control Station

1. Introduction. UAVs have been deployed in many sectors due to rapid technological advances and low production costs. Defence, agriculture, healthcare, logistics, and various other industries have turned to UAV technology to automate their business processes and make them more efficient. Furthermore, the development of open source autopilot software such as ArduPilot and PX4 has encouraged research and development in this field, allowing UAV technology to be adopted by a wider user base.

However, with the proliferation of UAVs, several challenges have emerged that can affect the safety and efficiency of their operations. The most important of these challenges is the reliability and stability of telemetry links. In particular, among US military UAV accidents, "In more than a quarter of the accidents examined by The Post, links were lost around the time of the crash" [1]. In the absence of hostile interference, which is also a big contributor to military UAV accidents, the rate of loss of telemetry links is expected to be even higher in the civilian sector. To overcome these difficulties, it is important to maintain continuous and error-free telemetry links. However, a variety of environmental factors and technical errors frequently disrupt the communication of telemetry data. Therefore, this paper presents a review of how to minimise the effects of unreliable UAV telemetry links and how these links can be optimised.

In this context, a study is conducted on the effectiveness and efficiency of redundant telemetry link systems. The goal is to ensure that the telemetry data from the UAV reaches the ground control station (GCS) quickly and that the link can be changed in the event of a link failure. As a result of our research, our telemetry link system is both fault tolerant and performant. A performant link significantly increases the probability of mission success for the UAV. Within this framework, we investigate the use and effectiveness of dynamic link switching and packet deduplication methods.

Key Contributions. Our work dives deep into the nuances of UAV telemetry links, striving for enhancements in both reliability and performance. The key contributions of this study are the following:

1. An in-depth examination of redundant telemetry link systems, spotlighting their potential to augment UAV mission success rates.
2. Introduction of an application layer fault-tolerant and high-performance redundant telemetry link system
3. Comparative analysis of dynamic link switching versus packet deduplication within a redundant telemetry link system

After this introduction, the paper subsequently delves into basic concepts in Sect. 2, reviews related works in Sect. 3, outlines the proposed methods in Sect. 4, examines the experimental results in Sect. 5, and culminates in Sect. 6 with conclusions and prospects for future research.

2. Basic Concepts.

2.1. Redundant Systems. In the field of computer science, redundant systems are critical in their role in providing data protection and service continuity. Redundant systems are systems that take over functionality when there is an error or failure in the primary system [2]. It is important to define the importance of redundant systems and the various types of redundant systems.

Redundant systems are designed to maintain functionality in the event of a failure. They ensure the continued functionality of the system in situations where the primary system is repaired or replaced. Redundant systems are especially critical in environments with high safety requirements, such as hospitals and aeroplanes.

System redundancy generally comes in two main forms: passive and active. In passive redundancy, the backup system is activated only when the primary system fails. This type of redundancy is typically used for data protection and recovery. In active redundancy, both the primary and backup systems are running at the same time, and both share the workload. This ensures higher system performance and service continuity.

2.2. MAVLink. Micro Air Vehicle Link (MAVLink) is a protocol for communication with small uncrewed vehicles. MAVLink is designed as a Marshalling library, which means that it serialises the messages of system states and the commands it needs to execute in a specific sequence of bytes, hence being platform independent. The binary serialisation structure of the MAVLink protocol makes it lightweight as it has minimal overhead compared to other serialisation techniques (XML or JSON).

It is mostly used for communication between a Ground Control Station (GCS) and uncrewed vehicles, and for communication between the vehicle's subsystems themselves. It is used to transmit data such as the vehicle's heading, GPS position, speed, etc. This protocol is used in widespread autopilot systems such as ArduPilot and PX4, and is used not only to control uncrewed aerial vehicles, but also to control autonomous systems such as Remotely Operated Underwater Vehicles and Uncrewed Ground Vehicles. [3]

MAVLink Message Format

Communication using MAVLink is bidirectional between the ground station and the uncrewed vehicle. The MAVLink protocol defines the mechanism for the structure of messages and how they are serialized at the application layer. These messages are then forwarded to the lower layers (i.e., the transport layer, physical layer) for transmission to the network. The advantage of the MAVLink protocol is that its lightweight nature allows it to support different types of transport layers and environments. MAVLink can be transmitted using sub-GHz (433 MHz, 868 MHz, 915 MHz, etc.), WiFi, Ethernet, and serial connections.

MAVLink messages are described in XML files. Each XML file defines the set of messages supported by a particular MAVLink system, also called a "dialect". The reference set of messages implemented by most MAVLinks and autopilots is defined in common.xml (most dialects are built on top of this definition). An example of a MAVLink dialect XML definition file is given in Fig. 2.1.

Code generators parse the XML definitions and create codec libraries for supported programming languages, which can then be used to communicate with UAVs, GCSs, and other MAVLink systems. MAVLink messages can be defined as two types:

1. Status messages: These messages are sent from the UAV to the ground station and contain information about the status of the system, such as its identity, position, speed and altitude.
2. Command messages: They are sent by the GCS (or other client programs) to the UAV to make the autopilot execute some action or task. For example, the GCS can send a command to a UAV to take off, land, navigate to a way-point, or even execute a mission with several linked actions.

These messages are encoded into the payload of the larger MAVLink frame, which is shown in Fig. 2.2

3. Related Works.

To strengthen the communication system of UAVs, Lau & Ang worked on a link switching algorithm [5]. In their system, the "heartbeat" message defined in Fig. 2.1 in common.xml is used to determine the state of the link. In the event that a connection is broken, the system automatically switches to a backup connection. This provides fault tolerance, and thus maintains the communication continuity of the UAV.

In addition, projects such as mavproxy, mavp2p, and mavlink-router support the use of parallel connections [6]. Parallel connections allow both incoming telemetry and outgoing commands to be exchanged between multiple connections. This provides a backup connection in case one link drops or fails. However, since packet deduplication is not implemented in these projects, this creates the effect of ”rubberbanding” in the case there is a latency difference between the links.

For experimental studies, most previous work has used the IEEE 802.11b (Wi-Fi) standard. Brown et al. [7, 8] implemented a wireless mobile ad hoc network on radio nodes in fixed locations, off-road vehicles, and UAVs. One of their scenarios is to extend the operational scope and range of small UAVs. They measured network efficiency, delay, range, and connectivity in detail under different operating conditions and showed that the UAV has longer range and better connectivity. Jimenez-Pacheco et al. [9] built a lightweight ad hoc mobile network (MANET). The system implemented line-of-sight dynamic routing in the network. Morgenthaler et al. described the implementation and characterisation of a mobile ad hoc network for lightweight flying robots. The UAVNet prototype was able to automatically interconnect two end systems through a flying relay.

Asadpour et al. [10, 11], conducted a simulation and experimental study of image relay transmission for UAVs. Yanmaz et al. proposed an antenna extension to a simple 802.11 device for aerial UAV nodes. They tested the performance of their system and showed that 12 Mbps communication can be achieved at a communication distance of about 300 m. Yanmaz et al. [12] conducted a tracking study on two UAV networks using 802.11a. In this study, they showed that high throughput can be achieved using two-hop communication. Johansen et al. [13] described a field experiment in which a fixed-wing UAV acts as a wireless relay for an

underwater vehicle. In that study only download data rates were tested, in particular, while Wi-Fi networking is suitable for creating multiple access points, the communication range is very limited, and many nodes are required for long-range applications. An advantage of the Wi-Fi network is its high throughput. However, for UAV telemetry communication, distance is a more important requirement than data transfer rate. This paper presents a UAV communication system that is different from previous research. Our system is based on a Ground Control Station (GCS) with two links to the UAV. In this way, a structure that can establish both relay connections and provide direct connections is obtained. Our system is flexible and can support different communication protocols such as serial protocols and wireless technologies such as Wi-Fi for data transmission. Because our system works at the application level, it is independent of the transport and data link layers. These features offer the ability to better adapt to various scenarios and communication needs. This work is differentiated from previous work by its new approach and more flexible structure in the UAV-GCS communication.

Our research goes even deeper into these issues. In particular, we investigate how link switching and deduplication algorithms can be used dynamically effectively.

4. Method.

4.1. Link Switching. The system calculates the packet loss in real time throughout the flight and shows which link has the least packet loss. To ensure the command packets sent from the GCS reach the UAV as they are sent over all the links, not just the active one.

If a link is detected to be completely down, it is disabled, and telemetry is received on the remaining active links. When the number of active links drops to 1, all telemetry data is received from that link.

The link switching algorithm's pseudocode is shown in Algorithm 1.

Algorithm 61 Link Switching Algorithm

```
for each packet do
    if packet is coming from the active link then
        route the packet to the GCS
        update last received packet time
    else if packet is coming from the GCS then
        route the packet to the UAV through all links
    end if
    calculate time difference from the last received packet.
    if packet received time difference ≥ link switching duration then
        switch active link with inactive link
        update last received packet time
    end if
end for
```

The dynamic link switching algorithm monitors the packet loss rate and delay on the main link and switches to the backup link if these values exceed the set thresholds.

Detection time is the time period between the end of the transmission of data packets over the main link and the detection of the end of the transmission. Ideally, the detection time should be as short as possible so that outage situations can be quickly identified and responded to.

Response times refer to the completion times of the operations performed after detection. When a link outage is detected, the system must react quickly to enable the backup link to be activated. Response times include the time required to activate the backup connection and ensure a smooth transition of telemetry data. These times may vary depending on the method of connection switching and the complexity of the system infrastructure.

The continuous monitoring of link quality process is used to determine the difference in performance between the main link and the backup link and to make a decision to switch links when necessary. Various metrics can

be used to monitor link quality; for example, parameters such as latency, bandwidth, packet loss rate, and signal strength can be evaluated.

Latency measures the time delay in the transmission of data packets from the main link to the backup link. In many cases, lower latency means better connection quality and indicates faster data transfer. The bandwidth determines the amount of data transmitted simultaneously, with a larger bandwidth providing higher data transfer rates. The packet loss rate refers to the rate at which data packets are lost. A low packet loss rate indicates reliable data transmission [14].

Various algorithms can be used for continuous monitoring of connection quality. For example, network protocols such as ping and traceroute can be used to measure connection performance and detect faulty points on the network. Monitoring software can also be used to track statistics on the sending and receiving of data packets.

The thresholds set during this monitoring process are used to determine whether the quality of the connection is good or bad. For example, when the packet loss rate exceeds a certain threshold, the link quality is considered poor, and a link-switching process can be triggered. These thresholds are predetermined depending on the requirements of the telemetry system and the application scenario.

Consequently, continuous monitoring of link quality is a critical step for the reliability and performance of the backup telemetry system in UAVs. This monitoring process is accomplished through the use of various metrics, and link replacement is initiated when thresholds are exceeded.

The step of determining the packet loss rate and setting thresholds is performed to ensure accurate and reliable collection and transmission of telemetry data. Various statistical methods can be used to determine the lost packet rate. For example, the packet loss rate can be calculated as a percentage of the difference between the number of packets sent and received. The determination of threshold values is important to identify situations where the packet loss rate exceeds acceptable levels. These values should be determined according to the needs of the UAVs and the telemetry system used [15].

For example, during a UAV mission, a threshold value should be set on the packet loss rate that occurs on the main link when the backup telemetry system is activated. This threshold represents a point at which packet loss exceeds acceptable levels. When the threshold is exceeded, a switchover from the active link to the backup link is performed. To properly perform this switchover, the packet loss rate and the threshold value must be taken into account. For example, if the threshold value is set at 5%, the connection switching process must be initiated if the packet loss rate exceeds this value.

4.2. Paket Deduplication. Packet deduplication is a method of checking whether a packet from a source has arrived before. It is used in TCP/IP routers, data storage systems, and systems with parallel connections [16].

Packet deduplication can be implemented in many different ways, but since our use case is real-time and sensitive, we use a temporary buffer that keeps the packets of the last 5 seconds.

Deduplication starts by checking whether packets from different sources are arriving. For this, a performant and suitable duplicate detection algorithm needs to work. There are 2 options here:

1. Store the incoming packet itself and compare every byte of each incoming message with the stored packets
2. Get the hash of each incoming packet, store it in a hashmap, and check if the hash of each incoming packet exists in the hashmap

The first option has two obvious problems. The first one is that it requires us to store all messages. We might need to store about 124 MAVLink messages per second (for the Ardupilot simulation environment), so in the worst case 263 * 124 bytes. If we use an 8 byte hash, that is 8 * 124 bytes, which is 32 times less memory space, which can be even more significant depending on the hardware the switch is running on and the message rates it receives.

As a hashing algorithm, we use the 4-byte version of MurmurHash, which is used in high-speed real-time applications such as Hadoop [17], ElasticSearch [18] and Kafka [19].

5. Experimental Results. In the experimental studies carried out during this work, the impact and performance of packet deduplication were evaluated. The results obtained are shown in Fig. 5.2

Data collection was performed using the simulation environment of the open source MAVLink-based Ardupilot autopilot software. In the experimental environment, a UAV was left in "Loiter" mode and a packet loss of 1% per second was inserted using the tc command available in Linux distributions. This scenario was designed to mimic the challenging situations that can be encountered in real world conditions. UDP was used as the transport layer protocol during the experiment.

First, data reflecting the state before deduplication was applied was recorded. Then, using a 4 byte version of the MurmurHash algorithm, packet deduplication was performed and the data were recorded as such.

The analysis of the experimental data was carried out by measuring the packet loss rate. Data recorded after deduplication was considered as the control group, while data recorded without deduplication was used as the comparison group.

The results show that packet deduplication is an effective method. It is observed that after deduplication, the packet loss rate is reduced from 10% to 30%. This shows that the redundant telemetry link system provides more reliable and consistent communication.

We also evaluated the impact of deduplication on transmission times. Although a buffer is used in deduplication, packets are not kept in that buffer before being sent. Therefore transmission times are not affected in any way.

Another part of our experimental work focused on the study of the mechanism of dynamic switching of telemetry links. In this process, we studied a system that forwards packets from the active link. However, in this case, the loss rate of the filtered packet is not lower than the loss rate of the active link packet, as shown in Fig. 5.1.

In some scenarios, this may cause the loss rate to be higher than that of the active link, even if the packet loss rate of the inactive link is lower. This is also shown graphically in our experimental results. When the packet loss rate of the active link reaches 100% and a threshold time (e.g. 1 second) is exceeded, the link is automatically switched.

Compared to packet deduplication, link switching is less efficient. Two main reasons explain this:

1. If the active link is broken during the threshold time, even if the inactive link is active, no packets will be forwarded to the ground control station (GCS) until the link is replaced.

2. The filtered packet loss can be as low as, but not lower than, the packet loss of the lowest link. This shows that the link switching mechanism has more limitations than packet deduplication in terms of communication continuity and efficiency in certain situations.

These results should be taken into account when determining optimisation strategies. In particular, under harsh environmental conditions and high packet loss rates, packet deduplication seems to provide a more effective solution than link switching.

6. Conclusion. In this article, a study on a redundant telemetry connectivity system for UAVs is analysed in detail. The purpose of the study is to evaluate the feasibility of using MAVLink packet forwarding methods for transmitting telemetry data to UAVs by duplicating MAVLink packets at an application layer level.

The packet deduplication method was found to be suitable for a real-time and accurate use. A copy detection algorithm with MurmurHash was used. This method is based on the principle of taking the hash value of each incoming packet and checking whether it has been received before.

The experimental results confirm the effectiveness of the packet deduplication method. In simulations with an additional packet loss of 1% per second, it is observed that the loss of deduplicated packets is on average 10% to 30% less. This shows that packet deduplication is an effective solution to improve the reliability of UAV telemetry links.

This paper also investigates the mechanism for dynamic switching of telemetry links. This approach allows the use of a backup link in case the active link is down. However, our experimental studies have shown that this mechanism has certain limitations. In particular, if the threshold time is exceeded and the link is down, the inactive link is not used until the active link is replaced. Furthermore, the link-switching method cannot guarantee the link that can offer the lowest packet loss rate.

These observations suggest that the link switching mechanism may be less efficient than packet deduplication in certain scenarios. Therefore, additional optimisation work needs to be done in order to make more efficient use of the link switching mechanism.

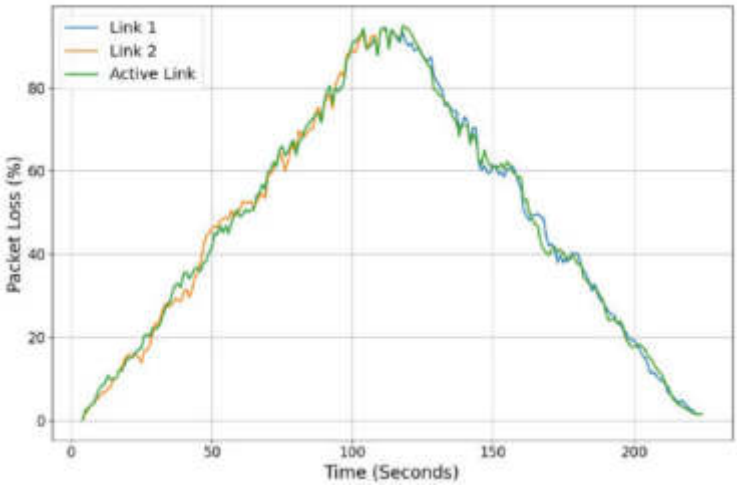

Fig. 5.1: Packet loss using dynamic link switching

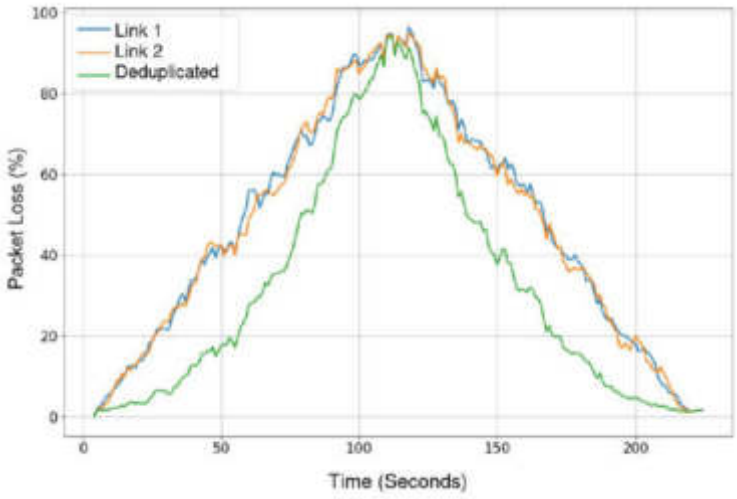

Fig. 5.2: Packet loss using packet deduplication

Furthermore, the scope of the study is limited to MAVLink packets. It is important to apply similar methods for different protocols or data types and evaluate the results. Further research on different types of telemetry data and protocols is recommended for future work.

The results highlight the importance of a redundant telemetry connectivity system for UAVs and show that packet deduplication is an effective solution to improve the reliability of this system. It is hoped that experts in the field of UAV technologies and telemetry will be inspired by this study for further evaluation and implementation.

In conclusion, this study has addressed the concept of a redundant telemetry connectivity system for UAVs and demonstrated that packet deduplication is an effective solution to improve the reliability of this system. Future work should support progress in this area with similar studies on different protocols and data types.

Acknowledgement. The authors of this paper would like to thank Mr. Alessandro Ros – developer of the MAVLink implementation for the Go language (GOMAVLIB) – for his support and code review.

INTEGRATION OF LLM IN EXPIRATION DATE SCANNING FOR VISUALLY IMPAIRED PEOPLE

THEODOR-RADU GRUMEZA[1], BOGDAN BOZGA[2]*AND GRIGORE-LIVIU STANILOIU[3]

Abstract. In this study, the authors explore an approach to detect expiration dates of food products using a live feed stream and the integration with Large Language Models in order to improve accessibility for visually impaired people. The main objective is to enhance their capacity to engage in common tasks like grocery shopping autonomously. The novelty of this research lies in employing Meta LLAMA 2, a large language model, and experimenting with both traditional and a new OCR solution to find the expiration date using image processing. This approach offers audio information about whether the product has expired or when it will expire, helping in shopping and product recognition for visually challenged customers. The proposed solution consists of optical character recognition, mainly the EasyOCR library, fine-tuned on cropped images containing only the expiration dates and a validation phase that filters and checks the extracted data.

Key words: Expiration date scanning, Image processing, Visually impaired people, Large Language Models

1. Introduction. Our research is centred on integrating Large Language Models such as Meta's LLAMA 2 [16] in expiration date scanning applications to improve accessibility for visually impaired people. According to the World Health Organization (WHO), 285 million individuals worldwide experience visual impairments, with 39 million being blind and 246 million having low vision [3].

The identification of the date on which the product is due, which is printed on each perishable product like cosmetics and pharmaceuticals, but especially on food products, is used to specify the date until that product is safe to use or consume.

Automatic expiration date detection [1] is challenging due to the non-existence of a standard and the different fonts, materials, and positions on which they are printed. Due to this inconsistency, a lot of food may be consumed after the due date, which can lead to food poisoning. Finding the due date of the product becomes genuinely concerning in the case of visually impaired people who may find it hard or even impossible to read and understand the expiration date on the products they have in the fridge or pantry.

Some solutions exist, but those are not widely available, easy to use, or work only in particular conditions. The classic OCRs [14] have appeared as a need to recognise characters in papers or other structured formats. These algorithms still have one significant limitation: they are trained to read text from clear and structured images, most commonly synthetically or documents. At the same time, the accent when developing new OCRs or upgrading the already developed ones was heavily towards adding new languages [6] and not detecting specific information in images from the real world. Specifically, product information, such as expiration dates, may be highly obscure and distorted, with a significant variation of lighting or even dotted formats.

To evaluate the effectiveness of detecting expiration dates on products, we compared a standard Optical Character Recognition (OCR) solution with our custom solution that was specifically fine-tuned for this task. Our aim was to determine which method more accurately identifies and reads expiration dates from various product images.

We considered two widely-used OCR systems: EasyOCR and Tesseract. Tesseract is a well-established OCR engine extensively used and researched, as detailed in [15]. Despite its long history and widespread

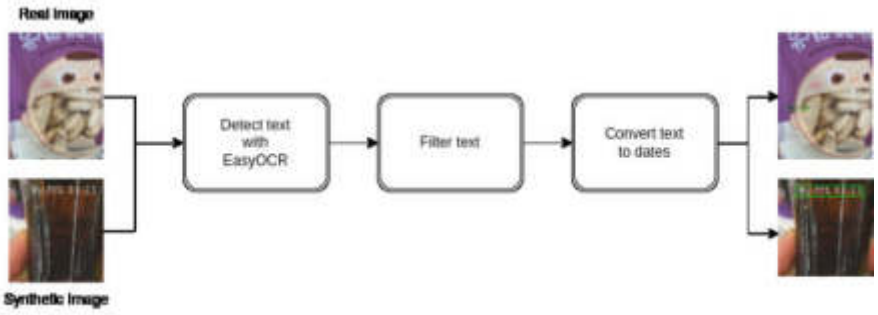

Fig. 1.1: Detection workflow

use, our preliminary tests with Tesseract yielded unclear results for this specific use case. It struggled with recognizing expiration dates on product packaging, including variations in font styles, sizes, and backgrounds.

On the other hand, EasyOCR is a more recent OCR system designed to handle a wide range of text recognition tasks, including reading text from complex real-world images. As referenced in [17], EasyOCR provides enhanced capabilities in recognizing text in diverse conditions, such as varying lighting, orientations, and noisy backgrounds, common in product images.

Given these considerations, EasyOCR was selected for our comparison. Its ability to more accurately read and interpret text from real-world images made it suitable for detecting expiration dates, which often appear in small, variable fonts on uneven surfaces. This choice was instrumental in establishing a baseline performance against which we could measure the effectiveness of our fine-tuned solution. By leveraging the strengths of EasyOCR, we aimed to achieve a more reliable detection and extraction of expiration date information from product images.

The literature review in the second section of this research covers integrating a Large Language Model with expiration date scanning using Optical Character Recognition [9].

The third section refers to the implied methods and the system specifications. It highlights some open problems that could be useful in implementing the approach for combining the LLM with OCR scanning and the phases while implementing the system. The fourth section offers the research results, emphasising our model's accuracy and a comparison with other solutions. The last section is dedicated to conclusions and future work.

2. Related Work. Several specialized solutions have been developed to address the problem of detecting expiration dates on food products. For example, Florea and Rebedea proposed an approach titled "Expiry Date Recognition Using Deep Neural Networks" [18], which employs deep neural networks trained on labelled datasets comprising both real and synthetic images of expiration dates. Their method achieved a general accuracy of approximately 63% when utilizing only real images. However, a significant drawback of their solution is the complexity involved in replicating the implementation and deploying it across various mobile devices or smart glasses platforms.

Previous works have explored various approaches, such as using neural networks with specific feature extraction techniques [11] and direct OCR application at different angles. These studies have highlighted the challenges in accurately identifying expiry dates, given their varying formats, locations, and printing styles on product packaging. Image pre-processing methods, like the Hough transform and adaptive thresholding, have been investigated to improve OCR accuracy, demonstrating varied levels of success. This review can delve into these methods, comparing their results and discussing potential areas for further research and improvement.

The study "Recognition of Expiration Dates Written on Food Packages with Open Source OCR" [7] takes the same approach to the problem, but it uses Tesseract-OCR. The authors developed a smartphone application that recognizes expiration dates on food packages by utilizing Tesseract's capabilities to scan and interpret these dates. The solution uses the OCR without any fine-tuning, demonstrating its capabilities and limitations. The detector struggled in specials when the data were in dot format or on shiny surfaces that reflected light, such

as cans. The study's results aren't clear since the general focus wasn't on developing the application and explaining how the solution works (which is real work) but on incorporating it into a smart fridge.

The most notable solution on which the complex implementation and which is used to compare the current solution is the paper "A generalized framework for recognition of expiration dates on product packages using fully convolutional networks" [13]. This solution develops a more complex approach by incorporating fully convolutional networks (FCNs) to enhance the accuracy and performance of expiration date recognition.

The authors of this study designed a complex framework that integrates image pre-processing, segmentation, and recognition steps. They used deep learning to improve the detection and interpretation of expiration dates from diverse packaging. The two authors created a vast dataset with both real and synthetic images to implement and test their solution. This dataset was also used to create and test this solution.

The quality and safety of food products are crucial for human health, with proper labelling of expiry dates playing a vital role in preventing the consumption of unsafe food. Food wastage, mainly due to expiration, has become a significant global concern, as highlighted by the Food and Agriculture Organization (FAO), which reports that approximately 1.3 billion tons of food are wasted annually. This concern has led to the development of various methods for expiry date detection and recognition of food products. Several approaches have been proposed, including Scazzoli et al.'s [12] method using the Hough transform and adaptive Gaussian thresholding for OCR accuracy, Ribeiro et al.'s [10] end-to-end deep neural network architecture for text detection, and Zaafouri et al.'s [20] automated vision approach utilizing a multilayer neural network and S-Gabor filters for image enhancement. Gong et al. [4] also introduced a unified deep neural network combining convolutional and recurrent neural networks for automatic date recognition in food packages.

Despite their contributions, these methods often process entire images to extract expiry dates, leading to extensive computation and inefficiency, especially in real-time applications. Many existing systems also rely on traditional barcodes like EAN-13 and UPC, which lack expiry date information, requiring manual input and monitoring. To address these challenges, the current study proposes a streamlined method that uses the Single Shot Detector MobileNet (SSD MobileNet) for object detection and Attention OCR for text recognition. This approach focuses on detecting the region of interest, significantly reducing redundant processing and enhancing accuracy. SSD MobileNet offers faster processing and lower latency than Faster RCNN, while the Attention OCR model improves text recognition through attention mechanisms. This combination provides a promising solution to reduce food wastage by facilitating more effective monitoring and managing food product expiry dates.

The article of Liyun Gong et al. [5] introduces an innovative camera-based system designed to automatically detect and recognise expiry dates on food packages. This system addresses a critical need for accurate labelling in the food manufacturing sector. Mislabeling expiry dates can lead to serious health issues and significant financial losses due to product recalls. This system aims to improve the reliability and efficiency of expiry date verification, which is currently prone to human error and equipment faults.

The proposed method utilizes a fully convolutional network (FCN), a type of deep neural network (DNN), to detect the expiry date region on food packages. This approach differs from traditional methods that rely on Optical Character Verification (OCV) systems, which can be inconsistent due to variations in expiry date formats, packaging, and camera angles. The FCN is fine-tuned on a dataset of food packages to identify expiry date regions specifically, minimizing the influence of other text on the package.

After detecting the region of interest (ROI), the system extracts the date characters using image processing techniques like the Maximally Stable Extremal Regions (MSER) algorithm. This extraction is followed by character recognition using the Tesseract OCR engine, which classifies the date characters. The process is designed to reduce computational costs by focusing only on the detected ROI rather than the entire image.

The experimental results show that the system achieves a high detection rate of 98% for expiry date regions across various types of food packages in different image formats. However, blurred characters can affect the recognition performance, indicating an area for future improvement. Overall, the system offers a robust solution for enhancing manufacturing food safety and quality assurance by automating the expiry date detection and recognition process.

3. Proposed Methodology. Our research is centred on integrating Meta's LLAMA 2 in expiration date scanning applications to improve accessibility for the visually impaired. This approach wants to offer audio

Table 3.1: Date Patterns for Filters

Pattern	**Example**
`\d{1,2}/\d{1,2}/\d{2,4}`	MM/DD/YYYY or MM/DD/YY
`\d{1,2}-\d{1,2}-\d{2,4}`	MM-DD-YYYY or MM-DD-YY
`\d{2,4}/\d{1,2}/\d{1,2}`	YYYY/MM/DD or YY/MM/DD
`\d{2,4}-\d{1,2}-\d{1,2}`	YYYY-MM-DD or YY-MM-DD
`\d{1,2}\s+\w+\s+\d{2,4}`	”12 Jan 2023”, ”5 April 22”
`\w+\s+\d{1,2},?\s+\d{2,4}`	”January 12, 2023”, ”Apr 5, 22”
`\d{1,2}\s+\w{3}\s+\d{2,4}`	”12 Jan 2023”, ”5 Apr 22”
`\w{3}\s+\d{1,2},?\s+\d{2,4}`	”Jan 12, 2023”, ”Apr 5, 22”
`\d{2,4}\.\d{1,2}\.\d{1,2}`	YYYY.MM.DD
`\d{1,2}\.\d{1,2}\.\d{2,4}`	DD.MM.YYYY or DD.MM.YY
`\d{2,4}/\d{1,2}`	YYYY/MM or YY/MM
`\d{1,2}/\d{2,4}`	MM/YYYY or MM/YY
`\d{1,2}\s+\w{3}\.?\s+\d{2,4}`	”12 Jan. 2023”, ”5 Apr 22”
`\w{3}\.?\s+\d{1,2},?\s+\d{2,4}`	”Jan. 12, 2023”, ”Apr. 5, 22”
`\d{4}\d{2}\d{2}'`	”YYYYMMDD”
`\d{2}\d{2}\d{4}`	”DDMMYYYY”

information about whether the product has expired or when it will expire, helping in shopping and product recognition for visually challenged customers.

Without needing to create a new, more specialized Neural Network that can be used only for this use case, we want to be able to extend it to other similar use cases. To fulfil this, we use a fine-tuned EasyOCR to enhance its capabilities for our specific application. EasyOCR is an open-source OCR tool that is known for combining Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) to detect and recognize text [2].

The fine-tuning process was conducted on the Google Colab platform, utilizing the NVIDIA T4 GPU. This setup provided a high-performance training environment where no particular settings were needed.

Regarding the integration of LLM in the context of expiration date identification and information retrieval, some open problems need to be addressed:

- How can we improve the robustness of expiration date detection in varying environmental conditions, such as poor lighting, low-resolution images, or images with occlusions and distortions?
- What strategies can be implemented to handle diverse formats and languages of expiration dates, considering the global variations in date formats and the use of non-standard characters or symbols?
- How can OCR systems be trained to differentiate between expiration dates and other date-related information on product packaging, such as manufacturing dates or batch numbers, to avoid misinterpretation?
- How can multimodal approaches combining OCR, natural language processing, and visual context recognition be developed to enhance the understanding of product labels, including expiration dates, ingredients, and usage instructions?

In order to train the model, we use both real and synthetic images. After fine-tuning the workflow as shown in Figure 1.1, the first step is the detection of texts in the test images. The texts that we extracted go to a filtering step. We use date patterns to obtain only the relevant formats as shown in Table 3.1. Afterwards, we used the parser from the dateutil library to convert the dates extracted using the patterns into datetime format. This conversion removes parts that passed the filters but aren't valid dates. Then, another verification that checks if the dates obtained were between 10 years ago and 30 years from the current date is applied.

Because we want to be sure that the information on the product respects the general date formats, we will use the LLM to double-check the obtained due date and also give audio feedback regarding whether the product has expired or when it will expire.

Fig. 3.1: Real images

3.1. Dataset. The dataset created by Ahmed Zaafouri et al. [21] was used for training and has 1102 real images of products and expiration dates that capture real-world variety, as seen in 3.1. Another 11860 synthetic images designed to extend the number of pictures with the model are trained. There were images in the dataset with food products that had packaging imperfections. Because of this, we had the idea to simulate the distortions of the products to enhance the dataset and make the images look as good as the ones taken in the shopping store, as seen in Figure 3.2.

Real images are important for training the OCR model to recognize the target text in real life because the packaging fonts and light conditions differ from one case to another. The synthetic images enhance the data, variety, and number of available images for training.

Some images contain more than one expiration date, for example, the first image from Figure 3.2. The total number of dates from non-synthetic images is 1244 and 16674 systematical ones 4.1.

3.2. Performance Metrics. The performance of the models was evaluated using several metrics described in a further paragraph. These metrics help us quantify the effectiveness of the OCR system in different scenarios, providing insights into areas that may need improvement.

Correct Detection Rate.

$$\text{Correct}(\%) = \frac{\text{Number of Correct Detections}}{\text{Total Number of Images}} \times 100 \tag{3.1}$$

This equation calculates the percentage of images where the OCR system correctly identifies the expiration date. In our research, this metric is crucial for understanding the model's base accuracy. A higher percentage indicates that the model accurately detects and recognises expiration dates across the dataset.

Partial Detection Rate.

$$\text{Partial}(\%) = \frac{\text{Number of Partial Detections}}{\text{Total Number of Images}} \times 100 \tag{3.2}$$

This metric captures cases where the detected date is incorrect but falls within a reasonable margin of error (less than 365 days from the actual date). This is important in our research because it shows the model's ability

Fig. 3.2: Synthetic images

to approximate dates even if not perfectly accurate, which can be useful in contexts where a close estimation is acceptable.

Missing Detection Rate.

$$\text{Missing}(\%) = \frac{\text{Number of Images with No Valid Date Detected}}{\text{Total Number of Images}} \times 100 \tag{3.3}$$

The missing detection rate measures the percentage of images where the OCR system fails to detect a valid date. This helps us understand the model's limitations in terms of its sensitivity and ability to recognize expiration dates under different conditions. A lower missing rate is desirable, indicating the robustness of the model.

Wrong Detection Rate.

$$\text{Wrong}(\%) = \frac{\text{Number of Incorrect Detections (More than 365 Days Apart)}}{\text{Total Number of Images}} \times 100 \tag{3.4}$$

This metric indicates the percentage of images where the detected date was significantly incorrect (more than 365 days off). It helps identify scenarios where the model makes substantial errors, possibly due to confusing background text or poor image quality. Analyzing these cases can guide improvements in the OCR model or pre-processing steps.

3.3. General methods for recognition of text features. The Convolutional Recurrent Neural Network (CRNN) combines Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) to extract and recognize text features. Understanding the equations used in CRNN helps fine-tune and interpret how the model processes the images.

Feature Extraction (CNN). The convolution operation used in the CNN layer:

$$(I * K)(i, j) = \sum_m \sum_n I(m, n) \cdot K(i - m, j - n) \tag{3.5}$$

This equation represents the convolution operation in the CNN part of CRNN, which extracts features from the input images. In our research, this step is crucial for identifying patterns within the image indicative of text, such as edges or shapes corresponding to characters. By adjusting the kernel K, we can refine what features are extracted, potentially improving the model's accuracy in detecting expiration dates.

Sequence Modeling (RNN). Using Long Short-Term Memory (LSTM) cells to model the sequence:

$$h_t = o_t * \tanh(C_t) \tag{3.6}$$

where:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \tag{3.7}$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \tag{3.8}$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \tag{3.9}$$

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \tag{3.10}$$

These equations describe the LSTM units used in the RNN part of CRNN. They are responsible for capturing the sequential dependencies in the detected text features, allowing the model to understand the context and order of characters in the expiration dates. In our research, this is important for ensuring that the text is recognized in the correct order, especially in cases where characters are closely spaced or overlapping.

Connectionist Temporal Classification (CTC) Loss. CTC is used to align input and output sequences:

$$\text{CTC Loss} = -\log(p(y|x)) \tag{3.11}$$

where:

$$p(\pi|x) = \prod_{t=1}^{T} y_{\pi_t}^{(t)} \tag{3.12}$$

CTC loss is used during training to allow the model to predict sequences without requiring pre-segmented inputs. In our research, this is particularly useful for handling varying lengths of expiration dates and different text alignments within images. By using CTC, we can train the model more flexibly, improving its generalization to different formats of expiration dates.

3.4. Enhanced methods for character-level detection and localisation. Character Region Awareness for Text Detection (CRAFT) is used for character-level detection and image localisation. It allows us to precisely detect individual characters, making it a complementary approach to CRNN for recognizing text.

Text Region Localization. CRAFT focuses on character-level detection using: Region Score: Represents the probability of a character at each location. Affinity Score: Represents the link between neighboring characters.

In our research, CRAFT's ability to localize individual characters improves the detection of expiration dates, especially in cluttered backgrounds or images with irregular text arrangements. Using the region and affinity scores, we can identify isolated characters and connected components, enhancing the model's performance on complex images.

Loss Function for CRAFT. The training loss for CRAFT is a combination of region and affinity losses:

$$L = L_{region} + \lambda \cdot L_{affinity} \tag{3.13}$$

This equation is used during the training of the CRAFT model. The loss function combines the errors in detecting individual characters (region loss) and the links between characters (affinity loss). By minimizing this loss, we fine-tune the model to accurately detect and connect characters, which is critical in our research for recognizing expiration dates in various layouts and fonts.

3.5. Comparison and Analysis. The performance of the models is compared based on accuracy and time efficiency. The comparison is done on the entire image and only on the section that contains the due date. These comparisons helped us determine the most effective OCR approach for our specific use case.

Table 4.1: Default Performance

Detector	**Correct (%)**	**Partial (%)**	**Missing (%)**	**Wrong (%)**
Default E	61.4%	7.3%	30.2%	1.1%
DBnet E	61.96%	6.25%	30.36%	1.43%
Default C	62.86%	5.36%	30.36%	1.43%
DBnet C	63.21%	5.0%	30.36%	1.43%

Accuracy Comparison. To observe the differences between detection rates for entire images versus cropped images:

$$\Delta\text{Accuracy} = \text{Accuracy}_{\text{cropped}} \times \text{Accuracy}_{\text{entire}} \tag{3.14}$$

This equation allows us to quantify the impact of using cropped images versus entire images for training and testing. By comparing the accuracy, we can understand how focusing on specific regions (e.g., where the expiration date is located) can improve the model's performance. This informs our decision on whether pre-processing steps like cropping are beneficial in real-world applications.

Average Time per Image. To evaluate the efficiency of the models:

$$\text{Average Time} = \frac{\text{Total Time Taken}}{\text{Number of Images}} \tag{3.15}$$

This equation measures the computational efficiency of the OCR system. In our research, this is important for assessing the feasibility of using the model in real-time applications or large-scale processing. A lower average time per image indicates a more efficient model, which is crucial for scenarios requiring quick results.

3.6. Iteration and Model Tuning. The effect of different numbers of training iterations on performance:

$$\text{Performance} \propto \text{Number of Iterations} \tag{3.16}$$

This relationship indicates that the model's performance typically improves with more training iterations up to a point of convergence. In our research, we use this principle to determine the optimal number of iterations for training, balancing between underfitting and overfitting. We can select the best model for accurate expiration date detection by monitoring the performance over iterations.

4. Experimental Results. We have done experiments to check and compare how this type of solution performs in different situations by comparing the performance of various stages of the fine-tuning with the due date written in different formats.

The validation set of images was constant, and we took into account the following metrics:

- *Correct* - represents the percentage of images in which the expiration date was identified correctly;
- *Partial* - represents the percentage of images in which the identified date wasn't correct, but the detected date was less than one year (365 days) apart from the real one;
- *Missing* - is the percentage of images with no valid date after the filtering step;
- *Wrong* - the number of images with a valid date was detected, but it was further apart than 365 days from the real one.

4.1. Default results. To check the OCR's default capabilities, we first run the detection without fine-tuning the model. Two detectors were used, the first being the default one with the model weights for the English language and the second using DBnet detector [8].

The results are presented in Table 4.1 where we evaluate both the full images, indicated by rows labelled 'E', and the cropped sections containing expiration dates, labelled 'C'.

Table 4.2: Performance for Cropped Images

Iterations	Correct(%)	Partial(%)	Missing(%)	Wrong(%)
10k	61.4%	7.3%	30.2%	1.1%
30k	61.96%	6.25%	30.36%	1.43%
50k	62.86%	5.36%	30.36%	1.43%
70k	63.21%	5.0%	30.36%	1.43%
90k	63.21%	4.82%	30.54%	1.43%
100k	63.21%	4.64%	30.71%	1.43%
Best Acc.	63.21%	5.89%	29.82%	1.07%

4.2. CRNN Architecture fine-tuned. The Convolutional Recurrent Neural Network (CRNN) backbone architecture was used, which is a text recognition network specifically designed to recognize sequences of characters in images accurately. The CRNN architecture combines Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) to extract features effectively and capture the sequential nature of text.

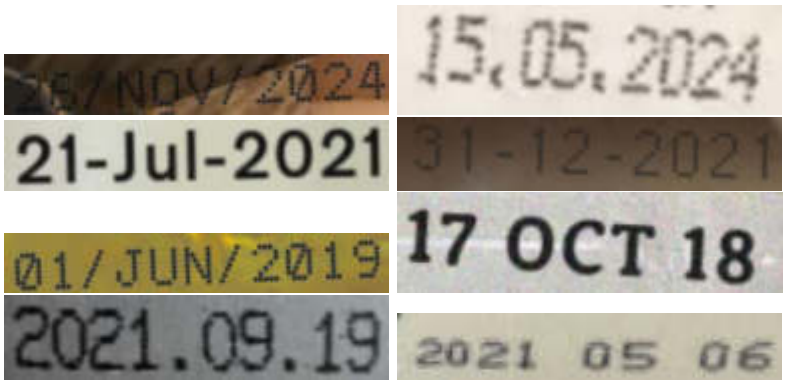

Fig. 4.1: Cropped dates

Fine-tuned using only cropped images. The model was trained on cropped parts of the images containing only the expiration dates as presented in Figure 4.1. This had the purpose of checking its accuracy when only the wanted text is present and no other unwanted information, as shown in Table 4.2. The total number of images tested is 666, all of which are real; the average time per image is around 0.022 seconds, including the detection and filtration phases.

The last row of Table 4.2, entitled "Best Accuracy", represents the result for the model that achieved the highest accuracy during the training phase. Overall, all the results are promising due to the low percentage of partial and wrong detections.

In a real-life use case for the missing detection, another image will be taken, and considering the low time needed for each image, this approach represents a valid solution.

Fine-tuning using the entire images. In this case, we trained on the entire image that contains the expiration dates, other text and noise. The purpose was to compare the accuracy in the case when no before-hand cropping was done. As expected, the results are not as good as in the case with only the wanted text, as can be seen in Table 4.3.

The same images were used to evaluate the previous model, but this time, the entire image was analyzed rather than just a cropped section. The average processing time per image is approximately 0.945 seconds.

The issue arises when dealing with large images, as the detector has difficulty distinguishing the expiration date from other text, occasionally merging them. This leads to more text being detected, which means more

Fig. 4.2: Partial Detection

Fig. 4.3: Wrong detection

Table 4.3: Performance for Uncropped Images

Iterations	Correct(%)	Partial(%)	Missing(%)	Wrong(%)
10k	48.49%	4.52%	0%	46.99%
30k	49.12%	4.47%	0.1%	46.31%
50k	49.68%	4.39%	0.15%	45.78%
70k	50.21%	4.29%	0.19%	45.31%
90k	50.62%	4.18%	0.22%	44.98%
100k	51.02%	4.07%	0.25%	44.66%

text might pass through the filter and sometimes get incorrectly converted into dates, negatively affecting the statistics. For instance, numbers from barcodes might be misinterpreted as valid dates, as seen in the first image, the second row of Figure 4.3. In this scenario, the LLM is employed to further eliminate unnecessary text, enhancing the accuracy of expiration date detection on the product.

4.3. CRAFT Architecture Fine-Tuned. We also experimented with the CRAFT backbone architecture, a text detection network specifically designed to identify and localize text regions in images. CRAFT is adept at detecting both regular and irregular text arrangements, including curved and rotated text [19].

Training and testing were conducted on the same image sets used for the CRNN section.

The primary difference between CRNN and CRAFT lies in their text detection approach. While CRNN is designed to detect entire words in an image, CRAFT focuses on localizing and detecting individual characters and symbols.

A significant drawback of CRAFT is that it is more time-consuming to train and slower than CRNN. Due to time constraints imposed by Google Colab, we could only complete a relatively small number of iterations.

For a model with 5000 iterations, testing on entire images yielded results of 49.1% correct, 4.37% partial, 41.27% missing, and 5.27% wrong, with an average processing time of 0.92 seconds per image. Using the same model on cropped parts of the images containing only the date, the results were 51.79% correct, 9.64% partial, 19.64% missing, and 18.93% wrong. This comparison indicates that the CRAFT model performs better on uncropped images, highlighting the importance of contextual information.

Figure 4.2 provides examples of expiration dates that were incorrectly recognized, typically due to one

character being misinterpreted. Figure 4.3 illustrates cases where dates were detected incorrectly, often because other numbers or text, such as barcodes, were misinterpreted as valid dates.

5. Conclusion and Future work.

5.1. Conclusion. In this study, we proposed a new approach to assist visually impaired individuals in identifying expiration dates on food products through the use of live feed streams and the integration of Large Language Models, specifically leveraging Meta LLAMA 2. By incorporating image processing techniques with optical character recognition (OCR), primarily utilizing the EasyOCR library enhanced with CRNN and CRAFT architectures, we aimed to provide an accessible and scalable solution. The results indicate that while our solution does not introduce a novel neural network architecture, it demonstrates the capacity to be readily updated and refined, making it a practical alternative to more complex models. Despite the current solution requiring further optimization to compete with the high accuracy rates of existing models, such as the work by Ahmet Cagatay Seker and Sang Chul Ahn [13], it establishes a solid groundwork for future advancements. The CRAFT architecture, in particular, shows considerable promise in terms of effectiveness in this use case, suggesting its potential for further development. Overall, our application meets its intended goal of enhancing accessibility for visually impaired individuals, enabling them to perform grocery shopping tasks with greater autonomy.

5.2. Future Work. Building on the promising initial results of the CRAFT architecture, future research will focus on several key areas to refine and extend the capabilities of the proposed solution. First, we plan to perform extensive model optimization and fine-tuning using a larger, more diverse dataset, which will enhance the model's accuracy and robustness across various expiration date formats and packaging types. Integrating the system with real-time processing capabilities will also be a priority, allowing for seamless, live detection and feedback to users in dynamic environments like grocery stores. Moreover, expanding the system's language support to recognize expiration dates in multiple languages is critical for its applicability in different regions, catering to a global user base. To increase the reliability of expiration date detection, advanced validation mechanisms incorporating contextual information from product labels will be developed, reducing false positives. We also aim to enhance the user interface, focusing on delivering more intuitive audio and haptic feedback options to ensure a user-friendly experience for visually impaired individuals. Finally, extensive field testing and deployment in real-world environments will be conducted to gather comprehensive user feedback, enabling iterative improvements to both the system's performance and user experience. These future directions will collectively contribute to evolving the solution into a highly accurate, reliable, and accessible tool, significantly benefiting visually impaired individuals' independence and quality of life.

ENERGY HARVESTING DEADLINE MONOTONIC APPROACH FOR REAL-TIME ENERGY AUTONOMOUS SYSTEMS

CHAFI SAFIA AMINA* AND BENHAOUA MOHAMMED KAMAL†

Abstract. This paper presents an innovative scheduling algorithm designed specifically for real-time energy harvesting systems, with a primary focus on minimizing energy consumption and extending the battery's lifespan. The algorithm employs a fixed priority assignment which is the deadline monotonic policy, we have chosen it for its optimality and superior performance compared to other fixed priority scheduling methods.

To achieve a balance between energy efficiency and system performance, we incorporated a DVFS (Dynamic Voltage and Frequency Scaling) technique into the algorithm. This adaptive approach enables precise control over the processor's operating frequency, effectively managing energy consumption while ensuring satisfactory system functionality.

The core objective of our scheduling algorithm centers on optimizing energy utilization in real-time energy harvesting systems, specifically tailored to extend the battery's operational life. Rigorous evaluations, including comprehensive comparisons against established fixed priority scheduling algorithms, validate the algorithm's efficacy in significantly reducing energy consumption while preserving the system's overall functionality.

By combining the deadline monotonic policy and DVFS technique, our proposed algorithm emerges as a promising solution for energy-autonomous systems, contributing to the advancement of sustainable energy practices in real-time applications. As energy harvesting technologies continue to progress, our algorithm holds valuable potential to provide critical insights for enhancing the efficiency and reliability of future energy harvesting systems.

Key words: Real-time systems, energy harvesting, embedded systems, power management, dynamic voltage and frequency selection (DVFS), Deadline monotonic policy, fixed priority assignment.

1. Introduction. The pervasive influence of real-time systems in today's technological landscape has propelled them to the forefront of various aspects of human life. From facilitating automated control systems to enabling the emergence of autonomous vehicles and revolutionizing medical fields, real-time systems have assumed a pivotal role in shaping modern society. As their significance continues to grow, researchers are earnestly dedicating their efforts to augmenting these systems and devising sophisticated scheduling algorithms to meet their stringent real-time requirements.

One of the most critical determinants of success in real-time systems is the task deadline. The seamless execution and accomplishment of tasks within their specified timeframes are instrumental in ensuring the overall effectiveness and reliability of these systems. Hence, meeting stringent temporal constraints becomes an imperative pursuit in the pursuit of optimized performance.

Concurrently, energy consumption poses as a significant challenge for real-time systems, with wireless devices being particularly affected. These devices, which often operate on limited battery life, are frequently deployed in settings where access to conventional power sources is scarce or absent altogether. As a consequence, the pursuit of innovative approaches to curtail energy usage while simultaneously upholding real-time imperatives represents a pivotal realm of ongoing research.

Numerous research endeavors have been dedicated to managing and minimizing energy consumption in various systems. One of the initial approaches to address this challenge was Dynamic Power Management (DPM), wherein the processor is transitioned into an idle mode to minimize energy usage when no tasks are ready for execution. Another notable approach is Dynamic Voltage and Frequency Scaling (DVFS) [4], which dynamically adjusts the processor's operating frequency to reduce energy consumption while ensuring

all deadlines are met. Extensive studies have highlighted the efficacy of these methods in effectively utilizing available energy resources [1, 2, 3].

Despite these advancements in energy efficiency, a major obstacle persists - the system's dependence on battery life. When batteries become discharged, the system's functionality is compromised, necessitating recharging or replacement. Regrettably, in some regions, access to power sources for recharging may be limited or non-existent [5, 6, 7, 8].

To overcome the challenges associated with battery charging and to enhance its lifespan, researchers have developed energy harvesting systems. Energy harvesting has garnered significant interest due to its potential to offer effective and sustainable solutions. For instance, wireless sensor devices can harvest energy from their ambient environment in real-time, enabling them to operate indefinitely. Such an approach holds the promise of theoretically achieving an infinite device lifetime. Energy can be harvested from various sources, including sunlight through photovoltaic (PV) cells (solar systems), wind, and vibrations, among others.

Within this context, we propose an algorithm for energy harvesting real-time systems, based on a variant of the deadline monotonic scheduling policy, with the primary objective of minimizing energy consumption. By strategically managing energy utilization, the proposed algorithm aims to extend the system's operational life. Also, we proposed a feasibilty test based on timing and energy constraints.

The remainder of this paper is organized as follows: Section 2 provides a comprehensive background and outlines related research. Section 3 presents the task model and architecture employed in our system. In Section 4, the background of the deadline monotonic scheduling approach is discussed. The proposed EH-DM algorithm is described in Section 5. In section 6, we discuss the worst case execution of our proposed scheduling algorithm. We proved the optimality of our algorithm in section 7. The feasibility test is presented in Section 8. Section 9 elaborates on how the processor's operating speed is computed. Section 10, presents the evaluation of the performance of EH-DM. Finally, Section 11 presents our concluding remarks.

2. Related work. In the context of real-time energy autonomous systems, researchers are dedicated to developing scheduling algorithms specifically tailored for systems utilizing energy harvesting. Over time, numerous approaches have been proposed to tackle this challenging problem. One of the pioneering solutions was introduced by Kansal et al. [9], who devised a model to accurately capture the power generated by a solar energy source. To address the scheduling problem, the authors employed a periodic approach and formulated it as a linear program.

In each period, the scheduling algorithm adapts the work cycle to account for any discrepancies between the actual energy levels and the anticipated values. This adaptive approach ensures that the system operates optimally even in the face of varying energy availability.

The work by Kansal et al. [9] represents a significant contribution to the field of real-time energy harvesting systems, laying the groundwork for subsequent research in designing efficient and adaptable scheduling algorithms to maximize system performance and extend battery life.

In the realm of task scheduling for real-time systems powered by renewable energy storage, Moser et al. [10] made significant contributions by introducing the Lazy Scheduling Algorithm (LSA). This novel real-time scheduling approach represents a variant of the well-established Earliest Deadline First (EDF) policy.

The fundamental operation of LSA is as follows: all ready tasks are prioritized based on their respective deadlines. The task with the earliest deadline is designated as the top priority and is executed first. Notably, LSA enables the system to run this task at full processor speed while ensuring the timely completion of all deadlines.

The ED-H algorithm, proposed by Chetto [11], is another approach in the domain of real-time energy harvesting systems. This algorithm adopts a distinctive strategy for task execution, permitting a task to be processed only under two conditions: when there is sufficient energy available or when the slack time is zero. In cases where these conditions are not met, the processor remains idle until enough energy is replenished, all while ensuring that the time constraints of the task are strictly adhered to.

Although the ED-H algorithm effectively manages energy resources during task execution, it introduces a potential drawback. The requirement for sufficient energy may lead to intervals of processor idleness, potentially resulting in missed task deadlines due to energy scarcity.

To address this concern and optimize the performance of real-time energy autonomous systems, further

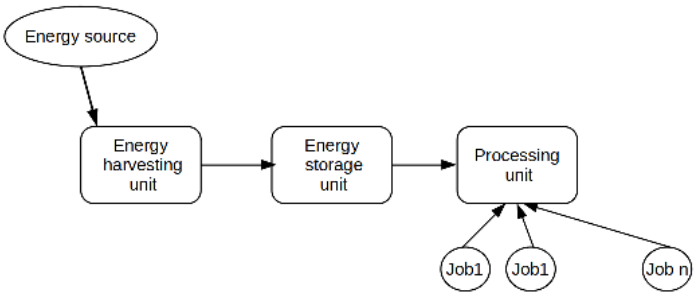

Fig. 3.1: Architecture model.

research is warranted. The focus can be directed towards refining the ED-H algorithm to strike a better balance between energy conservation and meeting strict task deadlines. By mitigating the issue of processor idleness and potential deadline misses caused by energy starvation, significant advancements can be made in enhancing the overall efficiency and reliability of real-time energy harvesting systems.

Fixed priority tasks scheduling is a well-explored area in research, with many studies addressing this important problem. Among these studies, the first algorithm in this context, PFP_{ASAP}, was proposed in [17] and [18]. This algorithm has been demonstrated to be an optimal scheduling solution for non-concrete task sets, proving its effectiveness in managing task priorities efficiently.

Another noteworthy algorithm is PFP_{ALAP}, which was introduced in [19]. This approach aims to delay job execution as late as possible, ensuring that jobs are executed only when sufficient replenished energy is available to support their execution. By adopting this strategy, PFP_{ALAP} optimizes energy utilization while still meeting task deadlines effectively.

In addition to the above, the PFP_{ST} scheduling heuristic was proposed in [20]. This algorithm prioritizes executing jobs as soon as enough energy is available in the storage unit to support their execution. When the required energy is not immediately available, PFP_{ST} switches to energy harvesting mode to gather the necessary energy for task execution.

3. System model.

3.1. Architecture model. The system considered in our work comprises an energy harvesting unit powered by a renewable energy source, an energy storage unit (reservoir), and a processing unit that operates at a given frequency.

The real-time system has access to both the timing characteristics of a task and the characteristics related to the available energy in the system. This enables the system to schedule tasks in an optimal manner, considering both timing and energy constraints. Figure 3.1 illustrates the architecture of the system.

3.1.1. Energy harvesting system unit. The system is powered by an energy source that collects energy from an external source and converts it into electrical power. We assume that the energy harvested from the ambient environment is a function of time. The energy is continuously harvested, and we denote $P_s(t)$ as the recharging function of the reservoir. The energy harvested during any time interval $[t_1, t_2]$, denoted as $E(t_1, t_2)$, is given as follows:

$$E_s(t_1, t_2) = \int_{t_1}^{t_2} P_s(t), dt \tag{3.1}$$

where:

- $E_s(t_1, t_2)$ represents the energy harvested within the time interval $[t_1, t_2]$.
- $P_s(t)$ denotes the worst-case charging rate on the harvested source power output.

For the sake of simplicity, we assume $P_s(t)$ to be a constant function, meaning that the energy harvested remains constant during each time slot. This allows for offline prediction, and it is computed using the following

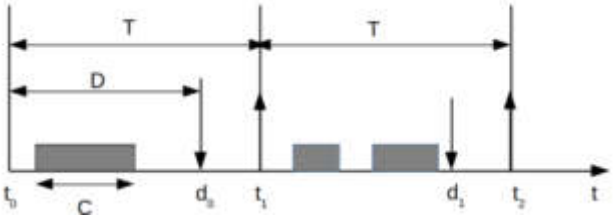

Fig. 3.2: Task model

formula:

$$E_s(t_1, t_2) = (t_2 - t_1)P_s \tag{3.2}$$

We supposed in our work that the energy is recharged continuously even during the execution of a job.

3.1.2. Energy storage unit. The system includes a battery to store the harvested energy. We assume that the energy level in the reservoir must remain within two limits: E_{min}, which is the minimum level of energy required to keep the system running, and E_{max}, which represents the maximum capacity of the reservoir. Thus, it follows that $E_{min} \leq E(t) \leq E_{max}$. The capacity of the storage unit, denoted as C, is the difference between these two limits: $C = E_{max} - E_{min}$.

It is essential for the capacity of the reservoir to be sufficient to execute at least one time unit of the jobs; otherwise, the taskset is considered infeasible.

3.1.3. Processing unit. The system incorporates a DVFS (Dynamic Voltage and Frequency Scaling) module, where the energy consumed by a task depends on the processor operating frequency.

Additionally, we make the assumption that the energy consumed during idle states or when charging and discharging the reservoir is negligible.

3.2. Task model. We consider a set of n periodic, synchronous, independent, and preemptable tasks denoted as $\Gamma = \tau_1, \tau_2, ..., \tau_n$.

Each task is represented by $\tau_i = (r_i, C_i, D_i, E_i, T_i, P_i)$, where $r_i, C_i, D_i, E_i, T_i, P_i$ correspond to the release time, worst-case execution time (WCET), relative deadline, worst-case energy consumption (WCEC), minimum inter-arrival time between two consecutive jobs, and priority of task τ_i, respectively. We assume that the energy consumption and the execution time are fully independent, and that $D_i \leq T_i$.

Each task consists of an infinite sequence of jobs. A job of task τ_i arrives at time $(r_i + kT_i)$ for each integer k such that $k \geq 0$, and it must be completed within D_i time units from its arrival time. During the interval $[r_i, d_i]$ where d_i is the absolute deadline of the job's i^{th} task , the job must receive C_i units of execution.

As mentioned in [11], the energy utilization factor U_e is computed as the sum of the ratios between the task's worst-case energy consumption (WCEC) and its period: $U_e = \sum_i^n \frac{E_i}{T_i}$. Similarly, the processor utilization factor U_p is calculated as the sum of the ratios between the task's worst-case execution time (WCET) and its period: $U_p = \sum_i^n \frac{C_i}{T_i}$.

4. Background algorithm. Deadline monotonic [12] is one of the major scheduling algorithms for fixed priority assignment. It assigns priorities to tasks based on their deadlines, where the priority of each task is inversely proportional to its deadline.

Deadline monotonic has been proven to be optimal for fixed priority scheduling and performs well when tasks have larger periods but relatively short deadlines. However, it loses its optimality when we integrate energy constraints into the scheduling process.

A sufficient schedulability test based on utilization was proposed in [13], but it is considered very pessimistic:

$$U(n) = \sum_{i=1}^{n} \frac{C_i}{D_i} \leq n(2^{\frac{1}{n}} - 1) \tag{4.1}$$

where n is the number of tasks.

Another exact test based on response time analysis was proposed for arbitrary fixed priorities, including deadline monotonic, in [14]. The worst-case response time (WCRT) is the maximum time interval between the arrival and finish instants of a task. The response time for each task is calculated using the following iterative formula:

$$\forall i \quad R_i = I_i + C_i \tag{4.2}$$

Where I_i represents the interference caused by the execution of higher-priority tasks:

$$I_i = \sum_{k \in hp(i)} \left\lceil \frac{R_i}{T_k} \right\rceil \times C_k \tag{4.3}$$

Furthermore, it has been proven that a task set is feasible with fixed priority assignment if and only if the response time of each task satisfies the condition:

$$\forall i \quad R_i \leq D_i \tag{4.4}$$

5. EH-DM Algorithm. Before presenting our algorithm let us give some definitions of slack time and slack energy, the reader can refer to [11] and [16] for more details

5.1. Slack time. The slack time at a current time t_c assigned to a job is computed as follow:

$$ST_{\tau_i}(t_c) = d_i - t_c - tdbf(\tau_i, t_c, d_i) - \sum_{d_k \leq d_i} C_k(t_c) \tag{5.1}$$

Where :

- $\sum_{d_k \leq d_i} C_k(t_c)$ is the remaining execution time of uncompleted tasks within $[t_c, d_i]$.
- $tdbf(\tau_i, t_c, d_i)$ is the time demand bound function in time interval $[t_c, d_i]$

The slack time of a set of jobs at instant t_c represents the maximum amount of time during which the processor could remain idle at time t_c, while respecting the timing constrains of all jobs. The slack time of a set of jobs is given by:

$$ST(t_c) = \min_{d_i > t_c} ST_{\tau_i}(t_c) \tag{5.2}$$

5.2. Slack energy. The notion of slack energy was firstly introduced by Chetto in [11], Slack energy of an instance of the current time t_c is computed as follow

Slack energy associated to a job of task τ_i is given by

$$SE_{\tau_i}(t_c) = E(t_c) + P_s(t_c, d_i) - edbf(t_c, d_i) \tag{5.3}$$

The slack energy of a task set is the minimum slack energy among all tasks :

$$SE(t_c) = \min_{t_c < r_i < d_i < d} SE_{\tau_i}(t_c) \tag{5.4}$$

Where : $edbf(t_c, d_i)$ is the energy demand bound function in time interval $[t_c, d_i]$.

Hereafter, we describe our algorithm, namely EH-DM (Energy Harvesting Deadline Monotonic), which aims to schedule tasks while minimizing energy consumption and guaranteeing all deadlines using an energy harvesting system.

EH-DM algorithm is designed to schedule tasks according to the deadline monotonic scheduling policy. The enhancement that EH-DM offers is that it considers not only timing constraints but also the level of energy in the reservoir. Based on this information, it decides whether to execute tasks at full speed, lower speed, or to let the processor idle.

Let us consider that we have a set of n periodic tasks in the ready queue initially. EH-DM follows the following rules when scheduling tasks:

1. Priorities are assigned offline according to deadline monotonic priority.
2. The processor stays idle in the time interval $[t_c, t_c + 1]$ if ready queue is empty $L(t_c) = \emptyset$.
3. The processor is idle within $[t_c, t_c + 1]$ if the ready queue is not empty but the energy reservoir is empty, $L(t_c) \neq \emptyset$ and $E(t_c) = 0$; it must charge energy to continue executing the rest of tasks.
4. The processor is busy in $[t_c, t_c + 1]$ if there is at least a ready task in the ready queue and a sufficient energy to execute at least a time slot for the ready task; $L(t_c) \neq \emptyset$ and $0 < E(t_c) <= C_{max}$; here we have two cases:
   - **Case 1 :** If the slack time is equal to 0 $ST = 0$, then tasks are executed at full processor speed s = 1.
   - **Case 2 :** If the slack time is positive $ST > 0$, then speed is reduced $s < 1$.

In rule 1, the priorities are assigned according to Deadline Monotonic policy and in the case when two tasks have the same deadline the priorities are assigned according to the task's index, the lower the index the higher the priority.

In rule 3, the processor should remain idle until it recharges sufficient energy for the execution of at least one time slot of the current task.

In rule 4, the processor can be active if there is enough energy for the execution of the current task. There are two cases:

In the first case, the processor should execute tasks at the maximum speed if $ST = 0$. In this situation, we cannot reduce the operating speed because doing so would increase the execution time of the task, potentially causing tasks to miss their deadlines. In the second case, the operating speed is reduced if $ST > 0$ in order to reduce the energy consumption of the tasks. We did not consider the cases when $SE = 0$ or $SE > 0$ because in both situations, it is better to reduce the speed to gain more energy for the execution of the remaining tasks.

Algorithm 1 EH-DM Algorithm

Input set of jobs
Output schedule

```
s = speedCompute(jobs)
for i = 0 to Hyperperiod do
   L = Readyjobs
   if (L = ∅) then
      Processor = idle
   else
      if E(t_c) = 0 then
         Processor = idle
      else
         if ST(t_c) = 0 then
            Execute(Job, 1)
         else
            Execute(Job, s)
         end if
      end if
   end if
end for
```

5.3. Example. Consider a set of two tasks given by τ_1 and τ_2 such that $\tau_1 = (0, 1, 4, 1, 5)$ and $\tau_2 = (0, 3, 8, 3, 10)$; the battery has a capacity of $C = 5$ where it is initially empty $(E(0) = 0)$ for the worst case; the energy harvested from the environment is constant $E_p = 1$.

6. Worst case scenario. The objective of this section is to describe the worst-case scenario that a taskset can encounter during its execution using an EH-DM scheduler.

The worst case scenario can be described as follows: All tasks are synchronously activated when the battery

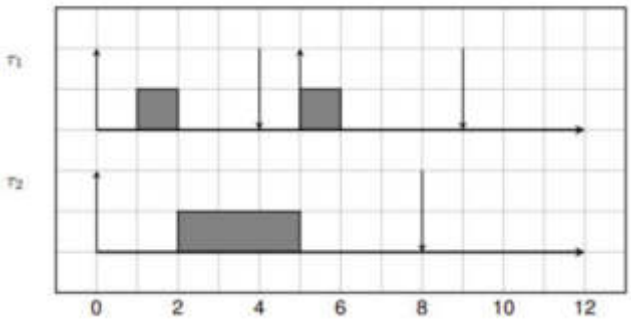

Fig. 5.1: EH-DM Algorithm

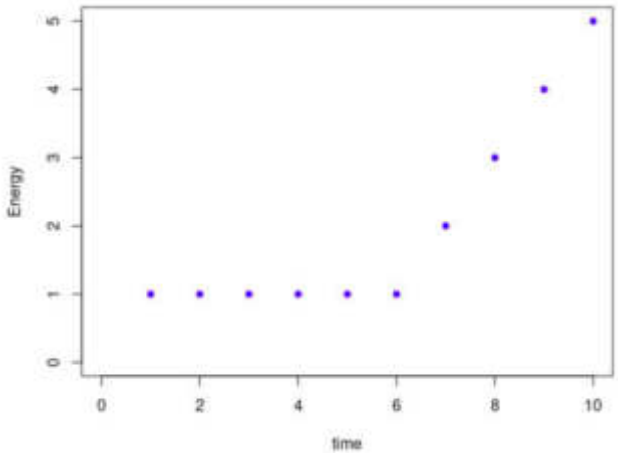

Fig. 5.2: Remaining energy in the reservoir

is empty. In this situation, the execution of tasks is postponed to replenish the necessary energy for executing at least one time unit of the current ready job. Additionally, the worst case arises whenever the energy harvested at each instant is lower than the energy consumed by the execution of one time unit of the current job. This means that the system consumes more energy than it replenishes.

As a consequence, tasks with lower priorities are at risk of missing their deadlines in such worst-case scenarios.

THEOREM 6.1. *Let* Γ *denote a set of n periodic tasks with constraint or implicit deadlines, ordered by deadline monotonic policy. The EH-DM worst-case scenario for any task of* Γ *occurs when the tasks are requested simultaneously when the battery is empty* ($E = 0$)*, and the harvested energy for each instant is lower than the energy consumed by a time unit of the current job.*

7. Optimality of EH-DM. The aim of our work is to develop an optimal fixed priority scheduling algorithm for autonomous systems, which takes into consideration timing constraints and energy constraints. We prove the optimality of our algorithm below.

THEOREM 7.1. *EH-DM is an optimal scheduling algorithm for periodic task sets with synchronous activation and constrained or implicit deadlines.*

Proof. Let us consider a taskset Γ of n periodic tasks. We suppose that Γ is not schedulable by EH-DM but it is schedulable by another fixed priority energy harvesting scheduling algorithm using the same priority assignment. This means that there exists at least one job denoted J_m that misses its deadline. According to

EH-DM rules, a job misses its deadline only if the energy available in the storage unit during the time interval of the execution of job J_m is lower than the required energy for its execution. Hence:

$$E_{J_m} < E(a_m) + (d_m - a_m) \times P_s(t) \tag{7.1}$$

If EH-DM is not optimal, then there should exist another fixed priority schedule that makes it schedulable; supposing that such a schedule exists, this means that at least one job is executed even if the available energy is not sufficient for its execution, which is not possible. Therefore, we prove that EH-DM is an optimal fixed priority scheduling algorithm for autonomous real-time systems. □

8. Feasibility analysis. In this section, we analyze the feasibility of using the EH-DM scheduling algorithm.

We consider the worst case to study the feasibility of this algorithm, assuming that all tasks are activated at the same time. This scenario encounters a critical instant when tasks with the lowest priority are activated simultaneously with all others having higher priority. Additionally, we assume that the energy storage unit is empty at $t = 0$.

In energy harvesting systems, scheduling algorithms must guarantee the feasibility of tasks concerning both timing constraints and energy constraints [15]. Therefore, we need to take into consideration two types of starvation as described in [11]:

- **Time starvation:** Occurs when a job reaches its deadline without completing its execution while there is energy in the reservoir ($E(t) > 0$).
- **Energy starvation:** Occurs when a job reaches its deadline without completing its execution, and the energy in the reservoir is exhausted ($E(t) = 0$).

8.1. Timing feasibility. To assess the timing feasibility of the EH-DM scheduling algorithm, we can use an exact test based on response time analysis, as proposed in [14]:

A task set is feasible with a fixed priority assignment if and only if the response time of each task R_i is less than or equal to its deadline D_i:

$$\forall i \quad R_i \leq D_i \tag{8.1}$$

8.2. Energy feasibility. To assess the energy feasibility of a task τ_i that is activated at time a_i, we can use the following condition:

τ_i is energy feasible if the available energy E_{τ_i} at the beginning of its execution is sufficient to cover its energy consumption during the execution interval, taking into account the harvested energy and the energy consumed by higher priority tasks. The condition can be expressed as follows:

$$\forall i \quad E_{\tau_i} \leq E(a_i) + R_i \times E_p - E_I(a_i, d_i) \tag{8.2}$$

where:

- E_{τ_i} is the available energy for task τ_i at time a_i.
- $E(a_i)$ is the initial energy level at time a_i.
- $R_i \times E_p$ is the energy harvested within the execution interval of τ_i.
- $E_I(a_i, d_i)$ is the energy consumed by tasks that have higher priority than τ_i within the interval $[a_i, d_i]$.

To examine feasibility for a taskset, we should iteratively verify the following two conditions for all jobs:

$$\forall i \quad R_i \leq D_i \text{ and } E_{\tau_i} \leq E(a_i) + R_i \times E_p - E_I(a_i, d_i) \tag{8.3}$$

9. Computing speed. The operating speed of the processor is computed offline for each time interval, starting from a job's arrival time and ending with an absolute deadline of the same job or another job. The speed is determined as the ratio between the demand function and the length of the interval. Finally, we choose the maximum value to guarantee the feasibility of all jobs. For each interval $[a_i, d_j]$, the speed is given by:

$$s = \frac{DF(a_i, d_j)}{d_j - a_i} \tag{9.1}$$

Algorithm 2 FeasibiltyTest Algorithm

  return *speed*

10. Performance evaluation. In this paper, we have proven the optimality of EH-DM algorithm for periodic, independent and preemptive tasks. In this section, we examine the performance of our algorithm and compare it with its competitors by analyzing the behaviour of each algorithm (PFP_{ALAP}, PFP_{ASAP}, PFP_{ST}) on the example from Tab. 10.1.

In this example, we consider the taskset presented in Table 10.1, and the capacity of the energy storage unit is $C = 5$, with $E_{max} = 5$ and $E_{min} = 0$. The energy is continuously replenished with a constant charging rate of $P_s(t) = 0.5$. Here, we specifically focus on the worst-case scenario.

We analyzed the performance of each method in terms of energy consumption, and then we measured the remaining energy in the reservoir at every instant during the hyperperiod. The results are presented in Figure 10.1.

We observed that when considering the worst-case scenario and starting the execution of tasks with an empty battery ($E(0) = 0$), both Algorithm PFP_{ALAP} and PFP_{ST} miss the deadline of τ_3 at $t = 18$, and the

Table 10.1: Example 2

	C	D	E	T
τ_1	1	4	1	5
τ_2	2	9	2	10
τ_3	4	18	4	20

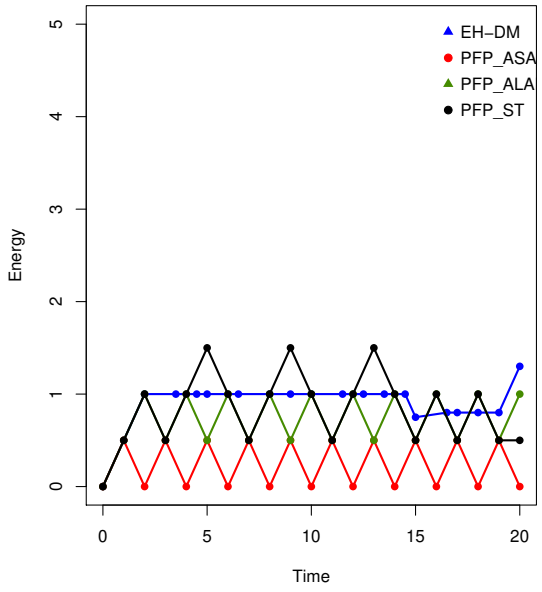

Fig. 10.1: Comparison between EH-DM, PFP_{ASAP}, PFP_{ALAP} and PFP_{ST}

last jobs of both τ_1 and τ_2 at $t = 19$ due to energy starvation. A deadline miss occurs at $t = 19$ for the last instances of τ_1 and τ_2 when using PFP_{ASAP}. This problem occurs due to energy starvation and the addition of idle periods to recharge the battery, which in turn delays the execution of some jobs and causes deadline misses. However, when using EH-DM, we observed that the execution time was extended without missing any deadline, and the energy was sufficient for the execution of all tasks, even if we started with an empty battery. This is due to the DVFS technique and its effectiveness in reducing energy consumption.

11. Conclusion. Due to the limitations of traditional battery power, there is an increasing demand for energy harvesting capabilities in various applications, including health, military, environmental, etc. An increasingly significant area of research is how to get an embedded device to operate perpetually and effectively. The major challenge is to perform effective processor time utilization while also optimizing energy consumption.

The aim of our work is to increase battery lifetime for real-time systems with energy harvesting, using fixed priority assignment. We proposed our first algorithm EH-DM to deal with this problem. EH-DM algorithm is a variant of the deadline monotonic algorithm for energy harvesting systems. The advantage of this algorithm is that it makes a better use of the energy and of the processor because it lets the processor idle only in cases where there are no tasks to execute. Otherwise, the processor remains busy, either operating at full speed or

with reduced speed to avoid wasting a lot of energy.

We will continue this study for future works to improve this algorithm in terms of complexity and development on real systems and to propose a feasibility test for this algorithm.

DATA CUBES AND CLOUD-NATIVE ENVIRONMENTS FOR EARTH OBSERVATION: AN OVERVIEW[1]

ALEXANDRU MUNTEANU[2*]

Abstract. Reliable access to analysis-ready Earth observation data and infrastructures for processing them has been a challenge with the increasing volumes and variety of data being generated daily through various Earth observation programmes. Recently, concepts centered around building cloud-native infrastructures that provide access to Earth observation data in efficient manners such as data cubes which facilitate rapid querying, filtering and retrieval have been garnering popularity. Moreover, efficient means of processing such vast volumes of data stored in data cubes through cloud computing frameworks such as Kubernetes are becoming more popular. This paper investigates the current state-of-the-art techniques, methods and technologies used in cloud-native environments with a particular focus on the data cube initiative and "bring the user to the data" paradigm, highlighting the usefulness of such approaches and their current limitations.

Key words: Earth observation, data cubes, cloud-native, scalable computing

1. Introduction. With the rapid growth of Earth Observation (EO) data generated through programmes constantly deploying satellites to monitor the Earth's physical characteristics, efficient data management and processing strategies are needed. Public sector initiatives such as the European Space Agency (ESA) Copernicus programme and the National Aeronautics and Space Administration (NASA) Landsat or through private EO companies such as Planet Labs, Capella Space and many others are contributing to an unprecedented volume, variety and velocity of data regarding the physical characteristics of Earth daily. EO data provides valuable information, helping to develop strategies for a multitude of areas, such as climate change, disaster management, agricultural strategies, urban planning, and forest sustainability.

One of the principal challenges that arise when dealing with EO data comes from its complexity and heterogeneity. EO data comes in a variety of forms depending on the instrument used in the data acquisition phase and the processing techniques that are applied. These instruments range from optical, multi-spectral, hyper-spectral, RADAR, LiDAR and thematic instruments designed to capture information regarding the atmospheric composition, ocean and land colour and many others. In addition, it is worth mentioning that each data source provides data at different spatial resolutions and is disseminated through various formats (e.g. NetCDF [65], GeoTIFF [48], GeoParquet [67], Zarr [57] and others). Specific data processing workflows are employed based on this information.

With the advent of large, scalable infrastructures, especially Cloud Computing, High-Performance Computing (HPC) and distributed computing architectures, efficient processing of large volumes of EO data has become promising [83]. Frameworks for distributed computing such as Apache Spark [86] and Apache Hadoop [7] have facilitated processing and analyzing large datasets across clusters. Hadoop enables distributed storage (through HDFS - Hadoop Distributed File System) providing fault tolerance and high availability through data replication. By default, Hadoop uses the MapReduce paradigm, designed for batch processing the data stored in HDFS. Additionally, tasks are replicated across the cluster ensuring fault tolerance. Unlike Hadoop, Apache Spark uses in-memory data storage, which gives it an advantage in some use cases. In addition to batch processing, Spark supports real-time data streaming.

Kubernetes [12] is a cloud-native orchestrator for containerized applications in cloud environments, capable of deploying, scaling and managing containerized applications. The main advantages Kubernetes offers are

[1]**Funding:** This work was funded by the Romanian Ministry of Research, Innovation and Digitalization under contract no. PN-IV-P6-6.3-SOL-2024-2-0248, acronym ROCS.

[2*]West University of Timișoara, Department of Computer Science (alexandru.munteanu@e-uvt.ro).

on-demand automatic scaling of deployments, rescheduling faulty containers, load balancing across containers or services, and efficient resource management.

A relatively recent initiative in managing large volumes of EO data consists of the development of Earth observation data cubes [38]. Earth observation data cubes are based on the data cube technology [10] where data is represented as multi-dimensional arrays that facilitate the process of querying, analysis and visualization of spatio-temporal data. In a typical data cube, metadata of the ingested products is kept within a DBMS, facilitating querying and filtering of the ingested products. In Earth observation data cubes, data is organised within multiple dimensions (e.g. latitude, longitude, time, spectral band). Recently, progress in standardising earth observation data cubes has driven current implementations to offer data that users can directly work with as part of what is known as Analysis-Ready Data (ARD) [43]. ARD proposes several preprocessing steps to be undertaken to ensure the quality of data delivered, thus creating data cubes that contain directly usable data.

Ongoing efforts through projects such as EOEPCA+[1] aim to standardize and design scalable architectures for supporting EO data processing. Other projects, such as Pangeo, PEPS, CODE-DE, EODC, Microsoft Planetary Computer, and Google Earth Engine, have deployed large-scale data dissemination and processing platforms which are hosted in scalable environments.

Copernicus Data Space Ecosystem (CDSE) is the most recent answer towards data cube approaches from the ESA. Data previously disseminated with the help of the now defunct Data Hub Software (DHuS) through ESA's ground segment and national replicas (also known as Collaborative Ground Segments - CollGS) are provided through CDSE. CDSE currently offers catalogue-based Application Programming Interfaces (API) such as STAC, OpenSearch, and OData, as well as non-catalogue APIs like OpenEO and OGC-compliant APIs. Data processing through On-Demand Processing (ODP) is also offered as part of CDSE through serverless functions.

Multi-mission algorithm and analysis platforms (MAAP) [6] is a joint ESA-NASA initiative designed to facilitate the analysis and processing of EO and in-situ data [5]. MAAP's implementation leverages open-source technologies and frameworks for developing a cloud-native approach to processing large-scale EO data. The principal reasoning behind MAAP is to "bring the user to the data" to reduce the significative overheads associated with data retrieval. Biomass harmonization and SAR data analysis are discussed by [29].

Integrating EO data cubes with scalable computing infrastructures, such as cloud platforms and HPC systems, has enhanced the ability to process and analyze large EO datasets. Architectures such as EOEPCA+ and cloud platforms such as the aforementioned Pangeo, CODE-DE, EODC, and CDSE all commonly offer user workspaces in cloud-based environments that are closer to the data to facilitate the scalable processing of data stored in their datacubes. Development Seed and Element84 employ cloud platforms like Amazon Web Services (AWS) to store and process large quantities of EO data.

In this article, we provide an overview of the state-of-the-art concerning the utilization of scalable infrastructures, architectures, technologies and practices for processing vast volumes of EO data, with a particular focus on approaches centred around using client-side Earth observation data cubes. We offer some insights regarding cloud-optimized data formats and the benefits of using them in cloud-native environments. We provide details about 8 different platforms that can be used for exploiting the potential offered through EO data cubes and information regarding the software environment or architectures those platforms use.

The paper is further organized in the following manner: Section 2 describes the current state-of-the-art in processing large volumes of Earth observation data, discussing modern HPC and cloud computing technologies employed by EO platforms. Platform architectures and undergoing standardization efforts are also taken into account. Furthermore, the various EO data cube developments are addressed in this section. Section 3 discusses the data cubes, platform standards and their current limitations. Finally, in Section 4, we draw our conclusions from this overview on the state-of-the-art of cloud-native environments for processing large volumes of EO data.

2. State of the Art. In a more generic term, the scientific community has discussed the use of scalable computing platforms for processing large volumes of data, particularly processing EO data stored in repositories following data cube approaches. In [9], the authors describe the use of current standards such as Spatio-Temporal Asset Catalog [71] and Open Data Cube (ODC) [38], as well as the use of distributed processing

[1] eoepca.org

methods such as Dask [15], Hadoop [7] or Apache Spark [86] for processing the large volumes of existing EO data. Highlighted by [9], the use of distributed computing can solve the scalability limitations of ODC raised by [82, 26]. Cloud-native data repositories for storing scientific data is a topic discussed by [3], highlighting the benefits of data-proximate computing and the use of cloud-native approaches to efficiently process large volumes of EO data.

The use of cloud-native approaches for analysing large volumes of Earth observation data, particularly with the data cube paradigm, has been a relatively recent development which has garnered popularity within the community, forming a solid ecosystem of standards, frameworks, platforms and software libraries [76].

A cloud-native approach towards defining processing pipelines for EO data cubes is described by [80] using the MapReduce [31] paradigm for processing Sentinel-2, 10m resolution products. Experimental results provided in [80] for performing land cover mapping at a continental scale using machine learning approaches based on Support Vector Machines (SVM) [32] and the U-Net [66] topology while using ESA WorldCover as the ground truth masks. The experiments were carried out within three different environments which facilitate both access to EO data cubes and computing infrastructures, namely Google Earth Engine (GEE) [28], Microsoft Planetary Computer [55] and the Science Earth Platform [81].

Two main limitations of the approach described by [80] are presented, namely that the implementation is highly complex, and users are required to manually define the dependencies on which the data cubes are built. Secondly, the range of algorithms that can be applied to the generated data cube is limited due to how the data cube is partitioned. Algorithms such as Principal Component Analysis (PCA) cannot be easily implemented using this approach [80].

2.1. Earth Observation Data Cubes. Various methods for creating data cubes with EO data have been broadly discussed in the literature [24, 25, 40, 74]. In [40], the authors discuss "achieving the full vision of Earth observation data cubes", where the prerequisites and methodology for building EO data cubes are outlined, most notably the data preprocessing steps for building ARD [43] according to the Committee on Earth Observation Satellites (CEOS)[2] CARD4L guidelines [1].

According to the CEOS CARD4L guidelines [1], a series of processing steps need to be performed on the data before dissemination. Namely, radiometric and geometric preprocessing, tiling, compression, choosing a well-suited data format, generation of multiple overview layers, and optimizing the data for temporal access [40].

Optimizing data storage using compression and choosing data formats and structures that optimize access to the data are also discussed by [40]. The addition of processing workflows, user workspaces and the ability to disseminate the data and value-added products is also highlighted by [40]. The benefits of Combining analytic interfaces with EO data cubes for facilitating the execution of processing workflows are discussed by [49] covering three use cases: analyzing the statistics of biosphere-atmosphere interactions, the dynamics of intrinsic dimensions of ecosystems and model parameter estimation.

The benefits of local or national level EO data cubes are highlighted by [75]. Thematic data cubes such as CBERS [64] designed for mapping biomes in Brazil or mapping agriculture [13] require smaller infrastructures to manage, reducing the load of more general purpose EO data cubes at the cost of not having all the data conveniently in the same platform, difference in technologies and choice of standards. This spans the need for federating access to various data cubes or platforms, fitting into the vision of the EOEPCA+ architecture.

Earth observation data cubes have been employed for solving various tasks such as mapping surface water over a temporal span of 25 years [59] using the AGDC, developing machine learning based time series analysis packages for the R language [70], rapid high-resolution detection of environmental changes at continental levels [44]. These use cases highlight the relevancy and importance of further developing such standardized, cloud-native approaches for processing large-scale EO data.

2.1.1. Cloud-Native Geospatial Data Formats. One of the central points of building cloud-native EO data cubes is the conversion of data from their various initial formats to cloud-friendly formats that facilitate random access and partial file reads over various protocols such as the HyperText Transfer Protocol (HTTP).

Particularly, the development of the Cloud Optimized GeoTIFF (COG)[3] format for raster data which

[2]https://ceos.org
[3]https://cogeo.org

Table 2.1: Cloud-native formats for storing vector data.

Format	Base format	Structure and optimization
COPKG	GeoPackage	SQLite, HTTP range requests
GeoParquet	Parquet	Columnar data layout, spatial indexing
FlatGeoBuf	Flatbuffers	Packed Hilbert R-tree [37], HTTP range requests
Geojson-T	GeoJSON	Tiled GeoJSON, partial retrieval

organises pixels into tiles which are indexed (using an offset table) for rapid access, with multiple generated pyramids acting as overview layers. Each tile within a COG file can be individually compressed, with popular choices being LZW, Deflate or JPEG compression algorithms. Performing partial file reads is possible for COG files via HTTP GET range requests[4] that correlate with the random access indexed tiles provide. Cloud-Optimized GeoTIFF files can be conveniently created with the help of Rasterio [23], a Python library that handles raster geospatial data. More precisely, with the use of the `rio-cogeo`[5] plugin.

A similar format for storing 3D point cloud data is the Cloud Optimized Point Cloud (COPC) format[6] which is based on the LIDAR Aerial Survey (LAZ) format. COPC files share a similar partial file, random access vision as COG which is implemented using an Octree [68] data structure. Similar to COG, COPC files also have overview layers computed also known as Levels of Detail (LOD). In terms of compression, LZW is typically used with COPC data. HTTP range requests can be used to access nodes from the Octree representation, allowing for partial reads.

In terms of cloud-native formats for storing vector geospatial data, due to the availability of multiple formats in existence (Apache Parquet[7], FlatGeoBuf, GeoJSON, ESRI Shapefile, Apache Arrow) paired with a lack of consensus in the community have led to the development of multiple suitable formats. Most notably, formats such as Cloud Optimized GeoPackage (COPKG), GeoParquet, Geojson-T (Tiled GeoJSON) and Mapbox Vector Tiles (MVT). Through PMTiles[8], support for HTTP range requests and generation of COG-like pyramids is aimed to be brought to vector data formats as well [78]. An approach for cloud-optimized tile archive formats deployed in the cloud is presented in [78]. Similar efforts towards raster encodings for web-native for time series data designed for large environmental EO data in use for streaming in web platforms are discussed by [34]. Table 2.1 contains popular cloud-native vector formats, the format they are based on, and their indexing method.

Among the formats shown in Table 2.1, GeoParquet has advantages over the others in terms of compression, querying speed and throughput [67, 53, 79] and is used in platforms such as Microsoft Planetary Computer [55].

2.1.2. Current Operational EO Data Cubes. With the development of the Australian Geosciences Data Cube (AGDC) in 2017 [45], the Open Data Cube (ODC) initiative was spanned [38]. An overview of the deployed ODC instances[9] in 2018 [38] discusses that at the time, four national instances were already operational: Switzerland [24], Columbia [8], Taiwan [14] and Australia [45] with 11 others being in development. Later developed instances such as the Austrian Semantic Data Cube [75], the CBERS data cube for mapping biomes in Brazil [64], the Romanian Data Cube [62] rely on the use of the Spatio-Temporal Asset Catalog specification[10] and cloud-optimized data storage formats which forms the new direction dissemination of Earth observation data is heading towards. Recent versions of ODC have also adopted the STAC specification[11] and provide access to data through compliant API's. Table 2.2 shows some of the currently deployed data cubes, their spatial coverage and URL's where further details and access methods can be consulted.

2.2. HPC for Processing Large Volumes of EO Data. The adoption of High-Performance Computing (HPC) has been discussed largely by [46] where authors discuss traditional general-purpose HPC frameworks such as Apache Spark [85], Hadoop [7], OpenMPI [21] and HTCondor [77] and their respective use in conjunction with Earth observation data. Particularly, the use of HPC and cloud computing resources for processing EO data organized in data cubes is addressed by [9] through the use of Dask [15] clusters orchestrated by Kubernetes [12]. The authors of [9] present an architecture leveraging those technologies to exploit EO data cubes that utilise the Spatio-Temporal Asset Catalog (STAC) [71] specification.

A software solution tailored especially for processing large quantities of geospatial data based on Spark is Apache Sedona (formerly known as GeoSpark) [85]. Sedona stores classical georeferenced vector data types such as points, lines, linestrings and polygons in custom Spatial Resilient Distributed Datasets (SRDD). Furthermore, Sedona utilises spatial indexing data structures such as R-trees and Quad-trees, enabling efficient queries. Queries based on relationships and geospatial functions are also implemented in Apache Sedona. Sedona is fully integrated with the Apache Spark ecosystem, allowing the use of Spark SQL, Spark Core and Spark DataFrames.

GeoTrellis[12] is a geospatial processing engine designed for execution in HPC environments. Developed on top of Apache Spark, GeoTrellis can be deployed in cluster and grid environments, allowing it to scale to fit various processing requirements. GeoTrellis supports processing both vector and raster data, it provides raster operations (map algebra), spatial operations and utilities that facilitate the creation of web services for disseminating the processed products [42]. Some limitations of GeoTrellis include two resampling techniques (Nearest Neighbor and Bilinear sampling) that affect the runtime of the overall process, as well as having no control over processing steps and job scheduling, therefore relying only on Spark's scheduling [42]. Raster processing using GeoTrellis is discussed in [41], where a cloud architecture is proposed, leveraging the use of Docker [52] to distribute the workload in a cluster.

Google BigQuery [11] is a serverless, scalable data warehouse product from the Google Cloud. With on-demand scaling, and serverless architecture there is no need of infrastructure management. BigQuery utilises a columnar format for data storage that is separate from the compute capabilities, data retrieval is done through an SQL-like language. In the context of a comprehensive comparative study for large geospatial data storage methods [16], both the benefits and disadvantages of BigQuery we're detailed. Integration with other Google services, reliability and serverless architecture, ease of use and standard SQL querying capabilities are mentioned as the strong points of BigQuery [16]. The financial model of pay-as-you-go requires cost monitoring by the users, varying ingestion rates and highly complex geospatial data might not benefit from the NoSQL

[12]https://geotrellis.io

architecture BigQuery employs constitutes the drawbacks [16].

Dask [15] is an open-source library for parallel computing that facilitates scaling Python applications for various tasks such as data processing, machine learning, and distributed computing. It is optimised to work well on large datasets and is a scalable technology, with the possibility of deploying Dask as a cluster. Dask can perform distributed computations with nd-arrays, which perfectly aligns with processing EO data. Dask-GeoPandas[13] adds support for partitioning geospatial data into spatially distributed chunks and facilitates the parallelization of spatial operations. Dask utilises a dynamic task scheduler to execute computations, making it well-suited for complex workflows efficiently. A Dask cluster is part of the Pangeo [2] project being available interactively within the user workspaces via Jupyter Notebooks [39].

Simple Linux Utility for Resource Management (SLURM) [84] is a workload manager and job scheduling system that efficiently manages resource allocation within clusters. SLURM allows for job scheduling using fair scheduling algorithms. SLURM includes job a dependency system, enabling for scheduling complex workflows. Task scheduling for three separate use cases for processing large volumes of EO data on the EODC platform was performed through SLURM [17]. The Pangeo project can also be configured to use the SLURM scheduler [2].

2.3. EO Data Exploitation Platforms. In the context of providing both EO data and access to nearby computing resources for processing data, several projects have been recently developed [76], most notably EOEPCA+, Pangeo [2], CODE-DE [72], PEPS [22], EODC[14], CDSE [56], Microsoft Planetary Computer [55], Google Earth Engine [28], and Amazon Web Services[15]. All these projects leverage the use of cloud computing and, in some cases, HPC for processing large-scale Earth observation data, which is organized within a data cube approach. This section briefly details the platform's methodologies, architectures, standards and software frameworks.

The goal of the Earth Observation Exploitation Platform Common Architecture (EOEPCA+)[16] project is to bring standardisation and federation by designing a cloud-native architecture in line with best practices in software engineering, aiming to facilitate the way EO data is processed. EOEPCA+ is currently developing an open-source implementation of the architecture's components. This architecture is divided into three layers, as shown in Figure 2.1.

The **platform layer** is comprised of microservices designed for data discovery and ingestion, running various processing workflows to generate added-value products. Within this layer, workspaces for users are also running, offering persistance, access to EO data cubes, visualization capabilities and code execution for users to process the available data further. This layer contains processing engines, which facilitate the execution of various user-defined workflows such as openEO Process Graphs[17] and OGC Application Packages[18].

The goal of the **federation layer** is coordinating access towards multiple platforms. A federated orchestrator can direct processing workflows to the appropriate platform (i.e., one that meets the workflow requests, is currently available in terms of resources, etc.). Resource discovery integrates cross-platform data catalogues, facilitating data querying capabilities amongst the platforms. Identity and access management is also coordinated at this layer, redirecting users towards their use spaces The Storage Controller at this layer, besides managing the platform's storage, allows for external storage services to be integrated into the user workspace, achieving data federation.

Lastly, the **application layer** contains interactive web-based tools for users to publish web dashboards and applications to disseminate the results of processing the data provided through the platform. The application layer facilitates the definition of processing workflows, executed within testing environments on the platform.

Projects such as Pangeo [2] have employed Kubernetes and have designed cloud-native approaches for processing large volumes of EO data using Dask [15] and Xarray [33]. The use of Zarr and Xarray instead of traditional NetCDF/HDF for storing Earth Observation data for facilitating it's use in cloud-native environments is discussed by [3] and [4]. Pangeo can be deployed in traditional HPC infrastructures [63] such as NASA

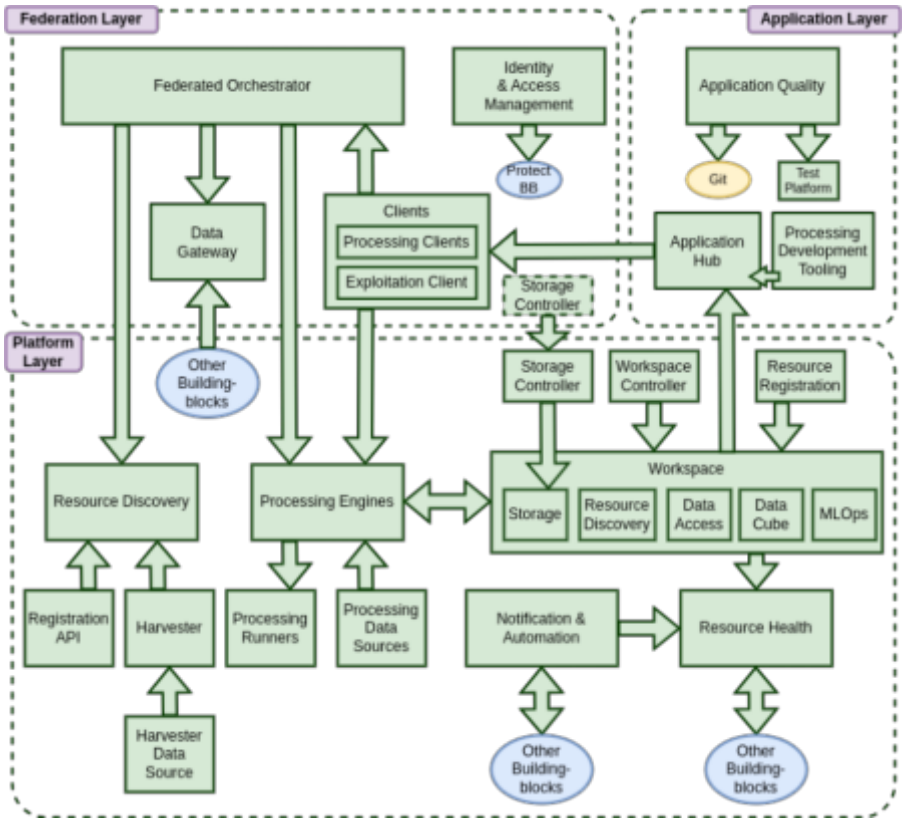

Fig. 2.1: EOEPCA+ High-level architecture[19].

Pleiades[20], Cheyenne from NCAR[21], Google Cloud Platform or Amazon Web Services. Within the Pangeo project, educational interactive resources can be accessed through provided workspaces running in Jupyter notebook environments. Use of the Pangeo project at the Centre National d'études Spatiales (CNES)[22] is described by [18], showcasing its usefulness and ease of use for processing data using HPC resources with Dask. One of the use cases CNES employs Pangeo for, namely numeric computations for analysing surface ocean currents on a large scale. Unfortunately performance assesments of Pangeo for this task are not provided by [18].

Figure 2.2 illustrates the Pangeo architecture. As aforementioned, the use of cloud object storage for serving chunked data with the Zarr format, coupled with querying capabilities provided through Xarray. This data is accessed through microservices running in a compute cluster orchestrated by Kubernetes, providing users with interactive notebooks and access to a Dask cluster that facilitates parallel processing.

Copernicus Data and Exploitation Platform - Deutschland (CODE-DE) [72, 73] is a platform built for disseminating EO data for the German authorities as a collaborative ground segment, developed concerning various user requirements elaborated by the German Aerospace Center (DLR). The CODE-DE platform was designed to suit multiple needs, such as project management, product assurance, systems engineering, data ingestion and archiving, querying and retrieval, processing environments, storage and dissemination of value-added products derived from raw Sentinel data [73].

The CODE-DE platform enables registered users to access various data processors and processing workflows,

[20]https://www.nas.nasa.gov/hecc/resources/pleiades.html
[21]https://www.cisl.ucar.edu/ncar-wyoming-supercomputing-center
[22]https://cnes.fr/en

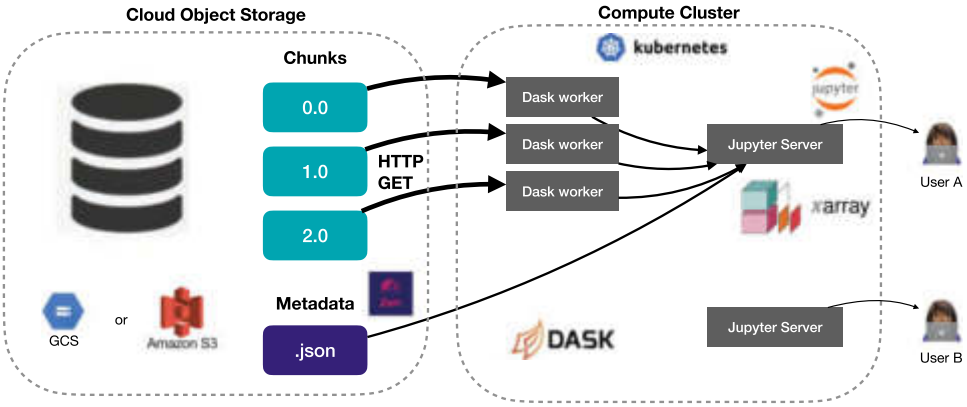

Fig. 2.2: The cloud-native architecture of Pangeo [3].

enabling them to independently process Earth observation data using selected methodologies and subsequently disseminate the resulting value-added products. The processing environment available in CODE-DE supports algorithm selection and spatial queries for specific EO datasets while also allowing users to monitor the current status of their processing tasks. Among the available methods are tools from the Sentinel toolbox, such as Sen2Cor [50], employed for the atmospheric correction of Sentinel-2 Level 1C products [72].

Users can interact with the platform through a web interface or via various APIs (OpenSearch or OGC-compliant services[23] like WMS, WFS, WCS). The data catalogue integrates with the various API's and is exposed to the user via a web application. Metadata for data collections is interactively generated using ISO standards and is accessible via OGC-compliant Catalogue Service for the Web (CSW). For products, metadata is automatically generated following OGC EOP[24] standards. CODE-DE services are modular and adhere to the INSPIRE conform discovery, visualization and download standards. Data processing workflows in the CODE-DE platform are executed through Calvalus [20] or Apache Hadoop [7]. They can be described and triggered either through a web application or through an OGC Web Processing Service (WPS) API [72]. The CODE-DE architecture is illustrated in Figure 2.3.

Plateforme d'exploitation des produits Sentinel (PEPS) [22] is CNES's solution towards providing access to Sentinel data as part of the Copernicus programme, PEPS is a member of the ESA collaborative ground segment. PEPS offers a web interface that enables users to query, filter, choose data preprocessing tasks and retrieve raw or value-added Sentinel-1, Sentinel-2 and Sentinel-3 products. Querying and filtering products in the PEPS platform is achieved through RESTO[25] catalogues [22].

PEPS offers several online data processing tools aimed at creating value-added products reducing download sizes (i.e. downloading results, not entire datasets) and performing preprocessing tasks, allowing users to access ready-to-analyze data. A couple of data processing capabilities are included in PEPS, such as computing Normalized Difference Vegetation Indices (NDVI), polarization extraction, atmospheric corrections for Sentinel-2 data using the MACCS-ATCOR Joint Algorithm (MAJA) [47], water masks generation, extraction of metadata and ortho-rectification.

PEPS services are executed on an HPC infrastructure in a containerized environment facilitated through Docker [52] containers [22]. An implementation of OGC Web Processing Service (WPS) [58] facilitates the definition of processing workflows which are scheduled for execution using the PROACTIVE Meta Scheduler[26] in conjunction with the Portable Batch System (PBS) [36]. The PEPS platform facilitates access to large-scale Earth observation datasets, which can integrate with external platforms or processing pipelines. The PEPS

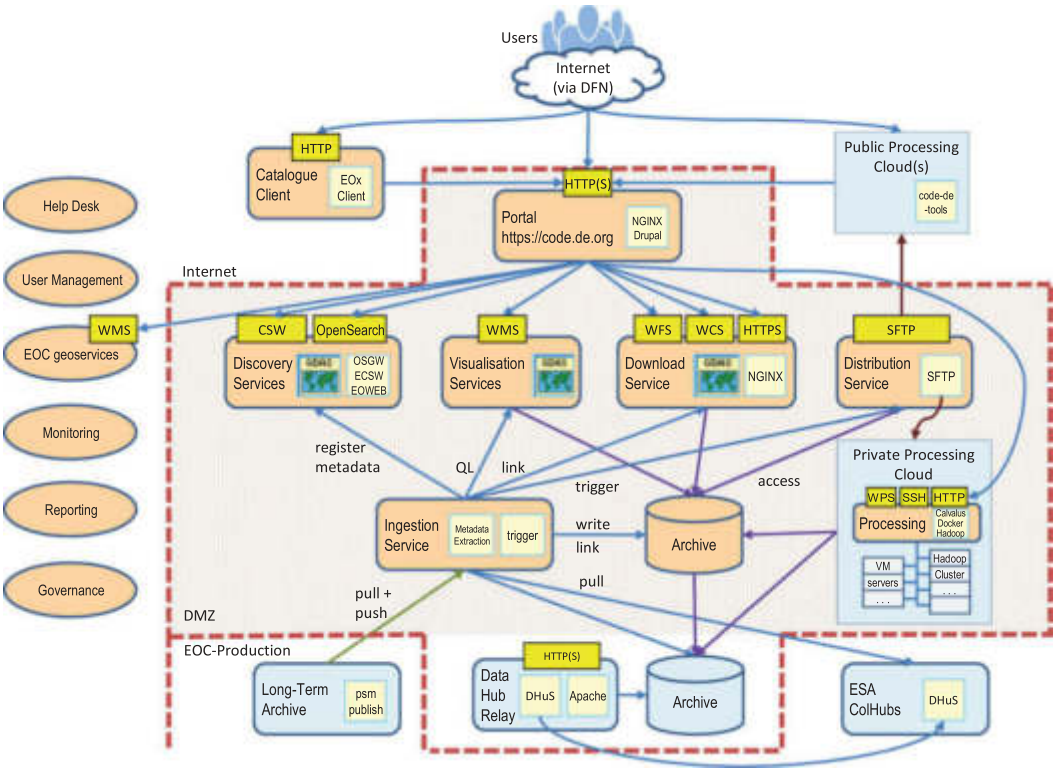

Fig. 2.3: The CODE-DE architecture [72, 73].

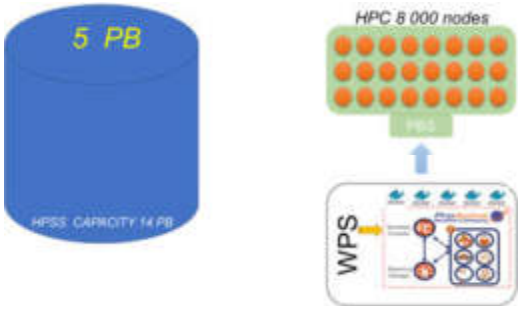

Fig. 2.4: The PEPS Architecture [22].

platform architecture is illustrated in Figure 2.4.

The Copernicus Data Space Ecosystem (CDSE) [56] is ESA's principal platform for disseminating data acquired through the Copernicus programme. Federated access, user identity, data access and visualization are all discussed from multiple perspectives (data providers, remote sensing experts, application developers, platform integrators and governance) by [60]. Through Jupyter Notebooks, interactive user workspaces are available within the CDSE. The workspaces are integrated [60] with the OpenEO framework [35] which promotes federation and makes use of distributed computing environments and enables the definition of processing workflows for big EO datasets. Multiple Data and Information Access Services (DIAS) are linked with the CDSE, allowing access to cloud resources that facilitate access to the EO data and offer VPS-based computing capabilities. Sentinel Hub, a processing service for EO data designed for on-the-fly computations, is also

integrated with the user workspaces [60].

An overview [60] of the API's provided for accessing CDSE. The Open Data Protocol (OData), OpenSearch and STAC are all offered. One important feature incorporated in CDSE, especially of interest to CollGS, is the notification API, which enables the registration of webhooks that are called when new products are added to collections of interest.

The Earth Observation Data Centre (EODC) provides services for accessing and processing EO data while providing compute resources based on virtualization. The use of the EODC platform for processing large volumes of EO data in a general sense is described by [17]. EODC was also utilised for retrieving geophysical parameters from Sentinel-1 Synthetic Aperture Radar (SAR) data by [61]. Although offering cloud computing resources, EODC follows a Virtual Private Server (VPS) approach for renting virtualized environments without the possibility of on-demand scaling.

Google Earth Engine (GEE) [28] is another cloud-based platform that facilitates EO data analysis, visualization and processing. By leveraging the Google Cloud infrastructure, GEE enables for processing of large datasets. The data catalogue currently contains Landsat, Sentinel, MODIS, climate data, land use and land cover (LULC), air quality, and other georeferenced datasets. The STAC specification was also adopted for the data catalogue. Interactive user workspaces are provided within GEE, allowing for JavaScript code execution and visualization. Furthermore, due to Google's rich ecosystem, interactive access through Google Colab offers the possibility of interacting with the Earth Engine as well. Programmatic access to GEE is possible via Python and JavaScript API's.

Microsoft Planetary Computer (MPC) [55] offers similar capabilities as GEE with a rich data catalogue focusing on biodiversity, environmental and ecological data. This data catalogue is also exposed using the STAC specification, leverages the Zarr [57] format, and serves vector data under the GeoParquet [67] format. The Planetary Computer provides users with workspaces through interactive Jupyter Notebooks. Dask is also provided within the workspace to distribute large processing workloads. Users can leverage Microsoft Azure's cloud computing power for large-scale environmental analysis, which is particularly beneficial for handling large datasets like global satellite imagery and climate models. Integration with Azure AI allows the use of pre-trained Machine Learning models with the data found in the Planetary Computer catalogue. The Planetary Computer is also integrated with Azure Blob Storage, allowing for the easy storage of processing results.

The Amazon Web Services (AWS) cloud infrastructure is a popular choice for private sector companies that process EO data, such as DevelopmentSeed and Element84. Like GEE and MPC, AWS benefits from a large ecosystem of technologies for storing and processing data in cloud environments. The use of AWS for improving land use and land cover mapping in Brazil is addressed by [19]. By leveraging serverless (AWS Lambda) functions, object storage (AWS Buckets), Tile Map Services and DevelopmentSeed's implementation of STAC catalogues[27], [19] have developed a platform for forest monitoring. A serverless land evaluation platform designed by [54] Amazon Elastic Compute Cloud (EC2) [69] was integrated with an OGC WPS compliant implementation [87] for EO data processing. Furthermore, NASA HPC workflows have been evaluated with EC2 [51] and compared to NASA's Pleiades infrastructure.

Table 2.3 illustrate the various cloud-native platforms for processing EO data, utilising a data cube approach for serving data.

3. Discussion. Current deployments of platforms that leverage the potential of cloud computing resources for processing large volumes of Earth observation data share some common traits. Undergoing standardisation efforts taken by initiatives such as EOEPCA+ aim to bring those platforms as interoperable and federalised as possible while following best practices from software engineering and geospatial data perspectives.

Platforms like Pangeo [2] leverage the Kubernetes [12] orchestrator for scalable deployment, efficient resource management, and on-demand scaling of distributed computing environments, facilitating efficient processing of Earth observation data. PEPS [22] employs a containerised approach using Docker [52] for managing the platform's components.

[27]https://sat-api.developmentseed.org/search/stac
[30]Implemented as modules in Pangeo and can be utilised depending on the available infrastructure.
[30]https://altair.com/pbs-professionalg
[30]Users can deploy their own frameworks on the VPS.

Table 2.3: EO Platforms.

Platform	Workflows	Workspaces	Distributed Processing
Pangeo	yes	JupyterHub	Dask, Slurm, Spark, YARN[28]
CODE-DE	yes	JupyterHub	Hadoop, Docker
PEPS	yes	N/A	CNES HPC (PBS)[29], ProActive
CDSE	yes	JupyterHub	Through OpenEO, SentinelHub
EODC	yes	N/A	yes[30]
MPC	yes	JupyterHub	Dask
GEE	yes	yes	GCP
AWS	yes	yes	EC2

Support for distributed computing frameworks such as Apache Spark [86], Apache Hadoop [7], Google BigQuery [11] or variants built for EO data such as Apache Sedona [85], GeoTrellis and more commonly seen in the platforms mentioned in Section 2, Dask [15]. Microsoft Planetary Computer [55] employ Dask for distributed computing workflows. CODE-DE makes use of Hadoop [7], while Pangeo's [2] versatile modules can integrate with Dask [15], SLURM [84] and Spark [85]. The PEPS platform utilises the ProActive scheduler to manage jobs executed on CNES's HPC cluster using PBS. Additionally, platforms integrated into larger cloud ecosystems, such as Google Earth Engine [28], Microsoft Planetary Computer [55], and Amazon Web Services, have developed in-house tools for big data processing workflows.

Workspaces in which users can explore data catalogues, define and submit processing workflows which are executed through schedulers such as SLURM [84], or use Dask [15]'s integrated job scheduling system. The majority of platforms described in this overview (Pangeo, CODE-DE, CDSE and Microsoft Planetary Computer) provide interactive workspaces through JupyterHub [39], which allows to write and execute Python code near the data. These workspaces typically include access to API's, libraries or SDK's for distributed or parallel processing frameworks. The joint ESA-NASA initiative of MAAP [5] aims to bring user workspaces close to the data by providing a cloud-based platform where users can access, analyse, and visualise big Earth observation datasets in a collaborative environment.

The choice of a standard, cloud-friendly data format such as Cloud-Optimized GeoTIFF (COG), Cloud-Optimized Point Cloud (COPC) and object storage makes partial file reads possible using HTTP range requests while also reducing the amount of data that needs to be downloaded to specific areas of interest of the users. Although multiple cloud-friendly formats for vector data have been designed, many Earth observation data cubes use GeoParquet [67] format due to its advantages [53, 79].

The Spatio-Temporal Asset Catalog [71] specification has been adopted by the majority of the platforms described in Section 2. Google Earth Engine [28], Microsoft Planetary Computer [55], Copernicus Data Space Ecosystem [56], CODE-DE [73] all expose data catalogues using the STAC specification. An issue with the STAC-compliant API offered through CDSE is incomplete product metadata. STAC extensions such as `eo, sat, sar, mgrs`[31] are not yet supported through this API.

The CDSE [56] implementation of federalisation for user access for data access, among other platforms like DIAS and processing workflows, ensures the availability of data and processing capabilities at all times.

4. Conclusions. In this paper, we have presented an overview of the current state of the art in Earth observation data cubes, focusing on cloud-native platforms designed for exploiting such resources. Several High-Performance Computing and cloud computing frameworks, job schedulers, and orchestrators, such as Apache Spark, Apache Hadoop, Dask, SLURM, Apache Sedona, Kubernetes and Docker, are briefly discussed, highlighting their importance in efficient processing and management of large volumes of Earth observation data.

Their implications in architectures for developing platforms that leverage the potential of EO data, such as EOEPCA+, Pangeo, PEPS, CODE-DE, Copernicus Ecosystem Data Space, EODC, Microsoft Planetary Computer, and Google Earth Engine, are paramount for facilitating the efficient processing of large volumes of

[31] https://stac-extensions.github.io

data that are being generated at unprecedented volumes. Earth observation data cubes particularities, cloud-friendly data formats, and currently deployed instances that serve collections amounting to petabytes of data daily were briefly discussed.

This overview has shown a strong shift towards leveraging cloud-native principles such as microservices, orchestration, containerisation, serverless computing and horizontal scaling in large Earth observation platforms. Additionally, the use of object storage for hosting products in cloud-optimized formats which facilitate the transfer of data and integrate well with specifications such as Spatio-Temporal Asset Catalog has become increasingly popular, with multiple platforms disseminating Earth Observation data in this manner.

Though COG and COPC are utilised "de facto" in EO data cubes, the lack of a consensus for vector data formats currently requires the use of different libraries and technologies capable of ingesting and processing multiple formats. However, GeoParquet [67] has garnered popularity among platforms such as and could become the most adopted format for vector data due to its data representation, ability to host large amounts of information, and ease of querying [53, 79].

This overview has shown that significant standardisation efforts, such as those undertaken through initiatives such as EOEPCA+, Open Data Cube, and Spatio-Temporal Asset Catalog, are essential for integrating various platforms and data sources. Federalisation efforts are paramount within such large ecosystems to ensure interoperability amongst platforms, seamless data dissemination, and collaboration across various institutions.

However, this overview has only paved the way for analysing these platforms' potential for processing large volumes of Earth observation data. Overviews on data access platforms such as [27] or data cube initiatives [38, 30], surveys on or individual insights regarding platforms [22, 72, 73, 2, 63] designed for processing big Earth observation data all contribute valuable information towards shaping the current state-of-the-art and the directions in which Earth observation platforms are headed. Inventoring software through collaborative initiatives such as OSS4GEO[32] aim to create a knowledge base for open source technologies developed for geospatial data exploitation. Comparative studies from technological standpoints, scoping reviews, and more in-depth studies should be considered and further developed to better understand the potential and limitations of Earth observation platforms.

AIMS AND SCOPE

The area of scalable computing has matured and reached a point where new issues and trends require a professional forum. SCPE will provide this avenue by publishing original refereed papers that address the present as well as the future of parallel and distributed computing. The journal will focus on algorithm development, implementation and execution on real-world parallel architectures, and application of parallel and distributed computing to the solution of real-life problems. Of particular interest are:

Expressiveness:

- high level languages,
- object oriented techniques,
- compiler technology for parallel computing,
- implementation techniques and their efficiency.

System engineering:

- programming environments,
- debugging tools,
- software libraries.

Performance:

- performance measurement: metrics, evaluation, visualization,
- performance improvement: resource allocation and scheduling, I/O, network throughput.

Applications:

- database,
- control systems,
- embedded systems,
- fault tolerance,
- industrial and business,
- real-time,
- scientific computing,
- visualization.

Future:

- limitations of current approaches,
- engineering trends and their consequences,
- novel parallel architectures.

Taking into account the extremely rapid pace of changes in the field SCPE is committed to fast turnaround of papers and a short publication time of accepted papers.

INSTRUCTIONS FOR CONTRIBUTORS

Proposals of Special Issues should be submitted to the editor-in-chief.

The language of the journal is English. SCPE publishes three categories of papers: overview papers, research papers and short communications. Electronic submissions are preferred. Overview papers and short communications should be submitted to the editor-in-chief. Research papers should be submitted to the editor whose research interests match the subject of the paper most closely. The list of editors' research interests can be found at the journal WWW site (`http://www.scpe.org`). Each paper appropriate to the journal will be refereed by a minimum of two referees.

There is no a priori limit on the length of overview papers. Research papers should be limited to approximately 20 pages, while short communications should not exceed 5 pages. A 50–100 word abstract should be included.

Upon acceptance the authors will be asked to transfer copyright of the article to the publisher. The authors will be required to prepare the text in LaTeX 2$_\varepsilon$ using the journal document class file (based on the SIAM's `siamltex.clo` document class, available at the journal WWW site). Figures must be prepared in encapsulated PostScript and appropriately incorporated into the text. The bibliography should be formatted using the SIAM convention. Detailed instructions for the Authors are available on the SCPE WWW site at `http://www.scpe.org`.

Contributions are accepted for review on the understanding that the same work has not been published and that it is not being considered for publication elsewhere. Technical reports can be submitted. Substantially revised versions of papers published in not easily accessible conference proceedings can also be submitted. The editor-in-chief should be notified at the time of submission and the author is responsible for obtaining the necessary copyright releases for all copyrighted material.
